Then followed a long and harrowing set of attempts to entubate it to hook up the respirator. All went well except that the animal was so small that no one had a hand small enough to reach down the throat, remove the aretynoid extension of the larynx, and entubate it. We even had the Captain down trying. He failed after a most valiant effort. I suggested we try to nembitalize the animal and hope that the relaxation induced by such anaesthesia would allow entubation. Bob gave the animal a shot. It didn't work and our animal was slipping into anaesthesia from which we could not lift it. Finally, Ken, whose hands are pretty large, but who is experienced, tried. Shortly he succeeded and the

animal was put on the bird respirator. Bob then began work and was able to place a very long large core hypodermic through the skull and to lower a gross electrode through into the brain. We obtained some potentials but after nearly 7½ hours on board and 1½ hrs. under anaesthesia the animal began to fail and died.

It was midnight and we were all terribly tired. So off to bed. The experiment, inconclusive as it was, was a great success as we had been able to prove the usefulness of the hypodermic brain probe, which completely eliminates the difficult and bloody operation usually encountered in such brain implants. In the normal work a section of skull is removed and one must go through a blood sinus which is extraordinarily difficult. Our substitute took 10 minutes and was essentially bloodless. It will make my future work vastly simpler.

A word about Bahia Allen Gardiner. It is named for one of the first missionaries who tried to colonize Tierra del Fuego, but who perished of starvation at Spanish Bay east of the Beagle Channel. He probably never saw this bay and it is merely named in his honor. It is a beautiful harbor—calm waters, wooded shores leading up to the rugged snow-crested mountains behind. Eddie went ashore with some of the crew and returned with a whole boatload of baleen whale bones.

December 6, 1968

Puerto Inutil, Navarino Island, Chile

With breakfast we hauled up anchor and stood out into Bahia Tekenika and headed across a corner of Bahia Nassau for Seno Grandi. Bill and I had been looking at this deep inlet on the charts with the hopes that we could work it over in detail. Our hope was that the HERO might be able to enter it and to anchor inside but both of us understood that chances for such pioneering were small so we had an alternate plan waiting—namely working it with a whaleboat party while the HERO tried for animals outside.

Accordingly, Bill Schevill, Watkins, and I got gear together and with Penny shoved off in the whaleboat once our suspicions had proven correct. The captain had previously sent out the whaleboat and made soundings of the entrance, finding it deep enough, but pretty narrow. He and the pilot decided against it. At any rate plan 2 went into effect.

It was a lovely sunshiny day with the high snowy peaks across Nassau all gleaming in the sun, but with clouds to the north. Right in the mouth of the Seno we encountered the largest (18 animals +/-) and most cooperative school of *Lagenorhynchus australis* we had yet met. They swarmed around the whaleboat riding the bow and cutting along within a couple of feet of those leaning over the prow. I could see the mid-dorsal white mark running from behind the blowhole to the base of the dorsal. It is faintly evident in animals out of the water and Bill and I have been arguing about its origin. I think it's partly pigmentary but also suspect that differential translucency of the skin has something to do with it too. It seems to me that light may be partly polarized under water and thus reflect back, producing or enhancing these pattern marks that are hard to see in air—we have noted other such marks—on pilot whale heads, saddles behind the dorsal, etc.

In support of my notion I was reasonably sure I could see the position of the mid-dorsal mark shift a little from side to side as the animal rolled under the bow. It bears more looking.

At any rate, we stopped and Watkins dumped his hydrophone over the side and almost at once began to record click bursts, and a kind of lower frequency click train. Then he recorded a sort of bark, composed of rapidly repeated clicks. This was the first really successful recording we have made of this quiet species. The large number of animals, and the nearness of them to the hydrophone (they nearly touched it several times) accounted for our success. Inshore species such as this often seem to produce very low-level signals. The same is true of the harbor porpoise and others, perhaps even *Cephalorhynchus*, though we still haven't heard it speak at all.

Nearby in the kelp were a dozen or so young southern sea lions so we moved over close to them and recorded again-picking up some underwater signals from them.

The water was flat and glassy and below the surface there was very little noise to interfere. Marvellous recording conditions for such a low-level beast.

On into the bay we went, through a maze of wooded islets. Steamer ducks were everywhere. Sometimes we encountered large groups which went steaming off down the channels leaving their broad white wakes. Our porpoises followed along until we were well within the Seno before turning back for their entrance again. *Lagenorhynchus australis* is certainly an entrance animal—if one wants to meet them the chances in the swift water or a confluence of 2 channels are much greater than elsewhere, or in the entry of a canal into the sea, or in a narrows where tidal currents whip along.

Like everywhere else we have been in Tierra del Fuego this place is essentially uninhabited. The chart lists an estancia in the upper parts but all I saw was a little cabin. No boats. In fact the last boat we have seen was in the Canal Magdalena just as we turned out of the Straits of Magellan. There we met a small fishing boat but in all the days and miles since then not a skiff even has been seen, except on the beach.

Once the llampas left us we cruised along close to shore looking for *Cephalorhynchus*. As I know them from experience farther north in Chile they swim within a few ft. of shore most of the time and seldom leave it. Finally, deep in the bay we encountered a school of approximately 7 animals, including a young. They were, as predicted, within feet of shore. They avoided us resolutely. No sounds could be heard. Finally, abandoning the sound work we set about trying to catch on. I suggested I go ashore with the shotgun and that they try to herd the school past under my vanage point. All went well until the animals were within a couple of hundred yards of me and then they dove and disappeared for a very long time. When next sighted they had abandoned their shore hugging tactics and appeared far out in the bay going like the wind away from the boat. The boat took up the chase but lost them in the open water. I watched all this and in the interim collected a few plants and watched a magnificent blue and rust-colored kingfisher with a big crest. He sat peering at me, only a dozen yards away.

The weather had turned on us and we began our trek back in blustery winds and ice cold rain. Two or more groups of the little porpoises were sighted but nothing we could do brought us within striking distance.

Our hourly radio check with the HERO told us that she was outside (it was 4PM), so we replied that in something less than an hour we would emerge, and so set out to keep the schedule. In the islands near the entrance we passed what might have been a

Yaghan Indian habitation. Phylly tells me they are temporary shelters of fishermen or shepherds. All along we have been seeing shell mounds near shore, mostly of mussels, and these likely are of Yaghan origin. This one had its mound of shells, fewer than most, and a house as well—a hogan-like affair of rude planks propped up on a central frame—the whole could not have been more than 8X10 ft. inside, and the rain was sweeping in freezing sheets past it and the channel in front was ruffled by the cold wind. A bleaker, more inhospitable place would have been hard to find, except for the trees behind.

I shot a steamer duck for Mac's visual pigment work. It took a charge of buckshot to stop one since they take off at quite a distance. When we picked it up we looked at a ponderous bird with short wings, obviously too short to raise that body into the air. On the terminal joint of the wing were 2 cartilaginous excrescences that looked like stubby yellow fingers. These, we suspect, are used when the bird climbs out on land. They are often seen snoozing on the rocks along shore and do go some yards inland. The legs and feet are very large with 3 toes completely webbed, plus a little separate toe, that is paddle-like. I think the main motive power comes from the feet with the wings beating simultaneously down and somewhat backward upon the water, lifting the heavy body enough that the feet can run, which they do alternately. The very heavy muscles of the hind legs attest to their importance in this peculiar mode of locomotion.

Before long, through cold rain and in strong swells we came alongside the waiting HERO and were hoisted aboard. The hoisting operation in a sea way is getting better—the ship more often swings around to produce a lee for the whaleboat, more often keeps a little headway, more often the bow painter attaches first, swinging the bow out a bit while the stern falls are hooked on, and the hoisting itself is uneventful now.

The ship left at once for Puerto Inutil, just north of Wulaia, and arrived there 2 hours later. This port is the most completely landlocked we have yet occupied. It is entered through a narrow deep channel that opens into a sizeable rounded bay, absolutely calm, with wooded hills coming down on every side. A lovely place that we fail to find a reason for its name—inutil, or useless. Looks like home to us, and a safe one at that.

Bill and I faced the increasingly onerous task of measuring and flensing the last porpoise. We were tired and wanted nothing better than bed but manfully marched up to the deck and 2½ hrs. later it was done—salted and stowed. Then, notes and bed.

December 7, 1968

Bahia 14 de Julio, Isla Butto, Chile

The shore party went over again early to obtain some samples and to try to photograph the steamer ducks which are very common in Puerto Inutil. They are mostly accompanied by a fleet of little ones that steam along behind when frightened, or gather together into a little ball of birds and crouch on the water surface completely quiet. I watched a group of these little fellows, still in their juvenile down and stripes, go through the same motions as the adults, except that they lacked any primary feathers and so, beat their little wings ineffectually on the water surface while their feet did all the work.

One could see the big hind feet running on the water surface. Like the adults, these little fellows “steam” with the neck erect and the head pointing forward, in exactly the same position they occupy when swimming quietly on the water. We noted, also, that the steamers can trim their buoyancy, probably by adjustment of air volumes in the lungs

and air sacs. Sometimes one saw them swimming at “periscope depth” with none of the body out and only the neck and head above the water.

Bill’s Watkins and Schevill and Anelio and I set out on a launch party that was to last all day, while Mac took the HERO out for porpoises in Bahia Nassau. We began by cruising the shores of Bahia Inutil, watching the HERO negotiate the narrow channel. It was a pretty sight—the fine ship green and orange slipping between green mantled cliffs in a calm narrow channel, white-capped peaks beyond.

Our main mission today is to pursue the little tonina, or *Cephalorhynchus*, a species I have harpooned north in Valdivia but which we have only seen here. Since Wat saw them in Wulaia we hope to find more in the area.

We skirted the shore out toward Murray Narrows, where I hoped the current and whirlpools would attract them. The main fare on the way out were birds. I had been asked by Bill McFarland to collect some Magellanic penguins for him so that he could sample the visual pigments (he has special interest in amphibious birds that must see both in bright sunlight and below the surface). Consequently I manned the prow while Steve steered us in toward them. Many were seen floating on the channel surface. They were seen usually in pairs, but sometimes in groups of up to a dozen birds or so. Usually they duck below the surface when the launch is 35-50 yards away but occasionally would remain on top until we were no more than 40-50 ft. away. I shot when they were probably 30-50 yards away and am sure that they were able to duck often before the shot hit around them. Only by using buckshot was I able to collect them with any frequency and even then, usually missed. On board they are lovely birds—their feathers form the most complete protection imaginable—a fine dense interlocking down overlain by gleaming white imbricate feathers, almost pearly in lustre. They need such protection in the 7-8 degree water. I suppose it’s much worse in the winter, too.

We finally swung out into Murray Narrows where a group of southern sea lions was encountered. Listening proved pretty unprofitable and so we moved on, across the channel to the Hoste Island side and back down, crossing over to Isla Strate. There we investigated a group of low rocks on the south shore and located a big rookery of sea lions. Some good sounds were obtained from them after we had disturbed water. The old boys were the most reluctant to leave the rock but finally lumbered in their rolling seaman’s gait into the water. The girls had all rushed off before, and gathered in groups excitedly poking their heads out of the water, bolt upright, to look at us. Then having drunk in our yellow foul-weather clad magnificence, they flipped and dove out of sight.

Anelio obtained a good count with some information on the sexual structure of the colony. The presence of a group of sub-adult bulls, he says, is typical of these groups after the passage of the reproductive season.

It was only a few minutes to pull over toward Isla Button, named for the Yaghan, Jemie Button, who was taken to England and after 2-3 years brought back by Darwin’s group on the BEAGLE. He was released at Wulaia, his ancestral home, and later participated in a massacre of a group of missionaries, I suppose as a way of showing how much he had learned in England. The massacre took place at Wulaia across the bay, and only the cook survived.

We ate our lunch on board the launch as she drifted in the calm water, all pleasant and calm. About this time we saw our first fellow craft in many days—a skiff powered

by outboard cruising over under the cliffs of Hoste Island and making her way toward Murray Narrows. No *Cephalorhynchus*.

We cruised the steep shores of Isla Butto, peeking in on the home lives of shags that were nesting on various precipitous cliffs in the area. The adults are black above and white below, with the entire neck and head black. It is the rock shag or cormorant (*Phalacrocorax magellanicus*), a bird of the southern third of Chile. The little gray-black young clung, usually in pairs, to their nests stuck in the cliff as we passed while the adults swooped off the cliff gathering momentum enough for flight before they reached the water level.

Anelio allowed as how he would like to inspect some islets offshore from the south end of Button where he thought sea lions might gather. We could see one low loaf-shaded rock that was white with guano, often a concomitant of sea lions as well. As we cruised across the still water we noted streaks of dull red below us. Shortly one was seen nearer the surface and we could see that it was composed of swimming crabs in untold billions. They were swimming in layers, often only one crab thick, but covering acres and acres, all jammed next to one another. The schools advanced along sharp fronts, like fish schools, with schools passing over one another, or streaming along in narrow bands. Sometimes they dimpled the surface, and all over the bay they were being eaten by thousands of sea birds and sea lions. The rocks of the loberias were red with them. I suspect the schools must have extended over at least a mile of sea in each dimension. They began to come in our scuppers as we stopped to snatch up some samples. They swam backwards, swinging their chelipeds together. On the inner margin of each claw was a fine sieve of cirri and with each swing of the chelipeds I presume brought the cirri into juxtaposition over one another forming a mesh of fine pore size. Anything collected on it lay right next to the mouthparts.

The crabs were uncommonly easy to catch. One could choose a nearby crab, lower a hand into the water, and usually scoop it up. It was as if they kept such rigid station that no attempt at avoiding your hand was tolerable behavior. I noted that asymmetrically on the abdomens of many was a large swelling, lighter red than the rest of the animal. I did not determine its cause though many of these we collected had the swelling.

Sure enough, on Don Anelio's island we sighted a large loberia. There were large groups of young males, all gathered together in a sort of *Otaria* YMCA, older males, and whole areas seemingly only of females. Young animals were in evidence. Once again we listened, and once again were able to record some underwater sounds, though not many. Anelio happily counted and observed while we played with the tape recorder and such.

Then we took the launch across to the mountains south of Wulaia and made our way up along the shore to Wulaia. A brief social stop was made to say hello (or hola) to our friend at the sheep station there. He offered us another lamb (which we refused) and seemed pleased we had stopped. His little bright-eyed daughter Hilda was especially pleased when Bill (Schevill) remembered her name and greeted her by it.

There in the mouth of Wulaia were 2 *Cephalorhynchus*, cruising along in their unobtrusive manner—one adult and a half-grown animal keeping close station. We approached, shut the engines down, and listened. Not a sound. One seldom hears anything from these small groups of animals. At one point they surfaced within 50 ft. of

the silent launch. I could clearly see the dark-gray pattern mark that sweeps up on either side of the head meeting asymmetrically at the blowhole. This was characteristic of the animals I took at Golfo de Arauco and Valdivia, and makes me reasonably sure we are dealing with the same species.

After this encounter we stopped trying to record and attempted to make a capture. Like it was in a script they refused to let us near. They surfaced in one direction and as we approached that place, dove and came up far in another direction. If the sea had not been calm we would have lost them at once and eventually did. All this was wary behavior indeed as we had not pressed them during our recording attempts. Bill Schevill, who has yet to see these animals out of water, was especially sorry to quit when the HERO arrived but I knew we were licked and the belts had begun slipping on the launch so deemed it best to follow her across to Isla Button where the evening anchorage was located.

I shot another penguin for McF on the way back and other than a brief survey of the anchorage for the Captain nothing else eventful took place on our last day of hunting in the Nassau Bay area. Tomorrow we begin the trek back toward Punta Arenas.

December 8 1968

Caleta Brecknock, Seno Ocasión, Brecknock Peninsula, Chile

We're on our way home. We will have one day more in the Punta Arenas area and then hit port early on the 11th. It has been a fine trip. We have accomplished a good deal, though the porpoises proved much scarcer than we had hoped, but then, studying porpoises is like that—only once in a while can a person find many at once to work with.

The ship hove anchor early and made her way through Murray Narrows, giving a 3-toot salute to the Navy observation post there. As usual, my watch on the flying bridge was not notified and was lifted half out of his shoes. It was poor George Harvey, who last time was tying his shoe, and bending over in front of it when the toot came. I hope something is done to move this horn so it doesn't cause such mayhem to others.

We had a meeting regarding packing and cleaning. Remembering sad experiences of coming in after another party on the *Helix* I asked that everything be made as clean as we found it and that everything be packed before we hit the dock at Punta Arenas. Accordingly, packing was started and cleaning started by the scientific party. I spent my time writing my impressions and suggestions of the HERO operation for NSF, and in getting materials for a report together.

The clouds had lifted over the Beagle Channel and unlike our other passage we could see the majestic mountains and glaciers in their entirety as we passed.

As we passed the first Chilean fjord west of the Argentinian frontier an LSM came out and followed off our quarter, tooting. I listened and finally told the pilot about it. He said they weren't calling us and steamed on. It later turned out he was angry at being tooted at and was ignoring them. He wanted messages by signal light as this was the custom. Finally the ship astern grew patient and the pilot [drawing] was drawn out on the bridge wing. He and the Captain of the LSM exchanged hot words—the LSM man angry at being ignored and our man angry at being called in so gauche a manner. The LSM, with all hands standing at the rail, finally cut away and retreated up its fjord.

Our trip was through flat calm seas. I picked out an anchorage area near Isla Aguirre, a locality that has never been collected. The pilot was able to oblige me by

pointing us toward Caleta Brecknock, about 2 miles east of Aguirre. We plan a launch party before breakfast tomorrow morning as our arrival will be very late.

Our passage continued calm and clear, allowing views of the Brecknock Peninsula that we had missed on the earlier traverse. The skyline is one of jagged snow-covered mountains and the foreground of lower granitic promontories and islets, mostly exposed rock, highly smoothed and worn by glaciers. Cirques are to be seen near sea level, sheet jointing is common where the rocks spall off and the vegetation is tucked in folds and crevices. The copses of trees lie against the rocks and are gnarled into their contours. On the forest edges one can see that the trees are tiny—like those of a Japanese miniature. I believe only 2 trees make up all or certainly the majority of these forests—the winter's bark, and the southern beech.

The anchorage was reached while there was still light—at about 2200. We slid up a glassy fjord, the Seno Ocasión, between granitic walls. These ramparts grew higher as we pressed back into the deepest recess of this channel. All around was bare spalling rock, laced here and there by cascading water. By the time the anchor was dropped—in 30 meters of water, the rocks crowded so close around that only 150 ft. of cable could be put out. We found a big buoy with heavy chain below and a long polypropylene cable was taken out in the dory and attached to it to secure the ship with its inadequate scope. Also it was prudent to control our swing with rock walls all about. Behind the peaks the sky grew red, dusting the clouds, with the last fading light. A magnificent setting, like anchoring in an alpine lake. [Drawing]

December 9, 1968

Chile, Bahía Gente Grande, Tierra del Fuego, Chile

A calm lovely day with the many snow- and glacier-clad peaks of the Cockburn and Magdalena Channels standing clear against the sky in contrast to their peekaboo shrouds of fog and mist on the southward journey—but I had little enough time to notice. All the preparations for leaving are in full sway—cleaning labs, packing gear, seeing to the stowage of our collections. I had the additional duty of trying to prepare a written report for the Captain and was feeling a little under the weather with some sort of stomach upset, so spent most of the day in the room below, typing.

We planned a long traverse that would put us in good position for the last day's effort in the second narrows of the Straits of Magellan, a little way past Punta Arenas. Accordingly, near midnight the pilot picked his careful way among the buoys into Bahía Gente Grande, named for the now extinct Ona Indians who apparently confronted one of the early explorers here. The land around is low pampas and there is little to attract the attention—low bluffs cut in some sort of soft sediment, and the grassy land behind.

We will leave a clean ship. Everything will be washed and swept and gear will be returned.

December 10, 1968

Bahía Whitsand, near Punta Arenas, Chile

What a final day for our cruise!! All during our previous days we had been seeing little but the ubiquitous llampa, and he seldom enough. Today we spent in the leaping bowriding, stern-inspecting hoards of the Commerson's porpoise, *Cephalorhynchus commersoni*. It went like this. At breakfast time the anchor came up and we slid out of

low Bahia Gente Grande into the Straits, and there headed eastward toward the second narrows, a few miles away. Llampas greeted us once, and I expected only more of the same until Bill McFarland yelled down from the bow that there was a porpoise ahead and it seemed different. Just then one leaped 150 yards ahead of us. I caught a flash picture and when decoded it was of an animal pure white in the body, with black head and pectorals, black dorsal and tail. It had no beak. It could be but one creature—so I called out “Commerson’s porpoise”. All day long these playful tiny porpoises raced in to swim along the waist of the ship, at the bow or to dive down by the rudder. They are one of the most beautiful porpoises I have seen.

The groups were mostly modest in size and seemed to be rather loosely organized. They might come in toward the ship as a fairly cohesive group of up to 7-8 animals, but this grouping would usually quickly break up into subgroups. The little fellows were seldom more than 6 ft. long, and adults were sometimes smaller—I would guess 5 ft. They often leaped free of the water. One could see pairs of them racing along underwater, showing as greenish-white blobs moving along very rapidly. When they leapt or when they approached closely one could see the black marks. With a few white caps they become very difficult to see very far away.

Mac collected one for us—naturally a female. We brought her on board and were able to dark-adapt her before giving her an overdose of anaesthetic. Mac was able to obtain the best possible material for his work in this way.

Shortly, in the second narrows, we put the whaleboat over for recording sessions. They had animals all around them for more than an hour, and may have had them touch the hydrophone but seemingly, the animals were silent. George thinks he might have something on his high-frequency tapes but it will take analysis back home to be sure.

Meanwhile on board the HERO we were trying to obtain another animal. Mac missed shot after shot—probably statistical retribution for his excellent previous shooting. He couldn’t hit his hat, and furthermore, the damned beackets broke off the harpoons with maddening frequency. I finally took over, missed a shot, and then hit an animal that was dead before he washed past the stern. The harpoon had pierced his heart and he died instantly. It was a male, and proved to have a peculiar serrated edge on its left pectoral. One wonders if this is a normal secondary sexual character, or simply an anomaly.

Watkins told me of the unusual flexibility of the neck in these little porpoises as they circled his hydrophone and looked up at the boat occupants. It will be worthy of a look at the cervical skeleton to see if there is anything unusual there.

The little porpoises were concentrated in the narrows. Considerable steaming in the broad bay to the east produced no animals and the time spent cruising before we reached the narrows produced only the lllampas mentioned previously.

We steamed back, heading for anchorage near Punta Arenas which we will reach about noon tomorrow. All the gear had to be repacked as we had hauled out all sorts of things in our frenzy with the Commerson’s porpoises, and I had to finish preparation of both animals. All was secured in time for an end of the trip party in which we presented Captain Hartshorne with a nice cow’s horn made into a trumpet, all signed by us as a grateful recognition of taking us safely around the horn. Anelio produced a grand effulgent Chileno toast and I did my rather drab best to toast him and the pilot. I wanted to toast the whole crew, who have been so marvellous, competent, and helpful during the

whole voyage, but somehow the gruff male attitude makes it difficult to produce such naked thoughts. Anyway, they and the Captain are great and competent folks and it has been a real pleasure sailing with them. Seamen all.

December 11, 1968
Punta Arenas, Chile

It took till noon to reach this sprawling red-roofed town of 60,000 set on the gentle slopes of a grassy hill. We tied up alongside an icebreaker and shortly my family and Berit Bloome showed up at the rail, all smiling and happy after a wonderful 2 weeks in Harberton, where they had been hosted by the Goodall family, owners of the Estancia there. Natalie Goodall was there too, and when they came aboard she looked happily at our 1,700-plus plant specimens. Next through unloading and then we leave for Santiago and home.

We had a feast at the Club Austral with toasts and such and made our various ways home—I to the boat and Phyl and the kids back to the hotel as there was no extra room there. Seems strange.

[Flyer insert about the HERO, map, and letter from Phil Smith to Ken]

December 12, 1968
Santiago, Chile

One of those hectic days with me dragging awfully. Ship unloading—all the hectic business of customs when one never knows if he is going to make it through or not. We did, thanks to Anelio's Spanish, without even overweight, and we had a horrendous pile of junk, too. Thence off to the plane and the long flight to Santiago (a stop in Puerto Montt). Francisco met us there and whisked us through and delivered us to, of all things, the Hotel de France. A mix-up in the office made them think we wanted this cheap walk-up with the john down the hall when we really wanted a spiffy room and bath with air conditioning, particularly in this heat.

December 13, 1968
Santiago, Chile

I dragged more—terribly weary I think, in accumulated fashion, from the trip and the events of the trip end. All paperwork—old bills to be settled, skulls to be obtained for Carl Hubbs from the Santiago Museum, and endless other affairs.

December 14, 1968
Santiago, Chile

At 12:15 we were down on the street amid the torrent of foot traffic that typifies Santiago—in L.A. all of them would be in cars—with all our luggage stacked behind. Francisco came scooting up ½ an hour late and we had to run across the street with everything to his car, illegally parked and race off into the death-defying swirl. It's dodgem cars with only occasional contact.

Easy time at the airport and then a long uneventful sleep-filled flight to Lima—where I saw the beaming face of my old roommate Hersh Peak leering down. He's now first secretary in the embassy here. He speeded us through to the Hotel Maury—old

home to us and then to his lovely house in the suburbs where we met Gale and the kids, had a fine evening of reminiscences and back to the hotel.

December 15, 1968

Iquitos, Peru

Our plane left early (up at 5:45, airport at 7, flight at 8) so we pulled ourselves out early without breakfast and grabbed a taxi. [Insert—flyer about Iquitos, Peru] Our flight was mostly cloud-shrouded though we did catch glimpses of the altiplano, the canyon country with its little stamp-sized areas of cultivated land surrounded by stone fences, terraces on the steep slopes, rock corrals full of animals and villages clinging to mountain spurs up where one wonders how they can obtain water. The clouds broke again and we were over the jungle—the vast unbroken forest—the same as I flew over in Brazil. Only occasional hills broke the level[?] and only an occasional twisting river wound like loops of rope brown through the green. Cumulus clouds spread in lines like puffs of cotton, attesting to the heat below.

Our plane stopped at Pucalpa, a raw frontier town dealing in oil and forest products. We looked out briefly, watched them gas the plane from a dump truck (a big rubber tank jounced and jiggled in the back and was pumped by a little Briggs Stratton pump into a strainer held in a funnel sticking into the wing tank).

Iquitos was reached an hour or so later—a jumble of houses on a peninsula jutting into the brown Amazon. Even from the air we could see the current was swift—debris and water hyacinths sweeping along amongst the various wooden boats.

A taxi took us, and our blissfully reduced luggage, to the Hotel Turistas, that fronts on the river. Iquitos is pretty undistinguished—a mixture of old ornate buildings of the rubber boom—all metal work and fancy tile, more modern plaster, wooden or tin houses—one storey for the most part—and thatched shacks on the outskirts. Most of the streets in the main town are paved, city squares are modern with the usual “tonto grave” generals in bronze, suits of clothes much too heavy for the jungle and curly locks. The fountain plays amidst the most garish combination of colored lights since Wurlitzer.

Our hotel is modern and nice with big cool rooms, modern bathrooms, and a splendid view.

A walk in the park, mostly devoted to collecting moths, with a little listening to the ghastly military band, a dinner with colona juice (a delicious fruit of the tomato family that tastes something like orange juice, but better). Then to bed ‘neath the air conditioning. It’s not too hot outside though, even though we are just a few degrees below the equator.

December 16, 1968

Iquitos, Peru

After breakfast, at 8:30, we were met by a spare young man who led us to a boat dock north of town where we piled into a speedboat powered by a 60 HP Johnson outboard. We were soon speeding down the Amazon, dodging floating trees and bits of debris. Like all river trips it was an unfolding panorama of vignettes. Women washed at the edge of the muddy stream, crouched on the mud that stepped up into the forest, showing where the river had receded. Back of each woman was a series of mud steps cut in the bank and a thatched house on stilts. These houses had half walls inside, marking

off the living quarters, a gaggle of chickens, pigs, Muscovy ducks, and various birds. Usually there was a long dugout, the keel and bottom hull formed of a single tree and the sides of planking lashed and caulked above. The heart-shaped paddle is used by all and one often saw 3 or 4 people in such craft, rowing along with an inch or two of freeboard, as if a wave would sink them. Sometimes a woman or girl bailed so industriously that one knew if she quit, the craft would sink.

As we went by the kids waved at us like boys and girls at the engineer on a train. We waved back.

The forest is largely scraggly here and all along the banks are little farms where the forest has been fragmented—a tall lupuma tree standing alone in a field, dripping with epiphytes and lianas—mementos of a wider forest now gone. Guava trees were in full white bloom—like the lilacs of home—and cecropia trees and palms stood spindly and alone. Back of it all, though, and intruding now and then to bank-edge stood the immense continental forest.

We watched the long, slim thatched-roofed colectivo boats putt-putt along, taking people home or to Iquitos, just as taxis do on land. Some bore families with chickens and pigs, some with the outhouse lashed crazily on the long overhanging stern, often with hammocks slung inside and the smoke of the cooking fire issuing from the thatch. We waved. A brief tenuous link of our world with theirs. How could they know us or we them? What we see are cardboard figures cut hastily and even in silhouette, out of proportion.

Rain came in a gray mist ahead of us. The boat man clutched a tattered plastic raincoat about him and I gave Joe—the cook—mine. It turns out they prefer plastic tablecloths as they are airier—tied in a square knot around the neck.

The kids, Phyl, and I retreated inside and watched it blot out the landscape on the windows and windshield as we sped along.

Two hours later we pulled up in front of one of the thatched houses, clambered up the slippery mudbank and into the house of the local store owner. The store is not much—it contains a few essentials like kerosene lamps fashioned of milk cans, sugar in big rectangular cubes, and a few other things. Beer in big bottles was available. The house was open to the air, dry and comfortable with the rain tapping on the thatch and running off the eaves. A cook fire smouldered behind on an earthen mound and made the thatch all black above. Meat, we were told, was hung near, and the fire hardened, partly smoked and preserved it. Wild boar was used as well as monkey and below us scuttled the pigs and chickens as well as a tame bittern and 2 trumpeters. Nancy, of course, made friends with the trumpeters and her triumph was to scratch them on their heads and have them put up with it. Various things of the Yagua Indians were tacked up on the walls. These Indians number some 2,000 people, all in this area. The ones nearest the river are a mixture of acculturation and old ways. Back farther in the forest they live as always and survive an 80% child mortality. Our host, Peter Jensen—a bearded University of Minnesota archaeologist, turned tourist entrepreneur, led us through the forest to his forest camp. As we walked through sugar cane and corn fields he pointed out the beautiful flame-colored bromeliads in the standing trees, showed us how sugar is boiled from the syrup in ancient flat pans after been run through a press operated like an areastre, with a big log arm that is pushed in a circle by workers, turning the press. The kids enjoyed a segment of cane. We walked on and Peter called in Yagua across the

creek. What he likely said was in effect “Get your clothes on and come visit us at the camp.” He told us he had invited them to the camp.

Our trail led us to a thatched house in the forest. In its open veranda were half a dozen Yaguas, an old old man in full regalia lying in his hammock, 3 women weaving on the floor and assorted little kids including Peter’s godson, who ignored him. the women were taking palm fiber pulled out like wool, holding it in their toes and pulling it taut across one brown thigh where they rolled it back and forth with their palms, producing a tightly laid twine that was very very strong. This was then stretched on a sort of crochette hoop making a loosely woven bag for carrying.

The clothes of the people were a heavy fiber skirt dyed in horizontal bands of reddish buff, a chest piece for both men and women hanging loosely and covering down to above the navel, a round corona of woven palm on the head with a mat of fiber over the forehead like bangs. The girls wore anklets and knee bands of fiber. All were banded reddish buff. No shoes. One nursed her baby and one wore a loose cotton dress.

We thanked them in Spanish which at least some understood (they also spoke Quechua (from the missionaries) and Yagua), climbed down the notched pole ladder, and made our way on into denser forest. Soon we emerged in a clearing where the “camp” stood—a series of 5 thatched buildings—beautifully made palm thatch, compartments and hammocks for 42, kerosene ice boxes with beer and soft drinks, and a couple of nice English-speaking Peruvians to tend your every want. We sprawled on the veranda, making friends with the macaw and parrot and soon the Yaguas arrived. They were all dressed now and gathered on the veranda for a smoke, which Peter provided. He brought out a tape recorder, a new item in camp, and induced them to sing and tell shady stories into it. On replay each dirty word or joke was greeted with floods of chuckles and laughter. The song brought more. Peter bet them they couldn’t hit a cigarette package set in a dahlia across the courtyard, so 2 of the handsome men tried. Their blowguns are shorter and of much smaller bore than the one I got on the Rio Negro. The darts they use for birds and monkeys are of palm and tipped with curare plus other ingredients which they won’t reveal. It looks like thin tar. The blowgun man pulls his dart from a palm leaf holder, pulls a tuft of cotton from another holder, wraps it around the little 6 in. dart about 2 in. from one end, licks the cotton fore and aft, inserts it, holds the gun with both hands on the mouthpiece and a finger extended under the barrel. With cheeks puffed he gave a little puff, almost silently, and the dart flew a good 30 yards. It took several tries, though, to hit the cigarette package.

The guns are made of a split piece of hardwood with a carefully cut half groove in each. I suspect a chalk string is held taut between the 2 as they are held together marking both sides. The 2 pieces are then bound together and glued with tree gum, the mouthpiece put on, and I suspect, the bore reamed with a pull-through reamer of some sort.

We ate a lunch of monkey meat (I found a shot pellet in mine), salad, banana chips, sandwiches and fruit and then went for a lovely walk in the jungle. Nancy, especially, was in constant joy over the moths, butterflies, frogs, and flowers we met. We saw the long pendulous *Oropendula* nests hanging from a tall tree. Several other birds called nearby. Regretfully we turned back and before long were on board our speedboat and making our way back up river, staying near the bank to reduce the current effect. Even so it took us ½ an hour longer to make the trip.

I saw a tuxuci dorsal fin fleetingly but no “buefo colorado” as they called *Ima* here. *Sotalia* is “puefo negro”.

December 17, 1968

Iquitos, Peru

Shopped in Iquitos and bought a Shipibo “grudge knife”—a little blade used by Indian men to settle grudges. They store up their woes for a year or so and then trade slashes at the muscles on the back of the neck—sometimes with fatal results we are told, sometimes with cut tendons and sometimes simply with the production of elegant scars.

Also from the Shipibos, who live up river, came a “curandero’s pipe”—used by Mestizo medicine men during curative sessions in which the patient takes the jungle equivalent of LSD. The mestizo pipes, we were told, are more realistic animal forms than those used by the pure Indian “curanderos”.

We visited an animal shipping company, peering at anacondas, shoebill storks, spider monkeys, and one spitting ferocious margate cat.

December 18, 1968

Lima, Peru

A long wait at the steaming Iquitos airport enlivened by Barb and Dick dickering with a gnarled old lady for 2 pig-tooth necklaces, and they obtained them finally by waving a dollar bill at her and wordlessly she forked them across. Finally, we boarded for the long flight across the jungle through magnificent towering clouds, up into the montane forest—mountains all clothed in dense green without a rock showing. The winding rivers pinched down and became white with current. Off in the distance I could see over a great escarpment into impalpable blue beyond, only the vaguest shapes suggesting land . . . like Shangri-la, a world of unknown rimmed with impenetrable forest, save by generations of forest men and women who made the journey as part of their lifetime.

The forest fell away and the land emerged. So did towns and farms and rock walls and finally over the spine of the Andes with snow, rock fins, and little emerald lakes. Once over, into the desert side it was minutes only to drop down into the eternal cloudbank of Lima.

We made our way to the Maury, freshened up, and went shopping for a few last items. Then a snooze at the hotel and finally to the airport again at midnight.

December 19, 1968

Washington, D.C.

The USA again, folks speaking English, peanut butter, the chance to carry on a subtle conversation, regimented traffic, people whose reactions one understands—in short, home.

After tangles in Miami with missed planes (our luggage was mixed up in Lima and came on the wrong plane), we arrived in Washington—the weather about like that of Punta Arenas—and headed for the Strouts. The end of a wonderful, variegated 6 months—to begin our own reacclimation—South America already relegated to the impalpable past.

Whale Hunt on the Alpha Helix, December 1-8, 1971

December 1, 1971

Enroute to San Juan Sea Mount, off California

This cruise of the *Alpha Helix* is for the purpose of studying the sperm whale, attempting to affix a depth-time recorder to it, and making observations on other cetaceans that we might encounter off the continental slope. Jerry Koozman, a marine mammal and bird physiologist is in charge. Tom Dohl and I have been invited so that we may learn sperm whale reactions to assist in our proposed capture plans. Dave Gasin, a New Zealander who has done quite a bit of work on the large whales is along. He is presently at the University of Guelph in Canada. Jm Fish of the NUC lab at Point Loma has prepared the instrument packages and may try recording with his special low frequency gear. Walt Garey, my roommate, who is operations officer for the *Alpha Helix* program is out to get away from the phone and to do some writing. Wayne Smith of the local educational television station is out taking films for BBC.

We have a good crew, some of whom sailed with me in Scripps days. I haven't gotten their names straightened out yet but will soon. We will spend about 10 days at sea and no fixed course is yet established though it looks like we will try the Sea Mount and maybe Rodriguez Doma and then turn south if luck is bad. At this moment the weather is gloriously with us. It is crisp and cold but the sea is flat calm with only a minor swell. On the *Helix* this is the greatest of blessings, since she has a smooth round bottom in order to keep from getting stuck in ice, and she rolls like an egg.

Tom and I arrived last night, made our way to the Scripps pier, and finding it closed wondered "what next," but Tom jiggled it and found it merely latched but not locked, so we went in, taxi and all, and unloaded right at the *Helix*. We walked a mile or so to dinner and met Dave Gaskin and then went to bed.

Promptly at 8 AM, as advertised, the lines were cast loose and we set out—but not to sea, instead turning into the harbor to pick up fuel. Sometime while the fuel was coming on board—about 12,000 gallons of it—someone noticed that the mast was bent and that their new pulpit had sprung in when the ship was in heavy seas on the last trip. So, back we went to the Scripps dock for jury rigging—a back stay to brace the rig. Tom

had previously pointed out to me how badly designed it was—I agree and will be a bit reluctant to go into it in any kind of swell.

Finally, about lunch time we cast off again and made our way out into the Pacific, turned up the channel inside of San Clemente Island. We passed an enormous school of *Delphinus*—perhaps 300 animals, feeding under birds. I would guess they were 10 miles off Point Loma at the time. Many had white spots on their dorsal fins, and many had totally dark fins.

We spent much of the time on watch talking to one another—getting acquainted. I felt that Dave Gaskin, particularly, was almost frantically feeling people out—trying to establish himself in our midst by talking incessantly of experiences. He is, I think, contentious and opinionated, but that may pass. Jim Fish is his usual delightful self—easy going, open and direct, quick to enjoy a good joke. I've enjoyed talking to Dale Rice, a quiet field management biologist with a considerable depth of knowledge of whales—in fact more than anyone on board I expect.

We had a nice seminar after a sumptuous meal in which Dale showed pictures of most of the species we might encounter. There are some really staggering shots of blue whales in particular.

A cup of Sanka, worry about how to crack the scotch without raising the ire of the authorities (Scripps ships are rather rigidly dry). A shower and to bed.

December 2, 1971

Cruising over San Juan Sea Mount

We arrived at San Juan Sea Mount today about noon, in overcast but quite calm seas. No whales were seen but a widely scattered school of *Grampus* appeared off the bow and we stopped to record and to listen for sperm whales. The big white scarred grampuses came by in twos and threes, never at the bow but often around the stern very close to Jim's hydrophone. They, as usual, were emitting a lot of squeals and a constant barrage of clicks. One could see their deeply furrowed foreheads clearly, and the tall, often malformed dorsal fins. Underwater they shone light, approaching as light bluish torpedos beneath the surface. Jim happily recorded what he thought was a pure culture of *Grampus* when Jerry noted what he thought was a seal in their midst. Soon we saw a rather good-sized group of *Lissodelphis* traveling right with the *Grampus*. No, Jim won't be able to tell who was saying what on his records.

Later two groups of *Phocoenoides* came to the bow—actually one group of two came in and the others—a larger group—plunged away from us in their peculiar rushing locomotion, and refused to let us near.

Other than these two sightings nothing was seen but birds and sky and swells. Toward afternoon the swells began to rise and by nightfall the good ole round-bottomed *Helix* was rolling according to plan. We began bracing ourselves, going down corridors and in the bunk. I'm not yet acclimated and resorted to the pills a couple of times to chase back the lump in my stomach, and the dizzy ache in the head that presages worse things.

This cruise, like most cetacean efforts in the open sea is 9/10 looking and 1/10 watching the animals you came for. One finds oneself gathering with shipmates in little knots to tell stories over the engine hum, become fidgety, and move off aimlessly for a cup of coffee, or to try to read (which usually induces sleepiness which is then followed

by a nodding head and a cat nap). I'm just enough off to be impatient and bored. I guess that's the word. With eight days ahead it should reach full blown symptoms ere we return. Tonight we head up for Rodriguez Dome off San Miguel Island and thence to Arguello Canyon.

December 3, 1971

Enroute to an unnamed sea pinnacle

During the night the *Alpha Helix* headed northward off gray waters off San Juan Sea Mount toward a rounded rock on the sea bottom called Rodriguez Dome. This dome is at the edge of the continental slope about 20 miles west of San Miguel Island. When daylight came we were skirting the unseen mountain many fathoms below. The ship circled over the area and crisscrossed it. The weather had held and the sea was without whitecaps but crossed by a low rolling swell. To the east a gray wall of clouds topped by a fringe of peach in the morning light threatened to sweep down on us. As the day progressed it did move over the sea toward us and shortly rain began to sweep against the bridge ports and over our improvised crow's nest halfway up the mast. Visibility dropped, and the wind picked up until the water was blotched with spilling white water where the wind swept the crests from passing swells. Down in the furrowed and moving valleys through which we passed kittiwakes and murrelets flew. As the wind picked up still further, driving trails of spray in lines across the sea before it, the shearwaters began their aerobatics. I never cease to admire their flight. In a wind they rocket up in curving arcs to turn and shoot downward in a steep curve that takes them within inches of the water. Then they turn and shoot up again like swift gliders. I've never seen them feed when doing this and one wonders if it is just for the kinesic love of flight.

Later in the day the hummocky outlines of Pt. Conception and Pt. Arguello showed through the haze. The ship had by this time turned up Arguello Canyon, and as we neared shore (the canyon is a submarine one and lay a thousand feet or more below us when we cut into it) the swells rose to impressive height—perhaps 15 ft. or more. This canyon had been the grounds for several blue whales when the *Helix* was here a few weeks ago, but nothing was seen—porpoises and no fins of larger animals.

I stood a last watch in my foul-weather gear and happy for it as the wind moaned around the rigging of the crow's nest as the rain and wind swept by.

Dave Gaskin told us about his *Phocoena* work and I continued to combat a mild malaise with Dramamine D.

We have turned south toward a pinnacle known to Dale Rice where we hope to find our animals tomorrow.

December 4, 1971

Enroute San Juan Sea Mount

A rough day cruising toward a pinnacle of rock that comes up from the sea floor a long way offshore. Dale Rice knew of this sea mount and thought it might be a place where whales congregated. But the weather got worse and worse and we were bucking into a rough northwest wind of perhaps 25-30 knots under overcast skies. Our only companions were sea birds—murrelets, kittiwakes, and black-footed albatrosses. My foul-weather gear proved itself as I was able to stand my watch in relative comfort while the others not so clad, had a more difficult time of it and generally carried out lookout

from the bridge. We turned and headed for San Juan once it became obvious that we were surrounded by storms, and that we could not expect the weather offshore to abate.

December 5, 1971

Off Northern Baja California on the continental slope

Last night the skipper put her in the trough and we rolled mercilessly—a feature the *Helix* does to perfection. My bunk was athwartships and hence I slid back and forth lengthwise until I learned to pile the extra blanket and my heavy sweater in the bunk foot and brace my feet against that and my head against the upper bunk edge. It stopped the incessant sandpapering effect but it didn't promote sleep and one had to brace with each roll.

The day calmed and we cruised southward in pleasant seas but without sighting anything except a school of *Delphinus*. People began to emerge at other than watch and meal times.

December 6, 1971

In the area of Islas San Benitos, Mexico

Last night was a joy as the seas were following and quite low anyway. It felt utterly flat. I should describe the dolphin school of yesterday. We turned in along the continental slope toward San Quintin Bay in what I called the fishhook. It is a series of indentations running north and south where this slope cut in towards land. About 2/3 out on this feature we came upon a school of *Delphinus* spread over about 6 miles of sea—or from horizon almost to horizon. I estimate there were about 300 animals in this area, all in small groups of 6, 12, 10, etc.

Many of these groups came to the bow and others leapt and played rather far from us and didn't make the effort to come in. The groups were very scattered and yet the group was obviously a school. It is interesting that the cohesion of this species allows it to spread so far.

Cruising today was uneventful—through calm seas with few birds or fish. Rather early West San Benitos hove into view—a cone with a base like a flattop—and then Isla Cerros or Cedros, a large island reaching almost 4,000 feet and fringed, especially on its north end, with copses of closed cone pines. We cruised down between the two, raising east and middle San Benitos and then, as we passed southern Cedros we could see the whaleback off Natividad and Punta Eugenia beyond—sere and barren desert.

Off Punta Eugenia perhaps 15 miles we spotted a single whale of small size—perhaps 30-35 ft.—for a long time all we could see was occasional blows but then we saw low views of its sleek black back—but never a fin showed. No one knows what it was. It finally gave us the slip entirely.

December 7, 1971

SE Guadalupe Island, approximately 100 miles

When we woke the ship was over Rosa Seamount, a double pinnacle at the edge of the Continental shelf approximately off Punta Abreojos. We were greeted by a school of *Delphinus*. These animals showed the unicolored dark dorsal fins of the southern *Delphinus* and the frosty gray snouts that also seem to typify them. We turned northward toward home into roughening seas. Off to the west of us a couple of bad storms, one with

35-ft. seas that has just sunk a freighter, and a couple to the north making the area we left unworkable. Actually, we had no choice in coming south if we were to hope to work, whales or no whales.

The water continues green. I think we hit a little oceanic blue today but mostly it has been green and dotted with *Macrocystis* rafts. The major excitement of the day was looking at the molas under these rafts. A couple were pretty large, perhaps 150-200 lbs. or so. Our course took us west of San Benitos and Cedros. The lower San Benitos islands were not visible against the bulk of Cedros, and all were away to the east 35 miles or so. Then we slipped out to sea where no land could be seen.

The seas became quite rough as we bucked into them about noon, but began to abate somewhat by dark. During the night it became calmer still, though a smooth trip north against the weather seems out of the question.

It's nearly always a bouncy ride from Cedros to San Diego. The weather made most of us feel a bit out of sorts; I was able to hold mine in check with a little Dramamine D but some others were not so lucky. In times like these one's routine regresses to an awful sameness. Motivation to be up and about fades. One finds that only certain positions allow one to read or waves of nausea sweep in. I usually react by getting sleepy and lying down for a bit of fitful sleep. My bunk works pretty well where my head is cushioned by a pillow and my eyes don't jerk over the page. I do better with weak glasses than with the stronger ones I increasingly require to read. Unless the book is gripping I find myself going back over sentences again and again and finally dropping the book as my concentration fails. *The Hobbit* or Hemingway work fine but a text on animal communication wouldn't wash.

We have a watch bill that puts us up in the plywood crow's nest twice to three times a day for an hour. I welcome these times, wind or no, as the clean air and cold make you alive again and there is purposeful activity to do. Then one comes down, looks at his watch to see what's next. Maybe a stop for a desultory conversation with someone on the bridge—reminiscing over old experiences at sea or in the wars. Most of the crew and many of the scientists saw service. Then you wander below. If it's 7AM you stop by for some breakfast, even though you don't need it. If not, a cup of coffee will do, and more conversation, often with your scientific colleagues in which you learn about each other—not in big gulps but piece by piece as old experiences, old friends, or acquaintances are discussed—especially the outstanding ones who are sure to have foibles worth mentioning. “Is it true that Pete Scholander hung by his legs upside down from a helicopter over the top of a redwood tree to measure the respiration of the growing tip?”

Personalities emerge but no one forces much. There's too much time and one's resources are husbanded, or let to come out as they might. Then, you wash your cup and take off for your stateroom and a new attempt at understanding the social communication of earwigs, or wherever the animal communication book happens to be now.

Then comes lunch. It is a tour de force. The two cooks Julian and Alex are superb. Each meal is a thing of art and each is different. They stand over the line and urge you to take more, or to return, barring immediate acquiescence. It's a tough life. None of us have much physical to do. Mostly we snooze or walk around bracing ourselves against the multiple motions of the *Helix* (a snap roll and much jerking about in an erratic manner). So, we pick at the delights and try to remember our waistlines.

Then comes another watch. Supper, another tour de force of about the same size as the dinner meal—meat, soup, vegetable, potatoes or rice, a nice tossed salad, drinks, dessert.

Darkness falls and everyone waits until 8:M when there is either a movie or a seminar from one of us. Everyone is invited to these things and many of the crew are the most interested listeners to the seminars.

Then it is 9 or 10 and we retire to the bunk for more earwig behavior or to a shower, or to wash clothes, or jaw with one another in the lounge.

Our scientific crew is a good one—compatible and interesting. My roommate, Walt Garey, is a fish physiologist who works mostly on salmon, but who also discovered that flying fish go into bradycardia when they fly into the air (the same thing whales do when they dive, or when a human puts his face into water, or when a baby is born—the heart slows drastically). Walt is a teacher, an open guy, and is now running the *Helix* program. He is deeply dedicated to it. I like him a lot and enjoy talking with him. Dale Rice, of the National Marine Fisheries Service, has had more experience with northern hemisphere whales than any of us. He is very quiet, full of knowledge of the sea around him—the birds, and other things.

Jerry Koozman of Scripps is a fine respiratory physiologist who specializes in diving phenomena. He is humorous, gentlemanly, quiet, rather easy going but sees that his job is done. I think he is an in-depth fine and thoughtful person. It's been a special pleasure to know him better. Jim Fish, who I have known before, is a bioacoustician who has designed the gear we hope to attach to a whale. He is a very open, down-to-earth guy, full of good humor and a fine scientist to boot. Tom Dohl and Wayne Smith fill out the bill. Tom of course is an old stalwart to me, and Wayne, while fitfully seasick most of the time, is emerging as a very pleasant and regular guy too. So. A good crew. I wish we had more action.

December 8, 1971

At sea, off NW Baja California

The sea calmed last night and by morning there were only swells and little wind. I went up to the bridge after my breakfast toast and shortly spotted a group of thin puffy spouts off the port bow a couple of miles. Dale rather soon identified them as killer whales, and in minutes we were upon them. There were about 15 animals, including one old bull with a tall wavery fin of 5-6 ft. who brought up the rear. We named him Ferdinand for this and set about trying to hitch the instrument package to him.

The whales were lined up more or less behind one another, and as I noted, Ferdinand was at about the end of the line. The remainder of the school included a sprinkling of ages and, presumably, sexes. There were probably two rather small babies—one showing a trace of the lemon yellow instead of white, especially in the spot behind the eye. There were a number of what were probably yearlings, and a couple of very bulky animals with rather low and somewhat falcate fins—we take them to be females, but of course, we don't really know. Then there were two animals with big bulky bodies and fins that stood straight up perhaps 3 ft. These might be young adult males. And then there was Ferdinand. His fin in side view was a tall straight-bordered triangle—perhaps a foot wide at the base and 5½-6 ft. high. In profile the fin was slightly

S-shaped and quavered noticeably both in the wind and as he dove and the rushing water hit its base.

We pursued the animals from 8:30 until after 3 PM, and during that time their schooling behavior changed quite markedly. Their formation was quite scattered at first—covering 200 yards of sea or more. Later, as the animals resolutely tried to shake us, they bunched and instead of trailing in a line they assumed a front that was sometimes like a straight line and sometimes diagonal, bunched or less regular in other ways. For the last four hours Ferdinand always occupied the end of the line, and was noted at both the right and left end. By this time the school had bunched tightly until it stretched over no more than 50 yards of sea.

The school tried a variety of tactics to shake us. At first they wandered near us and didn't seem to take us too seriously until Jim sent a dart into one animal. The animal crossed the bow and the red nylon stretched taut and then elongated 10 ft. and snapped. Its 300 lb. breaking strength meant nothing. Walt didn't toss the trailing instrument pack over because of a mix-up in signals. Then the animals began to dive. We were able to close on them quickly enough. Jim got two more shots, but both failed to attach. One bounced off Ferdinand's fin, and the other went over his back.

At one point the whales tried to outrun us. They almost could. They plunged along, not diving at all, at about 10 knots. Then, abruptly, they ceased this maneuver and began to dive and avoid us underwater. Still they couldn't shake us, though we seldom got near. Toward the end they simply wouldn't let us closer than about 30 flukes and the only indication of diving was an arching of the tail stock. The water is green and very dirty with plankton. We couldn't see the animals more than 8-10 ft. down.

Everyone retired from the chase windblown and cold. The rest of the day was uneventful cruising toward home. We got there late tomorrow afternoon.

Magdalena Bay, Mexico, January 25-February 3, 1973

January 25, 1973

La Paz, Baja California, Mexico

We're off on a trip to catch a whale and put a corset on it. This heroic endeavor will take place at Boca Soledad at the north extreme of Magdalena Bay. Our real objective is to learn to catch, harness and release a baby gray whale as a preliminary to satellite tracking. With us are Tom Dohl, Roger Grutey, Bob Gibson (Franklin Institute), Dick Pierce, and at La Paz we will meet Jamie Dominguez and Mario Camparan of Escuela Superior de Ciencias Marinas, Ensenada, and Jose Castellan of Consejo Nacional Ciencias y Tecnologia, Mexico City.

We drove to San Jose after I almost fouled up the works by waiting at the wrong place—but we made our plane only to miss our transfer to La Paz. It simply took too long to get our baggage and walk across the mall at the airport. But, fortunately, we caught the next plane, only a short time later. The flight took us over the gulf—a beautiful view of Puerto Refugio, Angel de la Guarda Island, Tiburon, and San Esteban and finally Ceralou and Espiritu Santo and then La Paz.

When we landed Ken Balcomb was not there, as we expected him to be. Finally we holed up at La Perla Hotel and had a nice fish dinner in the plaza and hit the sack. My

reintroduction to Latin bed pillows was the only problem. The weather is balmy and lovely. The sun set with a typical fiery gulf display.

January 26, 1973

Lopez Matios, Moclips Cetology Society Headquarters South

Up at 7:30, a nice breakfast and to the bus depot where we waited watching the sopilotes (turkey vultures) by the dozen soaring off to some business to the south. Soon the bus came and we were off to Ciudad Constitucion, a new farming town on the northern Magdalena Plain. It's a 2½ hr. ride over the undulating foothills of the Sierra Giganta. *Cardon*, mesquite, *Jatropha*, *Sinita*, and *Opuntia*, and the desert floor carpeted with orange *Sphaeralcea*. Very lush with recent rains.

At Cd. Constitucion there was Ken Balcomb with truck. The bus and Ken's truck were what we needed to get to Lopez Mateos. We piled all our gear in the truck and split the party. I went with Jaime, Ken, and Dick Pierce. We drove across broad fields of grain, past cotton gins and finally into the desert scrub. We stopped at one of the many drying ponds from the recent rain and found it crawling with ostracods and fairy shrimp. In the poolets, just about to disappear altogether, the movements of the numerous animals had deepened them, which probably inhibited drying. The little ostracods had their valves flowing with filamentous green algae. The biggest of them were maybe ¼ in. long. The fairy shrimp, looking like little Eurypterids, were larger—maybe 1½ in. long, including forked tail.

Soon we drove along Arroyo Soledad, an estuary from Magdalena Bay and soon over the flats we could see Lopez Mateos, its ironwoods, water tower, and galvanized cannery. Soon we could see Boca Soledad—a 300-yard stretch of water leading north three miles to the real sea entrance. The opposite bank was sculptured with 50-ft. dunes. Two boats rode at anchor in the windswept water. One was the *Louson*, our vessel. She is a beautiful little fishing craft—45 ft., 16 ft. beam, can haul 20 tons. She has a flying bridge you can enter from the cabin, 4 bunks, a beautiful metal swordfish plank, radar, the works. Soon we flagged the skipper Tim Houshar and went aboard. He's a good rugged fisherman, tough, bright. Dick and I complemented him on his trim ship. He was obviously pleased, I thought, as he was proud of her too. He had come over the bar at the Boca, following his skiff and in the trough had nearly rolled on his beam ends. There were breakers clear across. He told us about the *Martha Jane* that had caught Gigi, the previous gray whale that had lived at Sea World for a year. Mother had investigated the restrained baby and then come over to the boat and began to batter her. Three ribs were broken, the keel broken partly free before she gave up. I hope we find a more docile one and so does Tim. But, he has the guts to try and there can't be too many guys like that in San Pedro.

We unloaded food and gear, met with the local jefe (the head of the cannery). He checked out our papers and gave us the go-ahead, not cracking a smile about our strange mission. Speaking of such things, Jose Castello tells us that some people in his government think we are down here doing some military project relating to the Russians. He is supposed to be careful what he photographs so as not to get in trouble with the American Embassy. Hard to believe, I guess, that we're just interested in whales. Jose, a most affable young diver-biologist, is to take a movie of our attempt for Mexican TV. Jaime and Mano are just to observe us biologists. After some spaghetti (excellent) and

Pacifico beer we tried out the harness and went to bed in Ken Balcomb's house. There's no furniture but food boxes and cans made do and we sleep on the floor. He has three rooms and a leaky roof but its great for us. All we need.

January 27, 1973

Lopez Mateos, Baja California del Sur, Mexico

A lot to tell today. We caught a whale. We rose about 6:30, began breakfast and assembly of gear. Breakfast involved a bit of organization—finding things stowed in various cans and boxes. When done, however, it was great. Scrambled eggs and bacon, toast, coffee, and grapefruit. But it took time and we were late getting to the boat. However, gear gathered together, we were soon off down the channel toward the Devil's Bend, a winding channel that enters upper Magdalena Bay.

It was a beautiful morning, Vs of black brant flew by, a pair of white ibis stalked in the shallows near mangroves. Two sea lions appeared in the channel, one a lone female, and another with a gray whale.

Soon we encountered mother-young pairs of whales. Tim went to the end of the 35 ft. plank and readied his gear. We had agreed he would use a noose without a net in order to catch the animal by the tail, and then head net it later to fasten it fore and aft. He put one of his men, Randy or "R" who steered from the masthead. By hand signals and shouts Tim directed him over the whale pairs. Meanwhile the panga, a Boston whaler with a Mercury engine, criss-crossed over the animals. The rationale, which I think worked, was to frighten and distract the animals with two sources of fear to which they had to react. Thus they made mistakes and Tim could get his chance to noose them.

The pair we chased maneuvered away from us. The baby stuck very close to its mother—so close in fact that it sometimes rode up on the mother's flank as she turned and slid down over mother's side, actually in contact. The baby repeatedly changed sides seemingly taking "shelter" behind his mother's bulk. We pursued them rather rapidly—5-7 knots. Finally Tim got a shot as the whales evaded the panga. The baby came up a little behind where Tim stood so he reached back and placed the hoop over the baby's head as it rose to breathe. It was slow motion compared to a porpoise. Unlike the porpoise the little whale nearly stopped, dove, took out about 30 yards of line, and shook it off. Tim hadn't been able to get the noose over its pectorals. Baby and mother slid away to the south.

All around us, especially to the south were pairs of whales. Size of young was quite variable even though birthdates could not have been too far apart—instead it reflects the extremely rapid growth rate of these babies.

Ahead of us lay the sand-dune-lined channel on the ocean ridge while the inside is lined with low mangroves. Santa Margarita Island rises to the south, bluish gray, like the knuckled back of a sounding gray whale.

We came upon pair after pair and usually lost them because of confusion over which was the pair we were chasing and which was the old pair. Finally we turned up the Estero Soledad and Tim had a clear shot. All eyes were forward. In slow motion Tim placed the noose over the baby's head. This time it did not escape. The noose slipped back to the tail. We hauled the baby in, delaying the line on the foreward bit and finally, into the Estero, brought the baby and mother under the pulpit. Tim stood out in the basket with the colossal bulk of the mother crisscrossing under him, her 5½-6 ft. flukes breaking

the surface from time to time. She was patched with groups of salmon-colored whale lice and mottled with light-gray pattern marks. The baby was pulled aft enough that Tim was quickly able to drop the head net over her (she is a female) and we had lines fore and aft. This caused some interesting moments trying to keep them unsnarled and away from the mother. At first Tim tried to bring her alongside but the mother refused to leave and even aggressively slashed sideways with her tail and pressed against the baby. I suggested we take lines ashore and he agreed at once. We put one line in the skiff while the boat inched in close to the beach. With that line ashore and tended we brought the other in and shortly brought the baby into 3 ft. of water or so, too shallow for the mother. We tethered the animal fore and aft to mangroves and began to place the harness, which we did without significant trouble. Leaving three men to push her off we coiled and washed lines and put them in the skiff. The schedule went like this:

- 1245—netted baby
- 1325—harness in place
- 1342—mother left and went down the coast, close inshore
- 1347—baby pushed out into deeper water
- 1351—another mother and calf came close by
- 1400—baby picked up on receiver (28 microamp signal at about 300 yards)
- 1407—baby turned after long sortie into upper bay (turned by skiff) back toward main channel

Harness riding very well. No wrinkles or flutter, positioned well over pectorals. Antenna is out very well. In fact entire pack breaks water on each rise of the animal, antenna is out from 3-5 seconds or 1-3 signals on directionfinder, and down for 25-30 seconds.

1425—baby was cruising slowly and then began to rush toward the opposite side of the channel. About 300 yards away was the mother. She fluked twice and swam directly toward the baby.

1427—they met, mother slashed water with tail, circled baby and they went off together

It seemed as if an acoustic signal was the only possible way they could have contacted. On the beach the baby had phonated constantly, producing low resonant pulses a second or less long. The head[?] lateral and behind the head pulsed as sounds were being produced (no air was released during the sound).

The baby was heavily infested with lice of at least two types all in crevices or in patches. One I picked off was thumbnail sized. The baby was 16 ft. over the round (measured by knotted rope). She had 12-15 knuckles and they were sensitive to the touch.

For some time the harness rode nicely but then at—

1457—one limb of the harness broke free from lower plate and swung back, loosening the upper harness so it caught water. The reason was that the magnesium bolt was just too long to be taken up lightly thence the D-ring could be pulled free.

1500—Dick Pierce reports 10-30 microamps even with antenna slightly below water—when he could see yellow of harness. By the way the whale was named Carl which I painted on his float, but being a girl, it had to be Carla.

1605—Baby left mother and came to boat. I was in pulpit and saw her circle and purposefully go under boat, through, and rub against boat hull (which I could feel). She came up with the float broken half free and antenna snapped. No more signals.

As we passed the entrance of Estero Soledad the baby refused to go farther. The mother went on and returned later. This happened six times but the baby would never go farther. Finally, the mother returned and they went together up the Estero. We followed and lost them at dusk. Or rather we had to leave even though the harness had not released because of tide and shallow water.

The bolt was a five-hour one and we had waited 4:45. Maybe tomorrow we'll find the gear.

A few words about behavior. Once the baby was netted the mother ceaselessly tried to urge it forward, thrashed over the line, or used other maneuvers. She never attempted to attack the boat or strike at the pulpit though she often came close enough to do so. Her only attack was on the lines near the baby. Once she scraped under the lines and came up with a minor abrasion as a result, just anterior to the knuckles.

When the baby was ashore she tried to come to it, going into five ft. of water within a few yards of us. It was quite a sight to see 40 tons of whale nearly beached, head pointed toward you, within a few steps, and then watch her roll, throw a great flipper into the air and then slash sideways with the 6-7 ft. wide flukes while $\frac{3}{4}$ of her great, rounded body rolled above the water. Meanwhile our men worked with their backs toward her, putting the harness on. I was surprised to see her leave but perhaps, as Dick Pierce pointed out, the baby was phonating largely out of water and perhaps she could not hear her calf.

We ate a good lamb chop dinner and went to bed.

January 28, 1973

Lopez Mateos, Baja California del Sur

We'll try again today with another harness. Tim Houshan has rigged a fish-hook harpoon to place a yellow streamer on the mother. This will help him follow her and the baby when he is trying to net her. It helps greatly in following the animals to have a spot of yellow below the murky water. It's a beautiful brisk clear cloudless day, the water glassy except for current ripples. We rig gear and head south down the 1/3-mile-wide channel.

10:55—small baby netted 2 miles or so S. Lopez Matos. Tim missed one shot—slipped off snout. Baby rides in contact over mother's back, in contact with pectorals or flukes—like a remora almost. After rerigging Tim made another easy shot, this time from farther forward (animal ahead) and line slipped easily to flukes and held animal. Some time spent working baby toward shore. We put the head net over with no trouble other than the time the mother took to coming up under the line or thrashing at it with her flukes. Twice, at least, she came up under her baby, forcing it part way out of the water.

Soon we had the line tubs over the broad sandy shelf and not much later we had the baby over the sand in 3 ft. of water. As usual the mother patrolled in deeper water yards away.

Harness placement was quick and this time over the snout and soon it was bolted in place with a five-hour bolt and "Lee" painted on the side in honor of our accountant at UCSC, who we are sure would love to be here.

Times were:

1110—animal noosed

1123—team ashore hauling whale

1142—whale launched and quickly joined mother

1138—harness on and ready

The baby made no grunts so far as I could tell except during expiration. It was a male and had very evident fetal folds. It was 14 ft. long—straight line, snout to fluke notch. Grommet holes were 3 and 2 from bottom holes.

Jose, who had missed important shots, says he got the whole sequence on film and of course Tom, Ken, and others were shooting stills at a great rate. Jerry Koozman, who had just joined us, was delighted to see the whole operation. It went like clockwork. The flat weather, nice and sunny and warm makes it a pleasure just to be out on the boat, let alone catching and observing whales. As usual, everyone did his part. Jaime and Mario are proving to be excellent young workers, and I am impressed not only by how hard they work but about the very complete record of every thing we do they keep for their reports. Jaime helped a great deal with the head man at Lopez Mateos, translating and explaining for us. Jose Castello is a delightful guy, full of good humor and always busy with his work. He knows a lot and has worked with many of my colleagues.

1437-1444 (different watches)—harness cast off perfectly, floating perfectly upright in the calm water. It was transmitting nicely all the while. The lower limb already abraded through in one spot, probably from rubbing against mother's barnacles. The whale had also turned and rubbed upper right rear corner on mother as it was coated with what look like cyamid parts caught in the syntactic foam. Three of the handtight nuts that holds the lateral harness to the dorsal pack was a rear piece of syntactic foam our[?] radio housing was broken loose 5 x 5 in. [??] It's sure that some protection for harness from rubbing is needed. It's also doubtful, it seems to me, that the harness material will last very long. A good test and we learned a lot.

Much searching in the skiff failed to produce the harness from yesterday's whale, or the whale itself.

We turned for port because tonight we are invited to some sort of affair by the officials of the town.

Well, it turned out to be the neighbors who had quite a bash. It was in honor of the baby Jesus who had been born on the 25th and now was leaving the manger. Girls and young women mostly gathered around the kresch and chanted in response for a long time and then winding down sang songs about the posada. Then they took the baby, disappeared into another room, and came back with candles. One lady took the baby model and carried it to everyone to kiss. Then began dancing, food, punch, and lots of gaiety. The young bucks mostly stood in the street with their hands in their pockets, leaning on the hoods of cars but occasionally they joined in the dancing.

Note: the baby we caught today stayed almost where we caught it until the package came loose, as did yesterday's whale. Tomorrow we tag with a 24-hr. approx. bolt.

January 29, 1973

Lopez Mateos, Baja California del Sur, Mexico

Today we try for a 24-hr. track. The whale will be named "Baja" in honor of the Escuela Superior and Ken Balcomb will attempt to track it 24 hrs. with a skiff. Roger and Dick mouted a lifejacket light on the harness to help Ken locate the whale.

Everything has gone so smoothly that we could have done much more than we planned. Capture is easy, as is harness placement. However, we are delighted with what we have already learned and next time we will be able to plan for real whale biology studies, not just capture and harness testing.

Ken has found a whale he knows has been here for two weeks or so and which has stayed near the Shell Mounds 1 mile S. of Lopez Mateos. It's a slightly overcast but flat calm day so far and optimum for capture.

Well, we chased that whale for an hour and no dice. Then we switched whales and noosed one that Tim couldn't get the hoop over. The noose stuck ahead of the pectorals and wouldn't slide back. We had a helluva fight and finally Roger and I decided it would be too large for any of our harnesses so we got up as close as possible and cut the line. By this time the noose had slid forward ahead of the nostrils. I'm sure it will slide free soon.

Quite a few more fruitless chases were made with the whales simply refusing to get under the pulpit. The overcast prevented us seeing very far into the water, making following them underwater very difficult.

I'm beginning to believe there is such a thing as a nursery. All the calves near Lopez Mateos seem large. We have only encountered small young to the north near the big sandhill before Devil's Bend. Ken says some he has seen have spent two to three weeks in this area.

About at Big Estero S. of Lopez Mateos we caught a 17-ft. female. It was 1406 on line. Mother.

1426—skiff headed for beach with line

1430—landed and began to pull

1433—nearly in

1435—bolt in water, harness on

1441—started in launch

1442—launch

1445—came back in, mother with, went back out, launch complete

The mother was very solicitous of young, and angry, throughout capture and harnessing.

In the water she repeatedly came up under baby with her snout and once she poked at head net with her snout, pushing it about halfway off. The nets, by the way, are about two to three ft. too shallow for these large calves.

Once on beach mother came right in within a few ft. of us. I warned about her tail and almost no sooner than I spoke and she took a vicious pair of lateral slices at the nearest men, missing them a few feet but throwing a sheet of water over most of us.

The harness was quickly in place, four grommets from each side. It seems easy to bend the very flexible pectorals in these calves. I guess they are yet cartilagenous at this age.

The baby came back ashore twice and had to be relaunched. The last time Roger ended up much too close to momma for comfort as he pushed the baby out. Beyond the

call of duty for a pinnipedologist, as has been the case throughout the trip. He is a splendid field man.

We will take most of us back to Lopez Mateos and put Ken Balcomb on board with the radio. This harness has a light on it (glowing nicely at last sighting), and he should be able to keep track of it easily and get respiration rates.

Good day! The bolt is set for about 20 hrs. so it should come off tomorrow morning sometime. Jose says he got some great shots but did get salt water from the whale's tail in his camera. Even so he seems happy.

Not bad! For amateurs—three whales in three days and one let go on purpose. Now it will be hard for people to question that we can catch, harness, and track gray whales. I'm thinking about modification for the harnesses. For long times (two to three months or more) I'm wondering if metal mesh won't be required, or at least very stout coated fabric. I prefer mesh because it will allow water flow. Tom Dohl came up with the notion that an impact belt might work to compensate for growth. We need a tension device that will allow a slow expansion but stop the whale if he drags the harness against a rock. Since he will grow so much in a year we have to compensate for growth even on a traverse of a week. Otherwise we have to think in new terms.

I do not want to go to surgical techniques or to placement on the tail as was done with Gigi. Surgery is too messy and likely to be rejected. Placement on tail involves too much movement. Over the pectorals is best. It is the area that always breaks water, has least movement and the best natural means of fastenings (the pectorals). We just need to solve longterm expansion (growth), short term contraction (compression or diving), abrasion (from mother's barnacles and rocks on the bottom). We'll see.

Tonight chicken and some [?]-Pierce-Dohl spice special. Actually it turned out to be chicken in red wine. A couple of onions chopped fine with two or three cloves of garlic, browned in bacon fat, from bacon just fried, chopped fine, brown chicken parts and set aside, lightly sprinkled with flour. Then with a stew pot add two thirds beef boullion and 1/3 red burgundy to cover. A couple of bay leaves per chicken and thyme, salt, pepper. Simmer 30 minutes and EAT!! Eat we did, with a good salad and chocolate pudding which I made and succeeded in splattering on the wall. Man, it's hard to pour.

After dinner we wandered in the cool darkness checking out Lopez Mateos. It's a factory town. Most everyone works for the cannery—except the local merchants. Most houses are neat plywoods, paper thin with corrugated roofs. Some have bothered to use tar paper. Casuarina trees are the main shade over dirt streets that ultimately wander off into the desert. Everyone is well-fed looking and there are very few old people, though there are rafts of kids of all sizes. There are a couple of cantinas blaring their requisite quota of mariachi music into the starry night. We bought a couple of coffee mugs, looked at the meager merchandise, and finally wandered home to sleep.

January 30, 1973

Lopez Mateos, Baja California del Sur, Mexico

Pancakes for breakfast! Then we went down to the muelle to wait for the *Lousan*. We watched a load of thread fin herring and occasional sardines being unloaded by vacuum pump. Twice now the seiners have come in with holds full and a deck load.

Soon we were on board and found that Baja, the last whale, had stayed almost in place all night. The transmitter worked for a while and then quit and the little light shut

itself off after a while. It was loose enough that it worked up and down and pushed the switch. So our redundant systems both failed and they had to follow the animal, which proved simple. During the night the animals moved rather little though pods did pass them going into the estero. One pair passed right under the pulpit, outlined in phosphorescence.

The harness was recovered easily in the morning, within 50 yards of the boat. Take that, you astronauts!!

It was floating idly in the water with antenna vertical, except the radio wasn't working and the light was off. Anyway, "Baja" is back on board. There was very little abrasion. Only a little on the anterior edge of the belly straps.

In the evening Dick said the baby had been thrashing around rather strongly, coming part way out of water and rolling. But later she calmed and no further unusual activity was noted.

Well, we've gone north toward the Boca Soledad and will turn and make a count back south of whales in the channel down to Devil's Bend.

Ken Balcomb, Tom, and I kept counts on marine mammals, separately. We cruised from the Boca to the head of Devil's End, under overcast skies, not the best observation conditions as you can't see down into the water easily.

The harness was sighted by Ken in the eel gras S. of the Sand Hill "Colina Coyote." It was retrieved quickly and we found that the float had been broken away at the grommets and was rubbed with blue bottom paint, as was part of the harness. Thus when the calf rubbed the bottom she probably rubbed the harness hard enough to pull the D-ring over the belly pin and release it. Otherwise she couldn't have gotten blue paint inside it. The harness was nowhere badly abraded even though it presumably stayed on the animal for several hours. The block of syntactic foam was badly cracked and laid back and the antenna was snapped off flush with the housing. Bob Gibson got no signal when he pointed the receiver at it.

We explored the upper Devil's Bend a bit, following the oil drum channel marks. We could see the shallows close in, brown beneath the green water. Finally, rounding a bend in the channel the *Louson* ran aground and had to back off.

We turned and headed back to Lopez Mateos. Mario, Jaime, and Jose put together a really delicious taco and bean spread. They sprinkled oregano on the pinto beans and put cilantro in the sauce. Great!

Tomorrow we hike beaches north of Boca Soledad.

It was overcast, blustery, and cool today, and the wind blows in the ironwoods outside our house. Hope it calms for tomorrow, though overcast will make it easier hiking.

January 31, 1973

Lopez Mateos, Baja California del Sur, Mexico

This morning we headed north on the *Louson* toward Boca Soledad. We will hike about eight to ten miles of beach, looking for strandings. Ken Balcomb will stay on board and observe.

As we neared the Boca, a few open patches of blue showed through the otherwise glowering, misty sky. Later it cleared altogether and became calm and beautiful.

Tim was able to thread the channels for five to six miles up the water way above the boca. Hundreds and hundreds of black brants rose from the water all along the way, crisscrossing in front of us. Many other waterbirds such as kingfishers, egrets, herons, terns, and pelicans rose around us, alighting on sand bars amid the mangroves. Finally he could go no farther. We clambered into the whaler and wound our way about to the open water area where the chart says "Tides meet." We nosed up to a sand bar that was absolutely covered shoulder-to-shoulder with shorebirds—godwits, willets, and some lesser birds that may have been plovers. The pack moved nervously away from us, finally rising in a rush of wings—red, black, and white and tan flashes as they wheeled and swooped down to rest on a more distant bar.

A short hike over the hummocky four-o'clock covered dunes brought us to the ocean beach. Tiered breakers lined the flat shore. At high tide they eroded the base of beach dunes and flooded between them carrying flotsam and shells far into the dunes. There were six of us hiking, a couple of packs with food and water and a couple of knapsacks for beach finds.

I spent most of my time plodding in the reentrant canyons into the dunes. Everyone "did his own thing," as the saying goes. Some by the water, some looking for shells, or watching birds. There were enough mammals to see, sea lion skulls, very long snouted *Delphinus*, a couple of small gray whales and one 35-40 footer. The beach was paved with shells—cockles, big clams, big enough for soup bowls, little delicate shells with two rows of long spines. One interesting and perplexing thing. The beach was strewn with green turtles that had died ashore at different times. I counted 26 in the 8 miles. There was no evidence of injury to any of them and some were much longer dead than others—a mystery. All had barnacles on them, some very dense, and some barnacles quite large (50 cent piece approximately).

It was a nice long walk and I was tired when we reached the Boca. We sat on the beach watching the whales and bottlenose porpoises swimming along. I think I saw nursing and saw quite a lot of behavior in which the baby lies at right angles to the mother's head, and crosses back and forth over her. What was going on was not clear.

Ken had watched a mating and had recorded patterns from many whales. Tomorrow we set up an . . .

February 1, 1973

Lopez Mateos, Baja California del Sur, Mexico

Today we cruise down to the nursery area just north of Colina Coyota (Sand Hill) and anchor. We have seen as many as 20 whales in this broad bay and we hope to have some of them come near enough to the quiet boat to observe behavior between mother and young. If it works Ken may go to a tower installation later. Those who wish can go ashore to walk and observe birds. I think I'll stay on board to observe. Then in late afternoon we will return to pack up gear to go on board the *Louson*. It's a bright sunny day, calm, with thin cirrus clouds over part of the sky.

Tonight we have a fiesta for everyone including the crew (good fiesta it was, too).

February 2, 1973

Lopez Mateos, Baja California del Sur, Mexico

Long before there was light we were up rummaging around to get our crew over to the local bus stop by 5:30 for the trip to Ciudad Constitucion.

We made it in time and Ken, Jose, and I stayed behind to pack all gear for the trip to La Paz. Especially we had to pack all the skulls Ken had picked up to take to the Instituto de Pesca for shipment to Museo Nacional. They had become a cause celebre in the last couple of days. I had told Ken before the trip that if he planned to violate any rules his operation and mine would have to be separate. He had ridden and walked 200 miles of beach and had collected what could be some real rarities—the pygmy sperm whale skulls, a *Lagenorhynchus* south of its supposed range, and what is probably an elephant seal from the Gulf of California. He planned to take them across the border.

It became slowly apparent that Jaime is a very nationalistic and probably bitter young man about Americans. He has been refused permission by some U.S. officials to take mud samples in San Diego harbor and he was resentful. Also he was a self-appointed watch-dog type who had tried to get appointed a sort of deputy to check on people who collected specimens and hunted in Mexico. Permission was refused but the attitude remained. He was miffed at us too, I began to learn, because of the slowness of our correspondence (it came at the Christmas rush) and because at first we said we wouldn't pay his and Mario's way (we didn't have the money). Finally I invited him even though a supplement we sought hadn't come in. It did, the day before we left. Well anyway, we found Jaime trying to get copies of our permits, we found him questioning the disposition of skulls, and insisting on reporting a scratch on the back of a mother whale we had produced when she ran under the taut line to her baby. Fortunately no major injuries or mishaps occurred and if he wishes to put us in a bad light it will be a concoction of his.

I was justifiably nervous about all this as we want our relations with Mexico to be good. Using Jose as an informal intermediary I was able to clear the air a little. I talked to Ken and told him we had to turn in his skeletal material and that the best he could hope for would be a chance to study the rare specimens before they went off to Mexico City. He agreed well enough though wanted to be sure the material was't simply discarded. That I could understand. Anyway we packed up his precious bones, some mere blobs of liquid carrion.

On the bus poor Tom came down with the eephus (ancillary dysentery) and when we met them in Villa Constitucion he was green and doubled up like a dying stork. I got him to lie down on the sleeping bags in Ken's truck and bought some elixir of Lomotil and Neomycin and dosed him well. The stuff is full of atropine and chloral hydrate and acts with remarkable speed. He soon went to sleep and by the time we had reached La Paz his color was back and even though shaky, he could navigate.

I looked up the Pesca office and met a young biologist, Sr. Olquin there. He arranged to have the skulls cleaned and I paid for shipment to Mexico City (Olquin had no budget). Olquin wrote a letter letting Ken take the rarities to USA for study, to be returned to the Museo later. A good solution, I thought. Later I found Jaime had been around to check up on us. We finally won him around, I think, as he was very friendly the last day, perhaps because I told Jose about my activities in trying to get scholarships for young Mexican-Americans in East Los Angeles. Who knows? We'll see.

We had a victory dinner at the marisco restaurant. Lobster, white wine (chenin blanc from Santo Tomas vineyard south of Ensenada), marisco chowder etc. Very good! In fact the soup was certainly one of the best I have ever had!

Tom was positively chipper when we got back.

February 3, 1973

Home

Goodbyes, packing, customs, airplanes that were late, close connections, notebooks (this one) left on the airport tram, and retrieved just in time. Rain in L.A. and so Phylly tells me, at home. A splendid trip. Great to do some field work and learn to know Dick Pierce, Roger Genty, Gerry Koozman, and Bob Gibson under field conditions. They were great company, amusing, hard working, and interesting. I enjoyed Jose a great deal and aside from the stress of the last few days, the boys. And too, we accomplished our mission to a degree quite beyond my best hopes.

Granite Mts., San Bernardino Co., California, April 6-7, 1973 (class)

April 6, 1973

Granite Mountains, San Bernardino County, California

Off with the walking class. There are 30 of us traveling in a bus (20 people), a van (8), and my pick up (3).

We met at 11 PM Thursday, loaded without too much fuss, and shoved off. There were three meeting points along the way and we found that even the bus moved along quite well. Breakfast at the old White's Cafe in Mojave after a very rapid trip down Hwy 5 on the west San Joaquin Valley. Then off past Edwards Airforce base to Barstow, to Amboy and up to the BC. The new freeway past the Granites is almost open and though hated by me will bring us within 5 miles or so.

The winter rains had lighted the desert. Near Mojave desert gold formed carpets of yellow. A blue *Phacelia* patched it with blue. The desert is dimly building up. There seemed some kind of installation all the way to Barstow.

At the BC we drove straight to the cabin, unloaded, and there prepared for a hike. The weather was mild and the skies clear. It's not warm enough to urge most lizards out, but very nearly so. *Uta* and *Sceloporus* are evident.

I took the class to the Cottonwood Springs area for a walk around the spur in the Granite Pass and back to the cabin. We botanized along the way, some collected insects, some pounded orthoclase crystals out of the rocks. Todd and Ginger Keeler-Wolf who really know their plants helped me with the animals. Todd is one of those folk who identify birds by call and he ran up a modest list that most of us didn't see.

Several *phacelias*, a rock cress (*Arabis*), *Rumex*, a *Zygadenus* with green flowers, a *Phlox* evening snow, a *Salvia* (*mohavensis*), desert five-spot (*Malvastrum*), at Pisgah[?]. One of the most common was yellow throats, a blue *Phacelia* with a bright yellow throat.

As for birds we saw a ruby-crowned kinglet, black-throated sparrow, fox sparrow, Oregon juncos, robin, white-throated swift, Cooper's hawk, great horned owl, great catcher, lesser goldfinch.

The hike covered about 3½ fairly easy miles but everyone was ready for dinner when we arrived at camp. Miraculously no one failed to show up, though I had a tough

time getting them going at first. It's a good group and I don't think I have an eskimo interpretive dancer among them. A little guitar music, a bit of watching red-spotted toads (calling, amplexing) and to bed.

April 7, 1973

Granite Mts., San Bernardino, California

Today is observation day. I think it is a success. We had reports in the morning. I told the class the history of desert floras and climates—Madrotertiary and Arctotertiary flux, the pluvial events, etc. Ken and Maggie Asplund, who had driven up yesterday afternoon talked about water and temperature problems and then we had some reports from the class—geology, etc. It went well with winds whipping over the deck and threatening to push us off periodically.

After that and a little lunch we pretty much did individual things. Some hiked the rocks behind, others headed out onto the flats to look for birds, one group went to look at stalagmites at Mitchell's Cavern. I hiked slowly down the arroyo below the tanque. The air was brisk and the bushes were full of birds, in the squaw bushes and cat's claws. I followed a thrush up and down the creek. He rested on the sand—long slim legs, rusty buff tail, breast speckled with round spots. It had to be a hermit thrush, but that seemed way out of place. The more I looked the more it had to be. My last look convinced me more. Well, I don't know. I saw a lot more—Audubon's warbler, gnatcatchers, rusty sided towhees—one old male with a bright red eye.

I carried a load of cat's claw wood back for the evening fire. The blustery desert wind kicked up dust and gravel around me and down in the valley a dust pall swept the playa. It was too cold for most animals to be out, I knew, but we packed up a car to go night driving down by the vulcan mine road. Too cold though. Not a bug walked the asphalt. Back at camp a magnificent spaghetti awaited us, with French bread and salad. I'd picked up some beer and then we had reports from the archaeologists—it wasn't much science but we had a helluva good time. Might have even learned a thing or two. After that the guitars and harmonicas came out and the old Bunny Club rocked with a lot of blues—the dishes got washed and I sat up on the bunny rock and wrote notes, hence the disjointed nature of all this. Hard to discuss hermit thrushes with the good music rolling out.

Point Reyes, Marin Co., California, April 21-1973 (class)

April 21, 1973

Pt. Reyes (Laguna Ranch), Marin County, California

The natural history class and I have spent a fine day (yesterday) hiking in over the Inverness Ridge and down to Laguna Ranch which is now a youth hostel. This morning most of us walked down to the tidepools SE of Linantour Estero and have now come back for lunch. I'm finished and have decided to spend the afternoon in observation. Being a little weary I won't go far but intend to wander down by the creek. We are a bit over a mile above the sea here, up a broad grassy bottomed canyon. The hostel sits on the canyon slope overlooking the alder-lined . . .

The rounded hills on either side are punctuated with palisades of gray sandstone, usually topped with Bishop pines and stunted, wind-pruned Douglas-fir. Over the slopes is coastal meadowland vegetation—grasses, blue-eyed grass, plantains, some poison oak, clumps of *Baccharis* (coyote brush), thistles, and various other herbs. The moister spots are grown with clumps of *Juncus* rushes, Douglas iris, and berries like salmonberry, strawberry, and blackberry.

I'm sitting now in the warm afternoon sun alongside a quiet stagnant pond next to the creek. It's 50 yards long and a third as wide. It's choked with *Nitella*? except for meandering channels of greenish water and patches of a reddish buff colored floating plant. Much of the surface is covered with tracts of tan which turn out to be a tiny four-leaved plant with long hairy depending roots (*Lemma*?). The reddish plant is more complicated, having a flat branching pair of leaves also with long trailing roots. It ranges from green to wine-colored.

Around the pond edge is a band of arrow-shaped *Rumex* leaves and wild celery. Above, on the muddy banks *Juncus* . . . The pond hummed dreamily in the heat—blue-bottle flies flitting over its surface and butterflies flitting erratically amongst the bordering bushes. As in all observation, if it proves uncomfortable the pastoral scene is instantly submerged in the human penchant for movement. I was hot, some flies insisted on sitting on me, so I left.

I rose and walked toward the alders whose tops rose in a meandering line above the creek.

To get to the creek one had to beat through shoulder-high cow parsnips, willows, and berry vines. Down a cut bank of stream cobbles and gravel I went until I came to a wooden bridge that led to a cobble bar around which the gentle stream flowed. Red alders sprang from the bar, making mottled shade against the still hot sun. Nettles lashed my arm as I passed, leaving a sting that kept on for an hour or more. I dug a seat in the cut bank, took off my shoes to rest my hot feet. Socks rinsed and hung out to dry I rested [?] a downstream rim of stream, the old multibranched skeleton of an alder and banks tiered with green herbage. Ranks of nettles stood on the slope. A man-i-in-the-ground vine sent tendrils up a fallen branch to an alder and a salmonberry plant dripped over the stream, its berries yet pale and unripe.

Behind me the stream bubbled over cobbles making its lulling burble. Perhaps four inches deep the stream hurries, its cobbly bottom brown with diatom scum. Little rafts of bubbles beat by the rapids bob and duck in the ripples as they hurry past me and around the bend. Two fuse in an eddy under the big fallen alder log.

I am visited warily by birds. A robin thumps onto the bridge, sees me and jumps into flight upstream out of view. Another hops out of the undergrowth onto the cobble bar to drink, not noticing me. A bright yellow piliolated warbler skitters his nervous way across the brush of the dead alder. I'm not sure if his nervousness is due to me or is inborn. I've never seen a phlegmatic warbler of my [?]. The mosquitos notice me though and one tries to plumb the swelled vessels on my foot. I swat in the midst of lowering his drill rig. Mostly the animal life seems to be insects and spiders.

Striders skating on quiet eddies, their feet dimpling into the surface tension, shining threads of spider silk gleam in the glancing sun.

Squeaking produces some curious streamside dwellers. A plump sparrow with a speckled breast and a dark apron of brown hops onto a pencil thick branch an arm's length away, hopping and peering inquisitively at me—a chipping sparrow, I think.

He utters a single note that I can imagine says “chip.” Anyway he came to my squeak and went away disappointed in what he found.

I grow drowsy in the warmth and meanwhile the wind breathes on the tree tops overhead but it does not stir the air near me. The buzz of flies over the stream . . . I slip down farther on the cow parsnip leaves that line my seat to keep me dry. A snooze listening to sounds of stream, flies, and wind. Then warmth and sleep. Brief I think though as I wake to the chirr of a wrenit. The sun has left me and the damp sand chills me. Above in a shaft of light amongst the branches of the old alder gnats swarm. Why? They circle madly out of touch with all but the insect pace of this place. It isn't a random dance but a rapid purposeful circling. It soon takes them out of behind the nettles. Are they warming? I suspect so. Other great clouds are more random but all seem related to sunlight even though their members swing off into shadow from time to time. Bigger insects seem more obviously purposeful though some dance as they fly, like wasps who constantly dip their tails as they fly along.

The winds increase. They lift and heave the willows on the bank above. Broad nettle leaves stir and I am getting cold in the shadow. I made such a lump of obvious protein here on this creek bed that I'm out of scale in a mostly plant world. Those creatures that can know are frightened by me and leave. Too much animal for too little a creek I guess. I'd have done better to hide myself.

Back at the hostel a work party had cleaned up.

Bluff Camp, Carmel River, California, October 20-21, 1973 (class)

October 20, 1973

Bluff Camp, Carmel River, Monterey County, California

We left at about noon from UC Santa Cruz, amid reports of imminent rain. We drove up the Carmel Valley to the Hasting's Reserve where John Davis, the director, was waiting and gave us advice on a camp. He said since we wanted to do some riparian work he thought Bluff Camp was best. It is on the Carmel River just above Los Padres Dam, which I am told supplies much of the water for Carmel Valley. Since it was then past 4 PM we left quickly, backtracked, took the Tassajara Road, and wound around until we came to Prince's Camp, a hodgepodge of old trailers and junk.

We assembled packs and were soon off up a trail toward the dam. It's mixed chaparral-covered hillsides, with a nice oak-madrone, sycamore, white alder, willow streambottom. The stream is fairly large and tumbles over smooth gneiss and granite boulders to the dam. The lake behind the dam was very low and much mud was exposed along with dead trees. The trail skirted the dam to the west on a nice leaf-covered trail amid big-leaf maple just turning yellow, stands of poison oak in various shades of pink, red, white, and yellow. The forest is much drier than that at Santa Cruz. Chamise forms patches of dark brown on the hillside from the dead flower panicles. Oaks are in the moister locations with madrones even more restricted, moisture-wise.

Finally we left the dam area and headed for the camp. It was very dark by the time we slid down the talus-covered trail into a fine oak grove with plenty of room for all of us.

Hal, who had gone fishing, came in later. Sharon and Val were our chefs and prepared an incredible vegetable-based bouillabaise over oxtail soup. Hal flung in a handful of venison chunks, which we sought for like they were gold nuggets. Conversation, to the sack with sparkling stars overhead instead of rain. I picked a madrone to sleep under which pelted me with berries all night.

The class has divided up into groups, each with a project which we hope to compare with similar attempts on Santa Cruz Island. One group is looking at niche width in caddis flies. Another is looking at species diversity and distribution in oak woodland and chaparral. Another one is doing species diversity in the stream bottom, and the last group is looking at dispersal mechanisms in seeds. We hope that some of these things will reflect back on insularity.

It's Hollywood and Vine up here—troops of scouts, families, classes, etc. troop by. It's a three-day weekend, and even with a chance of rain, everyone's in the woods. I visited Dave Hart and his group who were looking at caddis fly larvae. They had found some net spinners and were trying to determine niche width. They had devised a whole series of tests for water velocity using ink blobs in the current. The larva had built a little wall around a leaf underneath against a stone with the web stretched out in a place where the current tumbled in a shallow stream between rocks. Between 1-2 ft./sec. and less than 8 in. deep. I wonder if leaf placement is done so as to funnel water into the net, and hence to increase food supply. At any rate Dave and his team—Val and Sharon—seemed to be full of enthusiasm about paddling about in the water and were making excited happy rounds when I left.

Downstream a bit was Rob Bosworth, Lambert Woo, Kathy Johnston, and Hal Thompson. They were sitting on the bank looking perplexed. Their task was to make a bottom fauna population transect of the insects, larvae, etc. There were so many they didn't think they could count everything. I agreed and suggested selecting stones every two or three feet and running transects. They went to work at once and soon were gaining an idea of bottom distribution. Lo and behold almost no life was on the bottom in the still pools—only in riffles and shallow places. Why? Anaerobic on the bottom? Not enough current to transport and trap food? Light? Competition with bacteria? They didn't find out but they did learn that there was a problem.

The plant diversity—oak woodland-chaparral group worked away just up the hill. They'd laid out a 100-ft. quadrant and were puzzling over some mysterious plants. One, I suspect was a broom that lacked flowers and was just stalk—pretty hard to key out. They'd cornered a group of ladybird beetles—swarming in a bush and were wondering what caused the swarm. The ladybirds were heavily spotted and quite variable within the group in this regard. I saw some mating, I think.

We found a red trumpet-like flower and had been arguing over what it might be. Dave said it was a fuchsia. I scoffed! Craig said it should be with Onagraceae because it had a typical onagraceous inferior ovary. Onagraceae, I scoffed! It turned out to be "the California Fuchsia" and a not a true fuchsia but in the Onagraceae. Chalk up two for the younger generation! Well, I'm a porpoise watcher anyhow.

They went off (Ben, Peggy L., Craig, Dena, and Frances Thompson, who hiked up to join us) to make some transects through the chaparral.

The seed dispersal people were off somewhere (Nancy Dockey, Peggy [?], Irene McGinty) and we didn't see them until dark.

So, I hooked up my fishing pole and started upstream to catch a little dinner. It's a lovely canyon with tumbling water, smooth granite boulders, broad gravely reaches, coming now and again against steep rocky faces. Usually there I found still deep pools all leaf-floored and brown that must be scoured clean when the freshets come. Alders and sycamores are the main cover and make a patchy light and shade. I caught nine plump little rainbows and wandered back before dusk.

A nice campfire with good reports all around, some good round and other singing and then off to bed, still under sparkling stars instead of rain.

October 21, 1973

Bluff Camp, Carmel River, Monterey County, California

We'd collected a lot of interesting things and so this morning was given over to writing, and identifying. Someone brought in some galls. These are fantastically varied and specific for different insects. How the insect commands the plant to build these and what the function of the various kinds could be I don't know. I cut one open and a little group of gall wasps lay inside an almost shelled capsule. The little wasps had wings folded and shiny and were covered with granular material like sugar.

Another interesting thing we saw was the water penny—a tiny creature (1/4 in. long) that clings to rocks and has a jointed back that looks for all the world like that of a chiton. It was fringed all around with hairs. Underneath was an insect with six legs, two little tentacles, a pair of little black eyes, and fringed pleropods astern round back and forth like oars in a slave galley. The we learned that it is a larva—and of a terrestrial beetle at that! So complete and so well adapted as a larva—why change and go through all the hassle of metamorphosis? It too must be part of the scheme—a resting period, a way of lasting over some inhospitable time. I don't know, but to sit in this single camp and see the life around us is enough. There's plenty here for a lifetime of wonder.

We straggled off down the canyon, and I waited for the chaparral types to come back.

October 22, 1973

Next day a nice hike down to the canyon—sat in the creek with Frances Thompson and then home. My feet hurt.

Santa Cruz Island, Santa Barbara Co., California, Dec. 10-15, 1973 (class)

December 10, 1973

Santa Cruz Island, Santa Barbara County, California

Here we are at the Santa Cruz Island Field Station after a good spaghetti dinner and a couple of ping pong games.

We started at 6 PM last evening in the blue bus, Craig driving. He is a jewel behind the wheel and we all felt very safe. Much conversation, fritos, a little wine, other

goodies, and before we knew it we were traveling through Santa Barbara. After some fiddling around we located McGrath State Park south of Ventura, where we could throw out sleeping bags. The place was alive with rabbits to the point that I wondered if we would be trampled—both jacks and brush bunnies. I had a good night's sleep except that the alarm I brought didn't work and fortuitously I awoke at about 3 AM, borrowed Dave Hart's watch and got us all up at 6:15 AM, more or less on time. At the Navy base we located the RV that would take us out to the island and met Irene McGinty up from LA seeing her anamorata—a labor organizer. Rob and Peggy also drove in. Shortly we were off on a flat calm day toward the island that rose along a long stretch of horizon. Our course took us north of Anacapa at 18 knots. Murres, kittiwakes, gulls, and shearwaters were seen as well as three schools of Dall porpoises and one big gray whale going southeast about five miles offshore.

The vessel swung into Prisoner's Harbor (named for prisoner's set loose by Mexicans). The little dock was lined with people from the navy and ranch and Lyndal Laughran the station manager.

We loaded all our gear and food (a lot because it was mostly vegetables) in a truck and headed for the station up in the central valley. The station is a nice couple of low buildings—bunk rooms, shower rooms, volley ball court under the big *Eucalyptus*.

We had a rousing volleyball game and then drove down to Prisoner's to catch the low tide at 5 PM. Everyone was a bit lethargic from lack of sleep but we enjoyed seeing the large array of animals and plants there. The abalones—reds and blacks at least, were above tide line in numbers. Many interesting invertebrates, such as *Pagurus*, hermit crabs, porcelain crabs, nudibranchs, keyhole limpets, and sea squirts. I was surprised at the number of cling fish (*Sisyogaster*). In general we saw a lot. I found one of those little intertidal mites, bright red, and almost as small as a grain of pepper, scooting on the surface film. By letting the reflection of sky glance off the pool surface, one could see him slightly dimple the surface. It never went through though, and finally left the water, running up the rocky pool edge.

On the way back we looked at some of the plants. The cliff edges were lined with a tree-like (that is, the form was like a tree) composite (*Coreopsis gigantea*). It had a trunk and a plume-like crown. *Marah*, the man-in-the-ground, was coming out, its new shoots searching among the downed branches of the live oaks. The toyon was heavy with berries—puckered the mouth they did. I was interested in the live oaks. They are really very distinct from those at Santa Cruz. The bark here is very smooth, unfissured and light gray. In Santa Cruz it is fissured and the trees of different growth form. The latter is not so clear as the bark characteristics.

A good dinner and ping pong, looking at specimens, and to bed. Brisk here. I'd guess low 40s.

December 11, 1973

Santa Cruz Island, Santa Barbara County, California

Today we divided into two groups—one heading for the west end and the other hiking down from the main S. ridge to Willows Anchorage. I went in the latter group. We were dropped by jeep at the crest of the ridge, about three miles up a rough dirt road from camp. As the cars left us we surveyed the trail ahead of us. We stood on a long E-W ridge, the central valley behind us, looking south over canyons and rough mountains to

the sea. The slopes around us were grassy or sparsely covered with gnarled toyon or scrub oak. The latter is huge—a real junior-sized tree, often 25 ft. high. Clumps of large-leaf buckwheats (an endemic and one from Santa Catalina Island) were scattered amid the grass. We descended down a rutted road gullied into the red schist—the oldest rock on the island. Down and down we went into a grassy canyon bottom. Just as we entered the wash we came upon one of the largest cherry trees on the island, a great old giant of several fused trunks, perhaps 50 ft. high. I was surprised by the size of the leaves—very large and broad—maybe twice the area of the leaves of the Catalina cherry. The trail turned down the stream bottom in a corridor of mule fat (*Baccharis viminea*), a favorite of mine. It reminds me of stream bottom hikes in the early day with its pungent pleasant odor permeating the moist air. To come back from a hike covered with its essence was always a pleasure I consciously enjoyed, though my mother sometimes complained of my smelling like “brush.” The toyons were bright with unusually large red berries, and Craig Matkin and I hassled over a big shrub—20 ft. tall—deciding it was a mountain mahogany (*Cercocarpus* sp.) of enormous size with very large leaves. Most plants here seem to have large leaves and often growth forms larger than on the mainland.

Further down the creek bed water began to dampen the sand and finally to rise into a small hurrying stream a couple of ft. wide. Its bottom stones were brown with algae and dark leaves trapped when the water washed them against small snags. We turned stones and Peggy Ledyard and Rob Bosworth came up with stonefly and caddis fly larvae. I added some more including one ½ in. monster with bulging eyes who slapped his triffid tail at my finger. Rob and Peggy, Sharon and I keyed birds, puzzling for a long time over a flock of sparrows—the adults were easy—golden-crowned and white-crowned sparrows. Finally we decided our puzzlers were winter juvenile plumage of the golden-crowned.

At the beach we caught the others—they resting a nibbling lunch, hunkered in the sand. It is a beautiful cove—palisaded cliffs on both sides and two small cliffed islands off the east limb of the bay. On the ridges the peculiar *Coreopsis* grew almost like dwarf palm trees, lining the skyline.

Back of the beach was a big shell midden—black soil filled with cracked shells, barnacles, limpets, abalones (all blacks), sheephead jaws, and mammal bones. I dug up a more or less complete sheep and then realized that two cabins had once stood on the mound, marked now by a few boards.

A short jaunt around the bluffs and we came upon a wavecut terrace covered with a tracery of pools, beyond arching pocket beaches at the base of tall bluffs in the tuff deposits. One big slumping landslide dropped onto the bench. The calm sea lapped in 2-ft. waves at the rocky edge, retreating to a lowtide sometime after sunset. We poked in the pools briefly and began the long trek back. At a water gap where the *Baccharis* formed dense clumps and where willows crowd to the water's edge, I heard *Hyla regilla* calling. Later near the Cheney fossil plant locality in Canada Sausa, I caught a tiny brown *Hyla*. Anyway, not long after we spied a cave up the hillside in the tuff, hiked to it, and sat hunched looking out its low entrance at the valley below.

The bench at the mouth looked to me as if it had been flattened by man by pounding. In fact I could see a line across the face of the rough floor where chipping seemed evident. Back deep in the cave the roof was brown, especially on the protruding

rocks, and I assumed this was from the wool of sheep, such as we had seen and heard on the canyon sides—long tailed animals that scrambled the hills.

Why do these caves form? Their floors are covered with dust. They are often hundreds of feet above the sea, too high I think for even sea level lowering to account for them. I suspect since the rock is clastic, with considerable pebbles, that water erosion is important, taking away the fine cementing materials. Later, when the depression is deeper perhaps condensed fog or seepage loosens the largest pieces, causing them to fall free and causing the fine dust layer to build up. Wind may clean this out from time to time, or even animals may track it out. In ours not one larger pebble was to be found in the dust and I suspect it came from man picking sharp pebbles from beneath his or her bare posterior and flinging them out the entrance.

Down an adjacent tributary rill we came upon a small grove of Santa Cruz ironwood (*Lyonothamnus floribunda*). These are rather straight-trunked shaggy barked trees with peculiar long leaves arranged palmately with incised borders. I tried to make a walking stick out of a dead branch. Wow, the wood was heavy, so heavy in fact that I abandoned the effort.

On up the creek bed I began to feel my injured foot coming back and so I slowed down and lagged behind, cutting a nice willow walking stick. Much cackling and chortling from our jolly crew came from up ahead, especially when I came upon a dense bush and found two of them crouching under it (Irene and Peggy L.), looking for bugs or something. I made a smart remark to the effect, “You look like you’re going to the bathroom”—followed by much additional chortling—they were.

The hill was steep but we were soon on the ridge looking back down our canyon, now deep in the gauzy spread of darkness. A soft cloudbank, like gray wool, rolled over valleys and hills to the west. Devil’s Peak was crowned with fog and the sun was just above, ready to plunge. We turned our backs to her, facing the east down our ridge trail. At the next ridge we faced back and watched the sunset—the cirrus turned pink and we watched the flush spread over the north ridge to our left.

Long before we reached camp it was dark. A piglet sniffed and crashed ahead of me. Nancy Dockery took up station behind me, saying she wanted the quiet for walking, but I wonder if she wasn’t watching me as I hobbled along.

In the warmth of the station we began dinner. Half an hour later the west-end crew came in, all full of tales. Dinner, conversation, notes, and bed. This central valley is really brisk this time of year. Steaming breath and probably around 40 degrees F. A little lame fox lives under the house. He came out, holding up his front paw, to take bits of bread and cheese from us, coming within a foot or so of our hands. These little fellows are patterned like the mainland gray foxes, but are much smaller and juvenilized—short faces like little kits, wide set eyes, and big furry ears. Lyndal is studying them. My foot is pretty stiff. I hope it goes away.

December 12, 1973

Santa Cruz Island, Santa Barbara Co., California

Reverse the order today. Our group to the west end and the others to Willows. We loaded a little faster than yesterday. Lyndal drove the lead vehicle while I took the rear jeep. Up the valley we went, past fenced fields above which groups of sheep stood—on their barren land that extends to the highest northern peaks, with green grass inches away.

A lamb had gotten through the fence and tried frantically to join its adults who ran up the hill.

As we traversed the valley to the west we looked at the oaks—big *Quercus agrifolia* in the stream bottoms and then some hybrids called *Q. mcdonaldi*—a mixture of *Q. lobata*, *Q. dumosa*, and *Q. douglasii*. Only *dumosa* is now on the island, yet even to me the effects of the others are evident—the rugose bark and something of the growth form of *douglasii*, and the leaves of *lobata*. The same oaks have been hard hit by the oak moth but were coming back—green leaves sprouting at the branch tips. *Q. tomentella*, an ovate-leaved species with pubescent branchlets and leaf undersides. Glossy, deeply veined leaves very dense over the crown.

Shortly we came into the great grove of Santa Cruz Island pines, on the north slope of the south central ridge near the west end. It is a dense forest of many sizes of trees, including dead ones. The road winds down toward the western coastal benches. There we cut south to Canada de los Sauces del Oeste, where we descended into a bluff-walled arroyo not far above the sea. There on one bank lay a great tree—maybe 50 ft. long, its bole half buried. Lyndal tells us it is either a Douglas-fir or a redwood (neither on the island now) and dated at 14,200 years old. From the bank protruded bits of wood, whole logs and other fragments. I found a cypress cone. A dogwood has been found, a *Myrica*, and others. We left and went up a steep road and then down a very steep decline to the beach. The road ran there behind the debris-filled barrier bar to the Christi Cabin in the main canyon. It's a dilapidated shed and red-roofed cabin with porch and TV antenna and one other outbuilding. It's used by island hunters who take pigs and sheep. The hunters there were cleaning some pigs and sheep heads were on the ground. We turned west over rolling fields, along steep grassy bluffs and finally out onto the terraces of the west end. It was a wild ride with Irene and Nancy threatening the men with various dire things, much singing of various kinds of songs, etc. We stopped above the beach and walked down to the sand to eat lunch. Gray skies and fog not too far above us made it a somewhat bleak scene. The sea broke on the north shore where the waves roll in from around Pt. Concepcion. On the south it was quite calm. The tide was dropping, so we could walk out into the intertidal. I identified birds, finding quite a number in the area. On the offshore rock many cormorants, probably Baird's, roosted. A great blue heron stood, shoulders hunched and white face peering nervously toward me. On shore black turnstones pecked over intertidal rocks in loose flocks, thin black and white wing patterns flashing as they flew. Many black-bellied plovers in winter plumage stood on the beach, and some probed amongst the meadow grass upon the bench. Also in the grass were very dark horned larks, lark sparrows, and savannah sparrows. On the sand the sanderling flocks ebbed and flowed with the low surf. One godwit, a few curlews, willets, and two snowy plovers were seen.

I sat on the dune edge watching two harbor seals travel along the beach, inside the surf zone, within a few yards of the beach. The seals (a pair) traveled about 25 yards apart most of the time. As a swell came in, even though the seals were facing the beach they could submerge with precision before the wave broke over them, I suspect from feeling the undertow.

Some times I saw them in the wave crests with the light behind them. They flowed in an arc down toward the bottom. As they approached the rocky shoal at the end of the beach one came to the surface, rolled and slapped the water with its pectoral, rolled

at the surface and submerged, coming up in the other direction. I saw the maneuver once more and a course change followed. The slap may therefore be a sound signal.

Later I walked up on the great shell mound on the east end of the point—rising maybe 50 ft. and covering 150 yards—pure shells, mostly small. Green grass grew conspicuously over the shells. I saw a few large shells, but mostly small. I wonder if the intertidal invertebrates had been grazed down by the people. Only small barnacles, limpets, etc. remained. I noted *Norrisia norrisiae*, cracked right down the middle, equatorially. I wonder how.

Irene took the wheel on the way home and it was a wild ride for a time as she started and stopped, squared corners, etc., but she took us safely around the road, clinging to the steep hills nonetheless. Nancy Dockery took over before we got to Christi Cabin and gave us a fine ride home—as good a driver as I’ve ridden with—just prop her up with a pillow and let her go.

On the way back a fox ran into the road in front of us and down the road. We slowed and stopped. He did too, looking nervously over his shoulder. A tiny little fellow, all foreshortened in his dimensions. Finally he scrambled up the bank to a grove of *Quercus dumosa* and disappeared.

Back at camp we ate “eggplant parmesan,” a concoction looking but not tasting like it. Val Knudson gave a fine report on the indian history of the area—maybe extending back as far as 38,000 years. One artifact was a walrus tusk figurine perhaps brought from Bering. Early peoples lived on the shore, and subsisted on shellfish and marine mammals largely. Later, a highland people developed under overpopulation. There were as many as 200 villages, friendly but separate and allowing no intermarriage. Bone and shell fishhooks came only when the highland people developed.

To the sack after much guitar music and singing.

December 13, 1973

Santa Cruz Island, Santa Barbara County, California

This morning spent writing notes and generally getting caught up on laundry, etc. Some went diving—Val, Hal, Lambert. Then, in the afternoon, after a rousing volleyball game, we drove to the pines for a look at the flora. We went to the west end grove. It was cold, overcast and misting. We drove to the ridge trail, hopped the fence, and began to look at the plants. The pines are small—maybe 30 ft. in the biggest, and 6-8 in. through. The pine (*Pinus remorata*) is distinguished mostly in cone morphology and is considered distinct from *P. muricata* on the mainland. It’s on Santa Rosa and in a fair grove at Lompoc on the mainland in Pine Canyon. That’s also where the southern Doug-fir are located.

Two manzanitas were encountered—an island endemic *A. insularis*—smooth bark with a rosy or bluish bloom that can be rubbed off and a lower denser *A. subcordata* that has tomentum on leaves and branchlets. We tried to psych out why some of the pines were dying. They seem to die from growing tip downward and out toward the ends of the branches. There were many galls on the branches, fleshy growths with beetles burrowing around the margin. The beetles were tiny little fellows, covered with hairs. I suspect they are probably tactile and help in excavating [?] within their burrows. But galls were as abundant, almost, on healthy trees as on dying ones. Galls all the way around a branch did not seem to spell its doom. I guess that they are not directly responsible for the

dieback. As white scale insect was common on needles too but didn't seem responsible either. As I recall the galls were immense at Pine Canyon, too, and I recall no dieback.

We descended to the canyon bottom—a number of interesting plants were encountered—a feathery low little *Adenostema*, two buckwheats, one endemic here and one from Santa Catalina, a *Comarostaphylos* (summer holly) that bears some resemblance to manzanita (they're both in the same family, Ericaceae).

On the moister slopes we encountered a gooseberry (*Ribes thacherianum*) and a chaparral currant (*Ribes malviflorum*), wood fern (*Dryopteris*), coffee fern (*Pellaea andromedifolia*), and a *Polypodium*, the latter very common in the deepest canyon. A broad-leafed canyon sunflower (*Venegasia carpesioides*) grew in the deepest canyon. Toyons grew very broad leaves in the shade and were very common. The rooting of pigs had disturbed the forest floor. We scrambled up the bank, breaking brush as we went, finally emerging on top of the ridge in the dripping fog—it became obvious that the trees might obtain much water from these western fogs.

Back at camp a fine party and split pea soup and garlic bread—the main effort concerned faking out some hunters who were to visit us. We had a nice prayer meeting planned—Sister Rosemary Irene was going to sing a little song while we held hands; Brother Dave was to give a little cautionary instructional lecture (“ping bong, ball of life” was suggested) . . . and then apple-cheeked Nancy would tell her little parable ending with a great curse. But, woe, the boys never came. [drawings of Dr. John Vanderburgh] During all this I was being plied with Jim Avakian's gin. Much singing, jig dancing, etc. Then to bed. It was a party for Hal and Dave who were leaving tomorrow.

December 14, 1973

Santa Cruz Island, Santa Barbara County, California

Notes this morning and then a trek to the Prisoner's Landing to see Dave and Hal off. They both were sad to go as this is the last trip for our group—perhaps particularly Hal who gave us a nice heartfelt send-off last night.

In the afternoon we ran transects in the oaks. I chose a place for the 100 ft. rectangular quadrant. It proved to have about 100 nettles and I identified one by smelling it. My nose tingled for a day.

The others ran linear transects up on the hill. Rob, Sharon, Val, and I ran two quadrants on salamanders, one on an area 10x10 covered with rotting oak logs and bark, the other in rocky rubble. We found *B. attenuata* only in the oak transect and *B. pacificus* in both.

After the transect was complete I drove the truck back (we were about ½ mile upstream from Prisoner's Harbor).

Back at camp it came to pass that the Vanderburgh Circle was formed, a natural history society that will be the sequel to this class and will, it is hoped, have trips to various points of interest. Maybe the first will be to Sierra San Pedro Martin—we will have stationery, a song, a flower, a rock, and heaven knows what else. Peggy Ledyard came up with the Vandeburgh name. Later, on a hike up the canyon I suggested “Circle,” which was deemed OK by some, too religious by others, and Nancy liked “Band” better—she snarled as she said it having visions of groups of students charging unseen foes. Well, it seems to [?] something's happening.

We looked at the moon and Jupiter and Venus with the Keeler-Wolf's Questar. Spectacular! We talked till late. Sharon and a grad student from UCSB who has worked on Embiotocids. To bed after midnight.

December 14, 1973

Santa Cruz Island, Santa Barbara County, California

Up at 4:30 to look for the comet. A bunch of us piled in the jeep and headed for the ridge above Willow's Landing. The cold of the valley gave way to the surprising warmth of the ridges and we found it quite comfortable. No comets graced the sky so far as we could see, but it was a nice dawn.

Back at camp after dawn I caught a few winks till 10 AM and then set off on foot to the narrows to look at the creek. Canada del Medio (Central Valley) winds up as a broad arroyo filled with very dense *Baccharis glutinosa* patches, narrows, and finally enters a steep winding rocky defile. The stream surfaces well before the canyon and becomes a nice creek with waterfalls, rock pools where stones have swirled rounded pot holes in the dense porphyritic andesite. We looked at the stream insects of which there were quite a number.

Web-spinning caddis flies had their little silken nets tucked at the edge of rocks where the current was strong. In one rock crack where the water slid over at the beginning of a cascade the little nets were lined up one after another. The larva lay off to the side inside a silken tube. All over the face of a smooth boulder were diptera larva, the suction disc on the tail holding them to the rock. Their heads could be seen wiggling back and forth in the swift sheet of water. Upstream in a deep pool I found a number of other forms—dragonfly larvae of two types, predacious diving beetles, back swimmers with their abdomens all silver with air held in hairs against their bodies. The water was crisp and cold but no mind. The crew dipped, screeched with the cold, dried off and dipped again. Up the canyon were potholes worse by the water with maidenhair ferns hanging from the roof.

I hiked back early to go over to see Cary Stanton at the main ranch. He had invited me over for a drink. We talked of this and that—of his ranch, of his relations with the station, etc. I had a very good feeling from it all. He has demanded certain things, all reasonable it seems to me. He wants real work done, he wants to be informed, he wants to pass on anything that might affect the ranch. Now that these things are understood and the people at the station are reacting properly the relations seem excellent. Lyndal and Paul, his assistant, I think, are doing an excellent job. The station is being used pretty fully and I suspect a lot of good work done. Cary is obviously proud of this and keeps a file of all published papers. He watches things like a hawk and people hear from him when things aren't according to hoyle[?]. A couple of drnks later and I came back for dinner. Notes, general horsing around, and bed.

December 15, 1973

Santa Cruz Island, Santa Barbara County, California

Up rather late, got the crew off in various directions on a sort of elective hike day. Sharon, Peggy T, and I got a spare jeep from Stanton's garage and we were off to the Pozo Canyon area on the west end. It was a bright, clear day, brisk, cirrus overhead, no breeze.

We bounced up the road past the pines and could see out over Santa Rosa to San Miguel beyond. We cut off on the Canada Sauces Rd., up over the grassy hills to Sauces, down into the canyon where the big tree lay in the sand, up a steep two-rutted track past some acres of wind-pruned *Quercus dumosa*—low, rounded shrubs a foot or two high sliced clean as if by clippers, rills of [?] where the wind funnelled up from the NW, about from Forney's Cove. The road wound up on the crest of the gullied, treeless hills behind us to the east. Ragged Peak rose, a few straggling pines at her crest. We wound down the hills toward Pozo Canyon. To our left a barrier canyon ran north toward the crest—Well Canyon. I stopped the jeep and we hiked through the grass down to the canyon bottom. We trekked up, seeing float[?] of a fossiliferous formation. Not long afterward we came upon bedrock on the walls—molluscs, [?], gastropods—and later we came upon the entire floor of the rill covered with *Turritella*—in the Upper Paleocene Pozo Formation. The *Turritella* shells were up to 8 in. long or so, many eroded so the interior chambers were exposed. We noted that they were darker than the surrounding matrix. Does entrapped sand in a fossil go dark and anaerobic and thus remain dark-colored, even through 70 million years?

We returned to the jeep and entered Pozo Canyon, going to the beach. We watched it both ways from the canyon, a long curving strand of clean sand, kelp offshore, a single sailboat and much flotsam on the beach. To the east we found the bluffs full of fossils—big pectens, many barnacles, some kind of burrows about 2-3 inches broad, layers piled upon one another, some branched and as much as 20 inches long. I suspect a burrowing clam.

Peggy is a collector of shiny things. She assembled an armful of abalone shells, wavy top shells, and others, I think by beauty in her eyes. She had a black abalone which had been eroded clean on all surfaces, down to the pearly base nacre.

Our time had run out so we returned to the jeep and drove back in the cold of late afternoon, the breeze at first in our faces and then as we turned up Canada del Medio (Canada del Portezuelo) it went behind us. Ravens followed us and flew in front of the [?]. At the *Eucalyptus* grove we came upon the Devil's Peak hikers—Bea, Craig, Peggy, and Nancy. They were tired from a long walk and jumped in the back for the walk in.

At camp we had a fine sheep dinner and Carey Stanton came and brought two cases of beer. Afterward much organization of the Vandenberg group took place. The bone of contention was to decide between the Vandenberg Circle or Band. The athletic types lined up on the side of the band, and the more reflective folks on the side of circle. No solution could be arrived at by sheer speech making so I suggested contents—a tug of war, leg wrassling, and balancing.

We chose teams and amid much shouting, threats, singing, general hilarity, etc. the tug of war took off—after a false start or two the bands won decisively in the tug of war. In leg wrassling Val, a novice and a band, was matched with that old pro Irene, a circle. Amazingly Irene lost 2 out of 3. Bea was matched with Dave. Though I knew Dave to be tough he proved no match for Bea who flipped him without hesitation. Then, because the circles said it was all too jockish and physical, we inserted a balance test. The opponents stood facing and with feet planted, hitting at each other's hands. Lambert and Nancy went at it—Nancy, of course, a "band." It was beautiful to watch—a pair of pros. It went 1:1 and then Lambert took the last—a victory for the circles, but too late—so the Vandenberg Band we are.

People faded off to bed—tired after long walks. Finally, at 12:30, I took myself off for the sack.

Granite Mts., San Bernardino Co., California, April 13-May 25, 1974 (class)

April 13, 1974

Granite Mountains, San Bernardino County, California

The hiking class assembled yesterday about 6:30 PM and we drove off into the night in our 40-passenger bus. We headed down Hwy 5, got lost, went through Arvin, and finally up into Tehachapi area. We turned off on a little road and camped not far off the highway. Nancy and I slept on the dead-end road, but most others slept off on the dirt at the sides. It was incredibly noisy—trucks revving engines as they shifted to make the grade and then the railroad on the other side of us. Noise or no, I finally drifted off to sleep.

Next morning we found quite a few interesting plants—swallows nesting under an overpass, red-tailed hawks nesting in a digger pine nearby.

Finally off we went over Walker Pass, looking at faults and ecotones. On out into the Mohave Desert, where we stopped, caught *Xantusia*, and a lot of flowers of various kinds. We drove on, and I folded up on the deck, getting a nice snooze. [List of students in Natural History Class, Spring Quarter 1974]

After a number of pit stops at various gas stations we hit the new freeway at Ladlow, shortly crossed the Bristol's, and cut off at the Kelbaker Rd. Excitement mounted as we came closer to the mountains and as we bumped down the dirt road under the towering granite pinnacles and as the bus scraped fore and aft the gasps and squeaks grew too. But we made it and unloaded at the top of the hill, quickly portaging all gear up to the cabin. Susie and John were there looking a bit perplexed at all the people (31). Lots of appreciative remarks at the Bunny Club and its remarkable contents. The weather was clear, warm, and with mild breezes sweeping across the bajada. Flowers were scattered and we had seen few places where carpets of color could be found. I suspect the fall rains hadn't been adequate.

We took a walk past Cove Springs and found no surface water at all, but Canterbury bells, paintbrush, and many other animals. We saw the color matching of the horned lizard, watched utas and birds of various kinds and finally wended our way back to camp for dinner and a good session on geomorphology. Then to bed, everyone tired and mostly flaked out on the front porch under calm skies and stars. I occupied the hanging gardens.

April 14, 1974

Granite Mountains, San Bernardino County, California

Up this morning for observation day. My job was to take out groups and work with their ability to write down what they see. My first crew was the anthropology group and we had a nice hike down to the tanque—catching a chuckwalla on the way, spotting birds, and looking at the flowers. At the pond we finally decided to describe fringillid flight. A group of purple finches was flying around the pod, settling in yuccas and on the bank of the earthen dam. They could usually be seen flying over the water so it was

possible to refine the observations. We finally began to see details—the two beats, the patch of wings downward so they almost touched beneath, the dipping flight. We quantitized—timing dips and estimating how far the birds swooped with each dip. A flycatcher flew by and was at once obvious by its flight. Doves swooped in an almost straight flight, swift backward-directed beats sending the bird along. Unlike fringillids there were pauses between each beat but velocity was so high the bird scarcely dropped at all, while the fringillid might drop two ft. or more. It was a good exercise though people seemed reluctant to write down what they saw, preferring to speak their observations. But since I wanted feedback from the writing process, we persisted until everyone had something on paper.

After lunch I did it all over again but this time with utas. We watched how they bobbed as they explored their territory—two quick nods of the head, a pause, a quick two or three ft. of locomotion, more nods, and so forth. The nods were initiated by push-ups and seemed to involve a sort of whipping of the head up and down. We watched this lizard make a circuit of his area and nearly come back to the home area where we had originally sighted him.

After working with this for a while we hiked off down the canyon nearby, watching birds—black-throated sparrows trilled at us from bush tops, a beautiful Bullock's oriole, black-chinned hummers, vireos, and an ashy-throated flycatcher.

On the hike back Liz Amadon called "snake" and there was a gopher snake almost completely in a mammal burrow, only part of a coil occupied by the burrow mouth in a patch of sun. The animal was warming while nearly completely buried. I tried to extract him but he crawled down the burrow. When I began to follow the burrow he appeared six ft. away at a burrow mouth, finally emerging where I caught him and showed him to everyone. We then let him go in a yucca clump.

One thing we saw that interested us all was desert rhubarb (*Rumex hymenosepala*). It is a very succulent green herb and when touched proved to be several degrees cooler than the air—so cool in fact that it was distinctly cold to the touch. It must undergo great transpiration.

Back at camp—burritos, reports, and notes, and to bed after a hike to see if the red-spotted toads were breeding. They weren't but the night was beautiful and clear and full of stars.

Oh yes, today we had a face down with Art Parker. He is a young, red-haired, heavy-set fellow who seems seldom to speak the truth. He started off by walking briskly to the bottom of the hill and calling for me. I'd said, "Come on up." "I can't," he said, "I've got a bad leg." Baloney. Five of us went down—four with notebooks and pencils and me. I had Val, Jerry, Stan, and Brendan write and not say anything—just write. It was a strange confrontation in which Parker admitted he didn't own the land, had no control over our comings and goings, and couldn't tell us how many people could come in. We agreed on various things to protect his cattle operation. His sidekick said, "What are those guys writing in shorthand?" Well, it kept them honest for a change if it didn't buy us any public honors.

Point Reyes Seashore, April 26-28, 1974

April 26, 1974

Laguna Ranch, Point Reyes Seashore, Marin County, California

We gathered everyone together by about 6:00 AM in the big blue bus and headed north up Highway 1. I drove my pickup as we would need it at Pt. Reyes. The skies threatened and spells of rain washed our windshield as we went through Samuel P. Taylor Park to Olema and finally to the Park Headquarters. The usual switch with the bus being unloaded above the Hostel and gear taken down and stowed. Finally all was done and half an hour later we were back at headquarters with everyone gathered round ready for the hike. Showers still came and gray clouds scudded up from behind Mt. Whethenberg as we set off down the trail, all strung out single file. Various marvels were found. There was a wild somatic mutant dandelion with an inflated stem and a broad, brush-shaped flower. Other flowers sprang from the stem [drawing]. Many flowers were out and everything was washed and clean and the sun began to come out.

We cut off at Meadow Trail, climbing through tanbarks and Doug-firs to a sunny mead where we had lunch, everyone sprawling on the grass, eating and catching their breath.

Up and away to Slay Trail where the Doug-fir-red elderberry association occurs. The firs I'm convinced have very many more secondary limbs here than in any firs I have seen—dozens on a single trunk and most are dead, lichen and moss covered. The forest floor is strewn with lichen and branch fragments. These epiphytes catch aerosols and dust and nitrogen—wind and rain sweep them to the forest floor where they must represent an important addition to the nutritive budget. Perhaps the limbs are adaptations to being near to the sea, as they are in some other shoreside plants on the North Carolina dune shores. In places these trees assumed the growth shape of cypress trees—multiple trunks and dense lateral branches—once again unlike other Doug-firs I have seen.

Down the coastal slope we went finally emerging into the chaparral and a magnificent view of Pt. Reyes—the sea was calm and shining with the Farralons very clear and sharp, the sweep of Drake's Bay, the esteros and the bluffs clear. We went to the bluff edge and hung over about a 200 ft. drop, watching the surging sea below. Now on the shore trail we strung out in a long line, each looking at this and that—a pair of hunting marsh hawks, one much grayer and lighter than the other. The brown one came up with a mouse from the grass. We were weary when about 4:00 we crossed the creek and staggered up to the hostel.

Dinner, notes, a little talk, music, and bed. We're out in the old milking shed, in the stalls. OK, the place is a little straight but I guess they have to be to maintain their sanity with groups coming and going. Tomorrow, observation day.

April 27, 1974

Laguna Ranch, Point Reyes Seashore, Marin County, California

Under the eaves of the AYH Laguna Ranch building are five nest sites for the cliff swallow, each perched on the cross member that holds the roof beams. A space about four inches high exists between the roof sheeting and the crossbeam on which the nests are being built. The roof overhangs about 10 inches beyond the beam and the nests and drops perhaps five inches below the nests, requiring the swallows to swoop up under the overhang to enter the nests. [drawing] The nests are flask-shaped, about five inches wide with a 2½ in. wide entrance.

Nest building. The birds fly into the nest, and if another is there they displace one another, the resident quickly leaving. Then the new resident pokes its head out of the nest with mud plastered on its bill in a fairly good-sized glob. It then places its bill in a place around the perimeter needing mud, with neck extended, draws its head backward with bill pressed downward. At the same time it “vibrates” and sometimes rotates its head from side to side, causing the mud to flow into place. The bill is open at least part of the time, and I believe the bird takes mud into its mouth and extrudes it in much more liquid form than that in which it carries it. Thus it flows into place.

My impression is that a tier of mud applications is applied around the whole opening before another tier is begun because I could see by the darkness of soil applied that it had been placed around the entire opening. The nest is built by first covering the area of beam and wall to be covered with mud with it and then building walls out and around this basic support in air. The roof is not so covered.

How do birds fly up and enter nest openings when they are required to do so in such a confined space?

First these swallows have a considerable capability at hovering. They swoop in, with the glide phase being replaced by slowing and hovering wing beats at least five ft. from the eaves and usually well below them—often two ft. or so. The bird then flaps up under the eaves in slow flight. Even so the wing beat takes the wing tips 45 degrees above midline and nearly touching on the downstroke. I heard them touch the roof occasionally but mostly their wing tips almost miraculously stopped fractions of an inch short of touching. At the last moment, as they swoop up and before momentum is lost, they fold their wings back and enter the nest mostly grasping the lip with their feet, which are scarcely extended below the contours of their bellies.

Sometimes a bird will fly in, stay a few seconds, and fly out. Apparently it drops mud in the nest on occasion. The amount of mud placed seems greater than is carried on the bill and we suspect it is carried internally either in the mouth or perhaps even regurgitated. Further it is much more liquid and leaves a wet spot wherever applied.

In a couple of occasions I could see the mud being masticated into very liquid form, applied by being flowed out onto the nest and occasionally dripping off the nest. The birds tried to catch the drips. They also pick loose bits of mud that aren't firmly attached and take them into their mouths.

April 28, 1974

Laguna Ranch, Point Reyes Seashore, Marin County, California

Observations on the mud-gathering behavior of cliff swallows.

At the junction of two dirt roads is a tiny puddle, nearly dry, that approximately spans the width of a tire track. One can see that on one bank where the bank slopes up at about 30 degrees, swallows have dredged up mud. They have left a series of marks going directly up and down slope for perhaps three miles. On the other bank, which does not slope nearly so steeply there are no marks.

Actually we did not see the birds come directly to the mud but saw them fly in low (13 in. off ground) and then view was blocked by a grassy tuft. Around the puddle on closer inspection are what appear to be bill marks. These are to be found on most of the perimeter of the soft mud except in the very center. I'm impressed that the mud is pretty hard.

We inspected the white flower heads of the cow parsnip growing in a nearby meadow and found a whole system of insects and spiders occupying the umbels. These are about four inches to ten inches across, formed of about 30 smaller heads that touch or nearly touch in many places. Each subhead is composed of about 15 complete flowers that seem to mature peripherally first and then inward toward the center. The result in a mature umbel is a hummocky platform on which an insect can travel across the entire umbel.

The odor is sweet and fairly strong. I could detect it from two ft. away. The individual flowers are complete with a low, rounded ovary from which a short stigma rises. The ovary glistens and seems to be the target of nectar-eating insects. These seem to include ants and wasps. Robber flies??? rest on flowers as does a white crab spider. Both of these were seen feeding on insects that frequented the umbel including a tiny wasp that had been captured. The flies were seen running their probosces over the ovary. As they walked over the umbel a thicket of anthers rubbed against the insects' lower surface. This surface is hairy as are the legs. Pollen was seen in the front half of the body. The proboscis has a pair of extensions that Jerry saw being used on the front legs perhaps to remove pollen.

May 25, 1974

Eshom Creek, Whitaker Grove, Fresno County, California

Allison, Larry, Eric, Wendy, and Brendan, and I went to the creek to study the niche of an animal. We settled on a funnel-net-building caddis fly larva, which we presume is of the family. The creek in which we found them is a rather small creek tumbling through granite boulders or running between low banks, sometimes cobble and sand choked or sometimes with pools as much as four ft. deep, with cut banks and overhangs under roots. In places the stream slips over granite smoothly and occasionally cascades or actually drops as short falls. I'd guess it was running about 200 gpm.

We located many nets of this caddis fly. They varied rather strikingly in size from about 1/3 in. across the mouth to ones as much as 1½ in. across. They were roughly formed of meshes and usually streamers, presumably of silk though they were covered with a grayish mucus-like material. One could watch the streamers and determine current direction exactly at the net. In my observations the current always flowed directly into the nets. Position on a rock did not seem determinate, that is nets were found under rocks, in crevices between them (most common), or even on top of smooth granite surfaces. In the latter case the nets seemed held open by the current and bowed up in a perfect arc.

[Drawing]

Size of net seemed relatively well correlated with current velocity. That is, usually small nets were in fast water, as if some relation existed concerning amount of water filtered per unit time. The nets are strong. They could hold a section of branch that drifted into them and which filled the entire net. Often it could be "rolled over" the upper net strand without breaking it. Nets taken out of water collapse into a tangled mucousy web.

We found no nets in still pools and most in cobbles at the lower end of pools where water quickened between stones. Nets sometimes faced upstream but always the

pendants revealed that the current also went that way. The deepest net was perhaps six inches down the shallows and had the lead strand at the surface. The larva were seen in the net but more often off to the side in rock-encrusted cases.

They move underwater inchworm fashion, first clamping with anterior legs and inching the body vertically under, then apparently clamping down with the posterior hooks of the abdomen. Wendy saw one such animal swing its anterior body around 360 degrees or thereabouts while so hooked.

We watched one crawl underwater in this fashion from still water into more and more turbulent deeper water and finally lost it at about six in. whe I disturbed it and the current wafted it away. We concluded that either the animal selected life conditions by a statistical loss of those who fail, or by sensing water velocity. We decided it had probably to be a relative sense, i.e. water velocity past something. We tried to test this by letting larvae select velocity but the results were inconclusive. We did note that they could spin threads and that they seemed to issue from the anterior abdomen rather than the posterior end.

We speculated about dispersal and concluded that [?] stream pattern might help but so would adult dispersal. We pondered the effect of wind, and of snow and cold, wondering how long they live and how they overwinter.

Yolla Bolly Mts., Tehama Co., California, June 7-9, 1974 (class)

June 7, 1974

Pettijohn Basin, Yolla Bolly Mts., Tehama County, California

The class piled into the old blue bus at 10:30 PM and we drove off in the dark toward Corning and the Yolla Bollys on our last field trip of the quarter. The bus hadn't been filled with gas so by the time we neared Davis and the cut off to the north it registered near zero. I rescued the operation in Davis by [?] 15 bucks in cash. Then off to Corning again while I tried to catch some sleep all folded in a rear seat, one leg over the arm and propped by a pack and the other wrapped around it resting on a small cornice of gear. I don't fold like I used to but nonetheless did manage some fitful sleep. At Corning we wandered around finding the Wolf farm, and finally located its pistacio-green house behind a double collonade of date palms and shaded by great black walnuts. In moments everyone scattered across the lawn and was fast asleep though the sun rose in the east and it was fully light. Once we woke (maybe three hours later) we found breakfast places in full swing—home canned peaches and apricots, dishes and utensils, paper bowls, piles of oranges and grapefruit to be squeezed, a fire started in a great old homemade grill. The wind had come up and whipped in from the northwest making my pancake cooking a difficult process. When I turned the cakes, as like as not they folded, or when I served them they showed tendencies to scale away like frisbies.

Anyway, hundreds of cakes, dozens of strips of bacon, and gallons of juice later we were done and headed off toward Red Bluff. The road out west through oak grassland—blue oaks, inland live oaks, and valley oak—many seemed to be hybrids. We wound up stream valleys and past small farms to Platira where Craig inexplicably pulled off—a tiny hamlet—and out stepped Dr. VanDenburgh—sporting a double beard, only faintly tinged with gray. He jumped in a pickup and drove off to turn off shortly. I

thought at the time that the faint gray might bode ill for old folk and cover the younger members but I said nothing except, "Thank heaven we've seen him."

Shortly the road entered the forest and we went many miles toward the wilderness area and Stewart Gap, through fine forest replete with yew and firecracker plants, a few dogwoods, a strange madrone that is much more yellowish green than our coastal form, and other wonders.

At Stewart Gap we hoisted our packs and started up the trail toward Pettijohn Basin. The forest is relatively mesic; golden brodiaea and ribes. Squaw lettuce (*Hygrophillum occidentale*) was everywhere and in bloom, a little cluster of whitish flowers, heavily dissected leaves, with yellowish green. Not long after we passed the Wilderness border, the trail leveled and finally dropped abruptly over into Pettijohn Basin. It is a rimmed, sloping meadow that is centered by a rushing tumbling ice cold stream, largely fed by melting snowbanks back among the white Doug-firs and ponderosa pines. On the upper slopes of the meadow are fields of *Veratrum* (corn lily or skunk cabbage). Down in the fold of stream flattish patches of stream alder (*Alnus tenuifolia*) crowd against the stream. Far up on the slopes, snow is deeper, clinging in multifingered patches in the avalanche chutes and over north slopes. The highest trees are foxtail pines, like those of some places in the Sierra.

Camp was made back in the woods where we found a nice fire circle and where a springy duff of pine and fir needles covered the stones of morainal deposits. I turned everyone loose on their own (a book told where they went) since everyone was too tired for useful intellectual effort. I trudged off with mildly aching feet toward Black Rock Lake, 2.5 miles to the west. The trail looped up the slope, dipping into valley folds and skirting ridges, almost always in deep forest. Finally the lake appeared, a tarn set in a cirque—shallow, mud-bottomed, logs lying here and there, a rushing cataract entered from the cirque. Here and there fish broke the surface and many rough-skinned newts (*Taricha g.*) crawled on the bottom.

I caught two nice rainbows and lost two more—enough for dinner. On the way back my foot began to hurt and by the time camp was reached I knew I was in for it, and that my vision of Dr. V. was right—he was for the younger folks this time and I'd have to take my lumps.

Nice campfire in the brisk night with Todd and Ginger telling us about the flora and history of the mountains. Nice discussion and off to the sack.

June 8, 1974

Pettijohn Basin, Yolla Boly Mountains, Tehama County, California

I woke up with my foot aching and it was soon obvious that I would spend my day with meadow. Only with the hiking stick I had picked up the day before could I navigate. Feels like a bone bruise or something like that.

After breakfast we all sat under a huge old ponderosa pine and talked about energy in nature—about how trees obtain carbon, how they respond in terms of balance with growth. How do buttressed bases on trees develop? How does the poised distribution of limbs develop? Then we talked about decay and how nitrogen gets in the soil (fixation, lightning), and how and what travels up trees. I discussed and asked questions about energy coming in from the sun . . . UV, IR, energy windows, etc., black and gray bodies, about re-radiation in trees and why it is warmer 30 ft. off the ground.

The two teams were dispatched—one to measure organic materials contributed by the mountain alder grove and the other to see if they could get a measurement of contributed organic materials from conifers by measuring the debris collected on top of snowbanks. They were equipped with 72-in. bootlaces and a weight watcher's scale. Walter Ward went off to measure light regimes using a hand-held light meter.

It was a pretty spring day, clear mountain air, warm sun in the meadow, and cool in the shade, few clouds, just mountain blue sky above and the $\frac{3}{4}$ moon above Black Rock Peak. The skyline is fringed with foxtail pines while the meadow is bordered by ponderosa pines, Douglas-fir, and a few magnificent old incense cedars and sugar pines.

I sat down to read the gospel according to Philip Munz—to key out plants. The meadow was full of ones I didn't know well. Most I could take to family or genus, but seldom beyond. I worked on one little white-flowered carpet plant, digging (I found it had a bulb), and finally ran it down to *Lewisia*, named after Merriweather Lewis. There were three other members of the same family there too. Finally I strolled around (slowly) looking for birds and came upon a number—white-headed woodpeckers, and red-breasted sapsucker, red-breasted nuthatches, chickadees, and a fine dipper—what a sleek bird, every feather in place, and every curve so perfect. It stood “dipping” on a log in the stream—finally drinking and then flying upstream among the alder branches with its quick wingbeats.

People straggled in, mostly from the lakes and ridges, which they said were spectacular. Larry Hobbs and party, who were to weigh alder leaves had instead calculated productivity in skunk cabbage (false hellebore) and gave a hilarious report, filled with new units of weight, area, productivity, etc. and finally related it to the cosmic all. Everyone dutifully hummed “Aum” and Walter told us about his light meter readings—I was surprised by the intensity of light transmitted through many leaves and of the amount of scattered light. It is $\frac{3}{4}$ or so, as much as direct sunlight in [?] places. The snowbank crew came in with ground clothes full of debris and good stories to tell.

We had a fine campfire—much discussion of Zen, purpose, systemic thinking, etc. Off in the brisk night. It did get cold, and my wool shirt was welcome.

June 9, 1974

After breakfast I packed my gear and headed slowly down the hill, learning plants and watching for birds. The others are to leave at noon and we will all board the bus for home. Another perfect day. I stopped at the Wilderness border where a nice spring issued from the hill. Amongst the alders were bleeding hearts (*Dicentra*) yellow violets, *Montia sibirica*, and other plants. A few draughts of the cold, sweet water and I trudged on down the hill, listening to the olive-sided flycatchers on the tree tops and pileated woodpeckers singing their raucous, insistent call.

It was hot and 1:00 PM when the old blue bus showed through the trees. Quite a time later the last straggler was in and Dave headed the bus down the long winding mountain road. Todd and Ginger were dropped off, a tire changed, and we watched the sun set over the hills as the bus rolled along in the dusk. I'll end here as it is getting dark.

La Paz, January 24-February 6, 1974

January 24, 1974

La Paz, Baja California del Sur, Mexico

I guess we'll make it, providing the bureaucrats let loose.

January 25, 1974

Lopez Mateos, Baja California del Sur, Mexico

Up at 6:00 AM, breakfast at the hotel and getting ready to leave by bus for Villa Constitucion. I called Joe Blum in Washington and he told me the permit might be ready this afternoon. I was to call back at 4:00 PM Washington time. Well, OK. Off we went by the nice big bus up over the foothills of the Sierra Giganta and Magdalena Plain. We called at Villa Constitucion and found our permits were finally complete. Whoopee!! Jose had arranged for the bus from Escuela Superior Tecnologia de San Carlos—the local fishery school—to take us down to Lopez Mateos. I had it stop on the plain not far above town to look at the creeping cactus of Magdalena Plain—like logs of cactus half buried in sand, most a yard to two yards long or so.

At Lopez Mateos we found our rooms at the cannery. We're OK. No one had been sure Jose's arrangement had been with people in La Paz. The rooms were next to the little lab across from the fish meal warehouse and downwind from the fish oil tanks.

The *Louson* came in just as we landed and we found Roger Gunty and Jerry Koozman on the beach in Jerry's camper. Whales were spouting down the bay and all seems in order. We can't work at the cannery and will have to rent a place in town tomorrow, but it goes remarkably well considering everything. Even the smell fades after a while.

Dinner at the local restaurants—tacos, burritos, and tostadas only, but sufficient. We walked back in the dark and began readying gear. Tomorrow we hope to calibrate gear and maybe get our expansive harness on a whale. Whew! So far it's falling into place, looks like.

January 25, 1974

Lopez Mateos, Baja California del Sur, Mexico

A good sleep in spite of late tinkerers assembling the harness gear and a midnight anchovetta haul.

Well, we're off in an incredible flurry of paper, hoping it will all clear away and we will have a chance to go to work. The trip is the second time harnessing whales in Magdalena Bay and I never had so much confusion and trouble with the bureaucracy as on this effort. Our funds from NASA came after the project termination in December, leaving us almost no time to prepare; the Marine Mammal Commission did not provide permits until this morning by phone, our whole operation was cancelled last week by NASA by an official who was frightened of publicity and restored next day, and the permission from the government (US) was cancelled because of passage of the Endangered Species Act, which carried a 60-day moratorium. We were reinstalled next day when a loophole was essentially constructed for us (we were working in Mexican waters under Mexican permit)—which we didn't yet have. They came along with Jose Castello later. But I dissembled and we were allowed to go on.

Our passenger list includes me, Roger Gentry, Larry Hobbs, and Tom Dohl of UCSC, Paul Sebesta of NASA Ames, Bob Goodman and Bob Gibson of Franklin

Institute, Jose Castello of Direccion General de Educacion en Ciencias y Tecnologia del Mar, and Sig Rich of Bonny Doon, and Jerry Koozman of Scripps.

Sig picked me up in the dark, we went to UCSC and picked up Tom and Larry, and headed for the airport. At LA I was called in and informed by phone that we could not work until the federal permit was issued in Washington DC. At Tucson Tom was to pick up an underwater housing and was stopped briefly by authorities. We made it.

A nice flight to La Paz over the Gulf islands. There we found our hotel reservations hadn't been made and everything was filled. We talked them out of rooms. A nice dinner and bed. The weather is lovely, calm, crisp, and clear with fine Baja sunset, the night balmy and bright.

January 26, 1974

Lopez Mateos, Baja California del Sur, Mexico

Up at 7:00 AM, nice crisp calm morning. Fog lay over the water like unrolled cotton. The *Louson* floated in it nearly to her gunwhales and one could not see the water.

A group went on board after breakfast to set up the antenna and test the radio transmitter.

Jose, Bob Gibson, and I went off to arrange for a cookshack for our people. We found one in back of a house across town that we can use. It's not much but we can prepare meals there and avoid costs of restaurant life. On our way back we visited the local theatre to see if we could show our 16 mm movie (the material from last year's trip taken by Jose Castello). The theatre is a plywood cavern with a dirt floor and rough wooden benches, a screen pointed directly on the wood, and two ancient projectors in back. OK, the proprietor said—in the evening. There is a show every night.

We set up a stove on the beach next to Jerry's camper and cooked up some coffee and made sandwiches surrounded by local kids just curious to see what we were doing.

I watched gulls and concluded I could identify Western gulls and herring gulls in the group, plus many unidentifiable (by me) immatures. Frigate birds are common, often diving amongst the gulls in swooping dives. There's just one here, *Fregata magnificus*.

In the afternoon I went on board and worked with the crew trying to calibrate the automatic direction finder. We hoisted antennae, checked cables, and for a very long time had either no response or a great ambiguity. Bob Goodman and Lanz finally isolated the trouble in the cables and ultimately fixed it. The whaler circled us far out and we were able to get a good continuous fix in it. It was dusk by the time we headed for shore and to the new cocina across town. Rog had cooked an absolutely splendid spaghetti using Portuguese hot sausage. That with salad and fruit, coffee, etc. made a fine meal.

Back at the cannery we watched with wonder as Bobs Goodman and Gibson demonstrated their remarkable little recorder and circuitry pod. It was tested by switching a bank of tiny switches on in sequence and reading the output of each part of the circuitry on a tiny light-emitting diode. This flashed in patterns which indicated the health of each component. It's beautifully compact and incredibly well thought out.

The field crew then had a meeting and decided on a protocol for tomorrow's intended capture. It will be a tight and complicated sequence with camera men, people monitoring behavior, respiration, tidal volume and air velocity, taking measurements, [?] for heart rate loci, listening for sounds, harnessing and hauling the animal in. Now to the

capture. We'll see. Then much scurrying about for each person to get ready. This all took till 2 AM but I went off to sleep earlier leaving folks chattering in the hall.

January 27, 1974

Lopez Mateos, Baja California del Sur, Mexico

Up before dawn and down the rutted sandy street to our cocina where breakfast was cooked (oatmeal and nuts) and served. The hot cup of coffee was most important.

Gear assembly back at the room took a long time—about 1½ hrs., and then to the *Louson*. We hauled up the anchor and went down channel to the south, passing a number of whales enroute. Down toward Colina Coyote we could see many spouting whales throwing their flukes and spy hopping. At about “Shell Mound” a mother-young pair was encountered with a baby small enough to take the expansible harness, which is our first test. We have set the soluble magnesium bolt for seven days and hope to retrieve it in the lagoon.

After some preliminary tests capture was started and the counts in the enclosed statement took place. In short, the baby whale died during capture, throwing plans into chaos. Should we attempt to hide the death? Well, aside from the fact that it could hardly succeed, and that it could lead to all sorts of additional complications, it was also distasteful to us all. Paul put it well when he said, “We’ve had enough of that sort of thing in our government lately.” Jose was worried that the Mexican authorities wouldn’t allow us to go on. So be it, we finally said, but it’s better to lay it all out on the table anyway, especially since our permit said that in case of a death we must report immediately.

So, much saddened and uncertain, we returned to shore. Bob and I constructed the statement appended and read it to all hands on the afterdeck at the *Louson*. A few minor changes were suggested but it remained substantially as we had written it.

On shore we laid plans. One group would photograph whales from the *Louson* tomorrow while Bob, Jerry, Jose, Paul, and I would go to Villa Constitucion to place various calls. Finally, off to the sack after dinner and conversation, gay, yet a front as everyone knew. Sig’s harmonica helped as did Larry’s limericks and the stories of others. Bob Gibson proves to be a treasure trove of old songs, which he sings in a nasal Philadelphia accent. Good crew all around and I think everyone is relieved that we’ve taken the straight course.

January 28, 1974

Lopez Mateos, Baja California del Sur, Mexico

After breakfast we divided into two groups; one went on the boat to listen and to photograph. Bob Goodman, Jose, Paul, Jerry, and I wet in to Villa Constitucion to call various parties.

There is one phone in town, in the supermercado, and is attended by a girl who threads her way through the thickets for you. One instructs her, she fills out a form containing about 10 blanks and then you wait, wait, wait. Finally, she rings in the single phone booth and you take over. In this way we called Washington DC, Ames, Santa Cruz, and Mexico City. The upshot was we read to secretaries the enclosed statement and Washington was hopeful, Ames wanted to help, and the U.S. Fisheries Attache George Rees said he wanted to pocket the report and that we should go ahead since it was an

accident. This took all day and we were exhausted by the end after standing first on one foot and then the other all day wrassling with the bureaucrats. But in aggregate we should get an answer from the US soon.

Back at Lopez Mateos we found that recording had gone well with some interesting, rapidly pulsed sounds being recorded in the presence of whales. If they are mammal signals they certainly are like no porpoise sound.

The photography was less successful. Tom's fancy Beaulieu had troubles with its automatic diaphragm and the whales didn't behave. I had three of Bob's gins and was feeling nearly no pain by the time dinner was over—which was fried grouper and delicious.

January 29, 1974

Lopez Mateos, Baja California del Sur, Mexico

Out on the boat today. One group took a hike around the entrance to the Boca and down the outer coast while Tom, Sig, and I made a census of whales from the Boca to Devil's Bend. The day was calm and clear and I counted over 200 whales. Included were some groups of adults that traveled tightly together—I wonder what was going on—mating perhaps, but most were mother-young pairs.

The Big Bay was thick with whales as was the narrow channel off Colina Coyote. That bluff and situation looks like a natural for observation—the colina is perhaps 60-80 ft. high and relatively steep on the water side and the narrow channel goes rather close to shore. I'd like to try it.

The hiking group came in and lo and behold they had a *Mesoplodon* skull found by Roger. In nice shape with even zygomatic arches and earbones. I don't know what species.

We showed Jose's movie at the local pelicula parlor. It came on upside-down, jumped around and car lights shone across the screen but we enjoyed it and were heroes to the local kids.

Dinner, conversation, and the sack. Tomorrow we call Patty again and hope for a decision. I'm not too sanguine as it seems enmeshed in bureaucracy, especially since our call to her today showed that the US people want direct clearance from the Mexicans who haven't been informed.

January 30, 1974

Lopez Mateos, Baja California del Sur, Mexico

Up before dawn for photography. Boyd ("Dildo") on the *Louson* says the whales are most active in the morning with much fluking, spy hopping, etc. We arrived in a thick fog, covering not only the channel but all vessels and the adjacent land. At about 7 AM the fog swept off the land and finally the *Louson* appeared as well as other craft and finally only a sheet of cotton a foot deep or so covered the water.

Boyd came in with the whaler and we were soon off to the *Louson*. Not long afterward we noted some whales thrashing very close to the sandy strand across from Lopez Mateos. Tom, Jose, and I jumped in the skiff and with Boyd driving we closed in on the animals. They paid remarkably little attention to us. There were two adults and one baby. The smaller adult, possibly a male, chased the female and the baby seemed at best an accessory, following as best it could the racing adults.

They rolled and thrashed within feet of shore. Boyd put us right on top of them and they rolled within feet of the sandy beach, sending boils of water up, all brown with sand. Sometimes the large adult (female?) rolled, throwing its broad flippers high in the air. We photographed and photographed until film was gone or my mirror stuck. The animals raced off across the channel, baby behind. The skiff followed them nearly two miles north toward the Boca. The baby was still with them when last seen.

Bob and I placed a call to Patty by phone patch through Oakland, it was nice and clear. They tune the antennas for your specific locale. Before our turn came we listened to a harrowing call from the "Bernadette" in which the recipient of the call, obviously a young girl (we could hear only one side), told that a man broke through her window and shot Michael twice in the head and followed this by a long rambling impassioned affair in which he wasn't really gone but where was Momma buried. "We put him in Mt. Hope." Well Momma wasn't in Mt. Hope so that was a mistake. She'd be better now. Jesus was the way and why didn't he see that, etc.

Patty sounded so calm when she told us that Joe Blum wanted to talk to me personally tomorrow and that today he was talking to conservation groups. Well, I'm hopeful.

In the afternoon, Larry came down with the Two Step and is now on Sig's drugs. I have twinges but shall wait and see. All but Larry went on the boat after lunch to go to Colina Coyote for observations and photography. Not long after, about a mile S. of Lopez Mateos, a baby whale was sighted thrashing on the beach with no adult in attendance. Seeing a chance for Jerry to get respiration data we stopped to investigate. It was a female young, ___ cm. long (over curve) in excellent shape. Jerry raced back to camp to get his gear while Tom, Jose, Roger, and I tended the animal. I found by stationing a leg firmly in the sand adjacent to its outboard eye[?] I could keep it from moving, so I stood there till Jerry came racing up with his gear.

The animal was a modest-sized young, ___ cm. total length over the curve of the body, and absolutely without either wounds or parasites. Its pattern of dark gray, black, and pale, pale gray was a most attractive one. The marks were mostly brushed longitudinally with the exception of a peppering of dark gray dots amidst the light color. It had heavy fetal folds, seven prominent ones, and perhaps a few additional shallow ones on the tail. The flukes were very flexible, more so than a swimmer's fins. The animal's ear orifice was rather large and open—perhaps ½ cm. in diameter. The head hairs were rather short—perhaps 2 cm. at places.

Both Sig and I placed our hands in the tip of the animals snout and it quickly brought its tongue forward, enveloped the hand, and caused considerable suction. I noted that once when Sig tried this the enveloping was done with the mouth partially open. The animal was able to clamp down hard enough to nearly create pain.

Jerry brought out his flow meter, which is a big, angled stove pipe with a small rubber inner tube over one end to fit over the blowhole. The flow is measured as a pressure differential across a capillary disc. He sat in the boat recording as Roger and I held it over the animal's blowhole. It reared up before breathing and thus Jerry was able to catch most breaths and to obtain some fine records.

After this session, which took more than half an hour, I did some recording. Tom held the gear and I pressed the LC32 against various parts of the animal in an attempt to pick up both sounds and heart rate. It grunted from time to time with blowhole closed and

one could see movements in the post cranial body concurrently. The impression was of swallowing or a nasal[?] maneuver. One group of soft clicks was emitted concurrent with slight opening of the blowhole and a movement of blowhole tissues.

The baby gave the strong impression of seeking the shore. Whichever direction one started[?] it, it would circle over deeper water and return to the beach. It was not a vestibular problem as such circling went both directions. It seemed calmest in shallow water when touching bottom. It rocked there, now and then circling its head up for a blow. Once I saw it lay quietly on the bottom in four ft. of water, completely submerged. Bob Goodman said it looked like it was seeking to touch a surface. This trenchant observation fits well with the penchant of babies during capture, of slithering over their mothers, especially the dorsal surface, and of lost babies rubbing or clinging, almost, alongside ships. Perhaps the abandoned baby seeks such surface contact and hence strands.

I wonder if the supposed female-male chases we have seen sometimes result in lost babies and hence in mortality. We've been puzzling what might regulate animal density in lagoons and maybe it is simply the intensity of male and female chases, that could lower fecundity and exert control.

The crew of the *Louson* reported a mating outside Boca Soledad with a male rolling over and exposing his penis. Perhaps the phalanx of males at the entrance is real and that it builds up somehow, perhaps with aggression.

A nice taco dinner prepared by Jose and the lady of the house (Francisca). An organizational meeting followed dinner, preparing for tomorrow should we be given permission to procede. We'll see. I call Washington at 11 to find out.

February 1, 1974

Lopez Mateos, Baja California del Sur, Mexico

Up before dawn and out to the *Louson*. Tom, Jose, and I went off on a rather inconsequential attempt to photograph from the skiff. The animals simply wouldn't allow us very close. At 11 AM, on the way down the channel, we called Washington, D.C., and received permission to procede. There were some conditions, mostly centering around ways of assisting safe capture. They questioned the qualification of our vet, Sig Rich, and I set them straight. While still on the phone I gave the order to procede. Everyone was tense, as can be imagined and chance after chance passed without results. Finally Tom noosed a big baby and the noose failed to slide back to the tail. Instead it hung up on the pectoral area (actually forward). Putting a head net on proved impossible because when we pulled on the first line it cast off head net. Finally I decided to haul him in on just the single line. We backed over near a sandbar and took the lines ashore. The mother repeatedly came up under the baby, rolling it out of the water on her side. It slithered over her, bent upside-down, sliding off on the opposite side. I was interested that the female seemed to take no note of the pulpit over her and continued to list the baby in response to the restraining line. There seemed some concerted or clear effort on her part to push against the baby and move to flail at the line or entangle it with her body or flukes. Her only regular movement was to raise the baby and to swim closely with it. Altogether a performance that did not indicate a remarkable intelligence and I must say this has seemed the case with each pair.

The evasive maneuvers of the whale are often quite effective, though they often fail when the animals get between us and the shore and they may surface beneath the plank. Though I have seen whales hit the prow of the *Louson*, I have yet to see them swing at her with their flukes. During capture a pair of adults circled the captive ([?] the mother), perhaps at closest 100 yards away.

Another thing we noted was that pairs (mother-young) tend to stay in a given piece of channel, perhaps 1/3 mile long and would usually turn at about the same place. Perhaps there is spacing and a spacing mechanism. Certainly the whales are relatively uniformly scattered though occasionally groups of 2-3 mother-young pairs will be seen. The male-female pairs seem oblivious and travel rapidly long distances up and down the channel past many mother-young pairs.

When the adult turned, which she could do with great flexibility, she often turned "wing down" with one pectoral. One could often note an incipient turn when she threw her flukes by a canting of the flukes, even if slight.

We had a helluva time hauling the baby in. It was extremely strong and the single line hampered us. She all but took about six men out to sea, line and all, but the rest came in as we horsed the animal, a male, onto the beach. Harnessing was tough since the animal was very big. But after 25 minutes it was done and the animal was launched back to the waiting mother, its instrument ticking away. They swam north at a good pace, crossing through several mother-young areas and finally we passed them, picking up fine signals on the direction finder.

On shore we looked for Dr. Bernardo Villa and Luis Fleischer his assistant who were to join us but they had not come. After dinner, however, they arrived, Mr. Sereno of the cannery having brought them in from La Paz, most graciously. He is perhaps Mexico's leading mammalogist and has worked on animals from bats to mountain sheep, and now whales. He proved to be a gracious, bright man, and we reckoned we had seen one another at various meetings.

Talk, readying of gear, and to bed. Tired, but pleased. I had a nice reassuring phone call to Phylly this evening tonight and it was wonderful to hear her voice, even if it did sound fuzzy over the radio. To bed.

(The previous notes hardly portray the complications we have been going through. Bob Goodman and I knew when we called Washington DC and especially Mexico City that we were unlocking Pandora's Box. These bureaucracies would be required to respond and only the attached letter could save us or review would come from National Marine Fisheries Service, the state Department (heaven help us), the environmental groups (heaven help us), the US Marine Mammal Commission (we're OK there), NASA (an incredibly goosey organization, afraid of its own shadow, conditioned I think by the long ordeal of keeping astronauts alive). Hinging on the outcome is not only our own program but much other marine mammal research, NASA Ames Animal Tracking Program, the fate of the animal tracking satellite, and more. Complicated beyond belief it is.)

February 2, 1974

Lopez Mateos, Baja California del Sur, Mexico

Well, what a day! Part real insight, part catastrophe and seldom down to the level trod by the common man. It started like most days with early morning arousal, breakfast,

the trek to the beach, shouts to the *Louison* lying at anchor offshore and shortly Boyd Reber jumping in the skiff to bring us aboard. Our party is swelled by two—Dr. Bernardo Villa and one of his students, Luis Fleischer, a young lad who wants to study marine mammals. The boat is, to say the least, crowded. This whale project attracts hangers-on like flies.

We turned south down the channel full of high hopes now that our agencies had told us to procede that we could quickly complete our work. A call to the Ames Lab set us back whe we learned that insufficient information for the head people was causing consternation there and the writing of a telegram (which had not been sent) cancelling NASA participation. It is thought that our letter did not go through channels but was suppressed somewhere along the line. Meanwhile we're supposed to get our work done. The animal we tagged earlier ticks along nicely and is located deep in the channel near Colina Coyote somewhere.

We made eight chases today and caught one animal which truly can be said the to have caught us. I'll not outline each chase.

A baby was noosed and again the noose did not slip to the tail but stayed around the pectorals. It was accompanied by a large, barnacle-encrusted female? and shortly by another. They were the most violent consorts we had yet encountered thrashing their tails and rolling over, supporting the baby partly out of water repeatedly. This baby, mind you, may weigh 2,000-4,000 or more pounds.

Tim cursed and finally decided to try the head net. Rog and Pat brought the line in while Bill in the crow's nest inched the vessel toward the flailing thrashing trio. Dangerous business indeed. As the huge creatures were brought under the plank, their 35-ton bulls rising to about eight ft. below Tim's feet (and mine as I was at the base of the plank). I could see that often their huge flanks reached the stern post directly below me. In the murk the flukes were lined by the white-pattern splotches and barnacles. Suddenly one flailed sideways, sending a sheet of water over all of us at the bow. Tim maintained his cool and tried again, this time placing the head net. Line was slacked and the animals moved off 50 yards or so. Suddenly we saw one adult heave its body into an incredibly powerful thrash of her tail, baby on top. The baby flew completely free of the water, broken head net flying free. Incredible, and thank goodness she chose to do it away from the boat.

Before this occurred I spent some time trying to understand the assistance behavior of the two adults. Often the two adults, which I guess were both large females, swam parallel to one another. At time one or the other supported the baby. A fair proportion of the time the adults had the baby between them and sometimes held it largely out of water as they swam along. But, equally often the baby swam outboard of one adult or the other. The lifting behavior continued even when the vessel lay some distance away quietly. It was also noted to continue after the ropes and nets were thrown off. It was strangely stereotyped behavior, to me, as if the reaction to fear or fright was only lifting, flight, and lateral tail lashing with no evident directed behavior toward the source of irritations, even when their tails touched our stern post. In short, these [?] show none of the obvious flexibility I see so often in odontocetes.

The body noose, of braided nylon, is incredibly strong, 20 tons or so [?] Yet it came in, broken. In looking at the line we found it frayed in many places and I feel it was cut on the mother's barnacles as it stretched over her heaving body.

Our last “capture” of the day began in Big Bay, not far from Colina Coyote. At 1433 we started to chase and nearly collided with mother and young, as they surfaced under the tow. Bill frantically backed the *Louson* away. 23 minutes later the first rope was slipped on and this time slipped to the tail. At once the attendant female disappeared. Now we were faced with a dilemma. If we took the animal ashore and harnessed it, and released it with no mother in attendance it would surely die and our harness would be blamed for the failure. It behooved us to free the baby if we could. That should be no trouble we thought, but the baby promptly presented us with an insoluble dilemma. It began to treat us as mother. It nuzzled the boat from stern to stern, especially under the stern and at about amidships where it often rolled close alongside the ship and parallel with it! It seemed to orient to the overboard discharges that were flowing from the engines that were flowing from the engines and presumably warmer than the surrounding water. It scratched itself repeatedly on zincs and other hull fittings and the tail rope had lacerated it. It also wrapped its line around the screw which turned slowly in the tidal current, we now being at anchor.

Shortly we cut it loose completely, hoping to release it and send a diver down to free the screw. That proved much easier said than done since, though free, it refused to leave. Once it rolled over and I could see it was a male. We poked at it with broomsticks, banging pans and shoved it away as hard as we could but to no avail. Then the anchor began slipping and we came closer and closer to the sand bar shore. Roger volunteered to dive in to release the line. Keeping a weather eye out for baby who could seriously injure him without intending to, Rog released the rope, having to come aboard twice when the baby slid aft. Now free we still couldn't maneuver for fear of cutting the baby. Finally after much indecision Tim gave Boyd the anchor line in the skiff and backed out into the bay when the baby went astern. It followed us like a puppy dog.

Finally Tim saw his chance, swinging the helm over and hit flank speed for open water. Soon we could see it plunging along in our wake.

Later the second animal was successfully noosed. It was a fairly large young with a small female. The noose slipped nicely to the tail but soon we noticed that the female was gone. No sign of her at all, almost from the moment of noosing. Here was a dilemma! Should we harness? If so the mother might not return and the baby might die. A dead baby with a harness was more than we could contemplate, not to mention our concerns for the animal. Then the baby adopted us—coming alongside and refusing to leave, pressing its whole body against the hull of the *Louson*. Shortly the baby took up station astern and even though by this time we were anchored the tidal current turned the screw and soon the line had wrapped around the screw. After some palaver I asked Tim to cut the baby loose in hopes that it would swim away and we could send a diver down to unwrap the screw. No such luck. The baby stuck to us with uncommon tenacity, often under the stern scraping itself on the zincs and drawing blood, which caused additional concern.

Then we noted the anchor dragging and the *Louson* sliding toward a not-too-distant mudflat. Roger volunteered to work on the line if we could devise a way of keeping baby away. Shortly we found we could alert him in the water if the baby began to move aft. He submerged, found five or six wraps around the screw, and in two tries (with time out for baby who had temporarily slipped astern) he undid us. The concern was not [?] but simply bulk and weight which might pin Rog beneath the hull.

Then Tim backed away from the baby, first loosening the anchor line and tossing it to Boyd in the skiff. The baby followed like a puppy and we feared mightily that it would get cut in the screw. But he made it and in deeper water was able to turn and head offshore. Soon baby blew and pursued us far[?] in our wake. Paul and I watched the little waif anxiously, hoping to see an adult. Joy! Joy! One came up and headed for the baby. I thought I could discern it to be the mother—small, smooth, dark. With this hope we headed up-channel to Lopez Mateos, having had enough for one day.

Feb 3-6?

I had to leave to teach at UCSC and so appointed Roger my successor (knowing that Larry would quietly react against this, but also knowing that Larry was a new grad student while Rog was a Ph.D. and an experienced field man and especially knowing that Larry was busy fighting, identifying problems of his own). I briefed Roger on how he should cooperate on decisions with Bob Goodman and with Dr. Villa.

Next morning before dawn I walked down the dusty Lopez Mateos street wearing my duffle bag, took the Camionetta for Villa Constitucion and a bus to La Paz, then the afternoon flight out to San Francisco.

At home there followed three days of lectures, phone calls to officials and reporters and finally a crackling indistinct call from Roger informing me that the *Louson* had been lost and a request that I come down Thursday for a board of review on the loss. I quickly made my plans to do so, in the company of Dave Winter of NASA Ames (Deputy Administrator, Life Sciences) who had to make an on-site review of the animal death.

Here is what I found. After I had left, the next day the crew caught another animal, this time a hulking beast of 19 ft. All went well as it came in, noosed head and tail, with respiration data being obtained and the animal launched back quickly because mother seemed to be wandering. They quickly rejoined and swam off, the animal being dubbed Patti. Meanwhile Knute (the other) stayed near Colina Coyote. Not long after (10 hrs) Patti passed the anchored *Louson* at Lopez Mateos and headed for Boca Soledad. The pair of animals went through the Boca and headed south! Some of the crew were able to track them across the dunes using the hand-held direction-finder. Then they were gone. Not long after, Knute and mother came up channel and were sighted swimming well. The harness and packs seemed to have no effect on either respiration or swimming motion. There was no yawning or rapid respiration.

The pair passed the *Louson* at night, forward and perhaps into the Boca and then came back making a long traverse down channel, and then back again. They moved out into the Boca with the *Louson* following. At this time the beeps from the radio were intermittent, indicating that the harness was still on the animal and that it was diving. Once signals were far out in the Boca they became constant, indicating that the whale had finally shed its harness (it was very late, the bolt should have eroded away many hours earlier).

The *Louson* followed. The entrance to the Boca takes a dogleg south, as do the whales who follow the deep water channel which is as much as 60 ft. deep in its inner portions. At about the turn in the dogleg the ship stayed close to shoal water and with a great thump hit a bar, spinning the ship around and causing her to heel sharply over. People slid and so forth. Gasoline drums (unlashed) skidded across the afterdeck. Two

men in the crow's nest (Jerry Koozman, Pat) hung on for dear life and then came down. The wheel house was a melee, though the ship seemed capable of inching off (they were perhaps 50 ft. inside the shoal area, adjacent to deep water, and maybe a mile offshore). People loaded into the whaler. Tom with all cameras held above spray. Soon everyone but the crew and Rog were ashore on the south bar.

It was decided to send Dr. Villa in for help since he not only had a commanding presence but, of course, spoke excellent spanish. Pat took him in the skiff and for some inexplicable reason started off full tilt out through the breaking 5-6 ft. surf. Dr. Villa was thrown against the wheel console causing a very deep bruise, and against his sternum which may have suffered a separation or crack. He lay crumpled in the bow while Pat leapt out and ashore and ran down the beach like one deranged, which I guess he was. Boyd, on the other hand, when he had come down from the spreaders after the initial beaching commented to Tim, "Hey Commander, that was a psychedelic experience!" and thereafter functioned well.

Paul instantly spotted the doctor's problem and quickly went to the skiff, grasping the bow as it rose up and down with each wave. Jerry Koozman joined him moments later and together they controled the skiff and brought it around to safety and finally to Lopez Mateos. There they found a fiesta day with ships crews away at Villa Constitucion and a bull fight. It was the same everywhere. No help. The *Island Eagle*, which lay at anchor almost refused to let them phone. Meanwhile, on the boat, Rog and Tim, Boyd, and John tried to kedge the ship loose and could only swing it part way. Nothing seemed to work. They had hit near hightide and now it began to drop. The boat began to pound[?] and sometime later the keel started to fragment, pieces floating away. Then the screw pounded through into the hatch and it began to fill and heel over. They knew they had to leave. At first they went on the anchor rope but could hardly stand (waist deep) against the current. Tim went aboard and they inflated the life raft and made it early to shore when they were picked up by a skiff and brought ashore. That night the sea pounded the *Louson*, rolled her over, taking off most of the flying bridge, splintering masts, ruining all electronic and other gear. The sad, sad sight of her hull, half capsized deep in the bay greeted the crew next morning. Tim, needless to say, is deeply shocked and almost speechless over the incident. When I met him two days later, he was still ashen and his palm moist when I shook it. Poor guy, so much tied up in the *Louson* and such a beautiful ship.

Later Tom and Larry walked the beaches in search of the harness so we could hope to recover something from the trip. Near the mouth entrance of the Boca they found Knute, buried deep in the sand with little but the antenna protruding. The harness had filled with sand and could not float—a misfortune we had not thought of. Inside the capsule, however, the recorder ticked away as usual, quite dry and with data intact. That recovery is enough, providing the tape holds data, justifying the cruise scientifically along with Jerry's observations on respiration, but, of course, nothing can recoup the *Louson*.

My trip down with Winter was a good one. He is a bright driving administrator who knows his agency has responded irrationally and who will seek to redress the problem. We traveled to Lopez Mateos by car and spent a day reviewing safety procedures and remedies. He is thoroughly on our side, and I find he may be the NASA choice to head the entire NASA biology program with the recent retirement of Dr. Charles

Berry. That would be something as we would now, I feel sure, have a personal friend in court. Dr. Villa, too, turned out to be a remarkable man and one quite committed to what we hope to do. He is a real patron (called Maestro by his students), a deeply human man, obviously deeply respected by everyone who knows him, who has called for and gotten national parks started, including one, I find, at Sierra San Pedro Martir, and is working on another in the Sierra Pinacate in northern Sonora. A gallant and fine man. I hope we can work together. He seems to want the relationship.

Well, there's much to do for next year but I think we can go ahead with some hope of eventual success.

[Journal a bit out of order for this trip—here are some bits that I couldn't figure out where they went!]

I felt terribly apprehensive for that little animal, hoping that in the narrow confines of this channel system mother would not be far away. I watched the baby with binoculars and could see surface and blow now and then. Finally, much to my joy, an adult surfaced near it and swam directly toward it. I could almost be sure it was the mother by the smooth dark unmarked back and now I'm at least reasonably sure they are together.

Again notions about these creatures orienting tactilely are greatly strengthened and the idea that a baby when it refuses to leave the beach, is involved in fulfilling a need for touching of surfaces. In the murk of this lagoon (visibility is near 1-2 ft.) the baby and adult never see all of each other but must touch instead.

This was enough. Everyone was emotionally, if not physically bushed, so we turned for Lopez Mateos and discussed the multiple frustrations and views of these remarkable animals. I was very pleased that Sr. Villa seemed only very interested in our progress and not condemnatory for the disturbance we caused. I was, however, given pause on this score should we not be able to refine our techniques to produce a less disturbing set of events.

Back at camp I turned the reins over to Roger and tried to patch up some of the irritations that seem inevitably to build up in an effort of this sort.

Whale Tracking, Baja California, Mexico, January 19-February 10, 1975

January 19, 1975

La Paz, Baja California del Sur, Mexico

Phylly and I drove to UCSC where Patty and Tom met us and drove to San Jose. The airport was fogged in but clear skies were less than a mile away so we had hope. About half an hour late we took off, transferring at Los Angeles. There PSA succeeded in losing our pop-up tent which I had spent hours yesterday repairing. No idea if we will get it or not.

The Aeronaves plane took us right down the spine of Baja. We could see San Martin Island, Geronimo, the various bays, Cedros Island, Scammon's, La Purissima arroyo and then the clouds closed in and by the time we landed the rain was dampening the field. Bernardo Villo and his son-in-law, William Lopez-Gormont were there, having arrived a couple of days ahead of schedule. They had been following bulldozers catching reptiles and small mammals up on the Magdalena Plain. William said the draw down on

the fossil water of the Magdalena Plain was about 2x restitution so people were talking of a “future ghost town” at Villa Constitucion in 15 years. Nonetheless they continue to clear land using a chain and two d9 caterpillar tractors. We stashed ourselves at the La Perla (as usual they had paid no attention to our reservations). Next time I’ll try the “Los Arcos” down the street.

We had a nice dinner at the Tepepan fish restaurant on the shore—delicious sopa mariscos, pesca mojo de ajo, and good chilled chenin blanc from Santo Tomas vineyard in northern Baja.

Tomorrow we try to retrieve the tent before the bus goes, and take off for Villa Constitucion. George Nichols joined us at the La Perla and because he sports an elegant white beard I was instantly aware that we had Dr. Van Denburgh with us. Prior to that I had thought that a negro fellow with a partially gray but very short beard in the LA airport was him. I was bothered by him. Tom said it was “equal opportunity.” George, however, is just right, though trimmer and neater than most Dr. VanDenburghs of my acquaintance.

January 20, 1975

San Carlos, Baja California del Sur, Mexico

Up at 7 AM after a fitful night on the swayback La Perla mattress, plus entertainment from some borrachos breaking bottles and revving their engines. No tent. So we decided to leave William and Tom in La Paz to check it out.

A nice sleepy drive to Villa Constitucion, which has grown about 5,000 people since we were here last year. Lots of new cement buildings are dotted about—a new post office, telegraph microwave relay, and others. Lunch and a haircut and then back to the station where we met Larry Hobbs, Candy Calloway, and Dick Pierce. They had had a good uneventful trip down. We then left for San Carlos to make camp adjacent to a big fish packing plant of the Pancho Compania. Bernardo had arranged it so we were inside a locked gate.

Some of the local fishermen report that gray whales feed on sardines in Magdalena Bay. One reported whales following the fish schools and another told us fish were harder to find while the whales were here. They fish inside the bay. Not conclusive but I’m inclined to think it might be true to some limited extent.

Our camp was soon shrouded in fog and Phyl and I spent a drippy night in the open.

January 21, 1975

San Carlos, Baja California del Sur, Mexico

Up at 7 or so, coffee, granola, packing. The truck left while Bernardo, Phyl, George, William, and I went to see the Capitan del Puerto, Sr. Armas. Everything seems fine there, providing our ship papers are in order. We looked at the pier, watched ospreys carrying sticks to their nests, and perched on a monument waiting for our truck to come back. We properly thanked our host at the plant. Desultory talk in the sun of this and that, wondering when we might get lunch or leave to set up camp at Colina Coyote. I hope we make it before nightfall, and get going on the whale watch.

San Carlos is set on a low peninsula jutting southward into Magdalena Bay. It’s a mixture of helter-skelter shanties and clean modern factory (fish processing) buildings,

ammonia tanks (for a fertilizer plant), broad cotton and wheat piers and clean new port buildings. Sr. Armas, the port captain, is an affable, bright man whom we were delighted to find had kicked the *American Eagle* out of Baja California. She was the boat who refused to lend the *Louson* help when she sank.

Finally, Dick came in the truck and we piled in for Villa Constitucion. There we bought gas and beer and left for Lopez Mateos. It's a long way, mostly over a good desert road and we arrived near dusk to find Candy on the beach perched on a pile of gear waiting for the boat. It took on the order of two hours per run when the boat was loaded—Larry figured it at 10 miles. In the fading light Larry showed up and we quickly loaded about half our gear (leaving the rest in the truck behind Sr. Serrano's house). It was a lovely ride down the channel, first in last light and finally in the dark. We found Tom's light back in the little bay (Caleta Calloway) N. of Colina Coyote. We pulled in to a lane through the low (6 ft.) red mangroves, unloaded through the muck and set up camp on a level pickleweed flat just behind the mangroves. Phylly, William, Bernardo, and I assailed our pup tent—a contraption of fiberglass wands and canvas that defied us all. I developed a "General Field Theory of Pup Tents" that had us snarled in duck decoy cord but resulted in an asymmetrical precarious looking structures that kept out the ground fog that rose later and flooded over the camp.

A good meal, a fire of mangrove driftwood (elegant coals), desultory conversation, and off to bed, with coyotes yipping nearby. Wonderful music for the camp.

January 22, 1975

Colina Coyote, Baja California del Sur, Mexico

Before breakfast I walked over to the Colina. Whales cruised lazily in the channel, each with a young animal alongside, the usual dense flock of godwits and willets perched on the beach below the Colina (Playa de los Norris). I decided to move camp closer so that we could observe more easily and frequently. Proximity and chance observation play, I find, an important part in animal observation. This was certainly the reason we learned so little while staying at the cannery and here we were 800 yards back from the beach. So we moved the whole shebang to a little sandhill at the base of the Colina on the north. Just above the highest tide strand mark there were still many small crab burrows in the sand amid the low *Croton* and *Astragalus* cover. A solenaceous shrub whose name escapes me (*Lycium*) was the biggest plant. Also common were a low *Atriplex*, a succulent, a long thin *Oenothera* in bloom, *Distichlis*, and a pretty yellow *Solanum*?

Our camp was set behind a hill about 30 yards in from the beach to minimize our disturbance of the whales. I set the tents with their backs to the wind and circled the camp with cooking tables to the south (plywood half sheets on supply 5-gallon cans). A ice camp. Back of us to the west lay a gently rolling flat that ended half a mile away against the beach dunes of the coastal strand. At night the breakers boomed in continuously, not being very evident during the day (sound conducted in vapor and reflected or channelled in an air layer, or is it wind?). Now we have a short hike up the colina and just up the sand hill by camp we can see and hear whales.

We set the watch and began observations. At first there was some confusion because I asked for too much information. We settled (mostly with Candy's advice) on

tracking and animal identification during watch and more detailed behavior otherwise. When off official watch, I'll collate after the trip and provide everyone with copies.

We were able to make the first steps. Most animals concentrated in certain areas, in areas where the animals stayed still, there was more fluking, spying out, rolling, and throwing of the pectorals. There was evidence of some reaction between adult females at times and no large aggregations. Once a female with calf came up channel from Devil's Bend, encountered another pair at Hobbs Channel (off Cabo Forment), and abruptly turned back south from the point of encounter. We noted that spouts were ubiquitous in the cool morning air but only evident sporadically in the hot afternoon. Obviously condensation is involved. So far we have been unable to see nursing though occasionally we see young at right angles to an adult at about the level of the first knuckle on the back, or over the urogenital area. So far we have not seen young wander far from adults, though often enough the adult will be down below the water for some time and the young will surface above. Adults, especially, will often spend long periods on the surface with the mid-back exposed, sometimes over 20 minutes. At the end of such a session they typically raise the snout, breathe and roll under, often to reappear and lie again.

Phylly took a hike out across the sand to the ocean beach where she reported there were whale bones, sea lion skulls, turtles, sand dollars, sea fans, and acres of shells. Obviously a good hike over there is in order.

Around the fire we discussed many things. Bernardo told us of Dr. Isaac Ochoterena the founder of the Univ. Mexico Institute of Biology, whom E. Raymond Hall called "the handsome Aztec," who went in the field with button sleeves, spats, a waistcoat, and tie and who asked his assistant to collect this or that plant or lizard.

George told us about the famous Dr. Van Gahn, who watches over pathologists—pinstripe suit, french cuffs. When doing an autopsy he rolled his french cuffs back two rolls and dove in sans gloves. He watches the group now as a spirit. Little does George know that we suspect he is presently carrying the spirit of Dr. Van Denburgh, the patron saint of collecting trips, since the good Dr. normally occupies the body of a white-bearded gentleman.

Off to bed, with air mattress supposedly fixed. Alas it leaked again.

January 23, 1975

Colina Coyote

Things are falling together, piece by piece as they do with behavioral observation. We've seen feeding or at least grubbing in the bottom with the mouth and very likely nursing plus much other behavior.

We have begun to realize that spying out is very localized and we have only seen it between Cabo Forment and the S. end of Isla Villa, in the channel. There we have repeatedly seen it.

While I was watching Animal #1 and her baby I saw the adult emerge snout first in a boil of mud, then moments later saw the same animal dive and emerge with a cascade of very muddy water pouring from the corner of the mouth. The mouth was slightly open.

Later we saw the same adult emerge and clean water cascade out in the same way.

George and Phylly describe "nursing behavior" as follows, and I have also seen much the same action. The adult female rolls lazily at the surface, often throwing one

fluke out of the water partway. The baby, standing off to one side nearly at right angles to her belly at about the vent, rams or thrusts against her and 10-20 seconds later rises to the surface for a breath. We have not seen milk or have we been able to see details because of the angle of vision.

Well, the motor quit when we sent the skiff in to Lopez Mateos for bread and the rest of our gear. It just stopped. Oh my! Fortunately we have a going home motor—a little six-horse seagull. Tom and Dick were out in her and the sonarbuoy they were trying to place over near the Canal Hobbs (MOCHO). It sank. The saltwater corrosible bolt leaked where it had been epoxied. Blup, blup down it went! Oh, woe! They tried to work on the motor and found aluminum on one spark plug. It's a new 65-hp. Merc and is probably having break-in troubles. For a while we thought it had a broken piston. But she turns over hard hence isn't frozen. Well, now what? I thought it over and decided we had to move it on fixing the problem tomorrow so if we do have trouble there will be time to get around it. So I'll send Larry and William off to see what they can do—fix it, rent a motor boat, or fix the engine in Villa Constitucion. William will translate and Larry will make the decisions about what needs to be done.

I'm sure Tom and Dick want to go, but I'd rather leave the logistics to Larry who has planned everything so far, and dove very well, too. I've probably affronted them a little but I have to decide how to handle things. So I do it. Dinner and off to bed in the cold air. We don't even have fog now—just snapping stars.

January 24, 1975

Colina Coyote

Today Larry and William go off to Lopez Mateos. Meanwhile, Phylly and Candy will stay in camp to measure respirations and dive times. The rest of us are off to the ocean coast to walk for osteologic specimens. Off we went across the flats to the dunes. We passed a couple of Baja jackrabbits, their ears up and their posture poised for a leaping run through the low vegetation. Bernardo and I had a chance to talk. He is a dignified yet humorous person, very gentle, yet full of resolve, especially when his country is involved. He is a master of concern for other people, always polite and a biologist to the core. He has known most of the old masters—Hall, Grinnell, VanDenberg, Klauber, Cain[?], and so forth. Obviously his skills have placed him high—head of his country's park service, head of his Department invited to head the Univ. of Puebla and other things. A fine man in all ways. William with him is young, bright, in good command of his field, perhaps a little unwilling to go out on his own, a little brash. I like him very much. He will, I think, go far. We swap plant names, being supported by our mutual lack of precise knowledge.

Over the barrier dunes we went. In the hollows were fields of land snail shells, all arrayed in a spaced fashion. I thought I could discern rows, probably based on underlying wind ripples. I suspect these light shells blow away from one another and hence space. In many cases each had a little sand shadow trailing it. Striking.

We emerged onto the beach—a 150-yard-wide with tiers of low breakers piled offshore. Beyond, out in the band of blue sea we saw whale spouts. One group moved south, as did three small seiners, obviously making for Punta Entrada.

The pickings were good. Along the scalloped upper beach were regular passes through the dunes, each filled with shells, detritus, and bones. We picked up about six sea

lion skulls, a *Tursiops* and two *Delphinus* of the long-snouted variety. We walked quite a long way, watched the truck drive by from Pt. San Jazaro—on as smooth a road as any in the world. It usually carries lobsters but this time it was the fish truck.

Far down the beach I called a halt for lunch and the turn around. Gauging the state of my feet I decided I'd be worn out by the time we returned to camp. I found Bernardo concurring. We lolled on a beach-edge dune, talked and ate our bread, dates, and fruit. On the ocean in front of us a group of whales moved south and two small seiners went by, headed for Cabo San Lazaro.

Trudging back up the beach we picked up the specimens and poked along. Bernardo had picked up a boat hull[?], George a gray whale rib, Tom a long bamboo pole, and others various items dangling here and there. The day was very pleasant and clear but we were sweating before we reached camp.

I went fishing and caught a *Menticirrhus* and some small mojarras. The tide was coming in, the moon beginning to shine when things got too cold for my thin shirt. Candy and Phyl had spent a frustrating observation day since all the whales had left at low tide and never did return. They were taking respirations and dive times. Toward evening Larry and William returned using a rented motor that pushed them along at something less than flank speed. Apparently the Mercury can't be repaired here with any security so Larry wisely decided to leave its repair till we get back.

January 25, 1975

Isla Magdalena at Colina Coyote, Baja California del Sur, Mexico

Today I plan to try to typify in words various movements and behaviors of whale adults and calves in the lagoon Tom and Larry will try for some recordings and the others will carry out the behavior sheets. It's a lovely clear day, temperature about 65 degrees F. and a slight breeze from the north. Coyotes yip in the morning air from an adjacent low swell of terrain 500 yards away, and two Magdalena jack rabbits hop in the flats nearby. A beautiful flight of white ibis soared in low over Caleta Calloway and settled in the pickleweed flat 800 yards away. Behind me in the channel I can hear the occasional sibilant deep respirations of whales.

I forgot—Dick picked up two bottles yesterday with notes in them. One was from Bunny and Burl who had emptied a vodka bottle on a cruise ship out of Mazatlan and would just love to hear from whoever picked it up. Burl, they noted, was the humorist of the group. One could almost see the lampshade.

The second was more somber, scrawled in red pencil across the corner of a sheet of paper in red pencil. It said. "Help! I want aground on a Island San Roka "I think." Please send Help Fast. Allmost out of Food and Water. Please send to Coast Guard Fast.—Mike Tiama"

There was no date and the bottle was high in among the dunes. The paper had a pinkish suffusion as if moisture had made the pencil run.

Typifications—respiration adult (Sancha). Adults sometimes breathe with nostrils just barely above the water. The adults straighten back slightly, usually causing a slight upward movement of the head. The nostrils swell before breath is released.

Sometimes breaths are released below water by both mother and young.

The spout is double just at base and merges upward into a single “mushy spout.” With any amount of forward motion respiration doesn’t seem to interrupt the motion. When floating, often the rearing up will cause the adult to slide backward slightly.

The baby typically rears up, throwing the head free of the water often without the body aft of the pectorals showing at all. The head sometimes is free of the water, exposing even the lower jaw. There is very evident arching of the back in the baby, just behind the head, thus throwing the head upward.

There is some contribution to the blow from water around the nostrils. When an animal rises rapidly from the water and immediately blows one can see the force of the air “tearing the water pooled on the nostrils [?] into the blow.” Most of the pooled water seems to contribute to the low part of the blow while the vapor column from within the animal goes upward farther.

Whales can blow without a spout. They do so when they rise slowly and blow leisurely without force. Thus the presence or absence of a spout is seemingly related to velocity of exhalation, hence a pressure gradient.

Spouts are almost ubiquitous in the early morning air when the thermal differences are greatest and dewpoint lowest.

Thigmotaxis: There is a remarkable degree of body contact between mother and young. I think I can see it solicited by both partners, especially by the young. The young animal will slide all over the mother from her head to her tailstock. The baby will roll over the female’s back, rotating onto its side and back and throwing its pectorals into the air. The mother responds by pressing up against the baby, sometimes pushing it half into the air, with it lying across her limply. We have seen baby’s being carried on the dorsal surface of the flukes of the mother. What is use of thigmotaxis? Some whales apparently go south, though most go north here.

Tides: Once again, for the 3rd day in a row the animals have begun to move out of the Devil’s Bend-Canal Central area forward of Bahia Grande. In all our observation time animals never seem to have moved over tidal flats, but instead stay in the permanent water, often at the very edges of channels. In fact much of the movement and activity seems to be along such drop offs.

The exodus occurs well before there is much reduction in water level, in other words apparently in relation to water flow rather than depth. Today’s movement began when water was up into the bases of the mangroves, or in other words very near high tide. The exodus is leisurely, a slow movement northward, accompanied by periods of floating, thigmotaxis, spying out but generally to the north. There usually are some concerted bursts of slow purposeful swimming.

Reactions between whales: Except for a few groups of threes, adults or pairs involved in chases, whales seem quite solitary, even spaced. The spacing results, I believe, from a low level of avoidance at close range between females with young. We have seen cases where females approached each other—one approached within 10-25 yards of the other and one turned 180 degrees and retreated back down channel. In another case two animals swimming head-on at the very edge of the channel met. One continued on track (the outboard animal) and the other veered in over the tidal flat about 20 yards from the drop off. Because I could just see the flat I’d guess she was in eight ft. of water. This is the only time I have seen an animal out of permanent channel.

[Drawing]

Spying out: Spyng out has all been concentrated at the mouth of Hobbs Channel between Isla Villa and Punta Forment halfway down Punta Forment or halfway down Isla Pierce to the south of Cabo Forment along Isla Pierce, in both cases mostly along the edge of the dropoff. Adults do most of the behavior though babies do rear out on occasion. The animals here have seldom risen above the pectorals. They often rotate slowly as they rise, often emerge upside down and often at 10-20 degrees from vertical but never, in my observations, more. The jaws of the animals seem often slightly agape, though usually closed.

When mother submerges the baby usually goes with her though sometimes one will see a baby at the surface alone for brief times.

In the areas where spy outs occur there is also the most pronounced underwater behavior. One can often see underwater blows, circling by tail beats underwater, and much stationing at given spots. Animals also return to the special spots after tidal currents have drifted them away. One animal has stationed for nearly two hours in one spot by Isla Pierce.

Nearly all spy outs are unaccompanied by mud. Only in three cases out of perhaps 100 examples have I seen mud.

When boat and seagull turned on and left for recording three adults with young were in view. One pair turned in off tip of Isla Villa, turned on speed and ran up along the drop off. These animals were 500 yds. from the boat to the S. off Isla Villa. 2,000 yards S. off Isla Pierce a whale moved away into deeper water. She had positioned for about 2½ hrs. and then 4-5 minutes later, began to move N. resolutely. Our channel is almost swept of whales.

January 26, 1975

Colina Coyote

Last night a sailing ship came poking up Devil's Bend and came to anchor at the north end of Playa de los Norris. It was being ferried to Los Angeles for an [?] by a Swiss fellow, Peter Kittel. I was fishing off Caleta Calloway when he came walking down the beach. He was a whale freak, acquainted with the usual people and books.

About that time, as the tide approached high, whales began to come back into the area. One came in at flank speed pushing a bow wave that surged onto our beach. Two others were close together and I suspected that we had a male in the nursery. Every time we see adult "males"? in with females we have adult whale to adult whale proximity, chases, high-speed swimming, rolling and thrashing, and throwing of flukes. Phylly reports that in one adult to adult chase the baby became agitated, bobbing around the mother frantically.

I'm on top of Colina Coyote now with Bernardo, having relieved Phyl and George who had the early watch. Tom, Candy, and Larry are going to Matancitas with William to observe at the Boca and William will call Mexico City and get gas.

Now for some observations.

Spying out: here at Colina Coyote we have seen only two "breaches" in which the animal rose to the fin stock or a little less and fell back with a big splash. Otherwise we see spy outs, which are very different. In these the animal simply emerges slowly, snout first and rears up about to the level of the eyes and slowly subsides. Since it nearly

always occurs near the edge of the channel, it could well be that the animal has its tail on the bottom and is simply pushing upward.

#1 Spy out. Off Isla Pierce. Out to eyes with baby at surface, belly of mother toward bay, mother oriented belly down Canal Central. Slack water.

#2 Spy out. Off Isla Pierce at channel edge. Came up dorsal surface first and then subsided, belly up channel facing N.

Five pairs down channel in first part of Devil's Bend area. Last night I watched an animal spy out off Cabo Forment in the dark using Night Vision Scope. There was a partly full moon. I have seen a five-second spy out in Bahia Grande. Almost surely standing on tail and subsiding back in attitude from which it rose.

I saw one animal rear up smoothly and as it descended its path wavered which would seem most likely to indicate the animal's tail was on the bottom and that it exerted pressure against the bottom as it fell back.

I saw one up for 17 seconds. It first reared up almost straight then fell slowly foreward until just the tip of the snout was showing, reared up a little way again, and subsided. Figure a 40-ft. animal with 6 ft. of head out of the water and [?] of flukes and body and one would expect the water depth to be 28-30 ft. where they spy out. Where is the baby during spy outs? I see no baby in sight.

Then the whales went underwater and we saw them seldom again. We had a very low tide today watching the high of last night which flooded the pickleweed flat where we first camped. So it seems pretty sure that the exodus we have been seeing is a tidal phenomenon. The whales do leave, going N. into Bahia Grande.

As to place phenomenona in these whales there are some whales we see over and over but there are some that move in and are never seen again. Nonetheless the place where we see spying out is one area only.

But with conger[?] observation it has spread along a wider area—from about the tip of Isla Villa down along Isla Pierce a little below Colina Coyote. I suspect it may have something to do with the presence or absence of a cut bank and a deep channel adjacent to shore.

Bernardo and I ran a "short term" behavior record, mostly dealing with respiration rate and spying out. Momma spent a long time below water at first her longest drive being somewhat over seven minutes. Later she spent a 15-minute period reathing rather often. The calf breathed rather often through the whole sequence, and the pair swam together a fair distance—perhaps 1,000 yards, and one major course change was done by the female underwater. She kept within the chosen areas and made one directional decision underwater.

Tom, Larry, and Candy, and William went to Matancitas to phone and to Boca Soledad to watch whales there.

Meanwhile Phylly and I took a hike looking for coyote skulls for Bernardo and William. We went south behind Colina Coyote down to the lagoon to the south. We came up with two skulls, one a coyote and the other turned out to be a badger.

Bernardo was very pleased as he thought maybe there was no badger from this area. Then Dick and I went fishing up at Caleta Calloway. As we walked out on the sand spit a single *Tursiops* swam up along the rather sharply sloping sand beach. The porpoise swam in until he was rolled well onto his side. He made passes at fish within a few feet of us, eyed us up through the water, cruised or turned back in front of us again. This time a

fairly large stingray flapped out of the water at our feet onto the sand as the porpoise passed. The strategy was to trap fish in the wedge of water against the beach. The fish were then limited by shore, surface, and bottom, and could only turn back into the jaws of the porpoise. Few fish were to be had so we trudged back to camp and soon the skiff arrived. Dick had created a pineapple upside-down cake and some sort of stew. Much conversation and to bed. Tomorrow we go out in the little yacht off Isla Villa to see if we can see down into the water where the whales are most common.

January 27, 1975

Colina Coyote

It rained a little last night and in the mornig there were various reports about the integrity of tents. Bernardo's dripped at the ridge pole, Phyl's and mine leaked at the door, Tom's came in the triangular window, and George reported complete watertight integrity. No report issued from the cook, Dr. Pierce, or from Larry and Candy.

At about dawn Geore scurried around outside putting on coffee. At about 7:15 AM Peter Kittel came ashore and took us on board the Kris to observe whales from her [?] mast. We went across to the mouth of Canal Hobbs, anchored and drifted out. The tide was very high. For the first time whales moved over away from the channel we had occupied toward Colina Coyote. Peter put on more anchor line and drifted us out. All the animals were over along the Colina Coyote shore. Most animals were quite sensitive to our presence, moving away when they were 80 yards away or so. For two hours this was the pattern, and finally our decision was to move nearer the channel center. This move was spurred on by the fact that we had run lightly aground. A bit of tugging on the anchor and running the engine forward we broke face and proceeded to the new anchorage. Almost at once we had animals around us and this continued until the tide began to change and the animals moved northward out of the channel.

Many times the animals moved close to us, sometimes close enough to be seen underwater. Rather little of the behavior seemed new to us. We saw much contact between mother and young with the baby being lifted on the mother's head, or on the tail stock or flukes. Most of the time the baby stayed alongside the mother and parallel. It tended to follow her down in dives, though surfacing more often if he was staying below for long periods. At times the baby wandered a little—the farthest from the mother that I saw was about 50 yards with a quick return to momma. Mostly they stayed very close.

We saw more spying out, some from close up and I am more and more convinced it's done with the tail on the bottom and the nose levered upward by flexing the back. Candy believes she sees it more often when adult whales are close together. I think she's right. It also only hapens when the movement of the animals involved is very slow. Spy hopping or breaching is very different and occurs only when animals are active and we are beginning to wonder if it might be mostly or wholly by males. Breaches come in groups, just like spins, and the highest breach is usually first followed by less active ones, rather like an animal taking out its excess energy and gradually tiring.

Our breaching animal this morning did so in front of the Colina and Phyl says she was impressed how slim he was compared with others. I've wondered at how broad the backs of mother whales are behind the blowholes (over the ribs). It is so extreme when an animal surfaces near that I wonder if the animal is somehow dorsoventrally flattened in this area since I cannot believe they are that vast in diameter. Maybe the loose ribs and

lack of sternal attachments allow the ribs to spread under the pressure of buoyancy from the lungs. Stranded animals I have seen have not looked nearly so broad.

Nursing still eludes us and seems obvious to be carried out mostly underwater. On one occasion I saw a young lying at about 60-70 degrees from mother at about the level of her vent and as she submerged and bent her tail stock the baby dove under the stock of the mother and twisted its flukes in such a way just at the surface as to swim up under the mother. Nursing? I don't know. Dick suggests nursing might not be so frequent as we supposed it might—a few times a day would suffice and points out that the mother has to have time to manufacture milk in between nursings and to release it.

This afternoon we run soundings and record whale voices.

[Letter from Dr. Bernardo Villa]

Reading the notes around the fire caused good discussion. How much body out of water? How high does a resting whale rise above the water. In other words, how much buoyancy is involved to counterbalance the weight of the animal above water when the animal is floating?

Larry describes a floating animal blow and then go down a few inches and then bob above median level, fluctuate four times approximately before coming to stability. Phylly describes an animal lying on the surface, flukes came up on the surface and all knuckles showing and then a lateral S-shape curve with flukes in original orientation to body. Dick describes animals blowing underwater and staying down, suggests this should increase density and sink.

I've seen underwater blows not followed by a surfacing until a minute or more later. Some animals float higher than others, some are nostrils only above water, others are fairly high. Indicates some flexibility in inspired air.

George tells me that when fats are cycled, triglycerides cycle under influence of epinephrine and fatty acids are often reused while glycerol is always made and releases heat, hence whales may in effect may be encased in an "electric blanket."

January 28, 1975

Colina Coyote, Isla Magdalena, Baja California del Sur, Mexico

This morning some folks will be preparing to break camp tomorrow, some doing the last checks on the scars and marks atlas. George, Tom, Bernardo, and I went up into Bahia Grande to try some recordings. The wind chose this time to blow and the chop made recording in mid-bay pretty unworkable. Two differences in behavior struck me—we saw some spyouts and each time the animal fell back rather than subsided. Bahia Grande has water 40 ft. deep or so and I suspect these animals were not touching bottom.

Second, we saw animals invert and throw their tails out, perhaps 10 ft. of the animal was in the air with the flukes waving. The slow subsidence suggested its snout was on the bottom.

January 29, 1975

San Carlos

Today is moving day and quite a day it has been too. Up at dawn packing tents and cooking gear with one hand balancing a cup of coffee and a bowl of granola. The tide was high and still coming in. By nine we had loaded the skiff under blustery clouded skies with intermittent rain falling, and George, Dick, Larry, Bernardo, and I had climbed

aboard. The rented outboard pushed us along modestly well, though we bucked a very strong flooding tidal current and it took us two hours to make Matanatas. We cruised up along the dunes, peering in amongst them at ever turn. One coyote slid along and climbed a dune not far away and we came across an adult and fat sea lion sitting on the sand bar, all alone. She may have been ill but was well enough to launch herself into the water. The tide flooded very high into the reentrants and the dunes by the time we landed.

We unloaded and filled the truck leaving Larry to start back for the next load. Not long after we started for Villa Constitucion. Larry's motors quit and he limped back to the dock. Then followed a long saga in which Larry finally located a boat and motor and returned to camp and at 4:30 left in the rain with this boat and another that had showed up. Phylly and Candy, William, Tom, and Larry piled in and after a long time landed at Lopez Mateos where Dick Pierce and Bart Gordon were waiting with cars.

Meanwhile we had set up camp at San Carlos on a sandy flat back of the beach north of town. George and I concocted a fine dinner that aside from us, went begging for several hours.

We had met Sig Rich, John Hall, Bart Gordon, Jerry Koozman, his two technicians, Krupe of San Francisco State (interested in cyamid parasites) and his two friends. Quite a crowd. It's amazing how this operation attracts people and how many more would have come if I hadn't turned them away. I think gopher-watching would be more peaceful. We've a good crew though, especially our field party has pulled together into a well-functioning group. Certainly yesterday through all the troubles of rain, motors, loading at low tide when you had to be carried out over a long mudflat—everyone has worked together. Phyl, who wasn't feeling too well, apparently worked like a trojan in the rain and across the mudflat. On the trip up, spray from the rather rough channel and rain wet many pieces of gear.

The crew, when they came in, were wet, tired, and hungry. They scarfed down the slim fare and scurried around for more. We had a little trivia session with Bart Gordon providing some remarkable examples. Off to bed with the rain mostly gone. No boats in sight, only the winking buoys out in Magdalena Bay.

January 30, 1975

San Carlos, Baja California del Sur, Mexico

This morning about 9 we saw the *Dolphin* coming in, a great white motor sailor, 100 ft. long, that will serve as our tracking vessel. Not too long afterward the *Orion* came in. She is a trim swordfish boat of about 42 ft. We checked in with various skippers and then Bernardo and I went around looking for places to store our shore camp materials and housing for those who will stay ashore. We located a visitor's house owned by the government cooperative (CONASUPO) that had three bedrooms, a livingroom, and bath! Bernardo, who is tremendously capable in dealing with people quickly, made the arrangements. We will be able to store all our gear inside and take care of our people ashore.

We then visited the Fisheries School and then Sr. Armas, the Port Captain again. All protocol taken care of, we went on board the *Dolphin* for a glorious meal of chicken patties and many other goodies. I assigned us as many as possible to bunks on the *Dolphin* since there is a baptismal party in the CONASUPO house tonight and we cannot move in till tomorrow. George, Phyl, Dick, and I drove to Villa Constitucion for some

wine and as we drove along the rain fell harder and harder. The sandy desert soaked up all we saw run off the road and the toads emerged and hopped in front of our lights. We emerged from the Supermercado with two gallons of wine and a jug of scotch (the latter for the boat). George regaled us with yankee tales. He is a helluva guy—humorous, very broadly knowledgeable and bright, and has good cool seaman's judgment. He's also a considerate guy who wears well. The kind I'd be happy to be on shipboard with.

At camp the rain came and came. We polished off 2/3 of the first gallo, sang songs, and told stories, and then went to sleep in the damp. We'd brought all the perishable stuff in—a great whale rib that George had given me [?] at Colina Coyote. I didn't want the ink to run.

Finally to bed.

January 31, 1975

San Carlos

I was going to try for a capture today but Larry convinced me we should wait for better weather—a clear period is due tomorrow. So we had a meeting and laid out everyone's duties and went over a few safety features. Everyone has a job and a place and a time in the boats. It was a real pleasure to see everybody turn tail to get their gear in order—the harnesses with Larry and Tom. Bart will handle the tape recorder and hydrophones and he spent time rigging a harness so he could wear the rig around his neck and thus wade out into water with the whales. Up in the lounge George and Dick readied the EKG machine. The paper rolls they had been provided were too broad so they simply sawed off a piece, and soon it was running. John Hall was off getting boats lined up. I noted George out testing the small boat he will drive tomorrow.

The *Dolphin* is posh but I'm not sure how versatile as a research vessel. She has a fine lounge and galley on the main deck, a big clean bridge and twin diesels that apparently are a bit too big for her hull speed. She's equipped with gyro stabilization so she doesn't roll much. Everyone has good comfortable bunks and reading lights. She's panelled and carpeted and has a nice athwartships lab aft.

Bob Newbigen, the skipper, has an enormous pot and is the same old guy who dumped me off seven miles away from the Scammon's Lagoon entrance . . . full of flatly stated opinions about biology and full of reasons why it's difficult for him to do this or that. But with a little jolly along he comes around and he's a cautious seaman who doesn't run into things and generally gets his job done.

There are a couple of other taciturn types—the mate Joe Mehlin, one of the seamen whom I have sailed with before. The cook, Julio, is reckoned as the best in the Scripps fleet and very good natured. The engineer, Jim Thomas is new to me and I think he is bright, direct, and good. He spent 24 years in the submarine navy, a good enough recommendation.

Tomorrow at about sunup we will scout for whales over near the sandbar that blocks the bay from the Pacific. If we harness an arrival we will go below it on the *Dolphin*, between it and the Entrada, so that it will have to go by us to get out. This will leave us able to navigate out to sea at night, which because of uncertain sandbars, we cannot do here. Then will follow a capture of an animal for physiological studies, and hopefully animal No. 1 will still be in the bay so we will be a full force on our collecting crew.

We've all had good warm showers, washed our dirty clothes, the ship has taken on water and fuel and we are ready to go. Now if the weather cooperates tomorrow . . . At least we should have the normal early morning calm going for us.[Map]

February 1, 1975

Puerto San Carlos, Baja California del Sur, Mexico

The hundreds of details seemed mostly in order today until we began operations. It took a long time to cruise out in the *Dolphin*, anchor across channel from the Punta Magdalena, a lobster camp on the island, and launch the skiffs. At first the skiff motor (another Mercury 65) faltered but finally came around. Then the automatic direction finder wouldn't give a reading foreward. Larry and John began troubleshooting and rather soon found a coaxial cable crumpled under a door. That was part of the problem but it was finally solved by shortening one of the leads. Then we didn't see whales with young. I'd hoped to get them, near the island N. of Punta Magdalena but all we saw were adults unaccompanied by young.

William and I went on board the *Orion* to scout and Peter Zimmerman the skipper took us out into the Entrada area where Magdalena Bay enters the sea at a 5-mile-wide channel. As advertised, it proved to be the mating grounds. We saw no young out of about 35 animals. There were several groups of animals, in fact nearly all animals were in groups of three or more. We saw one group of five that on at least one occasion had six animals. These groups rolled, threw pectorals and flukes into the air, and often fluked free. I saw five full sets of flukes in the air at one time. I was impressed that morning that the animals in these groups were small, 30-35 ft. or so, and often much less blotched by barnacles and cyamid crustacean patches than the big females deeper in these inland waters. At least some of these smaller animals were males as on four occasions animals rolled over throwing the ventral surface of the tail stock into air, showing the penial sheath clearly. Once such a male had an erection—with about 2½ ft. of the penis extruded and laying over.

We saw these mating aggregations well up into the bay toward Punta Magdalena and along Isla Santa Margarita to the south of the entrance. It was only when we turned and penetrated up bay toward Isla Patos that we saw mothers with young. Such pairs were all we saw at Puerto San Carlos, and there they were moving back and forth with the tide just like those animals at Colina Coyote. Near Isla Patos an animal breached and I saw a baby nearly, possibly with a third animal, I couldn't be sure. Earlier one had breached near the Entrada that seemed clearly alone. Yet, I'm now skeptical that breaching is always by single animals. I'll have to see several more to renew my faith in that theory.

At about 3 PM we began tracking a pair north of Isla Patos. Tidal flats were not easily seen and it seemed very far to a beach. We tried to maneuver the pair nearer shore but they resisted well and even though I was most anxious for a capture I acceded to Larry's calmer judgment that we would have serious trouble taking the animal over that long flat. Since the *Dolphin* cannot leave at night we had to quit for the day, in addition to the fact that daylight would soon limit us.

So, back to anchor, considering the day as a shakedown for tomorrow. We have a tide about 8:30 and will have most of the morning to work. Two more things—the

weather has stayed overcast and blustery but now, at sunset, we can see clear skies to the north and tomorrow we may have some sun.

Second, when we watched the five-member group of mating whales they were accompanied by a single $\frac{3}{4}$ -grown California sea lion. We could always predict where the whales were below—when we saw her at the surface. This behavior persisted for at least half an hour. Why? Often the animal was literally in among the rolling whales.

February 2, 1975

San Carlos, Baja California, Mexico

Closer, but no cigar. We cast off shortly after breakfast and proceeded down the blind channel east of Isla Patos. As we passed the island the cormorants that give it its name peeled off in long wavering skeins, flying right at the surface. There seemed thousands of birds, pouring past us. I'd seen some whales in the area through the binoculars so we looked out to the south and soon saw some spouts. Shortly two pairs of mother and young came up the channel and we picked one large young to follow.

Peter Zimmerman is a patient fisherman who knows the value of a good stalk. Without revving his engine he crept closer and closer and finally put Jay right over the young just off Isla Patos. The tide was down and so we could get reasonably close to the beach for stranding the whale. But the shot failed. Jay could barely hold the heavy net and pole and dropped it. The baby hit the net and bounced off without ripping it free[?] or sliding into the sack. The animals bolted up channel with us following along. It took a hour or so for them to calm. By that time there was no beach near so we could not try again.

Finally we herded them back toward Patos and by this time it was early afternoon and the water had risen producing a mile-wide shallows. What to do? How could we get the animal off after harnessing it? Would we be able to work in the waist-deep water? Well, anyway, we tried. And Jay made a perfect shot and the die was cast. Pete brought us over as close as he could to the bank and we all took off in the skiffs with the line. Fortunately the day was calm and warm—most of the clouds were gone, thank goodness, as it made working in the water much more comfortable.

John drove the skiff into about three ft. of water and we began pulling. The animal had the noose back over its pectorals and was being towed sideways and able to rise easily to breathe. By taking it easy and slacking off periodically we brought the animal in over the flat quite a way. I decided to try to work in as deep water as possible in order to reduce the problem of reintroduction. So we set about harnessing in waste-deep water. The animal, a male, was slightly over 15 ft. long and reasonably easy to handle. Sig Rich and I stood by on either side of the head to block the animal's vision. I slid the net noose loose and worked it forward over the pectorals and tightened it again on the head. Meanwhile Larry, John, and Dick put on the harness. Bart and George stood by recording. The whale repeatedly uttered sharp clicks which were made when the animal seemed ready to blow but didn't. Instead it tossed its head up slightly and made quick, small movemets with its jaws that seemed correlated with the sound. I picked cyamids for Jim Krupe. They were common enough around the blowhole, lips, and especially in the axillae. The cyamids clung to my hands and wrists and dug their sharp little clactyls into my skin. Man can they cling! I suppose that is an utter prerequisite for a whale dweller.

Then we launched the animal, its mother far up channel, but we could see the boat coming down channel toward us, presumably following the adult. The young animal floundered at first and repeatedly dove, forcing its snout in the sand. But as the water deepened it took off more normally, but within minutes Bartl shouted, "What was that? I heard a shot." And minutes later there was the harness drifting at the surface, its explosive bolt fired. Why we could not fathom. Tom later came up with the notion that the radio might have fired it, as it puts out quite a strong brief signal and such a charge could load up the capacitors in the timer. I suspect he's right. Anyway, back to the drawing board.

Larry and Pete and I scouted by skiff into lower Devil's Bend, in hopes that we might find whales there. But we didn't and had to settle for some mangrove oysters and a nice ride at dusk. Well, what will tomorrow bring?

February 3, 1975

San Carlos, Baja California del Sur, Mexico

Frustration Monday! All day we moved up and down the channel stalking animals. Pete is a past master of stalking. Without a single rev change he sneaks up on animals and they respond by continuing their slow swimming, though they continue some evasive maneuvers. Babies change sides over or under the mother and they make modest course changes often enough and sometimes radical ones. We had four shots today and netted one animal over one pectoral. The hoop entangled in the line and we had a tense moment or two before Jay the "harpooner" dropped it because momma was right with the baby and had her flukes up against the stern post of the *Orion*. I yelled and he dropped it overboard and the big whale sank away.

It was very windy today—to 25 knots or more and this more than any other weather variable, makes for difficult collecting. The chop flatens and obscures blows and it is difficult to follow animals underwater.

The team jumped in the skiff and headed for shore only to have the animal shuck the net when we were 50-100 yards from the shelf. I had been slacking line to allow the animal to breathe and it escaped.

We had no more chances though we worked very hard all day. Phyl, Dick, Bernardo, and William leave tomorrow and George will drive them to La Paz while the rest of us fish. I enjoyed them here immensely and Phylly had a fine time and was appreciated by all. The cook aboard will, however, be glad to see my crew reduced in numbers as they are many more than he bargained for and I can't see how to assuage him, though I am trying to have as many as possible cook ashore.

February 4, 1975

San Carlos, Baja California del Sur, Mexico

Uptight Tuesday! Three or four more shots today and we had an animal actually back out of the net. We fish in the channel in front of San Carlos down to a sandbar called Isla Patos and a little beyond. At the lower end especially most animals are single adults or pairs and trios of adults. These animals move with quick locomotion, often with a sizeable bow wake and often with flukes being thrown. Mother and young move much more deliberately. When hotly or persistently pursued the females sometimes [?] and spy out. We had one animal do this often. We had run it especially hard. It did this at least

four times and I have to say its eyes were out in air on all but one of these occurrences. Vision?

The wind had abated some but it was still rough work and everyone was tired when I called off the chase at about 4 PM. We are beginning to show stress. Pete cusses in frustration. Jay buries his head when he cusses. Larry was in the blue funk this morning—partly tired and partly sheer frustration. I think he is also weak with his hypoglycemic problem. I tried hard to assuage his problems and at least to some extent succeeded. His little gal Candy seems in generally good spirits though. I must say having their relationship pull Larry out of the group is not to my liking, and their relationship shocked Bernardo, I fear. But that's water under the bridge and Larry has done a remarkably fine job and continues to impress me with his cool seaman's judgment. I need him to counterbalance my impatience.

A lousy movie, a call to Pat (we have BLM asking us to carry out some flights over the Bering Sea for birds and mammals) and then to bed. Lights out at once.

February 5, 1975

Off Punta Belcher, Magdalena Bay, Baja California del Sur, Mexico

Well, Paul Sebesta, who flew in with a couple of friends chose the midst of an operation today to remind me that today is the first anniversary of the sinking of the *Louson*. I'd rather not remember. Anyway, it has been an exciting, fascinating, and successful day.

Everyone was on board at 8 AM, the shore party having eaten in the house ashore. Thus the galley was a little less cluttered today. We checked gear, did a little redistributing of personnel to lighten certain boat loads, and went out to hunt. Tom and John went for a flight over the lagoons and the cape, and we planned to pick them up by skiff if we were successful.

Almost at once we came upon a mother and young up the lagoon above the muelle at San Carlos. It was little "red head," a nice big baby and his rather smallish mother. I'd guess her at 35 ft. or a little less. The tide was dropping rapidly forward and the channel edges were clear.

The animals were obviously aware of us and evading the *Orion* in a deliberate ponderous sort of way. But after an hour or so we had our chance and this time Jay did not miss. The net was on and we began a really hard fight. At first we were afraid of the shoal buoys off the pier and the ships, which might entangle our line so we headed for the flats S. of the muelle. We arced around the pair always keeping the big $\frac{3}{4}$ in. nylon line taut and pulling up on the pair with our engine off when we had paid out too much line (700 ft. or more). Soon we were yards off the flat and raced for shore. The line parties had converged, aided by our radio communication with skiffs, *Orion*, and *Dolphin*. This allowed us to have people stand by until precisely when needed. George Nichols stood off the *Orion* in the big whaler and came along for that crew within a minute or so of being called. Soon everyone was on the beach. I noted stingrays as soon as I stepped overboard onto the sandy bottom. Later, I actually stepped on one that slithered out from under my foot. I had socks on but no shoes. No one, however, was stung.

Mother raised a great ruckus at the channel edge, and the baby struggled to stay with her but our line party of about 10 people pulled her in easily enough. Earlier when

we had just four people she had threatened to take us out to sea, as a matter of fact, we lost ground with her. Once we beached her measurements were taken.

The animal was very strong and heavy bodied and sported quite a crop of cyamids, the red head patches being these peculiar crustaceans.

Jerry Koozman and his people set up and took respiration measurements with their new gear. This consisted of placing an instrumented stove pipe that measures velocity profiles by a differential pressure measurement across a grid. Jerry literally can draw a picture of a blow with it. Dave, his assistant, and I held the apparatus over the blowholes until the animal breathed into it. After two such breaths the gadget was removed and the animal allowed to breath unimpeded.

We tried an electrocardiogram but I called it off rather quickly as it became obvious that we had serious artifacts and were most unlikely to solve them. Periodically, the baby threw his head up and blinked his great crinkly eyes, seemingly in disbelief. Here was leviathan being crawled over by liliputians for sure and just as otherwordly. What passed through his mind?

While we were doing these mudane things a drama was taking place off the beach. As we pulled the baby onto the flat the *Orion* was standing by $\frac{1}{2}$ mile to the south and about a quarter mile from the channel edge. She came up toward the struggling pair to begin trying to keep the mother nearby while we worked on the baby. She was 200 yards away when the adult female disappeared for about 45 seconds and then came up under the stern of the *Orion*. She thumped against the bottom so hard that the *Orion* was lifted about 3 ft. out of the water and heeled over at about 35 degrees.

Pete, needless to say, gunned his engine to "get the hell out of this" and in 30 seconds or so she came up again, this heeling the *Orion* over at about 30 degrees or so. Pete said he could look down and see her swimming below him and then rising to bump him. She came up three times at 45 second intervals under the stern, threw her fluke up by bending her tail stock up. He said her flukes were extended five ft. or so above the water, and waved back and forth. He did not see her swipe sideways with her flukes but instead only up and down. She hit the starboard screw at least enough to cause a vibration at 1500 rpm.

Pete ran the boat wide open in circles, attempting to shake her off but she kept up. He figured his speed at 14 knots. Finally he threw three sea lion bombs and she left. He, however, stopped and judiciously would not come back across the bay toward us for quite a time. I don't blame him a bit. She obviously associated his boat with her calf's troubles and sought him out with vengeance in her heart. Pete felt that if he had slowed she would have caught him and possibly done serious damage. How much intelligence is back of all this on the mother whale's part is anybody's guess but I am convinced that these animals can truly be dangerous and that when angered or separated from their calves they especially deserve respect!

On shore we quickly put the harness in place, this time secured by a 6-day magnesium bolt, and launched the animal. Bart Gordon was recording through the entire capture and recorded many sharp "clacks" made by the throat and jaws and several good examples of grunts. The baby clacked as it was launched and did so until it joined its mother 500 yards SW of us, out in the channel and then all was quiet.

The launching was pretty simple as we were at the channel edge (30 yards back). The baby swam resolutely as soon as water was deep enough and headed straight for the

rendezvous with mother. Once together there was some lunging half out of the water, much white water and then long dives. The pair at first headed up channel but rather quickly turned and headed out toward Isla Patos and the entrada. I gave orders to the *Dolphin* to follow regardless of who was on board and set a skeleton watch of Larry, Candy, and myself.

I went ashore briefly before this to say goodbye to Sr. Arnias and Sr. Toscana and to thank them. I found the whole town had been watching from the muelle and was buzzing with it all. As best I could I made arrangements for everybody and left a broom for them to clean with, went back to the dock where George Nichols ferried me out just as the *Dolphin* was weighing anchor. The whale had moved down bay past Isla Patos and the signal was getting weak. George stayed behind reading *The Voyage of the Beagle* and waiting for our aircraft crew to land so he could ferry them out. By that time we had named the whale "Newby II" after the skipper. We'd named the first one Newby but it got away early so we had to make this one II. The skipper made a wry face but I suspect was pleased.

We moved down the channel and signal strength began to rise below Isla Patos. Obviously the pair were nearly out of the basin back of the island and moving toward the entrance, but on the Almejas Bay side.

The ship is so calm, we have so much room, chairs for everyone and quiet. It's a luxurious and tranquil. What a palace to do our tracking on. If you have to track be sure to pick a converted 95-ft. luxury motor sailer with roll stabilizers, carpets, paneled state rooms, and movies every night.

It's dusk now and the whales move toward Almejas Bay so we are taking a somewhat better position to scan down that bay if the whales move into it. All is working well, a good signal, the X-Y plotter gives us records of respiration one hour out of four and the crew is all assigned to four-hour watches. George and I take the mid watch.

Quite a day! Oh yes, the flight crew went only over Boca Santo Domingo, Boca Soledad, the channel, Colina Coyote, Devil's Bend, Mag Bay, and Almejas Bay. There were ample whales at each entrance, including between 30 and 50 at Almejas Bay. John Hal and Tom Dohl report seeing whales in the shallows offshore between Boca Armas and Boca Santo Domingo leaving mud trails. These were seen only in the "green water" from about 75 to 300 yards offshore, outside the breaker line. The trails were solid, not pulsed as they would be if found by tail beats. John reports seeing a trail following an animal that surfaced and both concur such trails were a hundred yards long or so, and often curved. They felt they represented feeding animals. Tom said he saw some adults with young animals and commented that they were "tanking up" preparatory to going north. John reports most adults but sometimes in loose groups of up to three or eight.

They report no animals at all from Colina Coyote through Devil's Bend into Magdalena Bay.

February 6, 1975

Cresciente Island, off the mouth of Almejas Bay, Baja California del Sur, Mexico

George and I are sitting here on watch (12-4 in afternoon) with our mother-young pair now inside the mouth of Almejas Bay. I've been asking him to describe how he saw the "jaw clack" of the baby being produced. George says the baby opened the jaws 10 to 15 degrees, enough to see end of baleen and tongue, then the jaws made a tentative

closure, a short “rebound” and then a final closure upon which the sound was produced. It was a remarkably sharp “clack.”

Bart could not pick up a clack when the baby had its head arched out of water as it often did in this maneuver, but once it was below water he could hear it clearly. thus the jaws seem to have to be below to propagate the “clack.”

The whale spent the rest of the day moving over the flats south of the Almejas entrance, quite a lot of it apparently spent reversing, as they were rolling at the surface, throwing pectorals and fluke tips out and breathing much more frequently than before. Later in the evening they moved up into Rehusa Channel south of Punta Tosco, where they spent the night moving back and forth in a channel filled with about 50 other whales. Anytime you look out against the cliff you can see a line of spouts from near the point to back in the bay mouth. [Drawing]

Punta Tosco looks volcanic to me, with a sharp fault scarp on its NW side, typical hanging valleys and a very straight coast all along Santa Margarita Island. To the north on the island are peaks that look volcanic.

Our ship's crew consists of the captain, Robert Newbegin, an old merchant mariner who has been with Scripps since the late '40s. He doesn't run things aground, knows his ship, and responds to the needs of the scientists, albeit at times a bit mulish and growly. He's spent quite a bit of time helping this or that investigator. I suspect he must be near retirement now. He's terribly overweight, but it doesn't seem to affect his performance any.

Bobby Holmes is a very quiet, gap-toothed fellow, pleasant and unobtrusive who goes about his duties when asked. Juliano Cutudio, the cook, we've already mentioned. He's happier now that the galley is emptier, and I don't blame him much. He has his interminable solitaire game going and keeps his galley like the engine room—spic and span. Everything is on time and plentiful. Jim Mehling, the mate, is competent, quiet, but with a sharp opinion or two also. He gives the impression of quietly taking your measure and of having his own boundaries and definitions (metes and bounds?) well in order.

Finally Jim Thomas, the engineer, a retired Lt. Commander in subs and in research subs lastly—very bright, ambitious to be a naval architect, more at home with the scientists than the crew, I think. He'll not stay I suspect but will find creative work. He's up through the ranks. He told us about working on the U.S. sub *Dolphin* at 5,000 ft. of depth and tracking sperm whales on the three-dimensional sonar, swimming right along with their phonating. He called them “carpenter fish.”

A good bunch altogether and good to be with on a program. This work is slow and you really have to care for whales to get much excited about it. Weather couldn't be better. A low swell, calm, warm during the day and clear. Now the stars sparkle and the air is pleasantly cool.

Newby II spent the night sleeping quietly up against Punta Tosca and this morning began to wander a bit. I wanted to anchor over at the cliff under the point to look at the great aggregation of whales there, but Newby balked and we had to settle for a skiff in the water.

John, George, and I went over first, about 10:30 AM and the closer we got the more whales we could see under Pta. Tosca. I guess there must have been thirty around us as we came within 500 yards of the cliffs. The bottom shoaled under us and became green and later Tom sounded it, finding 12-20 ft. A tide rip flowed along it in the ebb tide

and the whales were diving, rolling, throwing flukes, and spying out in the roily water. We came in close to the Punta Tosca light and could see lobster traps ashore, and the crew of a tuna jack pole boat on a nearby sandy beach, lolling in the sun. Meanwhile we entered the whale group coming within a few yards of many. George saw one pair spy out, pressed together. We saw one pair roll, belly to belly and later Larry, Candy, and Tom saw an animal flail its extended penis into the air.

Several times we saw muddy boils of water around the animals but never did I see muddy water issuing from their mouths.

Our watch was coming up, so George and I had to return. It was hard to leave, surrounded as we were, by whales. Shortly after we started back we came upon four whales, rolling at the surface. We were able to get right amongst them, in fact so close we all had fears that a random fluke or pectoral might smack us. We were six or eight ft. away at times from a crusty, cyamid and barnacle-encrusted adult whale over 35 ft. in length and as we now knew, with a notably ingrown disposition. We saw them roll in contact but I, for one, had trouble sorting out what I saw.

At the ship, Tom, Larry, and Candy took our places while we went on watch (after a fine lobster salad).

Not long after the ADF signal became terribly jammed with skip signals, some apparently from Western Washington Taxi companies. For an hour and a half this continued and we tried to interpret directional signals in the hash. Finally I concluded it was mostly imagination and the whales had probably moved off to the south. We recalled the skiff but radio contact was all but impossible. We could hear the outboard motor but voices were garbled. I had the Captain get the anchor up and begin steaming toward Punta Tosca, away from the supposed location of the whales.

Finally we could see the whales headed our way over under the light and rather soon she was aboard, her crew a bit reluctant to leave the animals, but understanding once they knew we had lost our signal.

Off to the south and soon we picked up the signal and overhauled the animals, ten miles down the coast. I had the ship close in on the whales to get photos of the pack and check how it was riding. It was working perfectly—no apparent flutter, centered nicely, the antenna in good shape and the pair together. The other scarcely broke water but we could see her bow and see her big “footprints.”

I was pleased to note that each pair of blips on the ADF represented one breath by the baby.

At this writing we have pulled away so as to avoid [?] the course of the pair by our presence, putting them on our beam about three miles away. The sun has set in a fine clear apricot and blue Baja display over Pt. Tosco, while off dimly in the east we can see the monotonous coast of the La Paz Plain, as our animals work south.

A word or two about Punta Tosco. It looks ideal for whale observation to me. There are between 30 and 50 pairs of whales there inside and 30 or so singles in the mouth and they come right under the brow of the cliff. It is quite a cliff, some 524 ft. high right back of Tosco light. The whole mating group spends its time in this area and I feel many come within yards of shore. A trail runs along the cliff face from the light to a beach perhaps $\frac{3}{4}$ mile inland along the cliff face. I'd guess this trail runs about 200 ft. above the water. The beach it runs to is a nice sandy one, bounded by rocky headlands. I

could see a bench above the tide and think a boat could be hauled up on beach rollers easily enough. I'm thinking, you see, of an observation station here. [Drawing]

February 8, 1975

*31 miles S. of Punta Tosco, off Arroyo Guadalupe, Baja California del Sur,
Mexico*

The harness came off at 0155 this morning while the whales were making their way resolutely south a mile or so offshore with us hove to about four miles off their beam. We'll pick it up when light comes. It's nice and calm though fog is coming in now, obscuring the Southern Cross, amongst other things.

I've been thinking about our two whales with packs reaching the ocean going south and wonder if a whale not ready yet to leave the calving lagoon doesn't have some southing left in his soul. In other words the urge to migrate rises and carries with it the change of sign to the north. Our whales, disturbed by the harnessing leave the lagoon where they have been harrassed and move on the only heading to which their physiology is yet adjusted. Which brings us up smack against what it is that changes the sign within the animal, and how it works for both sexes.

The female is recovering from parturition. Progesterone recedes? The uterus folds and reduces in volume, lactation is in full swing. Daylength progression does not change sign. The days have been getting longer ever since the female started heading south.

Perhaps the press of imminent parturition helps the animal select a lagoon. Do the mating animals at the lagoon mouth help bottle them in during birth and early growth of the calf? It's a violent scene when chases take place and calves may suffer. Our two southward animals went out at night if that makes any difference. Smallest young tend, I think, to be deep in the lagoons. Calves are very vulnerable I suspect.

Anyway, I'd guess interval changes within the mother somehow shift movement from south to north, and that our animals have not truly been ready for such movement. When they will turn I guess will be mediated by the changes mentioned above. I suspect our animals will settle along the coast somewhere around Cape San Lucas and then head north. Will they go in the Gulf or outside? Are the many whales at Cape San Lucas other hormonal refugees or are they normal animals? If we found a lot of calves there I might suspect it's aberrant.

There is a "Cabeza Ballena" just east of San Lucas Bay so it has been going on for a long time. Are they excess whales?

The bay is shallow and there is no room for segregation. What are the whales doing there? We've seen some going north along the coast, probably from there. What happens on the other side? Can animals make a migration that starts S. and then goes North (i.e. up the opposite coast of Baja?).

I think we'll make a trip down to San Lucas to see, return to Punta Tosco for a brief look-see at the beach for next year, and then back to San Carlos and home. I'll pick up the harness when we have good daylight for photography.

At about 9 AM we picked the harness up, probably four miles offshore, beeping nicely. It was considerably the worse for wear but still functioning. The antenna tip was bent over at right angles. The spring coil at the antenna base was abraded but basically intact. The float was cracked all along one side through both fiberglass and foam but also still functional. The paint on the top of the float was quite scarified. Other than rust

staining, it had made no evident marks on the harness material. The aluminum base plate was considerably pitted along all sharp edges as was the radio pack case. This had occurred in 63 hrs. at sea, and in excess of 75 miles of traverse. It seems likely that much of the damage may have happened early, during the thrashing after capture, or when the whales lolled and nursed in the shallow water off Isla Cresciente. We feel the water velocity probably enhanced corrosion strongly and perhaps impact or shear of baby against mother could have speeded the final release.

Whales sighted enroute to San Lucas, four adults going N., four miles off Arroyo Datilari.

Well, we moved it to the main program log. What we saw was a whale highway running diagonally from about Cabo Falso to Cabo Tosco. We were in fleets of whales, all as far as I could tell adults and sub adults, until we decided to cut inshore to about two miles, a few miles above Todo Santos, then we scarcely saw any until Cabo Fulso when we ran into them again.

The point we chose to cut in is about the edge of a 100 ft. bank that runs directly offshore. The whales do not turn at the edge of the bank but ignore it, going into perhaps 400 fathoms. Most whales were going north and we saw many rolling and a few breaching. I suspect that whales coming this far south represent the juvenile or excess male portion of the population plus the non-parturient females. [Drawing]

Tom decided on martinis and for me—disaster. Three of his concoctions and I was ready for some serious sleeping. I slept through a movie but apparently didn't miss too much.

February 10, 1975

Cabo San Lucas

We were anchored last night in San Lucas Bay along with a dozen other yatches. There are a couple of posh-looking hotels, and a ferry landing since I was here in 1948. But the hills behind look the same. I guess no number of Winnebagos will change some of these things.

We cruised down toward Palmilla and saw just a few animals, some marlin and other fish. Most whales were around by Cabo Falso. On the reverse track we had choppy weather and didn't find much more than before. George feels the deep water causes a "pooling of whales" at each end with only occasional animals making the dash across.

I suddenly realized that some of the important exotica of this trip have escaped my notes, like the girls from the Greek Isle, a yacht that was alongside us in San Carlos. These two, Betty and Diane, were hitchhiking and definitely earning their way south, as they were free to explain. Betty says, "I turned a trick for ten abalones on Cedros Island, and I don't even like abalone." They were reputed to have 12-dozen lobsters in the freezer. The best, however, was their business card listing their company as "Psychological Services—Single, Family, Group" with the two girls' names in each corner.

Anyway we cruised back over the deep area, only this time about 4-15 miles out, on a straight track to Cabo Tosco. While we counted more whales at the start it was just as vacant in the middle and upper parts. George Nichols explains it by suggesting that animals pool at both ends, one group at Cabo Falso (where most animals are located) and another at the northern edge where the 50-fathom bank drops precipitously into 400

fathoms or more. Only occasionally do animals transit across. As at other places where a navigational decision is to be made they mill and dive and generally slow annual progression before taking a course and moving on. Hence, few animals were in the gap and many at each end.

Perhaps more interesting was that we saw no young at all, only adults of various sizes including many in the 30-35 ft. range, or yearlings and juveniles. There was much grouping and rolling about. I would say that this southward extension of the gray whale population was composed of the same group that plays around lagoon entrances and makes occasional forays into the lagoons. Whether there is a more complex structure involved, like, say, the bachelor herd components of pinniped colonies I couldn't yet say. It's just too hard to see in a short stint.

There was no calving at all at San Lucas and no whales at all in San Lucas Bay. The ship plodded along on one engine to Tosco, arriving as planned, about dawn.

My crew was anxious for a planned outing ashore. I wanted to look for a camp site because the cliffs seemed to offer such a fine chance for observation of the behavior of whales near an entrance. We have looked at nursing behavior now and need the chance to see activity at the entrances. So, the little 13-ft. whaler was quickly lowered and George, Tom, John, and I piled in. Larry and CC would follow in the next boat. We scouted the shore from the lighthouse at the end back into Canal Rehusa. The lighthouse is manned and seems to have a balcony and two or three rooms below the light. A single uniformed Mexican marine was seen entering and leaving.

Below the light is a lobster camp, a little cliff-walled cove for skiffs amidst the lava shore, traps strewn around the rocks. Down the coast inland the steep hills begin to drop from their 500+ ft. height to lower dissected country bounded by sand coves and ragged rocky headlands. Birds are everywhere. Thousands of gulls on the sand, cormorants, ospreys building their nests, crows nesting in cliff holes, and turkey vultures in fleets circling overhead. Red-tailed hawks wheeled over ridges and canyons. Out beyond us over the extensive tide flats in the channel were the whales, spouting, spying out rolling, and breaching.

We hit the sandy beach farthest out on the point, where an old wagon trail starts, then ends at the light house. Here I think, is camp. Low bluffs back the clean sandy beach and on this benchland I think tents can easily be set up with a little spade work and we should have fine access to both the flats and the trail behind. I figure a mooring just offshore would be ideal to accommodate the whaler and an avon rubber boat for the surf. It's not much of a surf—two ft. or three.

John Hal tested the surf fishing and caught about five nice *Hoplopagus*, a mollusc-eating snapper, each weighing three to four lbs. or more. Some critter took his 20-lb. test line and snapped it, and a six-ft. shark came in near his feet while he was casting, causing him to retreat for the sand. From the cliffs I could see fish flickering amongst the rocks and sand near shore. Schools jumped offshore and as we cruised in 20 ft. of water or so, what I think were barracuda shot away from our bows over and over. Truly it would be little trouble to catch dinner here.

Larry, CC, Tom, and I hiked the trail to the lighthouse. It's broad and very old, in places washed out, but generally passable for foot traffic. It runs along the cliff face and at its highest (about 20 ft.) one can look a long way out to sea across the Rehusa Channel. I figure I could see down into the calm water as much as 500 yards offshore. No whale

came so close but one came near and I could see something of him below the surface. I'm confident that at low tide one could see these huge animals in rather clear water (15-20 ft. visibility) and underwater. With luck they might come very close. The water's probably 30-40 ft. deep within 50 yards of shore.

The hills were a garden of flowers in bloom—succulent agaves in flower, a fruiting plant like a passion vine with bright red fruits that looked like tiny rattlesnake watermelons when green, fruiting jojoba (*Simmondsia*) plants, torota trees with mucilaginous sap, a crawling mallow with lovely yellow flowers with red spots in its heart, a *Cistus* or rock rose, yellow, crawling, a pretty padlike succulent Aizoaceae, *Encelia*, with yellow-brown centered flowers, a lemony composite that nearly overpowered us with its smell and many others.

Sour pitahaya is common and there are occasional cardon grande, and we saw many *Cereus* cactus and the little chilito or fishhook cactus, especially on the higher rocky hills. I thought we should climb the high peak to check visibility so up we went, clambering over loose talus and rocky ledges to the top. From there the view of the bay was magnificent. I could see clear over Isla Cresciente, back into Almejas Bay, and see whales spouting there six or seven miles away. The entire channel and its sand bars was outlined for us, and we could see out to sea and up along the rugged outer coast of Santa Margarita Island, where the afternoon chop ruffled the water to white. It'll make a helluva camp and with some work we should be able to learn a good deal about whales and their habits at lagoon mouths. I know of no other similar opportunity. Entrada at Mag Bay is not nearly so good. The hills are lower and the entrance broader and generally rougher. All the northern lagoons have low sandy entrances. We'll be back. Now to make it home.

Now we cruise inside Mag Bay toward our pier at San Carlos. The ship has stopped pitching (she scarcely rolls because of roll preventing vanes) and we retrack our steps of a few days ago. I wonder where our whale pair is now? I hope calmed and back to equilibrium.

We'll pack tomorrow and Larry will drive us to La Paz early on the 12th. Some of this is to avoid hotel expenses as we are very low on money.

It's been a good cruise and productive, and now I look forward to going home to see my family and home . . . the livestock, the meadow and fences, and yes, the University too, though the thought of memos and mail is not enticing any way you slice it. We'll spend tomorrow packing and cleaning up and then drive to La Paz early on the 12th to catch the plane home. Larry and Candy will drive up with the gear.

Granite Mts. San Bernardino Co., California, April 10-May 3, 1975 [??missing entries]

April 10, 1975

Granite Mountains, San Bernardino County, California

We arrived with Class III of the Natural History of California at about 3:30 PM to find the mountain shrouded in clouds. Veils of rain came down over the bajada. At the cabin the roof was still off and a few drops of rain fell. I assembled the troops and we began to build a makeshift roof. Timbers went up and were tacked in place, sheets of

plywood came up the hill and the tarps were hauled out and onto this jumble of uncut timber. By the time we were done a scum of ice and water lay over the floor but we had an amazingly watertight roof over most of the house. I built a fire on an old sheet of iron and soon people were clustered around the blaze and dinner was cooking.

Cruise on board *Regina Maris*, off Newfoundland St. Pierre, Sable Island and Boston, August 11-September 14, 1976

Cruise on *Elizabeth C.J.* and *David Starr Jordan* to tropical Eastern Pacific yellowfin tuna grounds, “Behavioral Cruise.” October 11-November 8, 1976

Outer Continental Borderland Cruise, *Vantuna*, September 8 – September 12, 1975

September 8, 1975

California, Santa Rosa Island, Beecher Cove

Well, it's been one of those “beginning of a trip” days. Great massive foul-ups of unpredictable and probably unavoidable kinds, resolving then into a good and useful trip.

Our trip is a survey of the outer continental borderland, primarily to determine whether or not whales and porpoises are concentrated over escarpments and also whether there is a genuine division between the inshore and offshore cetacean fauna. We will also check pinniped and bird distribution and will travel from near Pt. Concepcion south over Tanner and Cortes Bank and then home.

Our scientific crew is me as chief scientist; Larry Hobbs, chief accomplice; Lee Jones, head ornithologist (and only orny); Gary Farrens, pinnipeds; Deb Dag, escapee from the office; Bart Gordon, also escapee; Herb Hyatt, BLM scientist. We are on the *Vantuna*, the 85-ft. research vessel of Occidental College. She has a six-person crew: Captain Eldon McAllicher; Dick Powell, Alternate Captain; Mel Willard, Engineer; Max McClelland, Crew Max; Steve Karsten, Student; Marilyn White, Cookie.

Larry, Deb, Gary, and I flew to Long Beach and stashed ourselves at the “Executive Motel” after a good Mexican meal, and arose at 3:45 AM to pick up tagging gear. Out on the freeway our limping Dodge Polara blew a tire and we thumped to a halt and finally on the embankment with one wheel in the mesembryanthemums. Now what? We had a little leeway, time wise, but not much. Larry and I called the AAA and a completely incompetent clod finally arrived, all yawny, flashing his 70 IQ. Can you believe it—he forgot his jack—on a tow truck yet. He wanted to bring in another tow truck to jack us up but we did it with our bumper jack. Off we went to a gas station, stopping at a closed Standard Station due to open at 6:30. I called a taxi and made my way to the *Vantuna* dock. Herb Hyatt was there but no Lee Jones. Bart Gordon showed his fuzzy face so only one was missing. He drove me back to the car and by that time the station was opening and cranking up pressure in the compressed air tank to change our tires. I sent Larry and Bart off to get the tagging gear and we waited for the car to be fixed. Finally it was and we left making the *Vantuna* at a little before 8:00. As fast as possible we loaded and left—still no Lee Jones.

Finally out in the hazy channel a call came and Lee had gone to the wrong dock. He finally decided to meet us at Santa Rosa Island, and on that basis we set course for Santa Rosa Island. Nothing was seen across the channel but a couple of sea lions and it was NE of Santa Barbara Island that we saw our first cetaceans—a group of about 8-9 *Tursiops*, big fellows, all milling about in the calm water—it was a nearly flat day. Later, S. of Santa Cruz we came upon a small skittish minke whale that would not let us approach.

Marilyn cooked us a grand hamburger lunch, which all consumed greedily.

Santa Cruz materialized out of the haze as we skirted up into the Santa Cruz channel between Santa Rosa and Santa Cruz islands. Sea lion sighting picked up and rafts of sooty shearwaters bobbed in the tide rip. Skunk Point, all banded with blown sheets of sand like a skunk's back passed to port as we strained to see the pier and anchorage in Beecher's Cove. Santa Rosa is sere and brown this time of year. The cattle are off the island and little goes on, I'm told. Above the bluff is a grove of eucalyptus and a couple of big barns, several houses, and big stacks of hay bales. A road snakes down a hogback and looks like it would be greased after a rain by the mud.

The captain, who is normally affable (when in deep water) turned serious and severe as he saw his fathometer indicate bottom and surface together as he worked in toward the pier. Lee was there—all his gear piled on the dock. Finally the skipper inched in, only six ft. of water under his keel and we literally fished Lee off the rickety metal ladder. Fortunately, he jumped and we were off. Anchor was dropped soon enough, a roast pork dinner, notes, conversation, and to bed.

If the weather holds like this we're in luck. Tomorrow 1-2 ft. swells are predicted though Rodriguez dome should hold more.

Course note: Our course took us up the ridge NNW of Santa Catalina Island and to the E. of Santa Barbara Island, but about halfway Lee called with the info about St. Rosa so we changed course to make a direct shot at Beecher on account of time.

September 9, 1975

California, Santa Rosa Island, Johnson's Lee

The morning came with fog lying on the water around us and the ocean calm as a lake. Before breakfast Lee Jones had a good sighting of an Arctic skua, about the tenth for Southern California. These birds are big jaegers and pick on terns in preference to gulls.

Our course took us south of Santa Rosa, within sight of shore and there we encountered two minke whales going in the opposite direction (E). They avoided us. S. of San Miguel over the edge of the escarpment we encountered many seals (*Zalophus*), plentiful birds and then at the SW corner of this escarpment we came upon a big blue whale. It surfaced a few times for us, once giving me a fine view of its big spatulate head, its steel gray body, and tiny dorsal fin. Not long after we entered a huge aggregation of birds, common dolphins, sea lions, and Pacific white-sided porpoises. It was a feeding school and spread very widely over the sea. Because it was composed of little groups here and there it was really impossible to count, but had to involve several hundred animals. It was one of the biggest groups I have ever seen. In it were groups exclusively of young juveniles and various all-adult groups.

We turned WNW up about the three-hundred fathom line and continued to encounter Dall's, lags, and common dolphins. Our course then swung west toward Rodriguez dome and not long afterward we came upon several small groups of *Grampus griseus* and common dolphins. An amazing number of cetaceans was seen and some dozens spaghetti tagged (nearly 40).

It has been nearly flat calm—just a low swell with gray overcast, but visibility of two miles or more most of the day. Magnificent weather for this usually rough piece of the ocean.

At Rodriguez we turned and headed back for the anchorage at Johnson's Lee. A big blue whale was seen shortly after turning. He arched his tail, very slightly threw his flukes, and disappeared.

I was disappointed that there was no chance to work around Rodriguez, but tomorrow work on the Santa Rosa-Cortes Ridge would suffer.

I've been just a little off—not serious but enough so I don't want to read very long. I hope tomorrow to be a little better acclimated.

On the way back we cut closer in to San Miguel and could see the wind and sandswept areas at the west end. The new kelp cutter cruised inside of us, loaded to the guards. She clips from the stern and then turns her bow to go home.

[Drawn maps]

Near Johnson's Lee we encountered two minke whales, one actually in the outer margins of the kelp at times. It was pretty skittish but we did get close enough to see it throw its head free enough to see the lower jaw and to get in the wash of its breath which smelled awful even two hundred yards away.

I saw two spouts from the whale and several respirations without a spout. The spouts seemed to come when the whale was quietest—either at first or after we had let it alone for a while.

Johnson's Lee is an old army base—old barracks marching up the hill—probably 18 buildings in all—some soulless buildings with multiple widows all in a line—vacant—open—no discernible architecture except Pentagon.

The captain and Allemate captain are fishing and we are gassing about this and that—endemics on Santa Cruz, and other weighty matters. Tomorrow, if we have enough forms, we head for San Nicolas and the broken submarine topography to the west.

I forgot to mention in more detail our encounter with *Grampus* on the eastern slope of Rodriguez Dome. There were scattered small groups and occasional small sea lions, too, and flashing schools of sauries leaping en masse from the water. The big grampuses with their tall, sharp dorsals, scarred bodies, and blunt heads rather thoroughly avoided us, never letting us within tagging range. Two big adults were accompanied by small dark gray young, both in the “assisted locomotion” position. One adult had a very white head, apparently from coalesced scars.

The *Vantuna* started SW along the Santa Rosa-Cortes Ridge. Minkes and a few sea lions were seen near Santa Rosa and then the vista became largely lifeless—calm gray seas with a slight swell and patches of thin fog and overcast skies. One could see long distances and the ship was stable enough to make watches easy. Lee Jones, who is an amazing identifier of birds on the wing, came up with one petrel (Townsend's) new to California, Sabine's gulls, flights of sanderlings far out to sea (they're not supposed to be there), and a single albatross.

Captain McAllecher cursed and cursed at his navigation gear. The radar seems to work about 20 instead of 50 miles and the Loran has only one usable line instead of three. What this means is that he doesn't want to go out of sight of land very far and doesn't want to go on a sea anchor at night.

I'd hoped to hit San Juan Sea Mount and the true continental slope, but it seems that we will do better to concentrate on Lanner-Cortes Bank. By the way he reports 24 *Orcinis* at the 40-fathom spot N of Sixty-Mile Bank, ten days ago.

As we made our way in toward San Nicolas we could see the Navy working close to shore. Shortly a big twin-engine plane buzzed us and buzzed us again, the second time talking over the speaker. It was absolutely incomprehensible except for “090 degrees”—or was it “180 degrees”—we couldn’t be sure. The plane buzzed us four more times, more gobbledy-gook. We finally got on the radio and found via a circuitous route through the Coast Guard that they wanted us offshore until 5 PM (when the Navy quits), and in a course of 090 degrees. We did it and shortly after 5 PM we pulled into Daytona Beach on the SE end of San Nicolas Island. The island comes down to a fairly long sand spit as a sloping badland, a series of rocky headlands and long sandy beaches.

We anchored off the kelp beds, had a magnificent turkey dinner, and did a bit of fishing astern. The overcast is breaking and a bit of the sun comes out over the cloud banks.

September 11, 1975

California, at anchor, 1 mile E. of Bishop Rock, Cortes Bank

A long gray day—a bit more blowy than yesterday but nonetheless with blessed little swell and only occasional white caps. We travelled a watery desert, however, except for some interesting birds. Not a porpoise or whale was seen. We headed for West Bank to the west of Cortes but the Navy intervened again, sending their gobbledy-gook plane bellowing over us. Once again we had to have the Coast Guard intervene for us because the Navy wasn’t (as usual) guarding the frequency (Plead 2182). They ran us out toward San Clemente—they were shooting missiles or something.

We returned to our ridge later, skirting the east shore of [?] Bank down past Cortes Bank and out on a submarine ridge east of Cortes. Tom had called in and planned to fly over us but didn’t appear and didn’t appear. I, for one, was a bit apprehensive for him, but he finally showed up after 3 PM. Our ship to plane radio barely reached him. He told us there was a big group of *Delphinus* 15 minutes to the west, but it was too late for us to get there for a “sea truth” (counts of porpoises from air vs. from water). Tomorrow we’ll try again.

We turned west toward Cortes to see if the bank sheltered pinniped and birds. Sure enough, birds became dramatically more abundant and sea lions began to appear in some numbers. I wondered where they hauled out and soon had my answer—on kelp rafts. We saw several fairly well hauled out and dry from the shoulders up. It was remarkable how far out of water they were and how many occupied one raft. One dense raft seemed pretty nearly covered with sea lions and birds.

Off through the haze we saw [?], the drilling vessel of Global Marine Corp. on East Cortes, drilling for some corporation, anxious, I suppose, to prove possible leases prior to the impending sale.

The ship is a freighter hull topped by a big derrick. She rode in the center of a four-point moor, a satellite vessel whose utility I could not guess, off to one side and what I take to be a Japanese long liner nearby.

Lee spotted a red-billed tropic bird and some tiny murrelets (Craveri’s from the Gulf of California) and finally some black-footed albatrosses. The weather held pretty well. The swell is higher but still very calm for these waters. Lee notes the slightest nuances of behavior or pattern and usually has an identification at a glance. Only a few times did we slow to give him a better look.

We circled around Bishop Rock, which is below water but topped with two buoys. We anchored east, it turned out, mainly because of fine indications of fish on the fathometer. Sure enough, no sooner than the pick was down and fish began coming over the stern. Dick had dipnetted a hundred or so sauries and they proved magnificent bait. Bocacios, yellowtail, rockfish, widow rockfish, sheephead, scorpionfish, and jack mackerel all came aboard. Dick baited a good-sized hook (about #1) with a 12-inch jack mackerel and soon we could hear grunts and squeals of joy as his rod bent half down. He fought and fought, his rod tip being tugged into the water and him jacking the pole up with great heaves. After 15 minutes or so I could see a great flash below and soon a 150-lb. black sea bass rolled to the surface all purplish and bronze with vague white spots. We broke a gaff but maneuvered the fish astern where racks let us get close to the waer. We manhandled it over ito them and thence onto the deck. A male, it squirted a couple of cup's full of white milk onto the deck. What a fish! Probably it was 18-20 years old and I mourned a bit for it. It can't stand fishing pressure because of its slow growth and even these will go when the rigs are in place here.

Tomorrow we try again for a "sea truth" at the bank west of Cortes and head for NW anchorage at San Clemente.

What a meal (among other such meals) we had tonight! A 15-lb. standing rib roast with fixins. Marilyn does a fine job and is a happy soul to boot. Good crew all in all.

September 12, 1975

California, San Clemente Island, NW Anchorage

Another gray day, but the barometer has been nearly steady and the wind low. It picked up outside Cortes Bank and on up W. bank when we bucked head on out a fairly low but somewhat droppy NW swell. However which we turned toward San Clemente it began to lay down and by the time the island could be seen through the haze it was nearly flat calm.

Our first traverse was west along the south edge of Cortes Band to N. Bank and thence up it. Just off Cortes we came into an area where we made repeated contact with sei whales. There big, fairly centrally placed fins, blackish backs, moderate size (35-45 ft.), very erratic movements underwater, and their failure to throw flukes when driving give them away. I did not see the scratch marks often associated with this species.

Each time we sneaked up on a pair (there were two or more pairs), it dove and evaded us under water, travelling remarkably long distances under water. Try as I did I never got very good pictures even with my miraculous motor drive.

Rather shortly thereafter we came on a small group of *Grampus* that refused to play the bow. That was all the cetaceans for the day.

Once again communication with the plane failed. Tom called us and we called back. He had left. Not till we were in the lee of San Clemente did he reappear and when we tried to deploy a porpoise radio to test his ability to reacquire the signal by air he disappeared, not to be seen again. Through all this our air-to-ship radio failed to work at all. It's damned battery pack had not taken a charge. Well, we'll try again closer to Catalina when the flight isn't so long.

Good bird day. A northern phalarope, a Leach's petrel, and a sparrow came aboard last night. Cowbirds and savannah sparrows flew on during the day, hopping over

the deck. Finally, two cowbirds left us as we rounded San Clemente, flying straight for shore, but we never did find out what happened to the sparrow.

Black-footed albatrosses were commoner today and Leach's petrels fluttered and swooped almost constantly in front of us on the offshore traverse. Another red-billed tropic bird, murrelets, gulls, terns, jaegers, etc. were common enough. Lee is great to have aboard. He is so knowledgeable and quick and so willing to tell us what defines this bird or that.

At anchor no fishing but for jack mackerel, but a nice chicken dinner, good conversation, a calm night and tomorrow up outside Catalina, around the west end and home.

Outer Continental Borderland Cruise, *Vantuna*, January 5-7, 1976

January 5, 1976

Johnson's Lee, Santa Rosa Island, California

The wind howls outside, coming down the steep hills above the old army base. Three of us are anchored here. We have come in enroute to the outer continental shelf area on a regular cruise sighting and censusing birds, pinnipeds, and cetaceans for the BLM Southern California Bight Survey. We're on the *Vantuna* as before, with much the same crew. McAllicher is skipper, Marilyn White is cook, her husband Daryll is a hand, Mel is engineer, and two new faces, Bob ____ and Al ____ are serving as crew.

Our party is Bob Guess on mammals, Mike Honig on cetaceans, Gary Farrens on pinnipeds and birds, and his girlfriend Marie-Angi as general factotum, and me. The routine is to go north so we can have the weather on our stern and head south along the broken topography of the slope margin. We spaghetti tag, sight, record, and plot localities.

The *Vantuna* takes us out of the harbor near dawn and onto flat seas to the north. Over the slope of an underwater escarpment east of Santa Barbara Island we encounter a school of Dall porpoise. I can't but marvel at their power as they crash into the water and their pure beauty of black and white—20 animals who race in toward us and leave quickly, we a passing diversion in their activity.

Later, off the 17-fathom spot midway between Anacapa and Santa Barbara we came into 250 Pacific striped porpoises, feeding and circling. There were as many as 1/3 yearlings or younger animals in the school, some leaping, which is unusual for lags. One yearling repeatedly leaped in an unusual way, sometimes close to us. It emerged upside down and threw its flukes over its head, cracking them down against the water with a great splash [drawing].

We turned on the north rim of the escarpment of the Santa Cruz Basin and headed west along the island, which lay largely fog enshrouded to the north of us. We encountered three gray whales, two adults and a baby, not too far east of the Santa Cruz channel. I saw the baby throw its head up once and others confirmed it. Last week Tom Dohl had flown over a pair including a baby—so they give birth successfully outside the lagoons sometimes, on the southward trip. Later five more grays were sighted coming out

of the Santa Cruz channel heading SE, so that channel does serve some number of grays for passage.

As we passed the Santa Cruz channel (between Santa Rosa and Santa Cruz islands), the wind picked up to a fresh wind level, building up swells and white caps. We crossed it pretty much abeam, going under the bluffs of Santa Rosa when it poured down from the cloud cap enshrouding the upper slopes of the island. Even Johnson's Lee was streaked with wind and the ship rocks at anchor, the moon swinging up and down outside the galley window as we roll. A big tasty ham dinner, conversation, notes, and fixes on data, and reading. I'm reading *Who's Afraid of Virginia Woolf*, a corruscating play.

January 6, 1976

Santa Barbara Island, California

Up at dawn and the wind still blowing, though not so strongly as last night. We skirted out past the lower bulk of Santa Rosa—a barren brow island, full of dissected canyons and benches, into the Santa Rosa Channel, between Santa Rosa and San Miguel. It was whipping with wind. The *Vantuna* took it badly indeed, bucking and whipping the seven-foot swells. There was no chance, I could see, to make Rodriguez Dome, or even the west end of San Miguel, so I decided on a diagonal course out past San Nicolas, the idea that with the wind quartering us she should ride easier and we should come into San Nicolas with the wind astern. I went below and not too long afterward heard her change course and begin to buck. I went topside and found the skipper had changed course as he thought there would be no lee in San Nicolas and didn't want to risk it without anchorage. He was headed for Smuggler's Cove on Santa Cruz, 40 miles away. I talked to him and suggested he get the wind on the quarter again by heading for Santa Barbara, which was in better position for the rest of our work anyway. He did so, after some fussing around and we had a fairly calm trip to the island, which we reached about the last light. Our travel over the Santa Cruz basin was about as devoid of animal life as you could imagine. The weather became flatter and flatter the closer in we came, and finally at anchorage it was calm. Santa Barbara, which I had never been to before, is barren in the extreme, cinder cone, mostly ash, but with some low patches of cactus, especially in the low canyons. The sea lions climb a cinder sheet on the southeast corner, getting 75 ft. or more above the sea in places. A quonset hut occupies a little bench halfway up the cone, looking all bleak and barren.

January 7, 1976

Home

Mac, the captain, and I plotted out the closed areas and found we had only a narrow channel between San Nicolas and San Clemente to travel, if we wanted to hit Cortes and Tanner Banks, and that Pyramid was closed because of gunnery, as in fact, was 7/8 of the island, clear down to the US border at 60-mile Bank. I finally just gave up. The boat isn't fit, the skipper is afraid, especially of the 5,000-lb. A-Frame on the weak stern, and the balance that results from this and the winch on the stern, bringing the bow up and causing her to snap roll. Yesterday, for instance, I was thrown across the cabin on the bridge, slammed back-first against the bulkhead and crashed against a bunk (whose leg I broke) by one such swell. It literally threw me in the air clear across the cabin. I had a little wind knocked out, but it was the action of the boat that worried me most. She

simply isn't fit for open sea work. The skipper is afraid we'll pull everything loose on the stern, and if he's afraid, so am I. So I said, "Let's cancel out, run around Catalina looking for pilot whales, and then head in. We'll just have to get a better, more seaworthy ship that can ride at sea and take the weather." He brightened for the first time on the trip, became affable (also for the first time) and off we went. Tom flew over us (as did Bem DeBuss of the American Cetacean Society in the Goodyear Blimp) as we neared Santa Catalina. I had Tom take a count of whales along the windward coast, and we did the same. We came out amazingly close together—I think we got 303 pilot whales, and he got 285 from the air. It was an ideal circumstance—flat calm (but blowing on Tanner-Cortes), and lots of easily counted animals.

Crossing the channel was like plying a lake, and after dinner at the dock we made our way home. I arrived about 9:30.

Cruise on board *Regina Maris*, off Newfoundland St. Pierre, Sable Island and Boston, August 11-September 14, 1976

[Description of *Regina Maris*]

Dear Family,

I'm writing this while still at sea, off Maine. I've just finished preparing a final exam for the students which they will take this afternoon on a rolling ship in a strong breeze (which because of the grass on our hull pushes us only about six knots). Phylly and I look forward to getting ashore on solid land with a good place to take a bath and such amenities.

Yesterday was nearly flat calm and we made about 40 miles all day because the engine is down, having its exhaust pipe cemented with a goop called "Red Hand," which apparently at-sea engineers depend upon to patch various things, but it takes time to set up. While in this listless condition a Yugoslav freighter scared hell out of us as we weren't sure if she was going to run us down and she veered past us much too close for comfort, tooting happily.

We dream dreams of vegetables, of sheep, of music from the record player, and for me of my poor ole tractor up in Fritz's front yard, and of course, of all of you.

The trip has been a full one but with the sea's usual ration of boredom too, and discomfort. The days tend to slip by in the open sea without many marks distinguishing them and only when one comes ashore, or near an island, do you have mental landmarks. But, when we look back there has been much of interest that we will always remember. Skipper George is a fine person, very sea oriented, kind, humorous, but firm when he needs to be, which is every once in a while.

We'll visit Alan and Carrie and the Schevills and then go directly off to Washington DC, where the days will be full of family affairs, and many meetings for me. Maybe they'll even have made up their minds about the Commission post by then, who knows.

Mostly, I guess, we would like to be with all of you, and to hear your adventures in the potato patch, the checkbook, in the far pasture, and like that. The sprawled-out comforts of home where one can wander and make a pizza in the night or listen to the

2,000-year-old man on the record player seem delicious, and how I wish I wasn't going right to sea again on that damn tuna boat. It's a bit like a sentence, though I know in that case, too, I will see a lot of new things.

Anyway, love to you all, and enclosed are my field notes that I think you might enjoy reading to each other.

Love,
Dad and Mom

August 11, 1976
Maine, Portland

Phylly and I are on our way to Newfoundland to board the *Regina Maris* out of St. Anthony. I will teach about marine mammals for three weeks. The ship is scheduled to stop at Boston, we to debark, and make our way to Washington D.C. to tend to various matters, and then home on October 1st. We'll see how it works out.

We bought a nice zippered partly waterproof field binder in honor of my birthday, and paper, a ruler, erasers, etc.

The weather is bright and clear after landing in the fringes of Hurricane Belle yesterday

Up through Maine, with some sightseeing at Booth Bay, and then to Bar Harbor where we boarded a ferry for Nova Scotia—a big ship with restaurants, casinos, decks, and TV rooms. Going out of the Harbor scattered groups of harbor porpoises cut away from us—swimming much like *Phocoenoides*—that is cutting through the water and dashing a hole in the water with their heads inside of which I believe they blew. Both Phylly and I were glad to get off the ferry. The jet lag's still got me and I dozed a fair amount of the time, uncomfortably.

At Yarmouth we rented a car and drove out along the north shore, a rolling countryside of pocket handkerchief farms, compact New England houses, and dormered barns. Most are lined up along the highway and names like Comeau run in bunches. This or that French family seems to dominate for a while and then to give way in intergradient areas to another. These are Acadian tribe descendants.

At Digby, which is on the Bay of Fundy's shore, we stopped for the night and walked the pier, looking at the scallop boats with their big chain dredges and beams aboard. Most handled gear amidships and most were large—50-65 ft. I'd guess. Lights glimmered inside some, I suppose waiting for the evening's work. Do scallops burrow during the day and emerge at night where they are susceptible to capture by the dredge?

August 13, 1976
Digby, Nova Scotia, Canada

The pier showed the tides to be very great, in excess of 20 ft. I'd guess—long pilings one beside the other so thick one could scarcely see through the pier—the water was low and the draggers clustered in a little hollow of water against the pier with mud flats all but cutting off the entry channel. Dinner, a walk, and to bed.

Halifax, Nova Scotia

On down the Fundy shore through neat little elm-shaded towns, green lawns, Victorian or earlier houses, mostly white with neat black trim, gingerbread in moderate

amounts. The house trailer makes its inroads. The owners of these blots on the landscape seem defensive about what they have done to the scenery as many have "cute" nonfunctional white picket fences and gay floral borders, plaster lawn animals etc., alas, ending at the trailer door.

We spent a fascinating hour going through a reconstructed fort at Anapolis Royal, built before the Plymouth Settlement; it became a pawn in the French-English struggles of the time, was burned, and then reconstructed beautifully too, all adzed, pegged tenon, and mortice construction, tall peaked roofs, battlements, peculiar little banded canons, a bakery with big bread paddles, a forge with a big bellows and coal bed, dormitory rooms, a sick bay with the chimney running up through it. Beautifully reconstructed.

On up the coast we went till we came to Grand Pre, the site of the expulsion of the Acadians. We saw a lovely church and garden dedicated to them, a statue of Evangeline (Phylly and I read it to each other), saw the nearly 5-mile dike the Acadians had raised to drain rich delta farmland. A lovely green land, the people caught as pawns in a struggle that ranged far beyond them. On down the coast, stopping at a beach with the tide receded thence across the rocky interior of N.S., a low mixed forest of maples, aspens, birches, pine, hemlock, spruce, and larch, very dense with undergrowth.

August 16, 1976

Halifax, Nova Scotia

Phylly and I did the local fort, watched the red-clad fusilliers go through close order drill, looked at relics of World War I and endless military uniforms on dummies. At dinner time we wandered down to the dock where the schooner *Bluenose II* was moored. A lovely ship with clear lines and real grace. I steered Phylly into a nearby restaurant where we could have a nice view of the Bay. Before I knew it we were hooked into a 30 dollar dinner (each). It was good but oh my exchequer suffered.

Next day we drove across the island to Noel and finally to Truro where we arrived just in time for the tidal bore. We waited on the river mouth on the bank as tour buses and cars began to arrive. The river flowed muddily between low muddy bluffs, in a modest channel flanked by broad bars.

I watched the gulls and sandpipers to see if they had means to avoid the bore. Aha! Fifteen minutes before the bore was to arrive, the gulls, many of whom swam in the water or stood on shallow bars, rose as one and stood high on the mudbank. There were back-to-back herring and maybe ring-billed gulls amongst them.

But, two minutes before the bore arrived some of the gulls flew back to the water and actually one swam through the bore. The sandpipers could have cared less.

The bore came as a bubbling apron of water, hissing and spilling in a little wave. What was impressive was that this wave spread across the entry channel and very quickly rose deeper and deeper. It was a rushing wedge of water at its center, maybe flowing five knots. Very impressive.

We drove back, stopping for milk and cookies at a little country store. Back to the motel in the rain, packed, and went to bed after a hit of dinner and a true vodka martini.

St. Anthony, Newfoundland

Up on a gray, foggy morning and out to the airport which is built about ten miles from Halifax toward the center of the peninsula. We did all the things one does—

luggage, tickets, turning in the car, boarding the plane, listening to the stewardess tell us about oxygen masks and exits.

After a stop in Sydney we hopped the channel to Newfoundland, landed at Deer Lake—a little community of 2,000 people stretched along a long lake amid smallish spruces, birches, pines, and larches.

It quickly became apparent that we couldn't fly to St. Anthony in time for meeting the *Regina Maris* on Wednesday. Today's flight had been cancelled, tomorrow's was full, and there wasn't one on Wednesday. So it was hitchhike or take a taxi. We chose the latter though it cost 160 bucks for the 300-mile drive. I rather liked the idea anyway as we could see the country with a guide that way.

So we contacted Loudon's Taxi and Mr. Loudon was soon there—a nice affable Newfie with red hair and a sometimes impenetrable accent. He was about fifty and had previously run a grocery in Deer Lake. We had a sandwich at Freddie's, the best in Deer Lake, so Mr. L. said, and then off to the West through great, rounded rocky mountains clothed with modest-statured forest—through Gros Morne Park, finally down to Bonne Bay along the coast (at a place called Norris point), and thence up the coast along a road alternately paved and gravel, but never as bad as we had been led to expect.

Many little fishing villages lined the shore—little cubicle houses, with shakes or clapboard siding, stacks of lobster traps ready to be set, and skiffs beached along the shore. Many nice coves and anchorages were passed, often with broad, beautified salmon streams entering them. We saw a few sheep and cows but mostly it was just fishing that supported these communities.

As we drove north the stature of the forest decreased until finally at the Strait of Belle Isle, across which we could see Labrador, the trees were carpets a foot or two thick and wind pruned. Muskeg spread out—little pea-colored ponds dotted with erratic boulders, reeds, and tangled diminutive shrubs, and rock. By the time we skirted the Straits of Belle Isle, eroded bedrock planed nearly flat by the glacier spread for miles patched here and there with low vegetation. The road skirted Pistolet Bay, down some canyons filled with dense, boggy forest and finally at dusk we reached St. Anthony, which is a town of 2-3,000 people, a mission hospital, oil tank farms, around a deep protected bay. No George, so we holed up at a local motel and got ourselves organized a bit.

At Hawke Bay, a mining port, we had a grand halibut dinner in a rough little restaurant with a cold lock front door (it dips to 20 below here).

Not far north of us at L'Anse-au-Meadows are the first habitations of white man in the new world—Viking remnants from 1,000 AD or thereabouts. Maybe we'll see them.

It's a cold, rather monotonous environment here but very interesting to us. The seas have been flat calm and tonight it's drizzling a bit.

August 17, 1976

St. Anthony, Newfoundland, Canada

Well, we tried to rent a car here but the car rental outfit has quit, turning the business over to the taxi drivers. Somewhat reluctantly we turned to them, and to L'Anse-au-Meadows (pronounced locally Lancy Meadows). Since that was where the Vikings landed and lived we decided to tap for it and shortly a rather sleepy looking character arrived in his battered taxi and off we went. The road wanders north around the Milan

arm of Pistolett Bay, into a couple of small cod camps, each with its little compact houses, teepees of spruce poles standing behind for use as firewood in the winter (when everybody quits work and plays cards). The cod boats lay pulled up in quiet coves and what they call trap boats were often seen upside down as if being worked on. There is water everywhere, and peaty muskeg amongst the forest patches. Finally we came out on a beautiful set of meadows and cobbly coves, backed by rounded bluffs and very low forest—L'Anse-au-Meadows—and came upon a little cluster of houses and a Canadian Parks building, which proved to be a museum staffed by summer college student help. Both were excellent.

The museum told us of the eight house sites down on the meadow, three of which were long houses, which consisted of long sod walls about 12 ft. apart, ending at one end in an outside wall, and at the other in an interior wall that was open at the center and entered a smaller habitation room. A door facing downwind opened out of this room. In the center of the long room were fire pits and the sockets of roof-support poles that apparently help up a very steeply arched roof frame that may have been sod covered. There were forges for melting bog iron, a charcoal kiln, and what were called the one-room quarters of slaves, whose doors opened upwind. I was surprised to find that the excavations had not provided mollusc shells, when the nearby beach was littered with them, or marine mammal bones. No iron implements have been found, but I suppose they would rust into nothingness in the time allowed. The place was supposedly first occupied by Dorset Eskimos, and stone lamps have been found, and then about 900 AD in came Vikings, supposedly of Leif Ericksson's crew. We visited the excavation, still going on, of nearby peat flats to see if artifacts could be found. They were finding precious few artifacts but quite a number of tree stumps too large for the present forest. The gal in the museum was a student at St. Johns University working in Anthropology-Social Work and was having a ball learning about the local folk. The little village had been settled in about 1850, at a time when the French controlled the coast and English people were allowed only as transitory workers. The locals, who are English and Scotch, served as caretakers, keeping the fish camps for the French, and in this way got around the rule, and when the English took over became permanent. They were of just three or four families and had no contact outside except by boat until the mid 1960s, when the road came in.

Back at St. Anthony I tried abortively to catch a fish, by hiking up in back of the Motel into the waning afternoon, finding some streams and many mosquitos and much wet vegetation, some over my head, and getting nary a nibble. I made it back to our room just in time for us to catch dinner at the dining room, and thence to look out the harbor and see the *Regina Maris* at what is called the American Dock on the other side of town. After dinner Phylly and I took a cab down to see her and report in to George Nichols, our friend and the master of the vessel.

The ship is a bit over 140 ft. overall, a barkentine with a square-rigged foremast, four jibs, two fore-and-aft masts aft, and some staysails between the fore and main. She has an elegant bowsprit and figurehead, and the name in gilt on the counter. She is powered, other than sail, by a 871 Jimmy Diesel, has a wheelhouse aft which no one uses because the sails can't be seen, and a big wheel aft of amidships that two steersmen handle in rough weather. She was built in Denmark about 1906, served as a freight schooner, was converted to engines, and then refitted by some Norwegians who coated

much of her interior with formica and other such outrages. Our cabin is the best in the house—our own john through it does take 50 pumps to clear the lines.

St. Anthony, Newfoundland

We spent the day moving aboard from the motel, getting our bearings and setting up class schedules and ideas, walking around getting boots and last-minute items, and things like that. A local teacher at the Trade School here, Mr. Brown, came aboard and I showed him around. He reciprocated by taking me for a ride up to the old US radar base on the hill. The old dishes still there, and old barracks and engine rooms, etc. in disrepair. We had a magnificent view of the bays to the south. His son Rodney Bown, a young man of perhaps 12, is interested in whales and I talked to him a little. He was shy and didn't ask many questions so I told him stories. I promised to send him a copy of my book.

More palaver and to bed.

August 18, 1976

Off Tooker Bank, Labrador

We shifted docks and picked up water at the fish-processing plant across the harbor, and then headed out the channel with George at the con and Ann the purser at the helm. The *Regina* went out smartly, into the open sea, and then headed north past the St. Anthony point, and up toward the Strait of Belle Isle. Belle Isle itself was ahead of us, a long, rather low piece of terrain out between Newfoundland and Labrador. The day turned windy and a strong swell broken into white and tosscaps came at us. We had set all sails and now the square rig foreward came down leaning only the fore-and-aft sails. The crew climbed all over the ship as if they were old hands, young gals up helping to furl the topgallant and royal sails high aloft. Though the standing orders are for safety lines at all times, some do not always wear them, especially the crew. I guess they are a nuisance when you are trying to move around. The ratlin's provide a good way up and then the footropes and jackstay? provide good hand and footholds once aloft. The *Regina* rides very smoothly, seems to me, after all my rough pitching rides on oceanographic motor vessels. The sails steady her. She is steered from the big wheel on deck in front of (foreward) of the after cabin and a watch is kept 24 hrs. a day. Up off Belle Isle we encountered several humpbacks. Their low mushy blow, unique dorsal profile (low fin), and very broad white-bottomed flukes serve to identify them. We were also approached by schools of white-beaked porpoises—*Lagenorhynchus albirostris*. The remind me very much of *L. australis*. Both are large, with very prominent dorsal fins, and both rush through the water, beating spray as they plunge along.

I fared quite well with seasickness, but Phylly went below ere long, and only felt passable when she was lying down and stayed in her bunk most of the time. I guess when the weather abates she will perk up. After a discussion with the students about the program, its good and bad points, I went off to bed.

August 19, 1976

Enroute, Williamsport, Newfoundland

It blew last night and as the sun rose we were greeted with a pretty rough sea. I was pleased to note that the *Regina* rode very comfortably over the seas, without taking much water through the hassepipes or scuppers, though Phylly was uncomfortable

enough, not being very used to ships. She stayed below most of the day until late afternoon when the sun came out and the seas calmed. I lectured in the morning about spinner porpoise behavior and was pleased to hold my audience under such circumstances. Some of the students were just holding on back in the crowded little salon.

No whales today, though we did see some schools of *Lagenorhynchus*. Both the white-sided (*L. acutus*) and white-beaked (*L. albirostris*) are here and apparently were seen during the day. I clearly noted the lateral yellowish partitioned pattern of *acutus* on one occasion. The white-beaked porp is bigger (to about 10 ft.), very bulky, with a big dorsal, and has two pairs of staggered white blotches on its side below and aft of the dorsal, and is otherwise quite dark dorsally. Only the white-sided has a partitioned lateral pattern. It is a little smaller, also with a large falcate dorsal, nine ft. max.

As the afternoon wore on the seas calmed and we came closer in shore south of Belle Island, and could see the cliffed coast cut with fjords, which form the harbors here. We will spend the night and tomorrow at Williamsport. I am gradually learning the names of the various sails, lines, and other parts of this incredibly complex ship. The students and crew swarm all over her doing things that I hardly understand. Everyone seems to know where the right lies are to tack, or furl, or raise or lower a spar, or whatever, and everyone is capable of scurrying up ratlins and working at dizzying heights on various tasks. Whale watch is kept far up the foremast and most folks seem pretty adept at spotting animals.

Phyl and I did a little deck work, working on scraping and chipping paint on a companionway ladder that needed work, and about 5:00 we came close to shore and began to enter the fjord at Williamsport at about 7:00. The steep fjord walls rose very high above us, probably 500 or more feet and occasional waterfalls cascaded into the sea. Much of the wall was exposed rock, showing long dark dikes of rock fissuring the lighter rock. We wound our way in the 600-ft. deep channel until we passed the little village of Williamsport. It once housed families, most working at the whaling station farther up the fjord. There were some three-story houses like barracks, several smaller houses, a church, a dock, and a string of six lights that are the streetlights. There are 5-6 people there now that the whaling station is closed, amongst them a great friend of George's—Pearce Caravan, who now fishes cod. The *Regina Maris* docked at the whaling station pier, all rusting metal tanks, winches under the tide, the old slipway gaping with missing boards, the big oil tanks standing rusty behind, slack-windowed houses and offices, paint flaking off, and the ground littered with the trash of such a place. One tank was filled with stacked points of whaling harpoons of two kinds, the blunt Japanese that doesn't skip, and the sharp Norwegian. The favorite sport soon developed—singing into the top of a 40-ft. diesel fuel tank which reverberated so long that one could sing with himself in four-part harmony by changing key.

Pearce came aboard—a little wiry man who had to hug all the girls not once but several times, and who was full of stories, including one about the thrasher that helps kill whales—that has a sword coming out its belly, and how it teams with swordfish to kill whales. He also regaled us with stories of the Calumet River and his experiences in the bars of Detroit, etc. etc. He said it wasn't going to blow while we were here, but refused to say why.

Finally, George and I decided to try a little fishing in the morning before lecture and Phyl and I retired to our quarters, she feeling much better, and me tired from the day's activities.

August 20, 1976

Williamsport, Newfoundland

Up at just after dawn for a bit of fishing at the stream at the head of the fjord. George and I went up in the little zodiac, hell-bent for lection with a 25 hp engine on a boat for two. We skimmed the glassy dark surface heading for the head of the canyon where a broad stream flowed down into tidewater, between spruce forests. We landed, tied up the boat to a big rock, and staggered over the glassy slick rocks, dark with some kind of algae. Even the little pebbles slid over one another as if greased. One had to think about each step. Once upon the dry stones it was OK, though the bank was untrod by many fishermen and hence had no trail, so one stumbled through the grass to reach unseen boulders beneath. The river was broad and mostly fairly shallow. I caught a couple of brookies at the entrance where the river merged with the sea, or better, slid over the salt water beneath. There was also a pretty little trout in the stream of a bronze color with red spots down its sides. We caught none much over seven inches of that species (Arctic charr).

On the way back down I detoured through the low spruce forest and walked on the springy moss and sphagnum-covered forest floor. There were many *Amanita muscaria* scattered about in the gloomy recesses.

Back on board we explored the whaling station a bit and I found a nice creek running by its south end where the fishing was a bit better and easier since it tumbled from pool to pool. I caught two beautiful brookies and then went back to tell George and soon all sorts of folks were on the stream. It was tough going but I caught four and George a like amount, though he fell and we think cracked a rib. Nothing to do but let it heal, he says, and since he is an MD he ought to know.

I made the error of inviting a couple of Newfies to lunch without asking the purser (Ann). It did foul up the detail a little though there seemed plenty. But feeling foolish I retreated a bit. Later, at dinner the Newfies (the Randalls who are caretakers of the station) hung around with their little grandson Douglas wating to be fed and I had to tell them there wasn't food enough. Awkward, and one of those things I seem constantly to do. In the evening we had a beer party and singing session with Mike Taylor, the engineer presiding over the guitar, and as usual singing a lot of songs I don't know.

I'm getting so I know most of the ship's compliment now. Let me list them:

Tom Maguire—first mate, a good seaman and nice guy, from Ventura

Robie Price—second or thirdmate, also a fine fellow

Jim Watson—second or third mate, strong affable fellow

Paul Pennoyer—very quiet crewman

Mike Taylor—engineer, very calm and good, Dover, Main

Jim Goebel—very strong,, quiet, and a bit on the sober side (external appearance only)

Richard Kearsley—leftover crew from the Mediterranean cruise, long, smiling, gaunt fellow

Bill Monaco—early crew, very strong, athletic, quiet, perfectionist who works like a demon; he's all over the ship

Ann Radcliff—Captain George Nichols' roomie and purser. Quiet, temper close to the surface much of the time, strong, good

Jerry Brown—English lad, seaman, very capable, good in a song fest or a knot-tying contest, hard worker

Paul Tom Dubourg—the cook, a witty, affable guy of great good humor, good cook too

John Jake Salisbury—crewman left over, a little complicated and emotional, I suspect, though becoming affable enough

Students are:

Ann Preston of Boston—very sharp, has been an administrator for the government. 28. Land-use planner for courts.

Theresa Monk—slim, interested in whales, seems bright

Mark Sakaluskas—very quiet, but I am told sharp

Linda Noyes—not too interested in education, more in sailing

Don Eley—big, strong, bluff, bright and always with the witty needle ready

Mike Williamson—Maine, a teacher, in a top day school, thoughtful, bright, quiet

Kathryn Pyn (Kit)—Tall, willowy, red-haired, very nice, with a little smile most of the time

Ruth Stanbrough—Massachusetts. A hospital administrator, bright, committed to whale work, may want to become a biologist, a bit contentious but reasonable about it.

Randy Wells—slight, bespectacled, very capable graduate student of Blair Irvine. Working on *Tursiops*. Much more mature intellectually than most. Quiet.

John Hickey—intense student who has worked with Beamish, very driven and a bit studentish in that he asks for favor. Not much perception in his talks about what his audience cares about. Bright, a bit scatterbrained. (Pretty far off the mark—quite a bright and good guy . . . intense but very sharp.)

Jeff Norris—a mouseman from Michigan (early grad student). Very scattered thoughts, affable, good mind, but no especial sense of direction.

Hal Whitehead—English fellow came on board from a small sailboat, worked with Roger Payne, very fine young fellow. Great mop of untamed red hair.

Judy Perkins—fine young Gal with Hal in the sailboat (named *Patience*). Worked with Roger Payne on right whales. Very mature of mind and thought.

Ann Rittenhouse—an open, noisy profane young gal, full of energy. Bright.

Lea Donovan—Jim Watson's protector—very possessive, little gal, quiet, can't appraise her powers.

[Crew list for *Regina Maris*]

August 21, 1976

At sea, near Horse Islands, White Bay, Newfoundland

The sea was dead as a spike today. Not even birds were seen most the time. The sea lay flat and we made a knot or two. The *Regina* is wonderfully stable. I can't get over how the sails steady her, and she's heavy, drawing 12 ft. plus.

I spent some time learning about the ship. There's a book aboard about sails and rigging and I figure there are 135 names to learn, not to mention combinations of same.

The ship is wonderfully engineered and organized, having evolved over a long period of time. Every line is in its place, and I'm told you can go from square rigger to square rigger and find the same line on the same place on the pin rail, or the fife rail, and very much the same means of furling, stepping masts, building crosstrees—the only difference with these is that iron made some of the time-memorialized braces unnecessary so some parts like cheeks drop out. The British, too, use somewhat different names—for example deadeyes (which are little round washers for lines) are called lizards by the English. I learned to coil lines and hang them (belay) them on the belaying pins, and I learned how to set a sheet like the course, which is the biggest lower square sail. The students and crew are all over the rigging like monkeys. Ann Rittenhouse and Jerry went up and shinnied up the mast at the royal and sat on top of the spar. That would scare hell out of me. I made it to the crosstrees with my safety line snapped all along the way. It's a helluva long way up, even in calm weather.

We chipped paint and scraped old varnish as the crew is gradually making the *Regina* shipshape, Bristol Fashion, as Jerry says.

My trip up the main mast educated me about futtock shrouds, which are 1 in.-metal bars that connect to the crosstrees, and so I learn, are mainly to hold the parts of the mast together against the upward pull of shrouds and topping lifts and such like. But to the climber they are what one hangs on as you have to come up under the overhanging crosstrees, grasp the iron bars that slant outward to the edge of the crosstrees. It's a bit eery to be hanging upside down on these supports and then to clamber over the edge of the crosstrees to the platform, one's rear end dragging in space 50 ft. above the deck. I wasn't sure that the safety line was a good or bad thing. One hooks it up and then has to undo it to hook it up again, and usually at a Christawful time when hanging on is what one wants to do, and then the hook refuses to let go of whatever cable or stanchion it was clamped around.

We listened to a student talk by John Hickey, which I thought was better oriented toward his listeners than I expected, but I did not find it very analytical or useful. A piece about MSY, which really didn't say anything about MSY, but talked instead about common resource economics.

It did stimulate some discussion about the information deficit we face in managing whales, and how it might be solved without killing them. The antiwhaling sentiment is very strong on the ship, with some people taking a very emotionally based stand against all killing and without any understanding that the Japanese are no more monsters than we have been, but that the societal ethic governs.

Hove to, the ship rode very very easily at night. It was hard to tell it wasn't along dockside.

Phylly, by the way, is now fine and rosy cheeked and enjoying birdwatching and other diversions on deck.

At Sea of Cape St. John, Newfoundland

During my lectures on sounds, two minke whales came up to the ship and everyone rushed out, needless to say, to see them. They came right up under the counter of the stern and one could look down and see the whole outline of the whale with its white epaulettes standing out bright white against the dark water. They flirted with the vessel and then moved calmly off to stern. Pretty little whales, the largest about 30 ft.

We also saw some schools of *Lag albirostris*, and I was able to see the white patch that goes diagonally up the tailstock aft of the dorsal fin, and which is distinctive. These critters will have nothing to do with the ship, but cut under her and race away, the spray flying over their heads with each surfacing. We also saw them leaping in swifter locomotion.

I've been admiring George's actions as a master. He is low key and friendly, but when the ship is at all threatened he can be sharp tongued and abrupt—"hurry with the foreward spring line," or "get that bowline on the dock pronto." When takking the con in a tight place he is all business, demanding precise teamwork with his helmsman and with his professional crew. But, he is everyone's friend and teacher otherwise. But one learns where his stops are.

When one student missed the ship, and came alongside in a skiff, he would't let the person aboard but made him meet the ship at the next port. His order was not to be late and that was that. It's well done, and professional, and comfortable, and safe.

August 22, 1976

Cruising off Twillingate, Newfoundland

Before the lumps go down let me record the effects of the black fly. These insidious litle bastards are about 1/8 in. long and land on you when you aren't looking. They are common near streams and vegetation here. They apparently nip up a minor pot roast out of your epidermis and lap up the blood that oozes out, first being careful to introduce a shot of anticoagulant that makes the blood flow. The bite just sits there but about 36 hrs. afterward it has swelled up and is suppurating like mad and itching like about 10 mosquito bites all in one. I had been nipped pretty thoroughly on the lower arms and the damn bites kept coming up. They damn near drove me wild the second night except that I knew there was some super goop in the first aid kit, and I went back and found it in the middle of the night—a steroid mixture that reduces swelling. The lumps are only now disappearing and going away, and ceasing to itch.

Last night we came into a place called "Snooks Arm," which is a long bay (a fjord really) and we came in by lookout and fathometer in the dark. I could see very steep rocky promontories dropping into the bay on the side and a few little shacks and what looked like broken-down piers on the other, and a cluster of houses, some lighted at the very back of the bay up on a steep hill. It looked like a big stony bowl, and proved such. The very deep water, 25 fathoms or more, persisted nearly to the back beach, and we dropped the anchor in mid bay, layed out a scope of about 2½ times depth, hoisted the anchor lamp (just that), and set matches (on continuously, of course) and went to sleep. It was too late for a talk by the time we'd done all this. Anyway, this morning we rose to find our estimate of the bay was pretty close to the mark. The sails were set and the sea very flat, so we went out partly on the engine and then cruised across Notre Dame Bay, making our way toward St. Johns, but first such places as the Tickle, Fogo Island, and Funk Island (a bird sanctuary). Nice calm day but some well running, low cloud layer and scattered sunlight. Twice porpoise schools came near—one a fast-moving group of *L. acutus* accompanied by birds. The animals crashed into the water just like the somewhat larger *L. albirostris*, but they never came near us.

A manx shearwater flew by—a rarity, but there were very few birds—gulls and fulmars largely. Toward dusk we had reached Twillingate (off our beam) and the crew

fondly remembered their grand time in a bar there called Pig and Whistle, in which I gather they largely expropriated it from the Newfies for the evening.

Word games in the galley. One person looks up a word in the dictionary and writes its definition down and others write down their definitions, all are read and everyone guesses what the correct one is. Grand fun and many wild definitions such as "An old Chinese dish composed of catmeat and two redheads." etc. etc.

I'm lecturing in the morning now on conservation issues, and it's well received. In the midday I have started to learn the myriad lines, staring at the fife rail and spider rail of the mainmast. Tomorrow the pin rail. It's a maze, but much is coming clear, and I can do more than coil lines now, though not very much. I kind of know a luff from a buntline, but I figure there are well in excess of 200 new words to learn. Afternoon spent chipping paint from under the BT winch. It was red leaded directly after I finished.

Phylly's been looking at birds and talking to various people, especially the girls, and reading, and I think having a fine rest and time now that the seasickness has gone away.

August 23, 1976

At sea, off Funk Island, Newfoundland

About 11:30 Mike the engineer kindly poked his head in our cabin and told me the northern lights were making a show. I had mentioned earlier that day that I had never seen them. Up on deck in calm seas the horizon was banded with pale greenish light in two bands, one above the other. They didn't move or shoot as I had heard they do, so I repaired to the galley for a cup of cocoa and found the watch making usual watch bellyache noises (all good natured) and enjoyed my cup. Tom Maguire came in and announced that we had "heavy duty northern lights." They were shooting this time, in long vertical streamers, and there was the palest lavender caste to the green in some places. I guess they went $\frac{1}{4}$ way to the zenith.

This morning we were cruising our way along past Fogo Island toward Funk Island offshore. Fogo is a deeply incised island that is the home of a fishing people who resisted relocation by the Crown (which happened to many other outback folk in the name of providing work force for light industry and cutting down ferry expenses.) The Fogoers wouldn't leave and used their own ship for communication, and have been left alone. They're renowned as an unusually independent lot.

The day grew blustery and gray, with a chop and swell. But birds became quite abundant, with many Wilson's petrels dabbling and dipping over the waves. I saw several touching the water with a single extended leg. Then there were gannets—big white birds with black wing tips, black-backed gulls, puffins, and others.

Funk Island, which is a bird sanctuary, is low and rounded and small. Off it we encountered 4-6 humpbacks and were able to get rather close to some of them, and Judy Perkins was able to recognize one she had seen the year before—one she called Tongue Depressor. I was able to photograph on sequence of surfacing, blowing, and fluking all on one motor drive sequence. Hope it turns out. I used a 200-mm. telephoto and M2 setting at 125/sec.

Randy Wells, a fine quiet young scientist, very kindly provided me with the drawings of lines and their functions that are transcribed here. [drawing of Head Sails and Staysails]

The humpies were swimming along the deep edge of a striking drop of which rose abruptly from about 50 to 9 fathoms depth. They rather regularly dove for about 4 minutes below, and swam in pairs.

I feel kind of loggy today—it's a bit bouncy and very cold out, blustery, and took a half a bonamine for protection and it hangs on. Been better off without it, I'd guess. Phylly is doing well, except for chronic cold toes (which she has in Santa Cruz sometimes too). This ship's much better than most about boredom because there are the sails to tend to, lines to coil, and lots of work to do on varnish and the like, but nonetheless it's a slow life and a bit hard to adjust after keeping the schedules we do on land. But the exercise and the hard hand over hand work aloft or simply pulling on lines helps. I didn't do any scraping today. It was too cold and blustery for me to volunteer for deck work.

Just before dusk a minke came near and swam around us for some time, once sticking its very sharp snout rather far out of the water. Minke's don't blow. Also, I've not seen them inflate the nostrils or produce the cup in front of the nostrils that some other whales do.

Then a group of *L. acutus* swam up, circled the ship and dropped off astern. The yellow horizontal bar that extends out on the tail stock was clearly evident. I saw young animals in this 10-12 animal school swimming together in pairs with adults a dozen yards away. At one time the whole school speeded up, cutting water with their dorsals as they speeded along.

A nice dinner (meatloaf, cauliflower, fruit cake pudding and drinks). Nice. We hove to out in the channel with a 15-25 knot breeze, furling most of the sails. So far I mostly haul on lines—clewlines, sheets, buntlines, etc., when I see a need, and make up coils when everyone else flings the line on the deck. I'm getting better and may even try furling soon. But I'll wait for daylight and a little less wind.

Wall to wall gannets on one part of Funk. Phylly thought it was guano but it proved to be just pure birds.

[Drawing of fife rail and spider rail]

August 24, 1976

Broomclose, Newfoundland

The wind blew most of the night and had scudded us along half across Notre Dame Bay by morning. George had wanted to stay close to Funk because it was so good for birds and marine mammals, but no dice. Even with just a couple of small sails (staysails, I think) we had made many miles. Not comfortably either. The athwartships bunks we occupy threaten to sandpaper us down, or pull our epidermis loose from its deeper attachments as one slob back and forth in the roll.

It was damn brisk too, and intermittent rain swept across us, and only a couple of porpoise groups graced us, and rather few birds, mostly big, heavy-bodied fulmars. I talked on the tuna porpoise problem. There's lots of interest in these conservation issues aboard. And some students are very knowledgeable too. John Hickey, the one I thought least of, is really amongst the brightest, I think.

Phylly and I watched birds a bit, when it got warm enough.

Toward afternoon George decided to put into a long nook called the Broomclose, not far from Bloody Reach or the Cow Path, and various tickles, and to do it under power

because of rocks. For the first time I helped to furl, up on the yardarm. I only ascended to the Course (the lowest squaresail) but that was enough when one has to balance on footropes and lean over the yard to bunch the sail in and then tie it with a slip clove hitch. Damn particular too. Can't get pleats in your work as they might catch rain (who cares?). Jud Perkins and I were on our first try at such aerial work and commiserated with each other and got our safety snaps all rolled up in the sail.

The Broomclose is a lovely spruce bordered arm with a fine shingle cove inside and not too deep water. The bottom, however, tests out as rock and we have an onshore wind, so skipper George is being a bit wary.

Nice chicken dinner, and a lecture on currents by Ann Preston. Learned, or at least started to learn the pin rail lines.

[drawing of pin rail and cookshack lines]

August 26, 1976

Tacking in Trinity Bay, Newfoundland

A day spent sailing rather slowly around the headlands and into Trinity Bay. I lectured in the morning, read *The Blue Whale* (quite a lot better than I had expected), looking at birds and hoping for some marine mammals. None came, but I did see my first dovekeye, a very whitish alcid with a turned-up bill. We heard a very nice paper by Hal Whitehead on his non-lethal methods for determination of population parameters on the right whale. He has been able to determine most of the features used by population biologists by use of photographs.

I learned a few more lines, and am working my way back toward the main mast, but there are quite a slew yet to learn. A nice pork roast dinner. The weather is getting "fug" as George calls it, which indicates that the wind is coming up and will probably be around 25-30 kts. ere long. At this writing Phylly is snug in her bunk without too much roll to sandpaper her bottom surfaces, and I am about to quit and read about Alaska.

Judy Perkins told us about a friend, Jane Frick, who is working with Archie Carr on turtles, who knows where there is a peninsula in Costa Rica where sperm whales come in close enough to shore to be observed at the rainy season. This makes the place almost impassable and not many people get there but the whales do.

August 27, 1976

Trinity, Trinity Bay, Newfoundland

The night was spent tacking back and forth in the mouth of Trinity Bay and by morning we had made something like nine miles in our entry into the bay. All day long we watched a church and two houses on the shore. The only sighting was a brief one of some pilot whales. Some birds came near, including two dark swallows, but that was about it. I polished the binnacle, which was quite a task, and at the end coated it with petroleum jelly. Phylly worked on making whale sighting forms and transposing records from the log to them.

A couple of meals, some reading (I finished George Small's book on the blue whale—largely good, I thought, though perhaps somewhat overstated), palaver on the bow, capture of a lovely dragon fly into whose compound eyes we peered and then let it go, and much making up of lines, furling of sails, and such.

We will spend tomorrow in Trinity, leaving in the afternoon for St. Johns. I will enjoy the time ashore and so will Phylly. I've written a test for the students since some are taking a course for credit on the boat.

The entry into Trinity Bay was after dark, with the lights shining on the shore, revealing a round harbor, with low tree and grass-clad hills. Not till morning could we see the old dormered houses with their thin brick chimneys and chimney pots, geraniums flowering in the windows, the old wharf, greenish clear water with the stones of the bay bottom flickering in the gentle wavelets.

August 27, 1976

At sea, enroute, St. John's, Newfoundland

This morning was a lovely sunny one, warm enough that when Phylly and I went ashore, the wool pants I chose to wear were oppressively hot. Finally, in fact, I came back aboard because of them.

Phylly and I walked the town, which is an ancient one. It was first settled in the late 1570s and many of the houses in town are very old. The little gravel streets wind among neat houses with little tended gardens, most with wooden fences. The sun glinted off the old rolled wavy glass panes of the houses, and in many places we could see foundations made of stones, supported by newer cement. There is an old Anglican church set in a grassy meadow with a church yard alongside, its tombstones either fallen or in various angles, the soil around them hummocked as if by gophers or potato farmers who hillock their plants. On one side was perfect round harbor $\frac{3}{4}$ mile across, on the other, where we anchored another somewhat larger harbor. Both are well inside the headlands where the lighthouse stands, and where a fog bank swirled mist into the bay to be dissipated by the sun. Phylly and I explored the local stores (all closed on Sunday morning) some of the old houses, climbed to the schoolyard up on the hill where we could see the *Regina Maris* below us, talked to some of the old folks—pensioners are the major inhabitants, it seems, other than summer folk—much talk about who lived in what ruin.

Many of the houses in town have racks for cod—long ladder-shaped racks lying horizontally on 3-ft. legs, the tops slatted and covered with twigs. I found that when cod are dried the twigs keep the fish from sticking to the slats. The pensioners aren't allowed to sell fish, but can take enough for their own purposes. Many have cod boats, which vary from sturdy skiffs about 25 ft. long down to 18 footers. Most have a long, thin-bladed sculling oar and oar port aft, and a single cylinder Atlantic Gas engine. These are wondrous engines. They run with dry cells and one starts the engine by flicking the flywheel over a bit. It catches and the flywheel goes the opposite direction. Put put put, there is an accelerator lever that slows the engine down to a very slow put put, or up to about 5-6 knots. They are reckoned as the most reliable engine by local fishermen and everyone used them. The engine has no clutch and to reverse it one has to flick the flywheel just so and it goes backward, but mostly one simply slows down to such a degree that approaches to docks are gentle, or the sculling oar is used. Four hours on a gallon of gas, or about 20 miles.

We met a fine retired couple, Mr. and Mrs. George Lilly who lived in a lovely house up on the side of a hill. The old man was an interesting fellow who had been an accountant for the major whaling company on the Newfoundland coast during the 1930s.

He told us a good deal about the effort—six catchers, fished mostly fins, but also the others one would expect—humpies, blues (when they could get them), and seis. When the seis came they felt the season was over.

After dinner we let loose the gaskets (I worked the upper topsail yard—my highest excursion to date), and set the various sails. It must have thrilled some of the old seamen on the dock who had worked such boats in their youths to see the cloud of sail and see the seamen (and women) up aloft.

Phylly and George and I had gone into Trinity to get bread, milk, and ice cream for the galley, and to see the museum, too, in a little salt box house that had been given to the town for the purpose. The curator (Sunday curator at least) was a fine old gent named Goldsworthy, I think. He opened at two for us, and may of the ship's compliment trooped in. In fact we jammed the place. It was full of old flat iron collections, temperance banners, woodsman's wooden snowshoes, devices for boring long holes in trees to make ship's pumps and about a ton of books and papers. Everything was labeled by typewriter and scotch tape and no one stopped you from picking up the flatirons or anything else. Our curator kept up running commentary.

Try as we did we could get neither a paper or any news of what was going on in the world. No one could enlighten us about the Republican convention, even a lady from Brooklyn. Well, maybe St. Johns

September 1, 1976

St. Johns, Newfoundland

Yesterday we came down the coast rather close in at times, off a very bluff land, big rose-colored cliffs dropping straight into the sea. One big bird rookery was passed, but no marine mammals seen. Finally, toward afternoon we came to the slot in the cliff that enters into the snug circular harbor at St. Johns. About the only ark one sees is a lighthouse clinging to the cliff and a funny looking castle up on the bluff top, where, as I understand it Marconi sent his first wireless message across the Atlantic.

We were met by a pilot boat, a roundbottom little tub that rolled in seas in which the *Regina* was wholly stable. A pilot swung aboard, looking more like a truckdriver than a seaman, but he did bring us in nicely to the main dock on the waterfront, which was shared by two Russian and one Polish trawler (stern trawlers), a Coast Guard ship (Dallas), a schooner called the Myrtle and Grace (or something like that), all bedecked with flags from the nations she had visited. As usual the *Regina* was the big attraction and going about one's business on deck was a bit like being a fish in an aquarium—everyone lined up on the dock peering at each of us. We had a little birthday party for two of our crew—Ann Preston and Mike Taylor—cake on the deck, and wine. Later we wandered a bit of St. Johns looking for ice cream and entertainment. Not much of either. To bed. Poor Ruthie broke her wrist in a chicken fight (two people, one on top the other, attacking two others similarly arranged. She fell and cracked two bones. Seems OK though painful, and well set according to George.

We called home and all's well. They had a big rain which will do wonders for the fire hazard, and the pump broke, but otherwise OK.

The day was spent with various people doing various things for schedules and the ship. George off worrying about pilots, radio repair, fuel, and such like, others out after fresh produce like lettuce, and the things that disappear so quickly at sea. The engineer,

who is a renowned promoter, and very low key and smooth about it too, located a Dover man on the neighboring ship *Bowditch*, who had charge of the boatswain's locker, and miraculously there appeared on our deck and entire reel of new dock line—fine braided nylon at about five bucks a foot. I guess it's another problem for the Navy accountants, but they must have many.

For my part I called Washington to find out about the Commission and landed in the midst of the problems over the upcoming tuna-porpoise cruise. They still don't have a ship, the detail being hung up over our need to photograph. No word on the possible Commission appointment. I'm sure I'm hooked for that long cruise, which thrills me only slightly.

I tried Schevill but he was out so we settled for a letter.

In the evening George's doctor friend, Oliver Green, invited us out to the Conception Bay Yatch Club for dinner along with the crew of a 40-ft. sailing ship leaving tomorrow for Inverness, Scotland.

As we came on board prior to going to dinner, who should be waiting for us but a young gent named Anthony Jones, who tends the lobby of a nearby building and with whom I had struck up a conversation about various things including Newfie music (about which I know zero), but I had allowed a fondness for folk music, and lo and behold Mr. Jones had brought a record (which he insisted on giving us), a record player that was battery operated, but didn't work, and a nice little guide book to Newfoundland. We found he collects stamps and thus promised to send him some that I accumulate. Phylly suggested he might correspond with brother Bob, who is also a stamp collector, and Tony demurred, allowing that his writing wasn't very good since he had no education. I suspect he was near illiterate—a sweet young guy with every reason for success except opportunity. We were touched by all this because both Phyl and I are sure the five bucks the record cost meant a lot to him.

Through a light rain we assembled on the dock as Oliver Green and Mrs. Green arrived. The crew of the little sailing vessel was also there. Green is a tall, white-haired, courtly man, quite English, of the capable outdoor class. One senses he can and has done many things. Indeed he has—across the Atlantic three times in his recent 40-footer, with Montgomery in North Africa, a youthful enthusiasm for biology at Plymouth with D.P. Wilson, and work with whales, and thence to med school, a country general practitioner and then finding this too confining, made the long move to Newfoundland where he is an important physician and founder of the local "cruising club."

His wife, Jane, is a delightful, warm, tall, angular lady whose clear face belies her age—she is a grandmother some years over with five girls. Phylly especially enjoyed her.

The crew were sailing back after the skipper, Jock McLeod, had come over single handed. His little craft is "junk rigged" which means that his sails are heavily battened and do not require furling, but simply fall into folds. He's run the various lines through the bulkhead into his cockpit and can stay inside and run sails up and down without going outside, which must be dangerous for a lone man at sea. He's a tall very British gent, in spite of living in Scotland, whose passion and work is sail and who is very hard to steer onto any other subject. His partners were much the same, though one, David, was more interesting and seemed to be more aware of his environment. A nice evening, all in all, and I especially enjoyed the Greens.

This morning we did last-minute things, I went down the dock to inspect the little junk-rigged craft, and when I got back (after also invading the innards of a geophysical ship) we were ready to cast off. Fond goodbyes to the Judy-Hal axis, we left them waving on the dock, and thence out into the bay and beyond the squeaky spastic light house and into a rather large and confused swell, with much reflected swell from the cliffs. It got to me and my attempts to help furl the course were rather useless as the more experienced swept by me undoing my work and me hanging on for dear life up there above the slanting deck. I came down the ratlines the wrong way (to leeward) but nobody noticed. Right now we are off Ferryland and "The Hare's Ears." This place has more remarkable place names than any hunk of geography of my memory.

September 2, 1976

Off Cape St. Mary, Newfoundland

Another day's rather slow sail along the coast. North of Cape Race the sea was humpy with incoming and reflected swell but flat calm so the engine was used much of the time. Cape Race itself is a long low point of land all grassy (or so it looks) for a mile or two inland. What trees there are are stunted as if the winds which whip this SE corner of Newfoundland have planed them off. There is a fine representative lighthouse, red-topped and white stalked, with some red outbuildings, an antenna, and the low land. This coast is bluffed with many sea caves leading back into dark recesses where the waves shoot jets of spray into the sky. All along it's as if whales were spouting (which they didn't today).

Once around Cape Race the wind picked up and now we are under full sail and making about four knots. The ship slips quietly along, and if we didn't have a little one lunged Lister diesel generator banging away in the next compartment it would be silent with the water slapping outside the hull.

A long cod boat cruised up and three young fishermen yelled to us and began throwing cod at us, laughing uproariously as each slapped on deck, or against the wheelhouse or into the shrouds. Then they cruised away, their little Atlantic engine popping away.

The water is green now as we cruise the inside of the Grand Banks. Shallow here. Our plankton tow brought up sea urchins (and lots of plankton—ctenophores, chaetognaths, various larvae).

Phylly and [?] scraped the rudder of the jolly boat (which needs a paint job as badly as anything on board), chipped rust and started generally on the task of preparing the little boat for a new suit of paint. I'll get at her insides next.

About going aloft. I guess I don't much like it, though it's not fear of heights so much as just being inept and having the more experienced people keep undoing my gaskets cause I put them on backwards, or tromping over me as I try to get untangled from the cables. If the yards are braced around they push up close against the shrouds at times and I have trouble forcing my way through them, and don't much savor swinging around them over nothing but the deck 50 ft. below.

I do not like the feeling of going up the futtock shrouds where one has to climb an overhang. So aside from overhauling buntlines, which I can do perfectly satisfactorily I think I'll leave furling to the others and heave on lines on deck, make up lines on the belaying pins and things like that.

It's nice not having to prove oneself though there are those on board who feel these things are important tests. Second mate Robie is one. He tries consciously to bait me at times, undoing lines I've just made up, or simply standing in front of me. I'm determined not to be baited, and simply ask him for something else to do. I think he's coming around. The hardest case is Jerry, the British fellow, who is very uncomfortable around those with book learning and speaks fervently of wanting a regular ship's mess for crewmen (where they can be themselves regardless of these social pressures), but that's not likely to happen, first because the others are so well integrated, and also because there's not room. The first mate, Tom, is a delight. Works like hell, knows the ship like the palm of his hand, always a cheery word, and a funny one, gives me occasional jobs to do.

I've been writing on my book outline a bit and some ideas are shaping up. I think I'll get at that now.

September 3, 1976

In Placentia Bay, Newfoundland

"Cape St. Mary pays for all." A Newfie saying indicating that the area is exceptionally prolific. Indeed it is. After some days of having seen almost no animals, birds included, we ventured out into Placentia Bay today, past Cape St. Mary, and found the waters warmer (to 16 degrees on the surface), full of life, swirling with birds—gannets and shearwaters mostly. The latter swooped across the water almost constantly and rafted in the hundreds—a few sooty shearwaters but by far the majority the great shearwater . . . and whales.

I really can't give a reliable count of how many we saw because the ship circled so often in quest of this or that group. But there may have been as many as 30-40 in the area, or as few as six humpbacks and seven fins. There were also quite a number of *Lagenorhynchus acutus*. All were feeding, I believe. The fathometer trace showed a dense layer below the surface from about 1½ fathoms down to about 15 fathoms. It was dense enough to return a good trace. The whales of both species were diving without moving very rapidly and returning to the surface to breathe, or sometimes slowly moving at the surface. The finbacks of ten surfaced in a rush, producing a rather sizeable area of white water around the front of their snouts. The water did not, to me, seem to be related to swimming speed since animals that produced this bow wave weren't moving that rapidly. My suspicion is that they were coming up after having filled their mouths with water in the straining process, and that water was still flowing through the baleen as they surfaced and perhaps the throat was distended enough to produce the bow wave. Bow waves were produced mostly as the animal surfaced. We saw humpies breach, lobtail (once several times in succession), and flail their long pectoral flippers above the water. The humpies let us approach more closely than did the fins. Often they came within 30 yards or so of the rail, while no fin to my memory came closer than probably 75 yards. All the animals, birds included, were concentrated over the submarine ridge that runs along the eastern edge of Placentia Bay, 40 or more fathoms down, and to the west levels out in a broad submarine valley floor. I suspect the topography is a glacial valley. It leads ashore up the funnel-shaped Placentia Bay.

Our plankton tow through the area where the whales were congregated produced a not unusual assemblage and it may well be that the shoal was fish, and they weren't caught in the meter net—ctenophores, mysids, amphipods, chaetognaths, fish larvae, etc.

The weather is gray and a front is approaching. Dampy, is what George calls it. It is. Clothes cling, and anything we wear won't dry, especially with sea spray.

How do whales, or birds for that matter, find shoals of food? So far the underwater topography notion holds up well, except that many formations that appear to us suitable don't produce whales. But they can't be everywhere. Do they orient to the formations themselves, perhaps by listening to changes in background noise, as Bill Evans has suggested? Do they somehow echolocate, or hear, the shoals of food themselves? Do they intercommunicate between themselves and follow the signals of the whale that finds food? Do they smell it, as some fishermen believe? Is experience involved? Are migration routes involved? That is, do the normal traverses of the animal take them from bank to bank where food may be found? My guess is that the answer will involve more than one of these mechanisms, and that intercommunication is the most likely central modality, but who knows?

After dinner, much palaver, some scraping of jollyboat rudders, a new recipe from Tom Dubourge—he takes a cup of fruity red wine, mixes in 1½ cupfuls of roquefort, then mixes to a paste, broils chops on both sides and when they are about half done slathers them with this mixture (which also contains spices appropriate to the meat). The wine tenderizes, and the cheese makes a nice coating. Tomorrow we make it to St. Pierre, where we will spend the day and night before departing for the Gully off Sable Island.

September 4, 1976

St. Pierre, Off Newfoundland

"All hands on deck" was the first thing I heard today, coming through the cabin door from the crew member going through the quarters area. Once clothes were put on we went topside to find that we had hove to last night as we approached St. Pierre. One side of the little island is dangerous ground and the channel entrance is narrow and, as we found later, congested with boats. So, George wisely waited for light, and we moved in in the early morning light. The harbor consists of a series of low fingers of land enclosing an inner and outer bay, a roadstead under the shelter of the larger, higher, part of the island. I'd guess the main island may rise 800 ft. or so—all treeless grass and rock. The little town of about 4,000 people circles the back harbor, and one enters in past a group of old cannons, still on their trunions. We docked at the Customs wharf, which also houses the post office, a big, imposing, red-roofed building by the city square. As usual our coming was greeted with lines of curious onlookers on the dock. After some maneuvers we were warped around to the side dock facing directly into the town, a maneuver which George enjoyed doing, I know. He takes great pleasure in these ship-handling problems.

Shortly we were able to go ashore and to wander up amongst the very French streets—buildings right at sidewalk ends and built together. Varicolored (the same paint merchant that worked the Newfie coast was here), most with little entry kiosks to keep out the winter cold. We found a Musee, which was up a most tortuous set of rickety stairs, but filled with cannons and cod gear, ship models, photographs of stuffed birds, and other such things. This time everything was numbered and one was given a mimeographed volume of keyed titles. Thus I was able to look up the early knitting

machine, or the church bell melted down to a blob in the fire of '08, or whatever. We developed museum feet after a while and headed back for the ship. Phylly and I later walked a hill to look down on the little town, and then in the evening George, Annie, Phylly, and I had dinner at a stash called Le Cascade . . . snails, coc au vin, etc. George is fluent in French, which helps, though the rest of us have a word or two.

We wandered back to the ship where Phyl and I stood the watch from 10-12 for two of the more dance-minded types. We were treated to a fireworks display in the square, many of whose missiles passed right overhead. Much smoke, showers of sparks, bangs in the night, pinwheels castering over us into the bay, and the like. We were happy to be relieved by Bill Monaco and to go below. Damp night, fog drifting about, but still and warm, with lights shining on the water under the high fog.

St. Pierre has many cats, and some fine dogs that we enjoyed especially, including one fine spaniel type leaning in a doorway, who urged me to pet him. He then leaned on me, looking soulful. Nice fellow, all around.

September 4, 1976

Enroute, Sable Island, Nova Scotia

After sending runners out for fresh croissants we cast off on a bright calm sunny morning—quite unlike our fog-shrouded arrival. The multicolored houses lit up in the brightness, and the bay was beautiful. I photographed the little dories all pulled up on wooden ramps alongshore. Most have Atlantic engines, but with a universal joint on the shaft that allows the fishermen to pull up the prop when the boat is being slid out of water. These dories have a remarkable amount of rocker to them—very high bows and pointed high sterns, and much flare.

On out to sea, and because we want to get to the Gully to look for bottlenose whales we are motoring. Also, the wind started slight and rather much ahead, though now it is blustering and the sea is covered with whitecaps.

September 5, 1976

Enroute Sable Island

In the night the sea began to rock us more and more strongly and I dreamed of earthquakes until I realized what was going on. At breakfast Phyl found it raining above and retreated for more clothing. The sea was heaving with swells that crossed and tossed spray into the wind, shearwaters sailed in arcs about us dipping like sailplanes to the very surface of the water, skimming and swooping up and never touching the surface. A few gulls flew their airy flight astern and followed us. The petrels, buffeted by the wind, wheeled and turned in mini-imitation of the shearwaters. One could see their skill on a day like this when the wind blows and the sea heaves. For our part the ship heaves and tosses on the sea surface, water squirting in through the scupper pipes, or rushing in a sheet if we roll further. At the bows the ship heads into the waves and her flare usually stops her plunge into the water at the last minute, amid a welter of foam and green roily water, but sometimes she digs deeper and takes water on deck. She's solid, though, no shuddering as she breasts the sea.

I taught about narwhals and belugas, and did it briefly in the classroom as my pupils were apt to find physiological reasons for inattention (me too, though it didn't happen).

Well, Phyll is flaked out, just a couple of points off well being, and I'm flirting with the edges of malaise. They're calling first sitting, and that gives us about 15 minutes to contemplate whether we want food or not. I know we don't need, considering the indolent lives of "idlers" which we are (those who don't stand watch).

September 6, 1976

Off Sable Island, Nova Scotia

Most of the night we motored, but by dawn a couple of staysails and jibs had been run up to stabilize the ship. It was rough. Phylly and I in our athwartships bunks were sandpapered back and forth and stretched to and fro in our skins by the roll. Both of us were logy and a bit off today from the motion, and only in the evening did I pick up much steam. The day was a mixture of rough, tossing sea, the cross swells rising up in spilling white caps. Shearwaters were very common most of the day and their flight in the complexities of such swells and spilling water is a constant source of wonder. They never touch though their wings seem to sweep within an inch or so of the surface and their flight to stay a clean series of unmarred swoops down onto the water and up 10 ft. or so above it.

Rain fell in squalls, once while I was at the helm and I had to run for my foulweather gear while George stood in for me. The Regina is kind of cranky. The helm, which is by the leverage of cables and pulleys only, moves like a live thing and the sails can be felt to push the stern or bow over. For example if the mizzen is used the stern goes over and one must compensate with the helm. It takes strength to turn the helm, too, and I can see why two men are needed in storms.

Somewhere around noon we reached the gully to the east of Sable Bank and Sale Island, and then cut back and forth across it. The gully is a broad canyon in the edge of the continental shelf that drops to about 500 fathoms and rises right onto the eastern tip of Sable Bank.

I watched as the bottom dropped away on the fathometer. When we had exceeded the range of the fathomner (200 F) the call went out: "Whales." I gathered my camera gear and stumbled topside, as did Phylly. Three bottlenose whales were about 50 yards off the stern, moving slowly. Finally we found that there were five animals, one small young, a half-grown, and three adults including one large animal of maybe 20 ft. They are sleek animals, brownish fawn, with a lightish mark behind the melon, a very prominent bulbous forehead, and a pronounced beak that sometimes shows above water. Their rather large fin is well aft, somewhat falcate. I never saw flukes. The animals, true to form, had come up while the ship was hove to in a plankton tow, and didn't stay with us long after the engine was started. In between they circled us, sometimes within a few yards of the rail, especially under the bows, made traverses out maybe 200 yards and came in again. Gradually these circles took them farther and farther away and less and less close to the ship. I took perhaps 25 slides of them at various angles. Quite a show. The blow of the animal was either non-existent at times, or a low bushy spout of maybe two ft. in height. Though there was perhaps 15 knots breeze I think the spout would be low anyway.

I never saw flukes, and animals did not jump, and the only aerial behavior was a tendency of the young to throw their heads up more than the adults as they surfaced.

The water thermal structure at the region of the sighting was most unusual. It dropped from a surface temperature of about 15 degrees to about 2 degrees down 30 meters or so (most within 15 meters) and then got warmer again to 200 meters, only dropping slowly at that depth. [Graph]

We never saw Sable Island, but could see what were probably rain squalls over it. It is low (maybe 50 ft. or so), sandy, grass stabilized, light an open half moon several miles long, frequented by nesting birds, wild horses and gray seals, and the wrecks of dozens upon dozens of ships. It lies right on the edge of the continental shelf and is a trap. Winds come over it and any sailor taking into its lee stands the risk of the wind shifting and blowing him on the shore, either directly or on one of the cusps of the shoals at either end. Fogs abound, as do gale winds. Treacherous. It was too rough to try to land so George wisely headed back in toward Canso, Nova Scotia, and will take a traverse down the coast probably to Brown's Bank, tomorrow.

While I was lecturing on sea floor spreading, the call "Whales" went up again and out we poured into the evening dusk to see a school of perhaps 20 pilot whales (potheads) right alongside. There were several young, including one graying very young animal, with an attending adult. [Drawing] The whales rode the waves, changing direction from following us to ride swells briefly going the opposite way, and then turning again to follow us. The young threw their heads out just like *G. scammoni* does, and in other ways resembled them, except for the missing saddle and the prominent white marks,. Back to the lecture and then go below to read. A good whale day, one in which both Phylly and I were less than par and both of us beginning to feel the confinement of the boat more and more. My but I get a lot of sleep and reading time. We're just enough off not to have much ambition though. For instance some important editing I have to do lies unfinished. Oh well, it's a vacation, but we both look forward to the shore.

September 8, 1976

Enroute, Browns Bank, New Brunswick

We awoke this morning rather late—they called second sitting to which we belong, while we were still in the sack. The ship had made a turn after going toward shore away from Sable Island for a long time, and was tacking into the wind toward Browns, where we hope to see right whales, and others. It's overcast with spats of rain coming now and then. I gather the night had been clear and moon lines were obtained along with Omega fixes so we know where we are.

Various tacks took us down between Sable and the shore, and finally Jim the mate told me that Sable Island could be seen if I went up the ratlines. This I did, up to the Course and sure enough, far out over the now calm sea I could discern a line of lumpy black hummocks on the horizon, and occasionally a flash of the lighthouse that is situated on the middle of Sable. We came closer and closer and finally I was able to show Phylly the island by standing on the pin rail just above deck. From aloft I could see a long sweeping island composed of interconnected hummocks dark with dune grass. There is one large clear sand dune toward the east end, and one can see what may be the masts of a wreck near that end too. George found it takes five weeks to process permission to land so there was no question about us going ashore, and I suspect rather strongly that calm weather or no, he would rather not try. It is a trap that has caught many people and his power isn't all that great, since flat out we make about six knots.

So, I looked at that remote island, wishing to go ashore not pressing the issue at all. Someday maybe I can come and see it. It is a fabled spot, full of menace to the seafarer, full of interest to the biologist, and one of those little kingdoms that one can encompass whole. In other words, a good island. The land portion is 19 miles long and with the long spits at either end it extends 28 miles along the continental shelf.

Oil rigs are sprouting inshore of the island and we passed two, and one ugly looking supply ship that brings pipe and other supplies and is built to back under the rigs and offload long bunches of pipe into the center of the rig.

Sailing, in calm seas, mostly by motor, toward Browns. I delivered a not very inspiring talk about platanistid porpoises, and we heard an interesting one from Don Eley about redwood lumbering in the evening. There's quite a bit of channel fever building in the students (and us) now. Some of the students are wondering what to do next and how they might get jobs.

Well, to bed.

September 9, 1976

Over Emerald Basin, Nova Scotia

Wind fresh today, and the ship racing along at six knots held over and pitching into the sea. The weather was cold, and we ran through several rain squalls. Phylly and I spent most of our time below, except for my lecture on pinnipeds, which was good in spots and a little weak on local lore (since I've never been here before). I did find that Sable Island is an important area for both harbor and gray seals, in addition to horses, and that the Canadian government has a bounty on both species.

Two special diseases have developed aboard the *Regina*. First is the disease of Listeritis, which is an affliction of the after saloon where one can hear the insistent thrumming of the Lister diesel that runs the auxiliary generator. The effect is to put nearly anyone to sleep. We've taken to shutting off the generator during lectures, thank goodness.

The other is Tackitis, which is a headachy, sometimes even nauseated condition with skin rashes on the backside that develops from trying to sleeping in ay athwartships bunk when the ship is heeled over and your head points downhill, banging your scone against the bulkhead in an obligate to the ship's roll, and sandpapering your lower hide as you slide back and forth. Other than these afflictions and growing channel fever, all's well.

September 10, 1976

Over the Continental Shelf in 200 fathoms, NE Brown's Bank

Looking up at the deadlight in the overhead I could tell when I woke that the day was sunny. Not much roll either.

On deck it was flat and the *Regina* was making a majestic two knots or so, through scattered clouds and sunshine. A good day for sunning one's self, washing up, washing hair (which Phylly did) and other such activities.

Jeff Norris lured me up the mainmast for pictures, and not until I was on the ratlines did I learn his full design, which was to get me onto the topgallant yard arm, about 90 ft. above the deck, so he could take pictures of me clinging on for dear life, with his fisheye lens that would show how high up I was and the deck of the ship endless

distance down below. I'm used to going to the crosstrees above the course, but above that the ratlines are ropes only and narrow as they approach the masthead until I couldn't get my feet in one side with my big rubber boots. I'd brought my safety line and was clipping one in the scarier places, but this involves unclipping which is usually worse than ignoring the harness altogether, as you find yourself hanging from some nameless stay with one hand, over absolutely nothing trying to get the damn clip loose.

I clamped myself around the mast at the ____ and sat gingerly on the yard trying to get a handhold on the jackstays (which are metal rod railings bolted into the mast that provide handholds and a place to tie sail gaskets when the squaresails are furled). Jeff, who is one of the more timid of the students (he wears his safety harness) climbed all over the yard holding on with one hand while his feet swayed back and forth on the footrope (a cable below the spar that the crewmen walk on when furling sails or overhauling buntlines). With his free hand (where, did he get a free hand?) he took pictures. Then he was above me on the royal yard looking down upside down snapping away and asking me to look up.

I was glad to get down. The day had been calm but even so the mast at that height whips around unconscionably. I guess I'm just not aurally inclined.

About midday we noticed a big sleek freighter heading right at us. All of us watched as her bearing didn't change or as she seemed to waver on her course from side to side, as if she didn't know which side of us to go. We could see no lookout and couldn't raise her on the radio. George began to get anxious and ordered the engine started, even though some patchwork was being done on an exhaust pipe and the cement hadn't hardened. The ship came right at us, and we were dead in the water not knowing what to do. She threw an enormous white bow wave and must have been making a good 15 knots. As she was a quarter mile away we were sure she was going around our stern, and then when she was closer she turned right for us. George started the engines and began to try to get the *Regina* underway. Still on she came, and then tooted once. Then, when about 500 yards away she slewed around to starboard and crossed our bow not 250 yards out, casting a great bow wave that rocked us crazily moments later. Everyone exhaled in relief, little realizing how scared we all were. There was literally nothing we could do but hope, as we were dead in the water taking a plankton tow. We had the right of way on two counts. A ship coming in to starboard does not have the right of way and we were a sailing ship. She was a Yugoslavian freighter from and maybe 350-400 ft. long. Whew.

Got paint on both my rudder and tiller today, talked about locomotion, met with students over career opportunities, listened to a good student talk on green turtles, talked with George about plans for the *Regina*, and generally balonied it up. That's what one does, and thank heaven we have 120 ft. of vessel to wander on. The sea's still flat, we've gone out over the edge of the shelf, and an enormous red moon has risen, casting the ship and her sails in cool light. A lovely scene.

September 11, 1976

Over Brown's Bank, Maine-New Brunswick

The weather gradually became worse overnight and by morning we were rolling a bit, and I could see by the deadlight that it was sunny. When we went topside, that's what it was. No porpoises or whales today, but we did slide up over the bank, where we may

see right whales, and where the water was filled with fragments of sargassum. Nothing too special happened today. Many land birds have been landing in the rigging, especially flickers and various warblers. They are all lost, so far from land. We saw one exhausted flicker falter and fall in a flutter of wings into the wake. The loss must be very sizeable, considering that we are just a mote on the sea. The offshore wind catches them and sends them offshore. The effect is clear here at sea, but on land it would represent an almost undetectable spreading of animals from the habitats of their choice. I wonder if the Merriam Effect, in which ecosystems on mountaintops are more or less complex depending upon their size—small ones less than large ones aerially speaking. Perhaps some of the complexity simply gets blown away—birds, seeds, insects, and perhaps other things, so that the attrition from some species is so great that they fail reproductively. Who knows? It would be worth calculating.

I spent most of the day working on a tool chest, cleaning and scraping it, preparatory to varnishing it. I'm carving initials and a porpoise on it, and Jerry is making rope handles. He, by the way, has become very friendly now, I think because I've shown an interest in his work, which is mostly beautiful canvas work and sailmaking, but he knows much else in the seaman's knot and line lore. I spent a happy hour, for instance, poring over his copy of *Ashley's Book of Knots*, which is an incredibly compendium. It tells you how to tie hangman's knots, how to suspend celery, how to tie your necktie, and infinitely more. Creampuffs at 8 PM, and I gave a test today. Jake tried very hard to avoid it. Don't know if he succeeded.

September 13, 1976

Off Provincetown, Massachusetts

No whales or porpoises today, but very calm weather with the seas just lying there around us heaving calmly, lifting us like the sargasso clumps that float by. People are getting a little hyper now that we come close to shore. I feel both anticipating and a bit of reluctance to plunge into the thrash that inevitably awaits me. Phylly, I suspect, is more purely waiting such pleasures as land, clean sheets, a nice sit-down tub, and things like that, not to mention a good gam with brother Alan and wife Carrie.

My day was spent working on cleaning tools from the tool locker, and with cleaning up the paint locker. The tools were encrusted with rust but came out pretty clean. I then painted as much of their exposed surface as I could with red lead.

The students are beginning to corner me for advice now, and I've run through long sessions with Rit, Kit, Jeff, and Jake thus far. Good folks, all, some going through the problems of growing up, but all quality folk under such problems.

We've been going through country marked on the chart with various kinds of "swells," which I suspect are underwater drunlins, or some such, and tonight will turn toward Cape Cod and Provincetown, which we will make tomorrow morning.

September 14, 1976

Boston Harbor, anchored near George Island

The *Regina* sailed today through very calm seas on "the slow bell" or what is called iron wind"; i.e., the engine. The tip of Cape Cod was in sight when we first went on deck and before long we were cruising along past Provincetown.

I spent my day tidying up the tag ends of the class and getting the appropriate papers to George for his files. Then I worked on derusting a big vise on the deck workbench, red leading it, cleaning up the paint locker and then about noon George decided it would be lovely if I carved whales on the other two deck lockers. I had finished a porpoise on one, and a big R. So, while the ship was being spruced up by all hands I perched on the hatch cover and carved. I seldom looked up, as carving a humpback intaglio and a pilot whale from scratch was a bit of a job, but with jets now whistling overhead and small boat operators shouting advice about how we would have to fold our masts to get under the canal bridge (which isn't the way we are going). I carved on, finishing at dusk, just before George laid out the booze for our coming home party. Roast beef, wine, and a lot of Tenent's Beer afterward on deck (complete with pictures of pretty scantily clad girls with such subtitles as "so lonely," sitting pretty," etc.

The howling, dancing, and singing went on for hours.

Anyway, a good, rich trip, and one neither of us will forget. Tomorrow morning we make the short run to Commercial Wharf in deepest Boston Harbor, and then start our way toward Washington DC, via Strouts and Schevills.

Cruise on *Elizabeth C.J.* and *David Starr Jordan* to tropical Eastern Pacific yellowfin tuna grounds, "Behavioral Cruise." October 11-November 8, 1976

October 11, 1976

Off San Diego on board the Elizabeth C.J.

"Well, off on the greatest adventure of my life," as Max Schulman once said—but truly who knows what is ahead. I'm on board the *Elizabeth C.J.*, one of the premier tuna seiners in the yellowfin tuna fishery. She's an incredible ship—spotless, painted a light sea-foam green and white, 260 ft. long, with a long raking scoop-shaped bow, a tall mast on the after deck with an enclosed crow's nest where the fish spotters work using big binoculars. She's equipped with the latest—digital read-out satellite navigation gear that reads in latitude and longitude constantly, a weather chart recorder that spits out such charts on command, a great broad bridge with everything in its place and quite remarkable quarters—broad bunks, air conditioning throughout, a game room, a ladies' powder room decorated with violet carpet and gold wallpaper, and down below, all business—a huge immaculate engine room with two GM 2800 HP diesels that push us along at 17 knots (quite a change after the 6 knots of the *Regina Maris*) and a fish hold deck with space for 1700 tons of tuna that are sluiced in through collapsible metal channels to each hold. Right now there are . . . [?] filled with diesel. We burn something like 7,000 gallons a day.

There are four scientists aboard. I'm overall scientific leader, Dr. Warren Sturtz[?] is my project director and roommate; Dr. Bill Perrin; and Jim Coe who is in charge of a gear modification effort. On the *David Starr Jordan*, which waits for us at Roca Partida far to the south, are an acoustic team of Frank Aubrey, Steve Leatherwood, Don Jungblad, Dave Holts, Bill Rogus my new grad student and behaviorist, Dr. Ed Mitchell of Canada, and a photographic team, the Joe Thompsons Jr. and Sr. (father and son).

Our attempt is to describe the behavior of yellowfin tuna and porpoises in a [?] with the hope of finding ways of cutting porpoise mortality. We will photograph from ship board, from the helicopter and from skiffs, we will observe and divers will work below. We have 15 contracted net sets in which we can manipulate affairs and can then watch until the ship is full. We expect to be out six weeks or more.

Off Ensenada, Mexico, enroute tuna grounds

At the moment I'm a bit apprehensive about the complexity of our effort and being sure that everyone knows his place on each set. We'll prepare charts on this today and tomorrow and when we rendezvous we will talk to each person individually. I've made up observation sheets for most features we hope to record.

Our crew is mostly Portuguese and it is hard to communicate with some of them, but they seem affable enough for the most part and certainly professional. The skippers are Manuel and Joe Jorne, both Portuguese too, fellows who started with very little and now own two of these ships capable of paying off their 5.75 million cost in a couple of years. Both are in their 40s I'd say, on the squat side (like me), and I don't know much more at this time. They are reckoned as amongst the best in the U.S. fleet.

This morning we'll lay out schedules for everyone, and begin to assign gear and stations to everyone. I hope to rotate through the various places to have the chance to make things go smoothly, and to see the problem from all angles.

October 12, 1976

Approximately off Punta Eugenia, Baja California, Mexico

We're cruising southward, probably 20 miles offshore, in very calm seas (3 ft.). The roll is scarcely noticeable on this big ship. The crew has been getting various parts of their gear ready—the purse cable greased, the ponga engines checked and the little Bell Helicopter put in order. Actually, the latter was filled with preservative to ward off salt damage in the three days or so before we begin making sets.

It's been a gruff, even on occasion rude, time with some of the crew, but that is beginning to fade already and people are beginning to open up a bit. Some are obviously interested and with us. Hard to tell whether the fact that some of us are "feds" is part of it, and if I'm somehow known as being troublesome to the industry. To be sure, my own view is and continues to be that I want nothing more than to help the industry with its plight. I only want honest effort toward solution. This trip is one part of getting that cooperation and I hope deeply that it does some good. It's hard to tell what we can do. I only know it should have been done four years ago.

Anyway, the first day at sea, even on the very stable regal *Elizabeth C.J.* takes a little of the ambition out of one. But we did get some good things done. We evolved a schedule for personnel in the various sets (quite a task), worried a bit about safety (I'm not over that yet by any means), especially Bill Roger's efforts in the net, laid out a log for film in which everyone will register each roll and turn them in to me, and quite a few other details. We've learned what the capability of the helicopter is (about 2 hrs. 50 minutes aloft), where we can observe (there is a perfect platform below the crow's nest that looks like it could take all of us).

Over all this for Warren and I hangs the knowledge that the industry just exceeded its annual quota of porpoise killed (78,000) and our allowed take (390 animals) is

included, so if we are to continue we will require an exception from the government. I can't imagine them holding us up, but who knows about bureaucracy?

Most of us snoozed a bit today, on and off, and read our various novels. I'm deep in a long long one called *Shogun*, which is a good adventure story, but not much when it comes to accuracy about things like seamanship, and I wonder about the portrayal of the Japanese character. Well, it keeps me from other things. I smell steaks barbecuing on the afterdeck, and have just had a couple of drinks at evening happy hour.

October 13, 1976

Northeast of Cape San Lucas, Baja California

The day was spent getting ready for the work to come—laying out plans and schedules, figuring out how to handle film and things like that. Lots of food, some good booze before dinner, and then conversation afterward with one of the crew who had been born on the Azores in a sperm whaler's family. He described how they fished by long boat and how his mother used sperm whale oil to cook in—corn on the cob dipped in hot oil, yum yum.

I was feeling restless and had trouble sleeping, but blamed it on my apprehensions about the coming effort and how much remained to be done. But, by morning I began to suspect a belly ache—maybe a residual bit of intestinal flu, which I had a day or so before we left. Don't know.

October 14, 1976

Northeast of Clarion Island, Mexico

Well, we've made two successful sets today and I've developed a pretty good belly ache that's slowing me down measurably. The first set was a picturebook affair in the morning—big cumulus standing high veiled with rain below, and a nearly calm sea—maybe three ft. of swell and no wind to speak of. A flock of birds, all so far as I could see masked boobies and a few brown boobies, was seen a long way off. The helicopter was dispatched and sent back the word—"fish," and the chase was on. The pongas were launched very quickly—there's a sort of railway on the bridge deck where they are kept, and a big finger crane. They are lifted off with an open hook and the bow painter held until the engine is tested and then they are let loose and soon begin skimming over the waves. All used big Mercury outboards, and the owner of each has already spent much time getting them in shape—checking engines, renewing rub rails, etc. Once in the water they are directed by the man in the crow's nest—in this case Joe Jorge—who does it in voluble, excited and profane Portuguese—though he slips into English cuss words when the occasion demands. The boats pursue the porpoise in serial fashion, turn them back toward the vessel and then circle individually in an arc behind them which prevents their returning. Then they cut around them and cause them to mill while the *Elizabeth C.J.* comes up behind and once the porpoises are in a mill, the call goes out to let go. A man on the afterdeck whacks the pelican hook loose that holds a cable stretching up over the net and to the net skiff sitting on the after part of the net pile, her operator waiting at the controls. The skiff slides off pulling the net with it and the ship begins the circle. In the first case it was perfect—the set just long enough to use up the net and yet to close it when the ship had come around. The ponga boats stood by driving the animals away from

the last opening as it was closed. Then one of them stood by the net in case it was needed to drive the animals for some reason.

With the net out, the bow piece is run aft and then, as the net comes in, bunches of corks are pulled together (the bow bunches), which allows the remainder of the net to hang cleanly and the cork line to stay circular. The purse cable pulls in (tremendous strain)—one can hear the mast and blocks banging and slapping, and the winch whining low. Finally the rings are bunched and pulled up as a group onto the elephant's pecker—or ring stripper—a long metal boom down which a cable runs that pulls the rings on one after another. I was amazed to hear them clank onto the stripper and see a cloud of rust be banged loose into the air, even though they had just come from 50 fathoms down. With the rings in place the net is secure, and no fish or porpoise can escape, except for the rare one that jumps the corks.

Then, the net (750 fathoms around the corks x 65 fathoms deep) (fishes no more than 50 fathoms) comes in over the powerblock, and as each ring is reached it pulls free from the stripper and is stacked on the rail, very carefully, one after the other so they don't tangle. Corks on the starboard, mesh in the middle, the nylon-covered chain lead line next and then the rings of the port. Finally, judging from coded red net floats tied to the cork line the skipper knows it's time to back down. By this time the net has been reduced in area by 3/4, the porpoise school mills within 50-75 yards of the ship, and a shorter distance from the outer corkline. Not until about this time did I ever see fish, though the captain was calling out tonnage (he was right on—40 tons of fish). They come flickering in from below swimming in tight searching schools, looking for an escape. By backdown the pulling on the net has brought the big seiner in, causing the net to lobe out both fore and aft, but the big net skiff has hitched on by this time and pulls to counteract this effect . . . keeping the net from collapsing around the vessel. The bow bunches help this tendency, too.

In backdown the bow thruster is turned on pushing the bow out away from the net, the engines are put astern, and the big net skiff continues to pull away. The result is that what is left of the net stretches out into a long arc-shaped finger as the vessel goes in an equal backward arc. The porpoises, who have been staying bunched near the far corkline tend to get carried down this channel, which is maybe 20 yards wide, and becomes narrower and narrower, until finally it may disappear altogether as the oppose corklines come together. The porpoises tend to get swept down this channel and finally fill it from wall to wall. The captain pulls and animals slip and slide over the shallowly submerged corkline. There were two ponga operators and Jim Coe in our sets to help them out. Jim dove in and made his way down the channel in a small Avon raft, hand over hand. He did most of the rescue, signalling to the skipper when to pull with arm waves. We had about 350 animals in the net on the first set, and maybe 150 on the second and lost nary an animal.

Jim said the animals would sometimes lay below him on the slope of the net, looking up at him, and then, after some minutes time come to the surface and often enough go out of the net. At any rate, by working with them, Jim was able to clear the net in each case. I wonder how successful the other would be, or how motivated. Certainly they didn't get in the water like Jim did.

Once the porpoise were free, they did an Edward Everett Horton double take, looked around, and by what sense I could not discern (they squeak a lot in the net, Jim

says) decided they were out of the net and bolted for freedom, bursting from the water in clean arcing leaps.

Then the net came in and the slowest part of the operation began which is sacking up and brailing. This is the final drying up the net, in which men pull bunches of net together by hand, strap them, and haul them up by winch, and then do it over again and again, until the fish are crowded enough for brailing. In this operation a big dip net, closed by a chain at the bottom is suspended from a cable and lowered into the fish. The men on the net skiff, which by this time has pulled alongside, dip it down into the struggling mass of fish, and the winch hauls it up—a ton at a crack—thrashing, wiggling tuna, many over 100 lbs. in weight and a few monsters probably twice that size. For some reason the animals wound one another and the water is wine-colored with blood, most of it coming from the gills. The fish are spilled into a chute as the chain man on the brail lets go and the fish cascade out, often filling the big aluminum chute. Men alongside it guide the fish down the chute, which dumps below into the brine wells. There fish are sluiced to the proper well by water, and slide into be chilled down. 90 tons per well. We nearly filled a well today between the two sets or about 1/3 enough to pay the expenses of the voyage ($615/\text{ton} \times 90 \text{ tons} = 55,550$, or \$166,650 for the cruise).

Yellowfin tuna are beautiful creatures alive—fusiform and heavy, swimming with powerful quick little strokes of their tails. A gleaming gold band striped their sides, and blue shines above. The projecting fins are lemon yellow. But dead they turn gray and their fins are tattered by crowding in the sack. By the time they sluice below, even if fitfully still alive, they are drab.

I kept records on the second set, using my little handheld cassette recorder that I can dangle from my wrist by a line. I ascended to the crosstrees just below the crow's nest and made observations of the second set, trying to learn something about the porpoise and their behavior.

The following is a log of that set.

Start 1200, October 14, 1976. Loc 18 27 N 113 50 W. Solely spotted porps. Run directly oppose course of ship, 4 pongas. 50-60 porps, flight of birds, brown and masked boobies

1222: *E CJ* following in wake of ponga boats; porpoising a single tight group, often jumping from the water, now beginning to mill, ahead of ponga boats my estimate of porp numbers probably low, may be 200.

1226: Two distinct groups being driven into a mill by circling ponga ahead and boats behind.

1229: Boat let go. As pongas circle far side of por. school, 1/3 around. Porps mill quietly inside net mostly beneath the surface. One leap seen.

1231: School moving together deeper into net, 150 yds. from nearest net, animals swimming low in water.

1232: Circle essentially complete, net set made too large, so net is open by 150 yds. Being closed by net skiff, and winch. The entrance is being guarded successfully by ponga boats, as porps are clear across net as far away as they can get.

1236: 3 tail slaps, but otherwise porps milling slowly as far from us as they can get, but 150 yards from corkline. Calm weather, number of rain squalls. Many lifting tails out of water before diving, indicative of steep dive.

1241: Occasional splashes at surface indicative of interference or aggression between animals. Birds have moved outside net and are rafting. Porps mill.

1244: 75 yds. from far corkline. School elongated along 150-200 yards along net and 80 yds from corkline as far away as they can get.

1245: Net almost complete, far corkline at after quarter, nose outs to level of pectorals, and vertical dives in which flukes are thrown free.

1246: Animals moving very slowly, often lying at the surface with just the dorsal fin showing, for a few seconds and then submerging.

1248: A roll up. Porps swimming and diving very slowly, at far side of net, no evidence of aerial behavior.

1305: Net is rolled up for perhaps $\frac{1}{4}$ length of net. Porps mill quietly in unison, swimming as far from boat as they can get, but staying 70 yards from far cork line. Occasional nose outs, 2 blows under water, 150-200 animals, all spotters.

1330: Roll up continues, net 250 yards across.

1340: Finally coming in past roll up, piling it on deck. Porps still milling, moving slowly, recog. subgroups, milling circularly, stay away from net. Upside down leap and head and tail slap, as if driven out ban animal underwater.

These sets are a major source of mortality primarily because no one has figured out how to release animals prior to backdown. If bow bunches are released animals won't go near ship, and if cork line is depressed they may not swim through the resultant opening.

1340: Animals stay in deep water, and if it is rough the net can collapse on them.

1349: Porps as before. Baby just jumped.

1352: Long lobe of net developed, animals coming closer to far cork line and breaking water more frequently than before. Coming somewhat closer to far cork line, diving steeply, white water for lobtailing, and underwater aggression, low level leaping more frequent. A lobe developing, but porps stay out of it in deep water.

1355: Head slaps, come closer to *Eliz CJ* as net becomes smaller. Ponga boat tows not open.

1359: Porps close to *Eliz CJ* (50 yards) but still as far away as they can stay. Noseouts common as animals lie relatively doggo. Animals milling and undergoing low level leaps part way out of water. One can still see subgroup structure in school.

1402: Porps in tight group, 50 yards from rail, perhaps 20 yards from far cork line, staying out of complicated net where ponga is. Skipper decides to haul net in Starlite reaction from winch.

1406: More rapid surfacing, more at surface than below, coming up in phalanxes, several throw noses out. 7 men astern handling roll up, one man on watch, one on winch, one ponga. A marlin in net.

1410: Distinct subgroup structure, speed of groups varies, size varies from 2-3 to 12, 70 yards from us. Whole segments of school facing same direction, while other segments go in opposite direction.

1425: Net 200 ft. circle. Tight mill, as far as they can get and still maintain 20 yd. to corkline, subgroups together, oriented away from speedboat, first fish.

1427: Jim Coe jumps in. Fish within 15 yards of rail, marlin at net margin along net margin.

1430: Porps still in same position. Breaths explosive and obvious, spray of water with each.

1434: Good backdown configuration. 120 yard finger, porps out oward end. Chite marked by three buoys in two sets.

1441: Porps clustered at three buoys 20 yards from end of lobe.

1442: Animals at corks, maneuvered to end of channel, some going over. Almost immediately there's a release there begin long swift leaps and racing away. Jim Coe helps last few over corks. Fish out to end of backdown channel, easy to make a mistake. Ponga boat operators slap channel with ropes to drive fish back. 45 tons. 115-120 animals counted. No deaths.

October 15, 1976

Enroute Rendezvous with David Starr Jordan, 113W, 13N

Finally, at 10 this morning we made contact with the *Jordan* and laid plas for a meeting tomorrow morning early. We were able to lay their concerns to rest about plans (most of the details had been left unresolved when we went to sea, and the planning has been done here, between the four of us in charge, as it should be. But, nonetheless, the people on the *Jordan* rightfully had some concerns by being left in the dark.

The weather is flat—only a low, rolling swell sweeps across the glassy sea, under big puffs of cumulus; flat bottomed and often dark-skirted with rain. There have been very few birds today—a few boobies and a few petrels. Two young masked boobies circled us for a time, taking advantage of our propensity for flushing out flying fish. These swift birds watched as the fish burst from the water then flew in their wake, often catching them in midflight. I saw one caught just as it burst from the water, the bird having chased it through the water surface.

One killer passed us today—I find Bill Perrin has many records from the fleet in this area, and has seen them take a spotter in the wake of one ship on the tuna grounds. I had considered them rare in the tropics, but it's the more likely circumstance—they're rare or absent in areas of low productivity and these are rich seas. A couple of spotter schools were passed, unattended by birds, and Manuel dismissed them as not being worthy of being set upon. I was ready to let him take another set, and we may yet, because we will reach the rendezvous point this evening and there is plenty of time for the fishermen to make a buck. It makes them happy not to pass up fish, and it educates us—as long as it doesn't hold up our program.

We will have a meeting first thing, on our ship, and then quickly go to set No. 1, which is a water set, for acoustic calibration. This involves dropping a hydrophone from the helicopter, and making a set around it, and other details.

The crew loosens up. There is a language barrier with a number of them—many came from the Azores in their youth and all rattle on in incomprehensible Portuguese. But, we washed dishes last night, and make jokes with them when we can, and tend to our business, indicating we're here to do a job, just as they are, and they appreciate that. Jim's a great asset. He knows the fleet well, and has their confidence, saving porpoises, helping where he can, and such. I've been making progress too, but haven't been up to par, with my belly ache, and then my position makes it harder too, but, in time we'll get to know one another. Warren is amazing. In his very quiet way he knows about most of what is going on, and I suspect the fact that he's pretty grossly overweight doesn't make

any difference here, as a number of the crew are the same way. Sandy, the very sharp engineer is absolutely mountainous—sitting propped up in his corner by the coffee maker at meals, with one arm on the coffee bench and his big body leaning on both walls of the corner.

Last night the roll-up turned out to be a bear. It was very long and when rolled through the block they couldn't get it undone—the lead line all tangled with the rings and ring hangings. The net had to be lifted up in sections and manhandled by as many as 7 men to pull it loose. At dinner they were all despondent, thinking it could only be undone on a dock somewhere (Socorro Island?) but at some time after 11 PM a cheer went up and they had solved it. Everyone was covered with grease and dirt from the cables. There was little thought about food—Pope, the cook, had the noon meal ready about five times, but no one came in. I guess he gets used to that. He's a little busy bird-like man with an Adolph Menjou moustache (his real name is Alphonse), and thus far he has been unfailingly cheerful.

This vast comfortable ship is a real working vessel when she gets going. Every piece of gear has its place and is well planned. For the most part the crew know what they are doing, and get yelled at venomously if they don't. I'm impressed with them.

It's hard to realize one is at sea. You can walk the corridors without threading a hand on the bulkhead. The roll is only slightly apparent. We've had some winds and modest seas and it never seemed to affect us. I'll write further when we hit real seas and winds, which we pretty surely will have somewhere along the line.

I finished *Shogun* today and can turn my attentions elsewhere . . . a bloody book, but engaging.

October 16, 1976

Rendezvous with D. S. Jordan

We met the *David Starr Jordan* and early in the morning called over (about 7 AM) to find that their union radio operator doesn't operate before 7:30, and that one can't get them to put a boat in the water without 90 minutes notice. The crew of the *Eliz CJ* was scornful indeed, in loud and obscene terms, largely clouded in Portuguese idiom. But, finally we did get through and asked everyone to come aboard our vessel. Some had been pretty seasick—such as Bill Rogers, and Dr. Aubrey, the bioacoustician, but were now coming around. They had spent 2½ days at Clarion Island and had a good time there walking beaches, finding a turtle breeding colony, catching the big *Urosaurus* that lives there. Ed Mitchell was along and recording everything, as usual. He walks with a tape recorder in one hand, a little 35 mm camera in the other, a notebook in one pocket, a watch strung around his neck, and a drawing pen also slung around his neck. Nothing goes unrecorded.

Our meeting was a good one, settling many issues for everyone, and getting the program on track. The two photographers spent much of last year working with Cousteau and seem like pros. I distributed various orders, concerning film, picture taking, safety, and had some good talks with Dave Holts our man in charge on the *Jordan*. He's a fine guy and seems like a good choice there. I also spent some time with Bill Rogers, finding him relieved about fears over safety in the net, but happy that I tried to put safety as a first consideration and data wholly secondary.

Dave will get a tender from the *Jordan* and thus will be able to act directly as a buddy to Bill, which, I must say relieves me greatly. I, too, had been worrying a bit about that operation inside the net. The forces are great, and the chance to tangle serious, especially in the areas with 4½ inch mesh.

The following is a log of the Acoustic Calibration Net set. It consisted of the whaler from the *Jordan* going off a distance, deploying a hydrophone and a sonabuoy (broadcasting to the *Jordan*, where Ljungblud was recording), with first the ponga boats circling the skiff, and then the *Elizabeth C.J.*, which then set on the skiff. It stayed in the net for a time and then went over the corkline to record ahead and on the opposite side of the *Eliz. CJ* before tethering to the corkline at the backdown area until backdown was completed. No divers were in the water, and no attempt made to observe otherwise.

I plan to observe the tuna porpoise bond later from the helicopter and spent a little time talking to Joe Jorge about it. He describes it this way—at sea the tuna may be seen in groups below and behind the porpoises, or sometimes to the sides. One sees them by the brassy color they give the water, and by the glints from their bellies as they roll in swimming. He demands that I estimate the tonnage for him when I go up. In the net he says they follow the porpoise, and if there is a lot of tuna they may form a circle around the porpoises as they swim back and forth. Only as the net shallows do they leave because they are deeper and the porpoises tend to slide into the shallow end of the net. The tuna hit the net as it slopes inward, and sometimes become frightened and leave the porps, but not until very very late (in backdown, actually).

He also describes aggregation behavior, mentioning that tuna will gather around tiny bits of flotsam like half coconut shells, styrofoam coffee cups, a dead porpoise, a sick porpoise, whales, blocks of wood. The tonnage is not correlated with the size of the surface object at all, but one may pick up huge hauls from such things—120 tons sometimes. How very peculiar. I think the aggregation process itself may give a clue to what is going on—it may be a serial thing, in which the block of wood collects invertebrates, larvae, or whatever, and these collect small fish, and these other fish, or birds, or whatever, and finally tuna, who may attract each other. The functionality is obscure.

Well, I think we have good people here, and think things will come along.

The news came through about the closing of the fishery due to exceeding the porpoise kill quota—as of October 22nd and 0001 hrs. the fishery is closed and the boats can either take the observers ashore at various ports and cease porpoise fishing, or they can leave them aboard and cease porpoise fishing. the fleet is put in a peculiar stance—one that invites—almost demands, poaching. The foreigners, especially, I am told, Mexico, continue to porpoise fish, and kill porpoises in large numbers, and even violate the CYRA in the process. Our people are thus penalized in competition with them. Our people also face a peculiar situation in which the best boats—the ones that are careful and skillful and don't kill many porpoises are being penalized by the poorer boats who don't care, or don't know how to save the animals. The rule carries with it no incentive to do better, only to jump ship and go foreign. I think there is a way that could reverse some aspects of this. If, for example, the US fleet was classified according to kill rate into two classes of boats—first and second class, then it might be possible to divide the quota so that everyone could fish on porpoise through, say ¾ of the quota, while only first-class boats were allowed to fish on the last ¼ of the quota. This would provide great incentive

for all boats to improve their performance, and I think would uncover dozens of little stratagems for saving the porpoise that only the fishermen understand. We could have a race to perform better, and there would probably be an economic weeding of the fleet into better boats. There would also be much peer group pressure generated that would drive everyone. The quota would come to go farther and the porpoise schools would come to benefit, the US season would be extended, and I would hope, the example of the US fleet and the methods it develops could be exported.

The designation of the Interamerican Tropical Tuna Commission to house the international effort to save the porpoise is another example of putting the wolves in the henhouse. Above all organizations the IATTC is fish oriented, and bitter at NMFS for its work and restrictions on behalf of the porpoise. Wouldn't it be better to somehow divide the IATTC into porpoise and fish arms, and give each some control, but not total control? Thus, if the tuna arm became strongest the other would have recourse? It seems to me that setting these units against each other, with power to regulate take, would be better than hoping for some miraculous transformation of IATTC into a group that gives a damn about porpoises.

Well, things are loosening up. I can joke with some of the guys now, and not have them fall flat. It's coming. It's coming. I don't know if they will ever realize what my place is, or the place of Bill Perrin or Jim or Warren, but maybe it's better this way. It's too complicated to tell them what you are fighting for, and why their representation in congress is brave, and foolish, and why they're losing the battle, both at home and at the international level, and why the bureaucracy does what it does, and how the whole thing fits in the world as it is becoming. A complicated skein, and beyond most here, maybe all. No wonder some say, "Let's get in and get while the gettin's good, cause it ain't gonna be here tomorrow."

Clipperton Island, Pacific

We're lying to in a flat calm night after a good and complicated day. The night is dead calm and the ship is waiting for the morning to come so they can go fishing and still rendezvous with the *Jordan* early.

The day has been consumed with the orientation set, and a good one it was too. We had had a review the night before of what was coming and the morning we had a change of personnel, with me going over to the *Jordan* because I was to work on the glass-bottom boat when the time came for a set. This was to be an orientation set in which various people could learn their duties. The next one after that will be a tagging set, followed by two sets on the schools we have tagged.

The *Jordan* is built on the design of an older tuna seiner—with a lot of deck house going up to a flying bridge where the spotter scopes are mounted. These are 120X scopes held in bungee cord so that they take up much of the roll of the ship and it is pretty easy to scan the horizon with them. But, like all glasses, they make me seasick in a remarkably fast time. Ahead was the *Elizabeth C.J.*, looking remarkably sharky—very slim and racy, with her big skiff tucked up aft on the net pile.

October 17, 1976

Clipperton Island, Mexico

The *Jordan* is very neat, very well equipped and I found the crew friendly. One of my old shipmates, McLaughlin from the old Scripps days was aboard and we had a good time talking. He was one of the group in Turtle Bay, years ago, who got in a big hassle on the beach, got pretty drunk and came back to the ship all eight of them standing up in the skiff with about 2 in. of freeboard, singing at the top of their lungs. ("She had a dark and roving eye yi yi.")

We followed the *Elizabeth C.J.* most of the morning, had a big lunch and then in the afternoon the little bug helicopter found schools of fish and porpoise and they decided to make a set. By that time we were ready to do our work. I will go out in the glassbottomed boat to observe in the net (really to see how well the BB works). It looked nice—a Boston whaler with a compartment below with plexiglas in front so one can lay flat with your eyes about two ft. below the water. It take a 30-horse engine to push it along but it moves nicely.

Anyway, the following is a log of the set.

1354: Ponga boats, and porpoises passed the *Eliz C.J.* Lots of birds, mostly boobies (masked, browns, red-foot)

1403: Net in the water

1450: Glassbottom boat halfway across the corkline near future backdown channel; large school of porpoises, maybe 500 animals. Rogers with trouble with face plate. Porpoises near the *Eliz C.J.* and being driven over to the side near her by our activity. Dave Holts in, with snorkle. Leak in viewing chamber.

1459: We come over cork line moving in net with a single oar. Moving toward central area of net. Tuna seen. Swimming as deep as I can see—75 ft. or so, circling, coming within a few ft. of net. Porps aggregating near *Eliz C.J.* Ponga boat working to prevent collapse.

1508: Toward center of net, tuna moving as far down as I can see, circling. Plankton in water, can see about 60 ft. Porps swimming in tight groups, facing in same direction, all spotters, diving down and emitting long streams of bubbles. Tuna in the area do not seem to be following the porpoises.

1515: Have to leave the net, the corkline is moving so rapidly and under such tension that we can't get glassbottom boat over it, have to move to opposite corkline. Porpoises swimming deeply in backdown channel—much vocalization, nearly every animal is squeaking and emitting long streams of bubbles in the process. All spotters. Animal sinking tail first. Subgroup structure very obvious. Occasional individual animals. At time a sort of warp and woof can be seen, with subgroups swimming through one another in opposite directions (all diving or rising at a slant). Most animals are nearly vertical. Independent school of tuna going by, much more rapidly.

1516: One porp hanging at the surface with tail hanging down. White tips on spotter snout very evident. Dark genital spot very obvious. Some animals below me lying [?], not in trouble, but lying on the slope of the [?] below me. Some animals sinking tail first, not in any trouble. It seems more like a frustration maneuver. Spotters being swept past me hanging nearly vertically. Tunas swimming swiftly among them without obvious reaction. Some porps lay very deep down on the net—without the panel they would probably die, but they truly are not drowning, only frustrated. Spinners seen. Swift tuna go by, purposefully.

1520: Spinners going by, saw one swim into another and stun the other, partially knocked out, sank and then recovered. Mass of tuna going by.

1523: No more porps seen. Dense fish schools, can see opposite wall of net now visible.

1525: Channel now very narrow but fish still go by. Dave Holts: adults and subadults, not neonates, would have less than a foot interanimal distance, while coming up to take a blow, and then continuing on another dive. Really close together.

1526: Net bellied out under us. Tuna with bright yellow corselet fin and a gold lateral bar with an iridescent blue line above and the sharp long anal, ventral fins all bright lemon yellow—obvious signal systems as they are the things one sees farthest away. Very bright, almost fluorescent. Tuna travel with mouths open, as one would expect. Seven dead porps. One spinner and six spotters, caught at three bow bunch.

A few more general observations are in order. First, the reaction of the porpoise school seems to be a sort of averaging of the disturbances from all directions. With us thrashing around out in the net away from the *Elizabeth C.J.* we drove the porpoises toward the seiner. Every new disturbance of divers, skiffs, motors, whatever, tended to deform the school and move it. We succeeded in forcing the porpoise school out of the backdown channel and Manuel was screaming Portuguese oaths from the bridge. The porpoises that died were caught in the third bow bunch of corks, probably because of our actions. Otherwise the porpoises would have never approached these corks and entanglements.

The vertical and passive hanging of the spotter, I suspect, is their salvation in comparison with the spinner. They are swept out the backdown channel passively, many quite deep in the net lying passively on the webbing. I'd guess that the new Bold Contender system is a great help as much as anything because it provides a rampway up which they can slip. The new modification, especially, which allows the animals to pass out of the net without meeting any angles or corners—nothing but taut webbing.

Spinners, on the other hand, dart about and swim much more horizontally, in my brief observation, thus ramming the net, and if it can catch them it does. This swimming loses its coordination once the animals are in the backdown channel, at least in large part. The blow I saw one spinner deliver to another seemed inadvertent, but it was hard enough to temporarily stun the recipient.

I am curious about the startle reaction of porpoises at the exit from the net, as they determine they are free. How do they know they are free? Are they echolocating? Do they simply sink deeply enough that they find there is no net beneath them? What is it about their environment or senses that says, "Aha, there's no net around me," and then they take off. If we know this it might be possible to design ways of generating that same adaptive flight response in animals in the net, to, say, let them flee through a depressed section of corkline from which the tuna are somehow excluded.

The glassbottom boat is fine, but its glass area is vulnerable and there are problems in removing the ballast without making it unstable. On a shore, I'd take it into shallow water and take ballast out as the boat was inched into shallow water. Damn, I wish they'd built it like I asked.

[Drawing of Clipperton Island]

October 18, 1976

Clipperton Island, Off Mexico

Last night we moved down toward Clipperton, with the notion that the crew would go fishing at dawn, and then return to meet the *Jordan*. I thought they would go in the pongas, but lo and behold, they used the big net skiff, and everyone could have gone, including me. I was pretty tired and welcomed the sleep since I'd been at notes until about 11 the night before. But I did rouse myself just as dawn was streaking the horizon to look at Clipperton. I could see the net skiff moving in close to shore. The island is almost circular, with a few scattered palms and a brackish interior lagoon (with fish, I'm told), and in two places what look like rock piles sticking up maybe 70 feet. There was one wreck jutting from the sand. I'd guess it's about five miles across, a thin circular ribbon of sand that must be awash in a hurricane. I think it's French. A lonely lonely spot.

The crew and our people came back with an enormous load of fish—mostly serranids, *Dermatolepis* the major form, a couple of Rainbow runners, a few *Ulva*, one Chirritos, an eel, a helluva pile of fish in two hours.

Later in the day, we rendezvoused with the *Jordan* (later than we had planed) and began to search for animals for a tagging set. Not long afterward we located a school of about 600 animals or so, mostly spotters and some spinners. We had spent the morning getting ready, Bill Rogers had worked most of the night on tags, and we worked hard to crimp some loose wire ends on them that would create havoc on the animals, and to cover them with plastic tape. These are braided in three or four colors, and have numbers. At the same time four radio tags were readied, including one depth of dive tag. Things got a bit frantic toward the last as we waited for skiffs from the *Jordan* to come over to pick up our tagging teams, who would then tie up on the corkline. One of the engines wouldn't start, and the skiff for Tagging team A was lying unused at the side of the *Jordan*. A big of frantic calling and we got it freed so we could run alongside and tow it around to the backdown area. Later one of the Avon's engines gave out and that too had to be towed. Nonetheless, we were able to get all skiffs tied alongside the backdown channel and prior to backdown itself. Fortunately it was a nice calm day, cumulus clouds on the horizon, and about a five-ft. swell running with no wind. As backdown approached we were all ready, tags beginning to be lined up and numbers and colors recorded prior to being placed in animals. Bill leaned over the bow, his knees on the rough non-skid strips sandpapering them down unmercifully. I recorded, while Warren prepared tags and called off numbers and colors to me. It got pretty hectic but nonetheless we got out all but one of our tags, in contrast to the other team that had 22 left. The radio tags were successfully placed, and the *Jordan* began recordings. I think three animals were lost and some 25 tons of tuna taken, which keeps the whole operation well above the fleet average. There were estimated to be some animals in the net. All in all a useful operation, and now the *Jordan* is tracking the radiotagged porpoises and we plan to set on them tomorrow.

Tonight a 38th birthday party for Joe Jorge, a noisy, gregarious, skillful guy who has the respect of everyone on board. He works like hell, and sets a beautiful net, and doesn't kill many porpoises. He knows where the fish are, how to see them, laughs when five tons go over the net, but pushes onward to more and better sets. A fine fisherman.

I've been interested in the way a set works, because apparently no other fishermen, other than the Americans and a few of the Mexicans can make porpoise fishing work. Here's what I see. The school is sighted, usually by birds over the horizon,

and on this boat, by helicopter. Often the skipper goes up in the helicopter and makes the set by radio, or from the mast. Everything is done at high volume with speakers blaring all over the ship. There's almost no escape from them and I suspect all these guys suffer from a hearing decrement. They play their audio on the films they show at full blast, and the winches, etc., outboards, etc., make ferocious amounts of noise. Anyway, once the school is located they look for fish. If they see them they move in, launch the speedboats (on this vessel I've never heard the word Ponga). These deploy out to the side of the vessel, going in the opposite direction from it. They deploy in a J, with the rear boats forming the hook of the J, and the two boats the straight part. The porpoises are between the J and the *Elizabeth C.J.*

The speedboats and the *Elizabeth CJ* at the start are maybe a mile apart or a little more. The lead speedboat feints in against the running school, which may be diffuse, or more likely running into long, broken groups.

October 19, 1976

At Sea

The man running the set causes the J, and the *Eliz CJ* to sweep around these animals as the chase continues, gradually, gradually, over many minutes time, turning in on them. This is done by feinting at the running school with the lead boat (but never running in front of them), so that the porpoises run in a broad arc, gradually turning. The *Eliz CJ* gradually turns too, in a slow spiral that may take an hour from start of the run to the set, inward ever inward on the animals. She acts as a noise block to the animals retreating in her direction. The relative positions between the *Eliz CJ* and the speedboats never changes, but instead the whole group rotates and tightens as the porpoises turn. Finally, when the *Eliz CJ* has spiralled into the extent that the whole group of boats equals the diameter of the net when set, she lets go her net. This then blocks the porpoise flight from that direction while the boats continue to block it on all other sides. The porpoises then sense the net, and with the feinting lead speedboat no longer harrying them, with noise at the rear and side, they slow and mill, while the set finishes encirclement. Speedboats stay outside the open part of the net until the net skiff pulls it along the side of the *Eliz C.J.* and the purse lines from both sides are put on the winches. [Drawing.]

We carried out a tagging set quite successfully, in spite of some glitches. Four radiotags were placed—one depth of dive and three radios only. And about 60 dart tags were placed from two skiffs. The skiffs, Boston whalers from the *Jordan* were tied off on the corkline alongside the backdown channel, on each side, with the radiotag Avon raft at the apex of the backdown channel.

Our dart tagging team consisted of Bill Perrin, Warren Stuntz and myself. Perrin placed the tags, Warren loaded them, and I recorded. It was frantic. Bill shouted out the species, age class, sex, while Warren gave me the color of tags (up to four colors) and the number. Only because he sacked up as many in advance as he could was I able to keep the recording straight. We placed all but one tag. Estimates of 200-300 animals, mostly spotters, were given (25 spinners). The radiotag team got their radios out, and we repaired from the scene, satisfied. The ship took about 28 tons of tuna. No sharks. But, two of the motors hadn't worked (the skiffs had to be towed in at the least minute), and now, this morning the depth of dive transmitter has cut out, and one ADF has quit. And

the signals reported from the *Jordan* are very faint and they have called us off our fishing to see if we can help locate the school. We're moving in at this time, our skipper grumbling but complying.

The weather has been holding beautifully, light breezes, puffy cumulus and an occasional rain squal, but not too many, and about a 4-5 ft. swell. Easy working in the water. I forgot to make a note of a couple of behavior patterns seen by Joe Thompson and his son (also Joe Thompson). They saw a group of spotters facing each other, mouthing and nipping at one another as the net was being closed down (before backdown) and Joe Sr. had one adult spinner come at him with its jaws nipping, rushing at his throat. Joe fended the animal off with the camera, but did not think he got photos of the incident. He did feel he had photographed the nipping group. Joe Sr. also mentioned that he had observed tiers of animals in the net, a surface layer, a layer below it containing something like 1.5X as many animals per unit volume as the surface, and a third tier, deeper still, with maybe 2/3 the density of animals as the surface. These groups rotated to the surface to breathe.

I wonder if some of the splashing and thrashing that seems to come up in frequency as the net comes in represents this release of aggression, and if the aggression may in turn be released by crowding of normal school patterns upon one another. In other words, the structure of a normal school I expect to be ordered by aggressive encounters between animals. In this way mother-young groups might be rounded up and ordered, spacing of individuals and subgroups regulated, and perhaps school direction determined. When animals are crowded these patterns start to disappear and aggression rises? Who is being aggressive? Who is the recipient?

The following are tape notes from Experimental Set 9. The tagging set of yesterday went off well enough with most tags placed and four radiotags out, including one depth of dive. A frantic exercise at the end of the backdown channel with Bill Perrin tagging, me recording, and Warren Stuntz loading tags and shouting out numbers to me. After the set, which netted about another 15 tons of tuna, the *Jordan* team tracked the animals for much of the night, but lost the regular radio tags early, only keeping the depth of dive transmitter in contact. At about 3:15 AM the surfacing rate speeded, as if the animal was breathing fast, and then a couple of fitful signals and then nothing. I think it died, and suspect the first radios failed because of a flexible antenna that lets the antenna get swept backward as the animal swims. I doubt that OAR has tested them on a porpoise. Anyway, nothing, and no sighting of the animal. We tried all day to reacquire the signals using the helicopter and both boats. No luck. In the afternoon we let the *Elizabeth C.J.* make a plain fishing set, and it ended well after dark. Here are the notes.

1718: Speed boats in water adj to reasonably good-sized school of mostly spotters.

1739: Porpoise already beginning to mill. At 1/3 net.

1735: 1/2 net, porps well into net now, they are trapped. Swimming toward the mesh, backslap, animals moved at first swiftly toward the net when 200-300 yards slowed down at 150 yards of net, backslap, slowing, don't approach any closer, blowing unobtrusively, dense school 75 yards from net, as far away from us as they can get. Net almost closed. Constant tail slaps from a single animal across the 300 yard diameter. Net skiff moving direction under me. Purse line being taken in below me. About 100 yards of

net remain to be taken in. Speed boats are in the midst of the opening. Porps are as far away as they can get. Animals in tight school slowly.

1740: Swimming in a mill, rotary, subgroups going the same direction but other groups going the opposite direction. Approx 80 yards from far corkline. To the left of the backdown buoy. Slow swimming, simple forward locomotion, recognizable subgroups. About 150-200 animals, backslap.

1745: Net closed. Purse lines coming in rapidly. Tail slaps and head slaps, school seems more agitated, suspect rings make noise as purse lines come in.

1749: Animals all swimming in one direction toward the bow of the *Elizabeth C.J.*, as far away from the vessel as they can get. Sun is setting, clouds are all pink, reasonably bright. Will be dusk before backdown.

1752: Animals still all moving in the same direction (indicates an underwater mill or return). I saw a couple of head outs. One about up to pectorals. Even though school moves individually toward bow, the school as a whole doesn't move. Some animals at leading edge seen turning. Increasing number of animals throwing their flukes as they dive. Graduated tail slaps.

1754: Backdown channel almost in position. Net still circular. Bow bunches, but cork line simply curving.

1757: Some confusion, animals running into another, and white water.

1759: Nose outs increasing. Almost with rings in. May get pretty dark.

1800: Backslap.

1801: Struggle, animal throwing its flukes sideways, as if trying to perform tail slap but missing the water. Racing near corkline. Thrashing. School strung out along corkline 30 yards out.

1802: One lone tern seen. Porps spread out 30 yards from corkline in long band. Moving slower. Occasional subgroups.

1806: Considerable numbers of relatively explosive breaths.

1807: Considerable numbers of nose outs as if the hanging behavior is coming now.

1808: Animals against the corkline in some places, but as usual most are 30 yards away.

1812: *Dave S Jordan* coming around the stern.

1814: Quite a number of individually moving animals.

1815: Rings up. About to go on ring stripper. Duskish. Masthead light shed nice bright patch on water. Aggressive encounter, animals ran into each other and much white water.

1815.45: Melee, many nose-outs, lying doggo in the water, milling continuing. Animal poked head out of water and wiggled as if beating flukes. Many toward bow.

1819: Animals in long narrow group, most conc. near backdown area, but extending 80 yards or more toward stern of vessel. A 30-yd. gap still evident. Fish against the corkline.

1829: Blind set in that helicopter was on deck.

1830: Porps conc. in direct area of backdown channel. Net half the length of the ship, 80 yards out to far corkline. Still no major indications of fish. Porps in tight group right at backdown channel. In subgroups that dove rather agitatedly as net shrinks.

1835: Porps in very tight group as we move into backdown. So far, a perfect maneuver. Hard to see if Manny is going to lose fish. No bends in backdown channel. Frequently breaking surface. Staying away from both sides of channel, and from skiffs. Whitetip outside the net, swimming under backdown channel. 6 ft.

1841: Some porps are out already. Can see them breaking water beyond the net. Leaps start 30 yards or more from net. Most porps out, a few left.

1843: Quite a school of tuna up toward us, all breaking water in close to the boat. Tremendous thrashing of big fish up near vessel. Backdown continues. Milling mob of fish all swimming up against the current in disoriented fashion, many on their sides over the mesh. Hard to see in the net.

1845: Still backing down. Fish clear out toward skiffs. One crew member jumps in and walks on net out toward backdown area. Channel 25 ft. across.

1848: Backdown seems complete. One speedboat member seems to have fallen in at the end of the backdown channel. He's out and OK. Backdown channel completely closes.

1856: A few porps located at very end of channel, but now they're out.

1900: All out.

October 20, 1976

At Sea

I went to the *Jordan* early to prepare for a standard set, to do some observations on the glass-bottom boat of the backdown channel. Dave Holts and Bill Rogers are scheduled to dive in the net, Joe Thompson is scheduled to fly over the set in the helicopter, both before and after, Bill Perrin and Ed Mitchell are watching aerial behavior, Jim Coe will watch net and school shape.

At any rate, at about 11:00 a school was sighted, the helicopter put up. The following is a log of the set:

1148: Helicopter over school. Supposedly good fish; this set was interposed because we were unable to recover our tagged animals from set #3, yesterday. *Eliz C.J.* ahead a mile standing by waiting for photographers to get their photos of the unnetted school from directly above. Will launch diving team etc. as soon as the net is out.

The day is very calm, flat, hot, scattered clouds on horizon, no rain squalls, 9 kt. breeze, scattered white caps, 6-7 ft. swell, ESE wind.

12:10: Speedboats in water, helicopter over school.

1246: Net let go.

1251: Set complete, we come up behind. A very long period getting our boats in the water. The bosun moves like the second coming of Christ. He literally wouldn't start on the launching of the glass-bottom boat until the bowline had been cast off from the acoustic skiff, even though there were three guys standing around.

1321: 30 At corkline of backdown channel. Tied GB up with about 2/3 of bow into net at the middle of the backdown channel.

1327: Divers skiff (Avon) now in net and circling around the bow portion of the corkline. GB tied off. Nothing to see underwater from my vantage point, but net walls going down out of sight. Porps a long way off (80 yards est) in center of net. Est 250 animals, mostly spotters. Helicopter came over—100 ft. Animals reacted by moving toward the *Eliz C.J.* Much noise and downdraft. Porps in a mill in which they swim

parallel to far corkline (from *Eliz CJ*) dive at one end and mill back again underwater. Some throwing their tail stock into the air and thrusting out their heads.

1328: No animals seen underwater.

1335: I saw my first porpoises off in the distance just at the very edge of vision. They are beginning to move closer to backdown channel. Acoustic skiff has left for some technical reason, leaving me alone at end of backdown channel. Divers at center of porpoise school, with school forming a circle around them. Many are back of divers toward *Eliz CJ*, (I call divers and tell them to move closer to *Eliz CJ*).

I'm in an increasing lobe of net with animals out in front about 70 yards. Can't be seen from GB.

1337: Animals forming an almost perfect circle around divers again. A few animals, including a very young spotter, still not adequate viewing. Still see an occasional animal that must be on the periphery of the school diving near me.

1340: Just at limits of vision can see animals. There's a rather large lobe of net at the end of which is located the BB. Porpoises don't like to enter such lobes, so little can be seen. Some animals (spotters) right ahead of me, swimming nearly vertically downward (probably 70 deg.), going down perhaps 30 ft. below the surface, turning and twisting spirally as they rise to the surface again, swimming around one another—a group of 7-8 animals (spotters). Now another very tight group of 7-8 spotters in area, and some drifting singles, or slowly swimming ones. All swimming, except for some by spinners, is very slow. Tiers of animals evident, a lower tier which I believe to be spinners and an upper tier almost wholly or wholly spotters at my level or just below me. An adult male spinner with a large white splotch on r. side of its tail above midline (can see enlarged postanal hump). Mostly spinners in front of me now—some as much as 80-100 ft. below me at limits of vision. Some directly below me coming very close to net (10-20 ft.)—spinners probably.

1343: Quite a layer of slaps 70 ft. below me, more or less continuous but scattered. Tellya what!! It's mighty goddam hot in here.

1345: Porps at very limits of vision swimming near vertically, two animals spiralling upward in their peculiar arabesque. Another group (5-6) diving absolutely vertically so far as I can see, down to about 35 ft., levelling off and fading into distance.

1346: Backdown buoys coming up to power block, can see cork with 250 ft. to go. No major groups of porpoises. Ponga boats coming up (2) to help tend backdown channel. Animals still conc. in center of net, at very limits of vision—maybe 100 ft. away.

1348: Helicopter passed 100 ft. overhead, helluva racket, must be terrifying to animals.

1350: Backdown corks aboard. Backdown about to begin. I can see a few animals at limits of vision. Some animals very deep in net—just as deep as I can see (70 ft.?). Helicopter noises. Spinners deep below in a milling horizontal group, all pointing the same direction like a fish school. Moving very slowly. Some tuna evident now. Porps way below tuna in very tight mill, deep down backdown channel. Spotted porpoises near surface following one another to surface in twisting mode. Most spotters move nearly vertically (70-90 deg.) either up or down. Mother-young pair of spotters, baby pure color and in clear assisted locomotion mode—tight up against mother's dorsal surface, a lone spinner goes by, phonating. A whole group (spotters) (6-10) in nearly vertical arabesque

to surface. some others hanging more vertically down 30-50 ft., phonating (bubbles streaming from blowholes for a second or so). I can see mother-young pairs of spotters swimming below me in perfect unison.

Helicopter over me—scarcely any reaction. Backdown underway. Animals are being pushed up against the net by strong current. But able to swim out of it all right. Net slopes in a curve from nearly vertical at corks curving down three ft. to 80 deg., 70 deg. at 7 ft., to 60 deg. deeper below me. Animals are pressed against the webbing, but not very tightly. An animal can be carried along if it chooses not to move, but modest movements break it free and allow it to move up. They wiggle up the slope to the corkline, and are sluiced over. I'm surrounded by porpoises now. They are in the process of going over the line. They hit the bottom of the corks and struggle over. (Interrupted by a call from the speedboat in choice Portuguese-English via the bridge, the freight of which is that I'm about to sink and the skiff is holding up the corks for the backdown isn't going as normal. Remember I've lashed the corks to both sides of the skiff).

1355: Cut the lines loose. They were taut as fiddlestrings and snapped away with the first touch of the knife. The skiff wasn't down though, there's too much buoyance. I'd secured the bow painter to the corkline and thus could let myself out a distance from the channel to see animals come over it. I was tied up maybe 15-20 ft. beyond the corkline which now began to depress in a rather deep arc. One of the first over was a spinner mother-young pair. The baby, a plain-patterned near-newborn, was in a state of semi-shock. It swam listlessly and undirectly while its mother hovered near. Other porpoises rocketed by, but the mother still stood by in front of me. Finally the baby began to stroke and rather swiftly put it in high gear and the pair raced off. They took off at an angle from the net opening and downward at about 35 degrees.

Animals pour in gouts out of the backdown channel, and like racehorses out of a gate, are in high gear even before fully out of the net at times, and all go under me at the 35 deg. angle downward. Subgroups structure is not evident at all—just individuals or groups individually getting the hell out of there, at the same 25-35 degree angle downward. With me no longer holding up with the GB I can see clearly the end on view of the backdown channel. It is about 20-30 ft. across and perhaps 6-7 ft. deep at its center—much deeper than I had expected from surface views. The current in this opening was considerable. Streams of salps and jellyfish showed it clearly as they sluiced up the net inside and poured out in a visible stream to dissipate some yards beyond the opening. The backdown persisted for what seemed like several minutes (my tape recorder quit). Not a tuna escaped that I saw. As the animals emerged one could see them readying for burst of speed and the long dive as they headed up over the corks and into the open sea. The impression I gained was that they knew freedom was ahead while they were still in the net, and that spotters helped their own case by taking it quietly, while the spinners, with their horizontal swimming could get into more trouble in net folds and simply by hitting the mesh. If the mesh were larger I'm sure they would be in trouble. Philippe Vergne reported that he thought he saw a group of five or so spinners dive through the rings earlier in the set, and come up outside among the skiffs, and stay near until backdown was done. [Drawings]

October 21, 1976
Clipperton Island

Another island for the life list. Today was Clipperton Island day. The weather was pretty foul outside, unfishable and the poor rolly old *Jordan* was doing her thing to the distress of the scientific party aboard, at least, so we headed in to the inadequate lee of Clipperton, which was about 10 miles away. Once there groups divided into those going fishing, and those going ashore. I chose the latter. It was an interesting day, with a bit of nail biting thrown in for good measure. We chose the landing place adjacent to Punta Croix (one searches in vain for a point at this location). Through the glasses we could see that a fringing reef ran along shore, behind which was a shallow maze of channels and coral or *Lithothamnion* mounds and projecting rocks, perhaps 200 yards broad, before one reached the beach. At the time we launched the surf broke on the outer edge, just as the island pediment dropped off into deep water. The ships stood offshore a thousand yards or so, and were in a hundred fathoms or more of water. Like most atolls this one drops precipitously down into deep water and holding ground for anchoring is sparse indeed, even if the island were big enough to offer real protection from the wind.

The speedboats took us just into the swell where the surf was about to hump up, and there we transferred to a little two-man rubber raft. Glen, the helicopter mechanic and I went in together. The paddles that Joe Battaglia had made for the operation were lost on the run before ours so we had to paddle by hand—slow business in the surf. Glen took the bow and I the stern. I double bagged and tied my camera in heavy plastic and tied it in the boat, and off we went. We got most of the way in uneventfully, and then one of those 7th or 8th waves caught us and swamped the raft with water. We paddled on, endlessly it seemed. Finally we bumped onto the *Lithothamnion* ridge (thank goodness for this unspiny stuff—coral would have been fatal). I was on my knees when we hit and bumped over the rocks through the thin rubber bottom—bumped the bejeezus out of one knee, which is swelled up a bit at this writing (next day). My Dodger's cap went flying and was lost. Unhitching the bags and my camera I could see that in spite of all precautions some water had made its way in—the pressure of waves in forcing water in is something. Guess I didn't have it well tightened or inflated. I'm told an inflated bag keeps the water out, while a collapsed one lets it in. Anyway, the camera took one slide and then quit.

I staggered up out of the water, bearing the bag with its little pool of salt water, and made for the shore over the tidal flat. A fascinating area too. Flattish mound-shaped rocks, all planed off at tidal level, and every inch covered with life—a band of tunicates banding the inshore edges of many rocks with a mottled white and pinkish, calcareous algae, extensive colonies of tiny (1/2-1/4 in.) anemones covering many feet of some rocks, and in between fish swimming in the channels—little black pomacentrids (with no white dorsal spot), butterfly fish, and many reef eels—a very light gray one being the most common. These two-ft. eels wriggled and flowed their ways in the shallow water almost everywhere one looked for any time. A bright orange and white smooth puffer cruised in front of me, and later I saw the brilliant iridescent blue ulua (*Caranx stellatus*) racing over the flats. Sea cucumbers were common with their respiratory trees expanded, most were black, with bits of white coral stuck to them, looking as if they had been dusted with flour.

I stumbled ashore, took my camera bag up under a small group of coconut palms nearby, undid the bags, drained out such water as I could and tried to assess the damage—no water inside lenses, but the battery case was full, and only one frame went

through before everything was dead. Too bad, the island is full of spectacular picture opportunities.

As I set the bags down under the low palms I noticed that everywhere were the bright orange land crabs—like a cancer crab, and about six in. across the pincers in the largest ones. They dug shallow burrows in the beach, under the fragmented coral that makes up most of the highest island, and under coconuts and other debris. I wondered what they ate, and whether they had to retreat periodically to salt water to wet their gills. For food, Bill Rogers and I found that they ate the green parts of palm fronds, running the individual veins through their mouth parts longitudinally. Few fallen fronds were left unstripped. Later, we found them feeding on cast booby feathers, running them the same way through the little clipping machines that left only the central shaft intact. Just before we left I wandered to the central brackish water lagoon and found them clustered in a speckled orange band along the water's edge, and even a few submerged below water, feeding on the fresh water algae that formed rafts there. The one on board ship ate meat, so I guess they will eat anything that stands still long enough, and to prove it, they began to nibble on me while I worked on my camera. I'd guess they would be a major menace at night, unless one had cots to repel them. Certainly a person sleeping on the ground would be inundated by them. They would crawl all over you, exploring, pulling parts of you, and your clothing toward their mouthparts. Why orange? Is it warning coloration? Warning for what? The grapsid crab of the Galapagos is orange too, almost the same hue, but it is delicious. If these are edible, one could scarcely want for food here, as the island is covered with tens of thousands of these crabs that wait only to be picked up. I saw one other species of land crab—a pinkish flatter and smaller form, that was very much less abundant. The crabs climbed everything—far up coconut palms, up planks and earth piles—anywhere they could go. What do they do when the hurricanes come and the island is inundated?

Inundated it is. It is a ring of coral fragments, and a lone fin of rock, around the edge of a spacious central lagoon. The coral is broken into pieces 3-4 in. long, with coral pebbles intermixed, pieces of the coral matrix that have been rolled in the surf into cobbles or pebbles, through which run rings or zones of growth, formed long before and broken off. Lower on the beach the coral flour forms the soft, almost powdery sand typical of coral atolls.

The waves obviously sweep over the entire island, save the fin, which projects nearly 70 ft. above sea level at Rocker Clipperton, and must be the only real refuge in a severe storm. One can see benches on both sides of this ring of land, formed when either the lagoon is high, or the waves break high on the shoreline. The slope of the beach varies from a gentle contour to piled coral fragments so steep one had to shuffle steps into the berm to climb its eight ft. height. Even so, quite an attempt at habitation has been made in the biggest palm grove on the island just west of Punta Croix. Here, amidst several hundred palms, are perhaps 7-8 buildings—a shower-lavatory, a big mess-office building maybe 250 ft. long with rooms on each side of a central aisle, and a double roof, and a theatre (the best preserved of all), the foundations of others including what may have been a generator plant. Now, a few years after the buildings were put up, they are rusting into oblivion. I'd guess they could still be salvaged in part, but they are dank tombs through which the rains come, and whose members are scaled with deep rust. In the galley, stainless sinks have resisted and the pots and pans still hang on the wall, some

old cans on the cupboard shelves, but the floor is slick with fetid mud, the air stagnant and damp, with crabs scuttling in the darkness. Outside the grove is filled with the downed skeletons of palm fronds, skeletons because the crabs have taken away every vestige of green.

The leaves have fallen so thickly that most places one cannot walk but only stumble and thrash along, over the fronds, amidst the fallen coconuts lying so densely that they are like huge ball bearings rolling under your feet. Above, the forest rocks with the shrieking calls and flapping of the noddy terns and boobies. Bill Rogers and I pursued some little lizards, and finally caught one in the coral rubble—probably the bronze skink, that successful traveler of the Pacific world that has made its way by flotsam probably, to many islands. Here it is dark brown, with a very long slender tail, that curls in loops like a wire worm when the animal buries itself in little burrows. Its scales are smooth and like other skinks, and its eyelid free. I believe I could see the movement of a nictating membrane, but could not be sure, and Frank Aubrey later told me he had seen an up-down movement of an eyelid. I gave him our specimen to preserve.

The central lagoon is vast, and I suspect the frequent rains have slid fresh water in such abundance across the salt that a fairly deep layer of potable water results. It's slightly brackish to the taste—maybe 5% salt or a little less. Maybe after one's intestines equilibrated one could live on it, but better, shallow wells in the coral would reach a freshwater lens and adequate water, I'm sure could easily be found. There must be a ring of such water around the entire island, and it must be replenished by percolation each time a rain passes. Rafts of green algae float in the lagoon, one at least like a *Nitella*, a feather boa freshwater form. The shores were littered with vegetation fragments like a thin soup, that turned everyone else away from tasting the water.

Birds, birds. These islets are often homes for fleets of sea birds, the flattops from which they launch their lives into the surrounding deep sea. I wondered yesterday to see flocks of cattle egrets flying by our ship out to sea, lit up by the boom lights, and looking so out of place here 600 or more miles to sea. But today we saw them standing alongside the lagoon. Bill Rogers is a capable ornithologist and together we wandered through a bird colony near the habitation. The birds, mostly brown and masked boobies, occupied a long bench on the lagoon side of the berm. They were obviously spaced, about 20 ft. between birds, or maybe a little less, being the average, and one could quickly tell why, as one masked boobie shrieked at another that dared to land too close.

Many had two eggs, white, sometimes stained with vague blotches of pink or brown. None that we noted had more than one chick. The chicks were in all age classes, from newly hatched naked little critters, about a handful in size, to ones just feathering out that stood as tall as their accompanying adult. They were protective of their young as we came up, and would not leave the nest until the last moment, usually even then not launching into flight—only the birds without nests flew at our arrival, and then sailed in on us, just above our heads, their flight magnificent and controlled, looking down on us from a foot or two out of reach, feathering their wings and spreading or shifting the tail feathers to stay threatening above us. Probably three calls were noted—and in my non-acoustic soul I find it hard to remember them. The brown boobies came in two color phases—one with a whitish head and neck grading into the chocolate brown of the neck and upper chest, where the belly white meets it at a sharp line. The feet are greenish yellow, to pale jade green. Another color phase sported an all-brown head, and seemingly

slightly lighter-colored feet, but I could not be sure of this. The masked boobies (which used to be red-footed boobies) are lovely white birds with yellowish bills, with a blue base, a black tail and wing primaries. They have pinkish or coral-colored feet. One color phase, seen occasionally, had pinkish bill color rather than yellow.

Several examples of the wonderfully stereotyped behavior of the adult-young pairs was seen. In the brown boobie, the young (half grown) sometimes put on a sort of spastic behavior, with the neck lolling to the side, and the wings held as if neural circuitry was in bad repair. But when I shoed the adult away the young regained its control and behaved exactly as a well-adjusted threatened young bird should. He glared at me, wings in place, with his remarkable binocular vision, eyes focused directly forward like a human's, or like a bittern, looking straight at me past his rapier bill. I suspect to get too close is to have that bill dart out and stab, probably at eyes, so I stood my distance. In another behavior a single adult masked booby postured, its head first down and then up in a grotesque stretching motion, not unlike the posturing of the gooney bird.

Bill saw a warbler on the island—perhaps an Audubon's, and together we puzzled over a bird that looked a bit like a tanager—a fairly heavy beak, that flew low to the ground in the palm grove. I thought the flight was a bit flycatcher-like, with little flirts upward as it landed, but had to admit the bill was too heavy and it did perch on low things. Yellowish green in color, with darker wings, a lighter throat, and not much else distinctive. Then, later, out by a lone palmlet on the berm top I saw what looked for all the world like the Nihoa millerbird, a little vireo-like bird, with a slim black bill, hopping about on downed fronds and peeking at me from behind things. It wasn't as nervous as a vireo or kinglet though. Don't know what it was. Oh yes, Bill and I also found an earthworm. Wonder how they fare when the hurricanes (chubascos) sluice water across the island? It must flood in shallow waves since the houses seem to have survived by being placed back of the berm on the slope down to the lagoon, and the large patches of *Ipomea* (beach morning glory) seem to survive only there. A wild sight, I'd guess, to be on the island then. A row of casuarinas had been planted at the edge of the grove and were doing less well. I'm suspicious that the colony was a phosphate mining group, because there were rails, and much machinery that might be used for such mining. (The buildings apparently were left by French missile tracking personnel, as part of the French Pacific missile range.)

The place is littered with flotsam, like most such remote shores—old planks, rope, netting, buoys, a few net floats (quickly scarfed up by the crew who went ashore), lots of purple glass, old rotting iron machinery, rails, barrels, old boilers, sheets of green copper, and so forth.

By the time we made our way back to the landing the tide had begun to come in. Water had flooded over most of the exposed rocks, and the waves were breaking a bit close in, humping up higher, I think, than when we came in. I wanted to get back to the boat as soon as possible to work on my camera, in hopes that I could save it for this trip, so took an early traverse out with Joe Thompson Jr. He's a taciturn, slim young man who is helping his father on this effort. We waded out, waist deep to the rocks at the edge of the break. By this time sharks (for which Clipperton is famous) had begun to come in over the reef flat and were skulking along parallel to the beach. As I waded out I stirred up much coral dust into the water, leaving a trail, and the local contingent of sharks quickly began to follow me, providing an eerie and uncomfortable retinue to have at one's back.

Needless to say, I turned around with considerable frequency to see who was nipping or intending to nip, at my heels. None did.

Anyway, we reached the raft, which was on a line run from shore to the offshore boat, jumped in, and very soon were being towed through the surf by the offshore speedboat. The method is quick but it doesn't allow for much finesse, and we fell victim by having a wall of a wave rise in front of us and crash down on us before we could cross it. I saw it coming and burrowed down in the raft and held on. It churned us mightily and threw my camera bags overboard (prudentially tied in so I retrieved them), but we were OK, and soon on board a speedboat that took me to the *Jordan*.

Bill Perrin had come back loaded with wonderful flotsam, a particular piece of joy for his junk-loving soul, Joe Battaglia, however, took the prize as he came in towing about five net floats, a bunch of net, and god knows what else. One could scarcely see the man. Ed Mitchell, too, came back with many mementos to keep him busy labeling. Ed is very systematic and collects everything—eyeballs of fish, anybody's bones, and so forth. Jim Coe didn't seem to have collected as much, but he is full of joy over the chance to go ashore.

I was pleased to visit the *Jordan* because it helps to have me move back and forth between the ships. The old time-honored tendency of sea voyages involving multiple ships continues to hold true. They tend to form cliques sharply defined by the distance between the vessels. It is quite difficult to have enough communication by radio to assuage this much, but a few beers aboard, a little time gassing with the cook, telling stories, revving up about the successes of the day, makes all the difference.

There's some fine folks on the *Jordan*, a considerable bit more seasickness than here (she rolls about 100% more) and the crew, in part, is unionized in attitude, while here it is a group who works any hours needed, any time of the night. Men of the *Jordan* crew, however, have been very helpful, but some, like my old friend Mac, just plain won't move unless given 90 minutes warning (to launch a boat, for instance) and deliberately move slowly when we need things to happen fast. I almost lost my cool during a recent launching while a set was going on, and we needed our observation teams in place. But I held on. It's much better to keep cool and take some percentage of what you want than to blow your top, feel briefly better, and then lose it all.

Frank Aubrey, head of the acoustic subprogram, has been marginally seasick almost the whole trip, I'm told, and he is one focus of this stress, coming up with new ways of doing things that have been already decided, trying to force me into doing things I don't want to do, or can't, and handing down firm edicts about this and that—like no more night meetings because it's unacceptable to make the trip between boats in the dark. So, we are faced with when or how to have necessary meetings. My solution is to take our crew, who are wholly willing to travel at night, across to the *Jordan* after the day's activity is over. We literally have no chance to do it during the day. Joe Thompson was uptight about getting his clean clothes rained on in one such crossing, so, we'll not ask him to do it again, but we'll just get rained on, and my crew, who are a good spirited functioning unit, will make the trek. This does point out a certain smallness of attitude to those on the *Jordan*, but I think this sort of subliminal rebuke might not hurt. At any rate, there isn't much time left anyway, before the *Jordan* goes in. (I've caught the virus in spite of previous inoculation.)

Both Steve Leatherwood and Don Ljungblud are being wonderfully cooperative. Steve saved my life after the dunking by providing me with a shot of cognac, and I'll probably never forget it. Don, who has one leg off at just below the hip, came ashore in the rubber boat, and we had to help him hop ashore across the reef, one of us under each arm. He then assembled himself on the beach, and walked off, his leg a bit soggy but otherwise OK. They've worked like hell, tracking long hours into the night, and next time I'll be on board to help with the watch. Together we've figured out that the OAR radio doesn't work a damn because of the limp antenna that probably doesn't rise up much during surfacing in a moving animal, so we developed a splint and taped it on and get twice the signal strength. Bill Rogers, who has been seasick most of the time, has worked like a Trojan and is clearly one of the most promising young naturalists of my acquaintance. He has worked hours and hours on tags.

So it goes. Our crew here emerges, and many of the personalities aboard come out. Cowboy, one of the speedboat drivers is always in horseplay with the skipper, both Joe and Manuel are capable guys, Joe affable, very casual, Manuel capable and much more taciturn, but good company too, and relaxed with us now that he sees we want to work too. George, the net skiff captain, fully of good cheer, not capable in English, etc. It's comfortable now, and we can joke. Good fisherman people they are. I like them, just as I did my acquaintances in San Pedro. Jim Coe is almost one of the crew, hard-working, capable, liked by the fishermen, and a very thoughtful guy. Good sea company indeed. Bill Perrin continually sees what's needed, and comes up with good ideas. Much of what we have done had come from his suggestions, and from his drive to make things go right. Warren Stuntz, capable, low-key, misses very little of what is going on on the ship, handles the interface between the two of us with considerable finesse, which I know fully requires care. We rather continually cross each other's designated lines of authority, but our communication with each other has been good after a poorer start. He, like me, feels a bit disoriented, probably from the sea motion, and finds it harder to plan here than on shore. Well, enough for the day. I hope the weather breaks so we can get on with the tagging.

October 22, 1976
Clipperton Island

Today I spent aboard, nursing my sore knee and writing notes and getting various things shipshape. Some of the crew went ashore in the helicopter, but most of us languished on board with the wind and rain sheeting by, and the weather offshore foul and unworkable. I put in a plea for people to bring me back some samples of rock from Rocher Clipperton, the 60+ ft. high fin of rock that juts up out of the lagoon edge. Three samples came back, and all are of light gray crystalline rock; not at all what I expected from basement rock in an atoll—i.e. not basaltic lava, but perhaps phosphate rock. I won't know until my brother gets a look at it. (Very interesting continental extrusive volcanic)

I spent quite a bit of time concerned about communications and relations between the two ships today. We are developing a pretty good case of Baird's Oceanographic Disease, which is a disease that occurs on expeditions involving two or more ships with a common or multiple missions in the same time span. Its etiology is rising levels of righteous indignation on both ships, often leading in severe cases to complete

communications breakdown and sometimes rupturing of friendships, permanent clique formation, and other communications pathologies. In the case from which the name is derived the *Baird* and the *Horizon*, two Scripps research vessels were assigned to the East-tropic Expedition and requested to land at Easter Island, where the *Baird* was to pick up a tiki to be planted with ceremony, including mayors and things like that, in the Scripps lawn. Communication had become bad, and the groups potentiated against one another even before Easter was reached. Once there it became obvious that even though Ecuador had given permission there was no way to move a 40-ton tiki aboard, so the *Baird* bought a carved eucalyptus tiki and stored it below. The *Horizon* crew stole ashore at night, cut a log and hid it in their hold, and when they went to sea, assigned a team to carve it. Then they ran their stations at breakneck speed, gradually broke off communication altogether and arrived at San Diego two or three days ahead of the *Baird*, calling in the local officials and having the ceremony. When the *Baird* arrived with their official tiki no one met them. Some of the breaks between even old friends have remained in effect over long periods. There are *Baird* people, and *Horizon* people.

Our case involves a semiautonomous acoustic operation and there are probably confused expectations about who is to be in charge of what. My role is PI for the whole project as requested of me by the Mammal Commission. There was, I know, some jockeying prior to the trip about the role of the acoustic people, and a problem of our behavior effort being without crucial support from them, all near the last minute. I was away until four days before the cruise and came back in a bit of a vacuum about these past events. Even now it isn't wholly clear to me what Aubrey's expectations were, but I find him laying out plans for what we will do and then announcing them firmly to me, while we are laying out our plans here. We try to communicate by radio, and by exchange meetings between ships, but both of these methods have their problems. The exchange meetings take inordinate amounts of time and energy; bad seamanship from *Jordan* crew members makes it slow, and sometimes risky. Schedules of the two ships are different for meals. We can only take people aboard here for meals at noon according to our contract. The *Jordan* sometimes shows two movies at night. The rain gets everyone soaked. The tendency is to do it by radio, but it's no substitute really, since face to face resolution of these complicated schedules is critical. Pronouncements over the radio of plans sound cold, hard, and final, even if delivered with as much finesse as one can muster. One never knows the subtleties of the milieu of the other ship. Here we play a delicate game of winning the respect of tough, hardworking fishermen, many barely literate, and many with severe language barriers. The ship is an independent kingdom designed to go where and when the skipper commands. He isn't used to the complications and delays attendant upon research. But, we're doing well, by constant care, and we're getting our work done. On the *Jordan* it's science against civil service union, where the crew won't do this or that past hours, or without specific notice, and truly some of the crew has been so inured to changing demands and personalities that they treat everyone the same—as ciphers and a part of another world.

The immediacy of the work various people are doing gets lost between vessels. We know vaguely how hard Steve and Don worked in the first tracking, but the chance to show adequate appreciation, or even the need for it are lost. One cannot judge sensitivities across such a water barrier, as one can, face to face. When should a person back off, or change a tactic. Almost impossible to judge without personal contact. Well,

when you have strong personalities these things tend to magnify and righteous indignation arises, egos become enmeshed and it becomes difficult to back away without pain. But, I'll try to talk directly to Frank at the first possible time, to sort some of these things out. I'm confident this will stop the spread of Baird's Disease.

Not much else—a little reading, good notes, some big squid on the deck (jigged off the rail), and we wait for the weather to break.

Some of the problems the fishermen face are beginning to come out. Mostly they circle around a couple of problems. First, they are bitter against foreign competition that does not have to hue to the regulations of the American boats, and many are apparently on the verge of going foreign flag—one figure I heard was 20 boats have applications (to whom?) pending waiting on the outcome of the present rulings, quotas, etc. Already three boats out of Ensenada, and others elsewhere are captained by Americans who “run” the boats for foreign owners. A Madruga was one. They talked of new boats being built for the Mexicans in Norway of large size, but say the Mexicans have trouble filling the quotas they have, and that precautions by these boats re killing porpoises are minimal to absent. Last night we had two Mexican seiners near us, well after dark, with one having its net in the water. Probably just net repairs and not a set. But our folks talk of them landing tuna at San Lucas (where there is also a cannery) and at Ensenada (also a cannery) and trucking tuna across to Van Camp cannery. Tuna landed on the mainland coast is also trucked to American canneries, with no trouble. Apparently money will be put up for boats bought under foreign flag, and no attempt seems to be given to enforcing the terms of the Mammal act restricting such activity by US fishermen. But, if Mexico doesn't catch its quota it is legal for them to fish inside the CYRA line until they do—or in this case, all season because nobody keeps records of the tonnage caught. Our fishermen are very suspicious that it simply means open season inside the line, but not for US fishermen and that the Mexicans will never fish outside the line where it is rough most of the time. I've heard some comments about the violence and toughness of the Mexicans, as related to their low standard of living, and unwillingness therefore to conform to catch limits. They talk of bullets through the pilot house, and recently there was a hanging for a mutiny—two fishermen strung up off the deck house with purse rings around their necks. Others talk of new 2600 tonners with helicopters aboard coming out of Panama (who put up the money?)

The second problem has to do with quotas penalizing the good boats at the expense of the bad. The rule doesn't reward the good fishermen for good performance, but instead throws their kill in with that of boats doing ten times worse.

What to do? What could this trip contribute?

Well, in my view the results of this trip, thus far, amply demonstrate that a good boat skillfully handled, with the Bold Contender system and the fine mesh net (especially the latter) in the backdown area, can have very low kill rates—acceptable if fleetwide, I'd guess. How to get the fleet up to the standards we see here? I think the regs should reward performance, perhaps by establishing two classes of boats based on a year's kill record. Then, allocate a part of the quota to first-class boats only after the initial quota was caught. Soon enough the fishermen would begin to use every stratagem at their command to improve their performance, and I think we would see many new wrinkles developed. Little things that might make the difference but especially motivation, because it would mean dollars.

The foreign problem is much tougher. Enforcement of the MMPA with regard to US nationals fishing on foreign vessels that kill porpoise is a start. Next, is a closure of the transport of tuna across the border (apparently the US buys most of the tuna) until Mexico agrees to porpoise-saving maneuvers.

Next, the international commission mentioned earlier, but not the IATTC alone.

As for science, I think there are some possible departures. I do not think maneuvers to separate tuna and porpoise prior to a set have promise. Luring of tuna to logs could well be useful, especially if the odor hypothesis proves out, as I expect it to do. As for departures in our work here I see some. I do believe that porpoise can be herded inside the net. The method might be sound based, it might be based on something like a hukilau. The porpoises are typically averaging the terror that surrounds them. One can maneuver them quite easily by deploying divers, by net shape, and in general by any means that shifts the disturbance in one direction or another. Tuna are much less apt to escape early in the set since they typically are deep in the net, out of sight. Especially when there is trouble in the set, as for example a roll-up and men are spending an hour or two untangling it, it could well be an important advance to advise a way to chasing the porpoise out prior to backdown. In my view this will have to consist of two things—a way to herd porpoise (which isn't difficult) and a way to repell the tuna from being herded too. That's maybe harder. Could it be based upon the differential between fish and porpoise of fish having extremely acute sense of smell, while porps have none, or on porps having high frequency hearing while fish do not. Could, for example, porpoise be driven with a barrier that also produces bubble trails? Would fish come near it? My guess is no. Then, could the corkline be depressed and the porps let go while the other men fought with the roll-up. Since 80% of the kill comes in these problem sets it could mean a great deal.

Spinner porpoises appear subordinate to the spotters to me. They are peripheral to the spotters, and often deeper in the net, apparently. Their problem is that they seem to spook instead of floating passively in the vertical mode as spotters do. The fine mesh helps a great deal to save them. Bow bunches claim some animals. Maybe some design on them would help. Design to allow the skipper to backdown continuously with the tuna being held off in some way could help, except when the catch is very large and the channel full.

Our data will help count porpoises by helping to estimate what a given number of porpoises on the surface means in terms of those below the surface.

October 23, 1976

A long rough day looking, and waiting for the weather to abate. It did calm a bit in the afternoon, though we skirted squall after squall. The fishermen swear the porpoise schools seek out the rain and hide in it. Nick the navigator, a sharp guy says he's seen it happen a thousand times. We added two times today. Now, why should porpoise seek out rain? I'm less skeptical than I might be because of knowing that in the jack pole tuna boat days the fishermen sometimes sprinkled water on the surface to induce a feeding frenzy—the sounds of bait falling back as they leap. But, in a large squall other things might be at work. Does heavy rain produce enough white noise to mask communications sounds—say of spins, tail slaps, and if so what would be the reason for an animal to seek out such an environment? Are some aspects of sound emission changed in squalls? Do

porpoises jump more, exhibit more high level sound production? Who knows? Does the rain affect the behavior of the prey? Does it somehow make the prey more accessible? Apparently feeding relations are changed at times, because Bill and Ed report mahimahi quitting feeding during squalls (did they quit fishing/).

The light relations surely would change as darkness overhead and the prevention of direct lighting might make prey more (or less?) visible? The adaptation of surface fish to light may be to direct light, in which the silhouette is masked by the lateral bright line of guanine. Does this, under a squall, instead catch light and illumine the fish in a ring of light so that it is easier to catch? Mebbe. I like this last one best, and think it might be observable.

Less likely, it seems to me, is the fisherman's notion that the porpoise have learned to hide from them in the squalls. This perhaps assumes that they can form the second order transform that tells them that the boat is chasing them, not by sound below the surface as they are used to doing, by vision out of the surface, where their capabilities are poor. And they would have to conclude that there were men (or sensors) on the ship that could not see through rain. Or would it simply be conditioning that after repeated experience showed them that the chase ceased? Almost certainly the latter, in my view, if it exists. How is a school directed to squall in the first place? Who says "go" and how does this leadership say "go"? My guess on this is that aggressive individuals, maybe of both sexes, order the school from any position in it, but especially from the sides, and that this tends to form it and direct it. I'd guess that age classes are involved and that in this sense a school may have several "leaders" who may function in a very transitory fashion, since the school itself is such a fluid assemblage. The school can accept new increments on the feeding grounds, and these may pull away at times, spinners may leave spotters, for instance at some times of day or night. And the species school itself may fragment.

Well, on to today's set. We waited all day, with no results, and finally after the time when we felt able to put divers in the water (neither safe nor useful to put them in the dark) a school was spotted running near a big squall, and the speedboats put over the side. These ran in the rain, over the rather sizeable swell, often leaping like porpoises, wholly free of the water as they whined along. The set wasn't a wholly satisfactory one from the standpoint of the fishermen—some porpoises go away, and the final encirclement was a close thing, with the porpoise school skimming along inside the net skiff, not more than a few dozens of yards away. The following then, is the transcript of the set.

1605: Edge of rain squall, speedboats in the water, will be dark before this ones on the deck. Second set today, or rather the second school today that has run into a squall. Nick the navigator says this is very common behavior. About a six-foot sea with some whitecaps from the winds of the squall. We're passing along the edge of the squall.

1628: We're into the circling maneuver with the porpoise jumping in between us and the speedboats, we all move in the typical spiral. Bill Rogers and I have been spending some time peering at what is maybe a pigeon hawk (peregrine) resting above the crow's nest. A beautiful striped breasted bird, with a black mask, and black wattle marks, a fainter cap stripe and a banded tail, maybe 13-14 in. long—a long way at sea.

1629: Apparently some of the porpoises hav escaped between the *Eliz C.J.* and the first speedboat. My friend Fernando is driving one of the boats today—not the culprit I think. There is much impassioned English-Portuguese flying around me making blanked

spots on the tape too crass to record. Porpoises in the school are in a great leaping school, pouring from the water in clean arcing waves. Est. 150 animals, seemingly all spotters, traveling at top speed directly on our beam as we circle around them. Now ceased leaping, now group behind is leaping, now group in front leaps again, pouring in waves out of the water.

1640: Net is in the water (after a false start, and more angry words from the bridge about why it wasn't let go exactly on command).

1641: Animal leaping, broad-jumping through the air, landing on its side. 1/3 side.

Porpoises really quite close to net skiff now. I believe they will catch them but it will be close. All depends upon the lead speedboats shooping them in. They went in the net.

1642: Two-thirds net, skinning in by not more than 40-50 yards. Now clustered as far from the *Eliz CJ* as they can get, against far corkline, perhaps 80 meters from far corkline in a milling school. Leaping has stopped. Two leaps in succession. Over by future backdown channel. Porps in slow mill, approx 100 m from far corkline, towards bow portion of net. Net skiff coming along the bw of the *Eliz CJ*. Bill Perrin estimates 100 animals. All spotters. Tail out behavior now.

1643: Porps up toward bow end of net in a tight mill. Over by backdown corks. Circular school shape. Animals head slapping occasionally. Milling 100 m from corks. Purse cables coming in. Tail out behavior, some nose outs, most animals low in the water.

1645: Very gray afternoon.

1646: Considerable amount of vertical diving and throwing of flukes. Animals almost exactly abeam now. Couldn't get farther from *Eliz CJ* if they tried.

1647: Animals in rather elongate mill now directly abeam, approx 150 m off our beam, 80 m from far corks. Moving slowly, some throwing of the flukes, some diving. Head slap.

161-10: Two high leaps with animal falling back on its side. The school is the most aerial of any we have worked so far. Another lower leap. Animals have moved into central position in net, well away from ship 80 m from net. Another leap, leap, falling on side hard.

1658: Porps aft in net, on our aft quarter, 150 from ship, 70 m from corkline, some aerial behavior, elongate school, moving back and forth oriented parallel to corkline.

1659: Animals in same position as before, quiet mill, a bit closer to far corkline, rings can be seen.

1701: Animals in same position. Occasional aerial behavior. Jim points out we have a current running/sweeping net somewhat aft.

1707: Two backslaps, animals up toward backdown area again. Net is being changed severely by current, pushed back from bow and . . . Some head outs, quite a number of nose outs, some racing over by far corkline as if aggressive encounter was occurring.

1710: Backslap and aggressive encounter. Another backslap, backslap.

1711: Aggressive encounter, animal thrashed and threw its tail out of the water. Flurry underwater. Rings piling up clattering and clicking. School conc. more toward

stern now in large lobe of net, still in biggest open area 70 m from far corks. Quite a lot of diving and throwing of tails out of the water. Some formations evident, milling.

1714: Head slap, aggression may be around edges more than in center.

1715: Very strong aggressive encounters and a leaping out of a fair proportion of the school in center of the net. Relatively tight mill. Purse lines still coming in.

1717: Animals abeam 30 m from net and 80 m from us. Much throwing of the flukes as animals go down in high angle dives. Relatively tight mill.

1737: Animals quietly at surface, nose outs, vertical divings. Whole school has turned and is all facing toward the stern, toward the far corkline and they now begin to come back again.

1720: Thrashing against far corkline. Animals toward stern 20 m from corkline. Moves back toward bow, at edge of backdown area. One group makes this move while others lag behind.

1722: Two very clear groups, one in backdown area and one at mid net. Head slaps on periphery of school.

1723: Rafting near surface, brown of bodies evident through surface. Head slapping at periphery. Circular mill. Air amount of fluke throwing. Net over power block.

1725: Net over power block and agitation noted in school. Reacted by more rapid swimming, and by breaking water subsided to nose outs, moving quietly.

1726: Net coming fast. Sound skiff off bow.

1732: Moving quietly, some throwing of flukes and near vertical dives occur. Animals at backdown area. One group right at backdown corks. Porps in a fairly long school along far corkline. Prob. 80 m long.

1739: Net coming with backdown buoy 200 ft. out. Light is fading. Unusual amount of oil surface.

1741: Aggressive encounter at head of school. One animal appeared to slap another at edge of school. School spooked. Speedboat at corkline 80 m away with engine running. Circles to backdown channel. Animals all turn and move toward us away from speedboat.

1742: Net about half the length of the ship. Animals markedly closer to us as net closes down. Speedboat tied up at tip of backdown. Backdown cork aboard.

1743: Porps sliding back toward end of backdown area.

1744: Another ponga moving into position. Obvious increase in speed of diving and the amount of white water as boat pulls near. Also, they moved over against the far cork line in obvious response to arrival of boat 20-30 m away. Tight bunching of school now, as we move toward backdown. Four red corks in air.

1745: Net narrows, 1/3 length of ship.

1747: Move into backdown maneuver. Animals moving very quickly now and diving nearly vertically. Most below water. First class backdown. A fair number of desultory tail slaps as channel develops.

1750: Fairly dark now, tight tight bunches at end of backdown area, a little low leaps. Backdown in full flood, corks submerged, some taking off directly toward Steve Leatherwood in the skiff. Hope he was recording.

1802: Backdown completed. Some fish in the net (5 tons)

October 24, 1976

A frustrating day—no set. One school was seen this morning but it had very few fish and the ship went on by. In retrospect I wish we had set on it, fish or no. But we didn't. In the afternoon there was a very small school (less than 100 animals) which I at first wanted to set on, and then my people talked me out of it. No fish was bad for relations with the *Eliz. C.J.* crew, and resets on the same fishless school wouldn't help much. I assented and called it all off. No further chances arose. Frustrating. A good poker game helped and the Sunday pro ball games, and a betting pool enlivened the day. Back to our respective ships. I worked a tiny bit on the book outline. At night we traveled, we hope to better grounds.

October 25, 1976

Made a tagging set today, but the Gods conspire, and continue to conspire. We spotted a school today about noon, with the *Jordan* some 20 miles to our stern (2 hrs. or more away, and we are moving in chase, which makes it more like 4). It was a group of 20-300 porpoises, all spotters. The problem was to keep Manny Jorge in check while the *Jordan* got near enough to put its men in the net area. We had issued requests to keep the *Jordan* closer but the fisherman spirit is such that it's like trying to tame a wild horse to keep them in check, when it might mean slowing fishing. Predators indeed! One ploy as to put me up in the chopper to look at the tuna-porpoise bond. Here are my taped notes:

Took off from wheel house, swooped low over water and climbed to about 1,000 ft. Over school, est. 250 animals. Big rain squall maybe 10 miles away. The animals moving almost due south at the moment. Many leaping from the water. That direction will take them away from the rain squall. The school may be reacting to us. A smaller group (20 animals or so) ahead of main group, that may be spinner porpoise. Separated from main group by 150 m. approx. Can see shining fish bellies deep in water off to both sides of the school. 75-100 m away from main advancing front. School now composed of a main discoidal mass, with a smaller group off to the left, all moving very swiftly, leaping from water. White reentry marks.

1321: School shaped like a check mark with point going forward. Long left 200 m long. Animals underwater back in bite of checkmark. May be fish, shining.

1322: School shape changes to elongate oval, moving in direction. . . I no longer see any animals in lead. School a broad front. Leaping as they travel. Waves of animals coming out most of the time. Occasional times when school disappears. Dove. I can see fish moving along behind the school, and can see what may be fish out in advance of the school. 200 yards out beyond both wings of school I see fish. I see fish directly under the porpoise school, a few actually leading it. Deeper than the porpoise and shining to either side.

1330: Moving in on school again for another look at the fish-porpoise disposition. Porpoises moving in a fairly circular mass now somewhat broader than long. Leaping as they move along, in considerable number. School now quite oval shaped. School now elongating traveling along as a front. A lot of fish aft of the school traveling in the wake of it, down deeper. I think I see some fish out on the wings of the school. Shiners (fish) in advance of the school, but the main mass however is below and behind the porpoise. Fish clear out on the wings of the school on right hand side, deep down, and some in advance

on that same wing. Probably 75 m ahead of the school. It's not as though they were all below and behind, as advertised.

Animals now strung out in a long line, diving as they move forward. Some of the fish are well behind, probably the majority of them. There are very few birds, 3-4. The great mass of fish is now directly below the main part of the school. I can see porpoise below the water, about to come up.

Shiners again, below and behind the school. School now virtually circular with one little satellite group out behind 100-200 meters. I'm sure they will close together again.

1339: Back to *Elizabeth CJ*. Many flatbottom cumulus around, very few patches of blue sky.

1425: Lying to waiting for *Jordan*, she's 12 miles away out of sight. Porps are off port bow, a bit spooked by helicopter. We'll stay a little way away to keep the spook index down. I'm going to go out in net skiff in this set. My friend Big George will skipper.

1515: Speedboats in water, circling, some 15-20 animals escaped, running like hell.

1517: Porps in long line, some way way ahead, and some back in boat bend. Helicopter may have tired them.

1520: Not too long, I suspect before we get the word to be cast off. I'm sitting up in the prow of the net skiff piled up on top of this huge 10 ft. stack of net at about a 35 degree angle with our stern in the water waiting for the word to knock the pelican hook loose and to have the skiff launched. The skiff is huge—maybe 20 ft. beam, 35 ft. long, with a big powerful diesel and a well guarded propellor. Porps on beam seem to be moving relatively slowly. Long ways out.

1522: Expanded our circle a bit.

1538: More animals to be seen. Well within reach of skiff.

1540: More bunched, moving along in leaps. Amazing how much running they can take. They were chased by helicopters for an hour or more before this set. Skiffs have opened up again. Presumably.

1542: *Jordan* closer astern—8 miles away. No porpoise in sight. People on mast do. Circle pretty open. Twice normal net width. There, abeam of us, and low in the water I see school. Helicopter off. Tagging set 6. Second skiff is missing. The speedboats race at absolutely flank speed, sometimes leaping free of water. I see all four skiffs now. Circle has widened again and animals are way off.

1546: It's something to watch Joe feint with speedboats, opening and closing circle as animals do not behave themselves. Considerable part of school is fairly close in towards us. Leaping from water as they swim along. Helicopter serving as a speedboat, and it seems to be working. Low over water 6-10 ft.

1557: A little closer. Porps continue to leap.

1558: Much closer, drops of rain occasionally, some tried to escape at bow and were herded back in. Porps refuse to be bunched.

1604: Porps abaft the beam now moving more slowly. Deck speakers have come on. Porps have slowed.

1608: Leaping and running as fast as they can and turning away from boat, looks like a speedboat out of operation. No jumps.

1611: Tight turn, porps go away from *Eliz CJ*. Hard to corral. Turned back toward boat, running for speedboats to replace downed speedboat.

1616: Swimming very low on water now. Will be ours if we can hold out. About right diameter. Matias bends over pelican hook.

1617: He hits it and we're off. Cascading down net pile, with net leaping off stern. *CJ* looks huge.

1620: Third net, porps in middle of net.

1621: Half net. Engine on skiff on, beginning to tow. Skiff noise helps keep porps from running through. I get picked up by a speedboat and taken to tagging skiff at backdown area. Four radios are placed, and about 60 tags. We begin to track the radios but they are lost almost immediately. The porpoises are lost within less than two miles, we guess. The crewmembers of the *Jordan* follow them briefly on the ADF at first getting bunches of signals that gradually become more sporadic. By the time Frank Aubrey gets to the bridge they are gone altogether. Warren Stuntz and I went aboard to help track and were able to follow one individual that had been equipped with a small 1-second xenon flasher in addition to the radio. This unit gave out a very intense light frequently enough that we were able to follow the group for some hours, losing them on the midwatch. Always, the animals were at the edge of our vision, and when we turned toward them or put them on our bow they evaded us, and finally they were lost altogether. Even though we were within about 2 miles est. at times there was no radio indication. The radio was dead. My guess is that with the transmission range of these radios we have no hope. The animals probably spook from the sound of a ship four miles or more away and within two miles they are in full flight and one can very seldom get that close. Without more signal strength we really have no hope of radiotagging results.

October 26, 1976

I was up at dawn to see if I could help in case we were still on the animals, but we were not, so I went back to the *Elizabeth C.J.*

Having two ships, of different speeds is a very difficult problem, and having one that launches boats in seconds, and one that dawdles for $\frac{3}{4}$ of an hour at times to get three skiffs in the water is only to make it worse. Two ship programs of this sort are a thoroughgoing menace. And the gods (there *must* be more than one) of things mechanical have it in for us, for sure.

We launch into tagging recapture set No. 7. But first, some other details. As mentioned before, we lost the tagged animals due to faulty radios, and our searching for the school proved fruitless until we received a call from the *Sandra C*, a seiner under charter from the Tuna Commission. They had made a set and caught some of our tagged animals, including some with radios (two) along with 70 tons of tuna, and considering that several of our tagged animals were in her net that amount either accumulated overnight or two schools merged along with aggregated tuna from one or the other source. At first they didn't want to give up the radios but we finally prevailed and went over and collected two of ours. One, the skipper said had virtually exploded when opened, and the battery case was full of salt water. This was an old style stiff antenna model, and I noticed that the O-ring was missing. Was it missing when the animal was launched, or did the Captain of the *Sandra C* lose it when it was opened? No way of knowing. The other had a broken antenna, probably when the stiffener we put in was

wrenched loose. So, our improvement didn't work, but without it the range was useless, so we are trapped.

Knowing where this school was we asked Manny to make a set on it, and he responded with grumbles and went the other way, talking about the goddam charter and how we wouldn't have gotten himself into the affair if he had known how slow the *Jordan* was, or how much it would interfere with his fishing. He forgets that it's only due to a legal fluke that he isn't the only US boat allowed to fish inside the line. At any rate I went up to see what I could do with him, and pointed out that the sooner he got our tagging stuff out of the way, the sooner we would get out of his hair, that we didn't want to foul up his fishing either, etc, and then I left it to him to choose, and he chose to chase the tagged school. When we got to it, it had grown greatly and contained a subschool of some dozens of eastern spinners. The school was variously estimated at over 1000 animals, down to about 600 animals, but nonetheless at least 4-5x the size of the school from which we tagged animals. I was interested to see that spinners had joined and that the schools were so labile—just as I had expected.

We made a good set on them, and when it was all in found that about 70 tons of yellowfin had been taken—a fine set, and one that went a long way toward stilling the grumbling of the *Elizabeth CJ* crew. But, it was not without serious problems for us.

While at the corkline of the backdown area the animals piled up against us in phalanges, and began spilling over the corkline. It wasn't depressed very much most of the time and even so they pressed up against it, mostly floating into it, back first, turning and then flipping up and over the corkline, accelerating at once and disappearing. Many came up head-first, faced toward the line, and easily flipped up and over the line to freedom. The impression, and a clear one, was that they knew what it meant to be in a backdown channel and they knew that they could help themselves in getting over it. In short they are being trained, and apparently are by no means as vulnerable as the porpoise that are not so experienced outside the line. They don't panic even though crowded together, with few exceptions. I noted one spinner ram the net, and thrash, but the 1 1/3 in. mesh didn't catch him and he backed off easily, and then escaped. We noted the porpoises flooding out, and leaving us nothing inside. We gestured to stop, and I had previously talked with Manny to attempt to outline our needs to him—150-200 animals in the set, a net opened again to a size that would let behavior typical of a net go on, and a chance to tag. Tag we did. Dave Holts darted them home, Bill Perrin called them out, and I recorded as before. We put out about two dozen tags. All of these eventually went over the cork line as we were unable to stop the backdown and let the corks up. They just didn't come up, and all our hauling, gesticulating, etc., didn't do it.

Finally, with 4-5 animals still left I called it all off and retreated. The corkline just wouldn't come up, damnit. Later, we learned that it was because there were 70 tons of tuna in the net below us. No hope. They brailed and brailed, the big fish cascading out of the braile net into the channel way, bumping and thumping and smacking into the well combings and thence down into the supercooled brine below, where they would be rock hard in a few minutes. Joe Thompson photographed in the midst of this melee and then descended outside the net (a thing I'd never do, as that is where the sharks patrol back and forth) and he was met by an oceanic whitetip, which he pushed off with his camera and then scrambled, eyes wide open, into the Avon raft. No place to be. During brailing,

for example, the skiff is surrounded with sharks nipping at the net, taking out pieces and big hunks of tuna that are pressed against the webbing.

Well, we try again. I think another try at tagging is in order, and if the catch is less we may succeed.

In the evening Bill Perrin and I went to the *Jordan* for a long meeting that cleared up many things that needed clearing. Tomorrow we will be ready for either a standard set or a tagging set. The weather's improving.

Well, we'll test the hukilau soon, but before that we'll do another tagging inside the net, and then a standard set with a single porpoise in the net at the end for recording reasons. My guess is that a single animal will prove to be [?], but if he does, perchance, sound off, they expect to get some interesting data from him.

October 27, 1976

We've been trying to figure out how I could go back on the *Jordan* to Manzanillo and thence home. I'm anxious to save the time, and I think that Warren Stuntz could easily handle the work here, in terms of leadership. In fact, we have too many chiefs. Warren and I get along very well, but I'm sure it would be easier if he had a clear channel of duties. Besides, I have to go to HongKong and want to get back before Christmas, and then I've developed a pretty good case of heat rash of one arm that won't go away. But, I apparently left my passport at home in anticipation of landing in San Diego. Well, maybe I can go in as a medical case, or something like that. I'll call home tonight and see how things are going, and see if Phylly can locate the passport. Well, it keeps things exciting.

Set 8 (Tagging and Obs. Set. Perrin Maneuver)

0941: Clear calm day, 5-6 ft. swell running, scattered clouds. Beginning circling maneuver, speedboats in water, no wind. *David Starr Jordan* very close behind, will be able to get into position easily. Animals moving very swiftly, diving from the water in cascading jumps, as is typical of spotters when traveling rapidly. Estimated at 250 animals, but I think it's more like 100 animals. Is going to be a relatively short set as animals are behaving themselves nicely and turning in a group toward the boat.

0947: Not running very hard, hanging in tight group off port bow at 60 degrees at movement. We will get the wind on the port beam and then make our set so the vessel is forced out of the net, a force counter to that generated by rolling in the net.

1948: Nets in the water.

0948: 1/3 net. Don't see porps at moment, abeam, milling, almost as if they anticipate being caught and said, "Oh hell, we have to go through this again." There's one record of a *Delphinus* school being set on 5x in one day, so one can get the idea.

0950: Half net, porps well inside set. Heading toward aft corkline, two groups, one of which might be spinners. Thrashing near backdown corks. Circle a complete one, without a portion that needs to be taken up.

0955: Picking up purse line, perfect set. I will leave the recording now to go into the tagging skiff for tag placement, and Manny will hold the net open for us. We will then observe the animals underwater.

Bill Perrin and I were picked up by the whaler and taken over to our position along the corkline at the edge of the backdown channel. My task this time, was to jab in the dart tags, a specially pleasant task as it can't be too comfortable for a porpoise. Also,

Bill had bruised his ribs on his stint the day before and was having trouble sleeping and just couldn't do a repeat. So, I positioned a life jacket in the bow and was able to lean way out and maneuver around like a cobra waving its head. When backdown came I was able to reach and jab most of the animals for which we had tags until Joe Thompson came up under me and forced the animals all over against the backdown corks. It didn't matter, though I bleated in pain, because we passed the tags to Jim Coe and he was able to place the last two. Then, while Manny and his boys opened the net to a pond about 100-150 ft. wide and 250 feet long, and I'd guess 70-80 ft. deep, Bill Perrin and I worked our way into the net, in the Avon with the regular diving team. The sun was bright and the water crystal blue. I could see the fine mesh panels dropping deep into the water, finally to be replaced by larger mesh on the very bottom of the channel.

I followed a single animal for a considerable length of time, able to follow it because it had a four-color tag—yellow, blue, white, red. It acted more or less independently of groups much of the time, though on at least three occasions it joined them. It dove in a rhythm—several short submergences only a few inches to 3-4 ft. below the surface, followed by a long dive, then some short submergences, and then a long dive. The series went like this: 3, 3, 5, 6 seconds dives interspersed with breaths, and then dove down deep into the net, joining a couple of different groups enroute, staying below 158 seconds, then he came to the surface again in a near vertical ascension, and took three breaths at the surface of 3, 3, 6 seconds intervals, and then submerged again for 120 seconds. The animals seemed to have no reaction to swimmers in backdown area at all. He swam right by the divers to join a subgroup swimming at 35 ft. or so down, horizontally.

Then I watched a mother-young pair. The young had been swimming individually. It was quite small, plain colored, with protruding eyes, and it repeatedly dove deep in the net, as if searching for a parent, and then joined up with a spotter phase spotter[?]. I could see no particular agitation when they met, nor could I see any evidence that the adult attempted to chase the young one away. They just accepted one another in the adult-baby roles. Normal mother-young positions were [?] including assisted locomotion. They went into a pattern in which they would take one or two breaths at the surface after 1-2 second dives, and then dive for about 50 seconds. The dives that I counted were 47, 58, 65 seconds.

As to structure in the groups in the net, I saw many animals hovering at the surface, some swimming horizontally taking breaths at intervals, and others floating with the top of the head, and often the beak out of the water and the tail bending down steeply in the water—quiescent, or nearly so. Then there was continual interchange with this group from below, mostly in the form of steep ascensions or dives, and [?] a levelling out zone at 30-40 ft. down where subgroups swam off together in the rather typical porpoise groupings, 2-7-8, spaced within inches of each other, staggered with relation to which animal had its snout tip furthest forward. The backdown channel is just that, a channel, with webbing a curtain on the sides, sloping deeper down, with a flat bottom. I could not always see the bottom by snorkeling at the surface. It rose very steeply to the backdown corks, especially since we had supported them with extra buoys to make sure our animals didn't escape. I saw rather few folds. I saw a dead adult, lying on the webbing deep down, its belly shining. Bill saw two dead juveniles (calves). I noticed quite a bit of

parasitism in animals in the set. I noticed *Xenobalanus* from the tips of both pectoral flippers [?] the little lost baby, and noted *Conchoderma* from the gums of one adult.

Then, it wasn't too long after we came on board again that the lookouts (peering through high-powered binoculars mounted in bungee chord slings and swivel mounts in each side of the bridge) told that there were porpoise ahead. In fact the water around here is full of life—yesterday *Grampus*, *Tursiops*, some pilot whales, today streaker porpoise, pilot whales, and then a helluva big school of porpoise, with pilot whales around it, birds and a lot of fish. The helicopter is a wonderful addition. They can check out each school to see how much fish, and as like as not locate the fish from the air by watching for birds or running porpoises.

At any rate, it wasn't too long before they were on the next set, which we designated as Set 4 (reconstituted) and in which we were to have a behavior team in the water, the photographers in the water, me on deck checking differential behavior, Ed up the mast, doing aerial behavior, and various other people doing other duties. Warre went up in the helicopter after the net was set, and buzzed around looking at porpoises and fish. He saw 'em. There were on the order to 750 porpoises (spotters and spinners) and 65 tons of tuna, and at least five oceanic white tip sharks.

The following is a log, prior to my taking up my station for differential behavior.

Acoustics team will place a sonabuoy in the net.

1437: Pursuing a school of a lotta porpoises, supposed to be 1000 or more, and quite a number of pilot whales. Supposedly a lot of fish. The day continues to be beautifully clear, and 4-5 ft. swell, essentially no wind, puffy clouds. In the last set there was a white-tipped shark in the net, that apparently bit a hole in the net and escaped since it didn't come aboard. Obs. team came out of the water and in all of my observation swimming I never saw it. One of the dead porpoises in the last set had a huge mouthful of flesh taken out of the anal region including the posterior intestines by this fish.

Five speedboats in the water because of the size of the school.

1439: Going out in a line in advance of the vessel, speedboats curving out to the port a bit. The helicopter buzzes over it all like a little dragonfly, probably twice as far out as the speedboats . . . couple miles away, over the top of that school.

1504: Coming around in a very broad circle. Huge school of porpoises off the port bow traveling very rapidly, of three major groups, stretching over a number of hundred yards of sea. There are always some animals in the air. The animals are strung all the way from the 3rd speedboat to beyond the stern of the *CJ*, across a long stretch of . . .

1512: A number of booby birds over the school, beyond the front ponga boat.

1531: We're still circling. The animals are getting closer in. Some apparently are attempting to escape from the rear line of ponga boats judging from the fruity Portuguese being bandied about over the airwaves. I wouldn't be a bit surprised but that we might make a set next time around. We have to get the wind on our beam the next time.

There goes the net. Nets piling off the stern. Porpoise were hard for me to see foreward of the beam. ¼ net. Speedboats race along and throw up great cascades of spray, particularly because one of their favorite maneuvers is to circle. This closes up a gap. They'll swing out in a great circle, throwing spray in all directions. The animals are moving toward the corkline as planned. Still some birds over the school. So far only

spotted porpoise in the school. *David Starr Jordan* is closing on net. Porpoise school is collected over by the far corkline, and it is:

1542: Over to behavior log. I will be filling out differential behavior log looking for patterns between spinners and spotters.

In a nutshell, what I saw, and logged, as a fairly sizeable group of spinners (maybe 100) that sometimes broke in two pieces, but mostly stayed on the margins of the spotter school, especially inside toward the *Eliz. C.J.* and which once went between one of the Avon rafts and the corkline toward the stern of the *CJ*, where net was coming up, a thing I rather doubt that spotters will ever do. At that time the spinners were separated by perhaps 50 yards of open water from the main group. Spinners dive and stay below longer than spotters, and from our underwater observations, may dive below them, level out and move very deep in the net. They seem much less equipped with protective behavior than the spotters. The schools were very much influenced by the skiffs and gear in the water, and once . . .

October 28, 1976

Today, we will do standard set No. 5, which is a rather straightforward observational set, with divers, acousticians and photographers in the water. I will be on the Crosstrees with Bill Perrin and Ed Mitchell doing observations, mine of diving rhythms, if I'm so lucky. It's another clear day, with clouds scattered about on the horizon, but sunny here. No wind, and it seems to me, getting a bit hotter and muggier.

0956: In the mill, already, *Jordan* off our bow. 4-5 ft. swell.

1006: Half net, porposies are well into the net. Modest school of about 200 animals.

1010: About 100 yards astern of us open. Bill says there is quite a group of spinners, and I could not see them for a long time. Bill said they were down.

1019: A 45-second dive by spinners.

1022: 59-second dive. All these records are for the small group of spinners. It is impossible to measure rhythms in the spotters as there are too many indistinguishable groups, but the spinners stay nicely together, surfacing within seconds of each other.

After this session, which netted about 10 tons of fish (seen only very late in set by me) we went to the *Jordan* for a meeting about what had been found, and about future plans. I found my passport and will be able to get home when the *Jordan* goes in. That will be a great deal of pleasure for me. Not that this boat and the work hasn't been an experience amidst good folks, fishermen and colleagues alike, but I'm so jammed up with calls on my time at home that the extra two-three weeks will be bliss, and I'll be able to do the Hong Kong trip in time for Christmas, thank goodness. Back to *Eliz CJ* at dusk, a Streisand movie and notes.

October 29, 1976

We are cruising through calm waters and under gray skies looking, as usual, for birds and porpoises. Once they're found (by the big glasses on the bow) the helicopter goes up to check out the school for fish. This time Frank Aubrey will go up to drop a sonabuooy in front of an advancing school, prior to our making a set. I'll be in the mast with a 250-magazine motor-drive camera taking pictures of the set.

It's firm now. I'll go home when the *Jordan* goes in. It will be good to see the family again, and to see how everyone is doing.

I spent part of the morning talking to Sandy Romero, the chief engineer who was telling stories about jackpole fishing and various stories about the accidents at sea he has been part of—some terrifying tales. Once he was caught in the engine room when a generator was burning under the only escape ladder. He lived because he fell, full of smoke, into the shaft alley and washed back and forth. He lost all his hair, and the entire engine burned up, burning the deck out, and he thought the Devil had come for him when he saw these big-eyed monsters coming through the smoke—the Coast Guard with gas masks. That was the *American Boy*. Another was north of Cedros on a purse seiner, in a terrible storm and he and the skipper were discussing whether they could turn back for Cedros and shelter, the skipper said “no, they'd capsize” when they felt a great swell drop the ship and then felt her heel over so far that water went in the pilot house, and made the wall the deck. Sandy grabbed a torch and cut the purse cable. The net was overboard, and the net skiff down in the water somewhere. Once relieved of that burden she righted herself, and ultimately they were able to make port on their own steam.

He also spoke of jackpole fishing off places like Cabo Corrientes, and Punta Tosco, Baja. He said the mast lookout would call down what the school was—spinners or spotters, or whitebellies—and that would determine whether they would take 1-pole rigs out, 2-pole, or 3. The spinners carried small fish; skipjack and small yellowfin, the whiteels in the Gulf (*Delphinus*) mixed fish, and the spotters, the larger fish. He said that when they found red swimming crabs, they knew there would be fish and porpoise. Once he had taken 120 tons of fish from around two whales south of Punta Tosco. He mentioned that the spinner schools were larger then, and that the fishermen knew right where to find them. This was all coastal fishing, because they had to make bait inshore and then get to the fishing grounds. No one knew, he said, that there were porpoise and tuna offshore.

Standard set No. 11. The attempt on this set will be to mark the dorsal fin with a paint for measurement of dive rhythms. We had to scratch the drop of a sonaboy ahead in the uncaught school because this particular school was very wild and even the helicopter far overhead split them. The acoustics crew was not ready to do the test in which they catch a single animal, let the rest go, reintroduce and record the single animal, and then let it go. So, an attempt at tagging, which involves capture, is it. I have little faith in their chance to catch an animal prior to backdown from a skiff or an Avon.

Anyway, Bill Perrin, Ed Mitchell, Jim Coe and I went up the mast.

1256: speedboats in water deployed out ahead of the vessel. Warren tells me that one aspect of the chase is that because the boat is going in a broad spiral, when the porpoises come to the wake, they turn, and because the wake fades with distance aft, it is less effective in front of the vessel, hence the placement of the speedboats (or at least one reason for them being placed there). Thus the spiral wake acts as a trap for the advancing animals. I thought some of the advance animals have escaped over or under the wake. The helicopter is presently bolstering this effect of the wake by hovering over it, just in advance of the firstboat (Luis) Warren says the speed boats follow the wake to some extent as they go around, if the behavior of the porpoises allows. The relationship between netsize and catch is interesting, too. It is obvious here.

1408: Animals just now being trapped well enough for a set.

A smaller net would require a longer chase, to be squeezed down tighter, and as the animals get wilder and wilder the importance of the large net becomes greater and greater. Even now, this boat fishes with the net seldom closed at the end of a set, but extended on the cables a hundred yards or more, and guarded by speedboats while it is closed. Even so, sometimes it's a close thing. This vessel can take chances a little vessel couldn't, and can reach out for more animals. Thus the 200-ton boats fills itself about as fast as the 1700-ton boat.

Porpoises right in this side of the wake, turned along it and leaping along this side of it. Turning in toward the center.

1408: Net let go. Another aspect is the length of chase. Some of these sets use every bit of gas in the speedboats, and some even drop boats along the way, out of gas, and thus the time allotted to corner or corral the animals is regulated.

The porpoises react to the net by what seems to me to be a sort of "Oh Hell, here we are again" phase, in which the animals slow, and begin to mll—probably they detect the net ahead, but maybe they also say "Oh hell. Wait till the beggars back us out, and let's hope they do a good job."

The school looks half spinners, their big sail-like fins showing clearly. Unable to record meaningful dive sequences because there may be 200 spinners in the school and they come up in various parts of the school and not in coordination. The subgroups that do come up are from about 10 animals up to 30 or so, seems to me, which is about how many we had all told yesterday.

1423: One thinks this means is that there isn't cohesion in diving groups of large masses of spinners. Spinners at both ends of the school and in the middle. I've seen them on all sides too, now. There does still seem a tendency for them to occupy the edges though there are so many animals the effect is swamped here.

1446: Steve trying to catch an animal, ultimately fails, using hoop net. Saw spinner with oval white mark at base of dorsal on left side (3 in. long, 1½ in. high) traveling with a spinner with a tattered dorsal—a narrow notch cutting diagonally into the tip of the fin. [Drawing of two spotters with truncated dorsals.]

One of yesterday's tags seen on an adult spotter. We can tell it was yesterday's tag because of the orange reinforced waterproof streamer at its base. It's on the right side, part way down the side anterior to the dorsal fin. Try as we did we couldn't identify anything further about it.

Divers are in the water. Second bow bunches in. Rolling net.

1502: In spite of the fact that I had looked at the school with glasses since the first part of the set this was the first time I saw that single tagged animal. I guessed 600 animals, but Bill Perrin feels it may be a little over half that. Oh imprecision, imprecision, in telling school numbers.

1513: Lots of what seems to be aggressive behavior in spotters, especially. Tail slapping, white water all around, lots of thrashing. Saw adult with two young, one on each side, lots of thrashing. Explosive breaths noticed again, as backdown approached and as animals become crowded. One can see little puffs of vapor, and one can hear the exhalations. Particularly evident in spotters.

1515: Chopped off dorsal in spotter noted. Much thrashing in spotters, again, Bill Perrin jumps in with Jim Coes raft to try to recover info on tagged spinner.

1519: I leave to photograph backdown.

Later I learn that this was three near-catastrophes day. First, when Bill Perin took his raft around to the opposite side of the *Elizabeth C.J.* to be joisted up, they didn't give him time to unsnap his tow before they brought the speedboat that was towing him aboard. Up he went too—and fell back in the water, losing a diving slate and one swim fin—fortunately he is OK. Then, young Joe Thompson, I learn, lingered in the backdown channel and became tangled with some line around his dive unit, and was thrashing about with Joe, Sr. helping him. Bill Perrin pitched in and got him out. He was frightened, I'm told, and well he should be. No one else in backdown channels. Then, finally, the helicopter radioed back that it was on zero gas, trying to track the rest of the school. They came in on the 8 gallons phantom reserve that Bob the pilot has arranged. They made it, but we had already dropped the big net skiff and run to the rescue. Enough for one night.

I'm full of lethargy. The old sea malady that strikes when one doesn't have enough physical work to do. Well, it won't be too long until I can stretch my legs in Manzanillo. But until then I shall feel less than fit most of the time, I fear.

And the catch!! I thought there wasn't much until I saw the backdown channel peaked with white back of the porpoises, where the fish were breaking water. As the net came in further the whole channel was filled with breaking fish—lovely amber and blue beauties, up to maybe 150 lbs., and then the net was sacked up alongside the net skiff, and big bulges of fish were crowded into the folds of the net. Finally the skiff and the men aboard the *Eliz CJ* got the sack in place (corks up) and began to braile. Before they were done they and between 55-60 tons on board. A good day's work. But Manny was still out in the chopper hoping to set on the remainder of the school, but darkness got him first, so he will have to wait for tomorrow. Not a porpoise was lost. More and more it is evident that the present system, wisely used throughout the fleet, will push the kill more and more into the foreign boats, and that the real problem now is 1) to educate and insist on performance from our own people, and 2) to do something about the foreign kill.

October 30, 1976

A fishing set made today (Fishing set 15) in which a group of spotters, which had been travelling with a streaker school, which escaped, was caught along with about 10 tons of tuna. Bill Perrin reported that a single tagged animal was in the set, but no one could identify the tag.

Joe Thompson recorded yesterday's tagged animal on film, so it might be identifiable. The film needs to be checked. I merely watched the [?]
—the weather was rougher—big swells and the Jordan was 15½ miles away at capture.

October 31, 1976

Set No. 11. The acousticians will capture a single animal and after the others have been backed out, replace it in the net and record from it.

The day is partly cloudy, some squalls, but mostly cumulus and there is a pretty large swell running—6 ft., perhaps, no wind. Joe Thompson will go up in the chopper for photographs of the school before the set, and during the set, and then again over the backdown operation.

9:38: Joe Thompson has just left to photograph. A flight of cattle egrets over the stern (4) floating along in their effortless flight. Porpoises are off the bow, and I see one

bird. Guys on the speedboat deck listening raptly to a soccer game from Lisbon. Portuguese boat—good people, lotta skill, lotta noise, lotta drive, lotta pride. Speedboats in water at 1032. Rough ride for operators.

1043: Boats circling tightly as is *CJ*. Set pretty soon. Animals in good position moving relatively slowly.

1044: Helicopter takes off. Near Chirique today—a big seiner with a helicopter aboard. What are they doing here? Luis up in the lead boat is leaping out of the water as he hits these swells, spending a fair part of his time in the air or close to it. Luis runs well inside the ship's wake now, leading us into the spiral. The porps are very cooperative, just off our beam. Fairly simply set.

1047: Net skiff in water, animals not breaking water at all. A few little flecks when they surface, small group.

1048: 1/3 net. Half net. Animals well inside, very quiet, 100 m from net skiff. Almost a perfect set, that is the circle will be complete without needing to haul in the cork and purse lines very much.

1051: Set complete. In going up the mast now. This open elevator going up a slightly raked mast past frames that slide by inches away is a dangerous affair. It would be easy to fall into the frames and be sliced by the rising elevator. We switch to Perrin's tape recorder which will do the recording in real time. I will monitor aerial behavior on set 11, in cross correlation with Mitchell. I estimate 75 animals.

School is now up and 80 yards from corkline on our beam. Quiet spotter school. Cannot find entire school, no aerial behavior that I can detect. Animals occasionally throwing flukes, desultory headslap. Animals throwing flukes but diving quietly. Most are not. Simply submerging quietly, school moving toward bow of ship in quiet fashion. There goes tails out as animals dive.

1103: Helicopter over school, flying directly over net. Animals mostly submerged. Two tail slaps as animal is directly overhead. Some throwing of the flukes. Now animals are propwash of helo, and as this happened there was diving of the animals. Two animals came up and did nose out, waving nose in air. Another dive and throwing of flukes as helo goes directly overhead. Animals all below with helo overhead.

1104: All below. One comes up, others come up as helo circles away, but returned, diving, animals throwing flukes as they go down. Animal rolling on side throwing pectoral out of water. Fernando in water in net below (minor rollup). Helo right over school, very low down. Animals throwing flukes in some numbers and diving as helo is directly over the top of the not more than 15 ft. above the water, catching them in a very strong downdraft. Animals are below, thrashing tail slap. Unsolicited behavior on part of helicopter. Animals back at surface. Helo returns over them. Animals taking this remarkably calmly. Some are diving slowly. It gives the impression of calmness but actually the animals could be frightened and averaging the terror. Animals surfacing directly below hovering helicopter. Each time this happens animals throw flukes out of water.

1106: Animals back at surface with helo away. Helicopter lands on ship. A couple of explosive breaths and animals surface. Essentially all at the surface. More below when helo was over. 4x5 times as many fins as when helo was over them. Saw one explosive breath and thrashing tail under water.

1108: Animals [?] much rafting at surface, with head outs. Two animals waving flukes sideways. Animals turned on sides. Animals thrashing below surface and a number of tail outs.

1110: Animals about 80 yards from far corkline slightly abaft. In tight mill. School is 20m across, small group. Animal raced out of water, not very fast, leaving white water.

1111: A thrash at surface, a jump sideways out water. Another thrash, a racing just barely under surface churn of white water. *D.S. Jordan* hove to and side away net skiff in water. School very quiet. Two head slaps.

1112: End of net on deck, vibration on platform. Animals moving slowly, fair number of tail outs as animals dive. Thrashing of tail sideways in water.

1113: Some rafting behavior. Animals quite a bit closer to *CJ* now that bow bunches are in. Rings still coming in. Animals still milling quietly.

1114: Some tails thrown out as animals dive, but very leisurely, as animals average unfamiliar things around the [?]. Staying in typical position abeam, and 70-80m of far corkline. Milling, slightly abaft the beam. tail slap, thrashing.

1115: Tow boats come into net—acoustic skiff and another [?] Bill Rogers up off of bed of pain, and he is there. Leatherwood is there. Sonabuys about to be placed in net. Pushed porps some what further abaft beam. A little closer to far corkline than before. Slow moving diving and occasional thrash of flukes, but no leaping.

1116: Ponga boat into position off bow, I believe, taking line for 3rd bow bunch. Porps well abaft the beam, having been moved over there by the presence of skiffs in the water. Head out. Closer to corkline than they have been. No more than 30 m from corkline, but stretched out compared to former quasicircular shape, but still in a rather quiet mill. Schools move much further aft as sonabuoy and behavior skiffs crowd them. Animals moving quietly.

1119: Real tail slap, another flurry, another flurry of animals on its side, two head outs, nose outs, others resting quietly at surface in hanging positions, skiffs moving toward them. Many more head outs. I should say several. Little bits of white water here and there, 30 yards off on port quarter.

1120: Saw thrashing to side of tail, mass of white water. Animals in long line parallel to corks. Diving skiffs has animals directly between them and far corks. Tail slap from animals equidistant. Moving quietly for most part. Tail slap, nose outs.

1121: Shape of school has changed into elongate one now, parallel with net. Animals oriented in line toward bow, 40 yds. off vessel. Sonabuoy and dive skiff close by, astern of school as school moves away from it. Animals average terror. Blow under water. Animals quiet. Head out, pair came out together, pressed together, white water.

1122: Couple of evident breaths. Big stern bend in net, long lobe-shaped. Animals moving around in a mill away from divers and skiffs, coming into center of net. Rings up.

1123: Rings up. Nose out. Moving quietly, not too tightly spaced, fairly typical school spacing.

1124: Nose out tail out, rafting animals, moving slowly. See animal underwater upside down adj. to animal in normal position. Animals more or less in center, 70-80m away from net. Animal thrashing at surface, going in a swift circle over another animal, in a kind of chase. Second animal got pushed partway out of water in a chase. An animal twirling at surface next to another animal very close to it as if pursued by 2nd animal. I

can see pursuit under water. I can see pursued animal is a plain pattern juvenile. I saw it under water the chaser is a speckled adult.

1125: Blow under water, head out. Animals move in front of advancing skiff. Two animals racing together at surface at:

1126: Humping part way out of water 2-3 nose outs, some rafting animals, some in rolling dives without much disturbance of the water. Quiet patterns really. Rings on stripper (shock is in the corn).

1127: Animals near backdown area, many rafting quietly with noses out—hers milling around central group. A couple moving relatively rapidly. Current sweeping by with backdown area completely closed and big stern bend. Rolling net now.

1128: Animals reacting by moving from divers, some noseout animals rafting, some diving, throwing of flukes. An aggressive encounter in peripheral area (most thrashing is there and not in the centralraft) one animal hit another in the air, not very hard. Rafting animals throwing flukes. Pairs of animals occasionally coming up together, now moving between sonabuoy and far line. Boats converging on both sides of school. School bunching more tightly.

1129: Now moving between sonabuoy skiff and far corkline. Boats converging on ...

1130: More diving, school not so rafty. Three however with head out, as if hanging vertically in water. Much rafting.

1131: Animals rolling and diving adjacent to skiff, beyond them a number of rafting animals with noses out, lying at surface. Nose outs more evident. Rafting more evident. Some parts continue to dive, while other parts dive. The rafters hang at the surface for a minute, minute-and-a-half and then dive shallowly. Tail slaps fairly strongly. Thrashing at the surface with the flukes above the water. You can see that the animals were going down together in some sort of tight maneuver in which they were in one another's way. Some animals still rafting, nose out, and others circling, diving in groups of 3,4,2, surrounded on both sides by skiffs.

1134: Animals pushed up 25 m from far corkline, rafting many noseouts, a few animals circling and diving. The rafters and divers seem separate animals. Malfunction in tape.

1137: Animals are still being held against the net 40m away by two skiffs. Rafting prevalent. Many animals that can't be seen so there are many below the surface. Over against the backdown area. Net coming aboard well. Other animals come up to the surface. So there's one rafting group and one diving group. Rafting group probably has 25 animals in it. Here come the divers up, surrounding it really, and one can see the breaths of the divers as they surface. Rafters really quite quiescent. Not more than 15m off behavior skiff.

1139: Rafters all pointed toward bow of ship, moving out ahead of the behavior skiff. With some of the divers coming up under and ahead of them, but the rafters continue to raft, as well as I can see. Some parts break off from time to time, and seem to dive, but parts stay at the surfac for considerable lengths of time. A thrash in rafting group. They got very tight. I believe a diver came up under them, and ahead of them, but the rafting group continues to raft.

1140: The school is moving toward the *CJ* toward the backdown channel in a very tight raft, estimated 30 animals at surface. One can see them all facing the same direction,

some with noses out of the water, really tightly crammed together. A number of nose outs, another group came up from below. I can see another group coming up from below. Below the rafters. I think group may be even smaller than I estimated. There may be no more than 50 animals, the rafting group is 25, I'd guess. Pieces of rafting group break off and dive. Very little aerial behavior. Not much aggression, not much movement. In rafting group one can see animals with nose out, and tail down.

1142: Animals between skiffs, moving very slowly. There's one diving group that's gone down under the acoustic skiff. I can see them in the water coming back to surface, spending quite a long time down there actually. Animals rafting, being washed along by the current, simply moving along together, crowded, passively, backward away and between the two boats. Diving groups surface and directly they reach the surface they dive again (do not raft). Rafters are left at the surface. Very quiet. Just sausages.

1143: One can see the animals far down in the water. 22 animals rafting persistently, another group, maybe a few more coming up by the acoustic skiff. Animals came up in column and formed roseate pattern-like petals of a flower as I observed in Hawaii. Some animals coming up and blowing leaving quite a mist of spray blowing away in explosive breaths from most of the animals, as is typical of this time in the set. Bursts of spray from nostrils. Bursts bursts bursts. I think many animals spend quite a lot of time below the surface because the surface number fluctuated widely. The diving animals seem to be the ones . . . There is a real separation between who dives and who does not. (Later Perrin shows this to be sexual—mothers and young in rafts, males etc. in diving groups.) I can see a couple of animals hanging in the water, and I can see a group of animals below the rafters, resting down there without much movement. I can see two such groups without much movement. They come to the surface and dive again. We are not too far from backdown time. We have to get our people out of the water. I yell to them.

Steve Leatherwood goes through an evolution with the acoustic skiff—actually it loses its forward gear and he has to pull and over hand out of the net. Oh shit, Steve . . . but he made it. What in hell are you doing, Steve? What is Leatherwood doing? Against the *CJ*.

1148: Acoustic skiff moving along edge of *CJ*. I gather they are trying to leave. The animals are rafting in a very tight group, the animals touching and all tangled together. Some aggressive encounters among the diving animals especially. Animals surface in a very tight group as if they sense the time coming for release by backdown. Rafting group same size as it has been. Helicopter takes off to photograph backdown. Acoustic skiff out. Aggressive encounters common, but rafters quiescent, others diving.

1149: Helo taking off. Rafters reduced in number. Most diving in response to noisy helicopter, not far above. Animals very tightly pressed to each other, both in diving and rafting groups. Both groups in contact.

1150: Helicopter off. Rafters about the same. Rafters don't breath hard. Hard breathing a function of diving. Nets coming in again now. School still divided in two. Rafting and diving. Many rafters with noses up out of water and then quite a thrash in raft and a struggle. Most of rafters driven slightly underwater.

1153: Rafters and divers in about same proportions. Divers to surface. Backdown started. Acoustic skiff out of net 1155.

Sonabuoy in the net however. 4 came up in perfect unison. Divers doing that. Helo over low. Fewer animals now seeming to raft. More diving.

1156: Preparing for backdown, in backdown, lobe of net same rafting group facing *Eliz C.J.* Helicopter over animals. They have moved backward into backdown channel. Ever closer. Come out there to grab them. Very close to end of backdown channel. Some divers up with explosive breaths.

1157: Corks below, and animals just about to go over. Some are, some facing net, some sense release. Swimming off, nobody trying to catch an animal. Leaping through the air. One animal obtained. One on skiff. One animal just over backdown channel swimming right by corkline.

1158: Most of backdown completed. A couple left in net. These swam back into net. Most animals have left in typical leaping fashion to the southeast. Two animals remain. Fairly broad backdown channel, narrowing it. Captive animal in Avon coming up. Trying another backdown. Three boats at end of backdown channel.

1201: Single cattle egret—light airy glider.

1204: Sign off.

1220: Lone animal circling quietly in net, pretty much at surface. Occasionally we could look down and see fish milling directly under it and behind it. The porp turns sharply and cuts off some tuna at times, but the impression is that the fish follow the porp. Net 80 ft.[?] Porp out. It did not leap, but simply submerged and disappeared.

To summarize impressions of this school and its behavior. There developed a cohesive rafting group that did not dive much. It was surrounded by a series of subgroups that did dive consistently, surfacing only briefly, and toward the end of the set, diving for apparently long periods as indicated by their evident almost explosive breaths. The rafters were clearly the most non-aggressive part of the group, seldom having thrashings or white water amongst them, while chases, nippings, and other evidence of aggression were much more common in the diving animals. Not much fish—5 tons or so.

In the afternoon we performed data set No. 12.

1549: Set up pretty late, net halfway out, time off of the Greenwich Mean Time due to inaccuracies in other clocks. I'll be going out with swimming team this time.

The school was apparently about half spinners and half spotter at the start, and something like 50 spotters were lost by the bow during the chase. I sent most of my notes to the *Jordan* in a sonabuoy hydrophone. We could simply pick it out of the water and speak into it. The following then, are impressions in addition to the tape recorded by Frank Aubrey. The seas were pretty hig—7 ft. swells, though no wind to speak of, and I borrowed a big, heavy pair of fins from Warren, went down the inset ladder on the downstream side of the *CJ* (away from the net) rolled into the big Avon with Don Ljungblad, Steve Leatherwood, Rod (a crewman and diver) and Dave Holts.

We went around and slipped into the net when it was wide open, before it had begun to roll. In such a circumstance the water area is so great that it is difficult to get close to the animals, though ultimately we were able to do so. The water was full of little medusae, pulsing along, trailing their stinging tentacles. I had a T-shirt and shorts on and never felt a sting. It's an eerie feeling diving in the open sea, even though in a net. Before pursuing one knows the bottom is open and that nothing but water intervenes for 2000 fathoms or so down. But, getting near the animals dispells this sort of aquatic

claustrophobia (I'm sure there's a name for it). Almost at once I saw yellowfin tuna below, travelling in a very open school, down 30 ft. or so. Then porpoises. I'd guess the school, of 150-250 animals, 2/3 spinners. The spinners were ghosts—pale, pearl gray against the blue water. The spotters on the other hand, were much more difficult to see at a distance because of their color and pattern. At first the spinners were in clearly spaced schools, traveling with a clear distance of a foot or two between animals. Later in the set the interanimal distance closed and the animals came to touch one another. The spotters were close from the start, often travelling in dense touching groups. Spinners usually were around the spotters. That is spotters tended to be central, and sometimes below spinners. Never did they intermingle at the subgroup level. Nonetheless the school as a whole moved together. In shape underwater, one could see a surface rafting group, and then typically a columnar mass of animals extending down into the haze at 60 ft. or so, composed of tiers of animals. This mass was usually taller than wide, and I guessed that 60-80% of the animals at one time or another, were below the surface, cruising quietly. Spinners tend to travel horizontally most of the time, while spotters are much more wont to travel vertically or nearly vertically. I noted some aggression, largely in spotter groups, consisting of nipping and chasing. One adult speckled spotter pursued a plain-colored spotter out at the periphery of the school, perhaps in an attempt to herd it back into the central area.

There was much release of bubbles by both species, especially toward the end of a set. These came out in long streams of small bubbles, and I presume accompany squeals. I was echolocated, especially by one male spinner who cruised near. I saw no reproductive behavior, and have seen none during any of my observations, except maybe one example of pectoral caressing (knife-honing behavior in which one pectoral slides over one surface of a neighbor's pectoral, then under it, over it, under it, etc).

I saw definite segregation in the tuna schools according to size, and I saw the following behavior. A group of maybe 20 5-7 lb. yellowfin streamed after a spinner group moving horizontally below and in front of me. They moved past some more quiescent spotters and spinners. Then I saw the large tunas schooling together too, without references so far as I could see, to porpoises. Most of the time in the net I saw no fish near the porpoises.

Quite evident in spinner porpoise schools was positioning in which juveniles, young and subadults, all assumed the typical position of "above the midline, with beak aft of the adult" when swimming. This was not wholly immutable, and for example changed on tight turns, but was the common posture in straight-path swims.

During backdown most of these animals, spotters, and spinners alike went out back first, and seemed to have no idea they were leaving the net. Some of both species swam back into the net. Those animals facing the end of the backdown channel quickly realized they were about to be released and made efforts to get out, thrashing over the corks, sliding over, and they quickly sped away, while the others sometimes took a few moments to realize they had freedom, to turn and flee.

No porpoise were lost, thanks again to the efforts of Jim Coe. Our losses are very low on this trip. Back on board I was one of three guys who won the Sunday football pool—what does a lousy professor know about football, eh, when some of the crew know the state of every quarterback's knees, the attitude of the coaches, etc. But, there's no

justice, I guess. I was glad two crewmen shared it with me since Jim Coe had swept the field last week and we interlopers shouldn't clean out the fishermen, should we?

Anyway, the swim felt good—especially the exercise. A not especially inspiring movie and to bed.

Oh yes, most interesting of all, Bill Perrin was able to psych out from the mast that the rafting spinners were males and young (with young often below the adults in the raft). While the adult males and some others were in the peripheral diving groups. This is evident because the adult male spinners are sharply dimorphic, having sail-like dorsal fins canted forward. I strongly suspect that this sexual and age segregation is the case in spotters too, though they are not dimorphic enough to determine easily. It appears to me that we are seeing a normal pattern confined within and potentiated by the net. That is, in nature, mother-young groups are typically found in the centers of schools. They tend to be cohesive, tight groups. The maintenance of them in this position is determined, I believe, by aggression from peripheral animals. In the net aggression is largely peripheral too, and the mother-young group persistently rafts. Aggression seems heightened in the net, probably by fear and the surrounding nature of incoming threatening stimuli, and I suspect the movements of the school are mediated in this way. They average the terror, by occupying the position farthest away from all frightening stimuli.

November 1, 1976

Well, the weather is getting rougher . . . the wind is blowing, and there are some strong currents. We are pretty near to Clipperton again. A school of spotters were located.

1011: School located by helicopter, boats not in water, half overcast, swell moderated to some extent, wind has picked up 15 knots or so. There are scattered whitecaps. Bright sunny and hot. *David S. Jordan* hull down on horizon off starboard quarter.

1025: Speedboats in water, helicopter up, speedboats directly in front of us, just beginning the counterclockwise spiral (they always set counterclockwise). Boats curve off to port. Counterclockwise because davit is on starboard for speedboats and net gear is on port.

Large flock of birds, many more than over any school in the last few days. Boobies of two species—masked and browns. At least 100 birds, one long frigate bird high overhead, up among the helicopter. I see only spotter porpoises in this school. They are turning inside the *CJ* wake now. Really in pretty good position. Here come the bird up inboard of the second speedboat, a flock of them, behind the porpoises, staying behind them during set. Porps in pretty good-sized group, leaping as they swim.

1042: Net skiff inwater. Looks like a perfect set so far. Birds still flying in some numbers to rear of porpoise school. Pure spotters I think. Only 20 miles or so away from Clipperton again. didn't seem to lose many porps in set.

1043: $\frac{3}{4}$ net. Can *David Starr Jordan* reach us in time for work. Cattle egret landed on deck. Husky chased away. Hull of *Jordan* in sight. Porps 70-80 m from far corkline. I'm going up in crosstrees to see better. No differential behavior today, but will look at rafting behavior.

1050: Single animal produced a very sharp blow. Corks coming in?

1051: Still pure spotter school. Number of animals up at any one time is 25-30. Would make school 125 animals or so.

1053: Helicopter landed on deck.

1055: First evidence of rafting group, first noseouts occurring. Raft quite central, raft consists of 20-25 animals, thrashing at edge of rafting group. Other animals are swimming and diving. There is a possibility of another raft at the head of the school. Looked like raft turned and went opposite way without submerging much. Now turned and going back the other way.

1058: Fairly well -defined raft at rear of school, animals lying horizontally at surface and moving slowly. Animals ahead diving and swimming, some thrashing in group ahead. Some turning of diving groups back toward the rafters who move slowly. Thrash in advance group. Another thrash in head [?].

1059: No spinners at all. Great leap, animal falling back on its side. Some chases in peripheral subgroups, during diving patterns. Rafting group moving at rear of school.

1100: Lead line broken. Manuel in water. Eduardo in water too, going in with heavy nylon. Could have ripped lead line off. Corkline coming over the stern.

I suspect there is quite a lot of male chauvinism in porpoises, as they round up the girls and children in these central groups, with snaps of the jaws, and tail slaps, etc. Head slap, head slap, at rear of school in diving groups.

1105: Quite an evident central raft. Seems to come and go, actually. See it for a few seconds, animals traveling under. Getting corks around to stern now.

1118: Can't truly make a well-defined rafting group that doesn't seem to move and disappear. Some stay for quite a time (minutes) but they generally move below. There are other groups actively diving all the time. *Jordan* standing in now, 3 miles out. Some hope of getting here before net's all in. An occasional well-defined blow, as if the animal had taken in water in its blowhole. Watched raft stay in sight for 28 seconds, then throw flukes and dive. Stern end sweeping out behind the vessel—large. Towboat towing directly astern, first time I've seen that. Bow bunches not brought in.

1119: A head-out in central school. Most animals rise to surface, take a single blow and dive again, some throwing of the flukes. School not very evident at moment. A fairly clear raft off to one side of the school now. Nose outs in rafting group, desultory raising of flukes but group as a whole stays at surface 28 seconds.

1123: *Jordan* nearly in position. Rings not yet up. Net siff pulling to port quarter. One set of bow bunches drawn in. Quite a lot of aggression in a diving group, a lot of thrashing.

[#?]: Series of head slaps from single animal in diving group in periphery of net. Animals out near backdown area.

1128: 51 seconds rafting groups. Quite a number of noseouts, aggressive slapping on margins of aft but not in center. Rafting group in much the same location, often just below surface. I can see their bodies through the surface OK, but they don't go away or dive and disappear. Nose outs there. Still there. Underwater blow that came up as a ring. Rings still not up. See peripheral groups diving more quickly than central groups. Some head slapping on periphery. Rafts are scattered, not pushed in a tight group like yesterday. Water's a lot rougher. White caps in net. Animals leaping from the water or leaving white wakes out on periphery.

1135: Rings still not in. Skiff is in water off *Jordan*. Still not a tight raft like other day. Two tail slaps, one on either side of school. School is more diffuse than yesterday,

but typically the fastest moving animals are on the outsides of the school. Did I see a spinner? Some boobies landing in water in net. Underwater blow.

1138: Net skiff now pulling bow to port.

1140: Pretty evident central rafting group, with animals nosing out, putting their heads out, and staying at surface with animals milling and diving around them. I suspect the rough water has some effect, if only to make it more difficult for me to observe. Blow underwater at edge of raft, another out near edge of school. See the vapor of a blow by the vapor rising in the air.

1141: Fast-moving animals at edge, slow-moving animals toward the center really pretty evident really.

1142: Two Avons are very close to going in the net. Separated pods in rafting area scattered over a fairly good-sized area. One avon in net (Thompsons). Net skiff has stopped pulling and is pulling in its tow line. I think they may change positions again, to pull it out of its stern bend. Even though rafting animals are moving quietly that is not to say that they escape from being aggressive. There often seems to be some racing into those groups, and thrashing especially at the margins. Even though divers are at the net they have not entered the water.

1145: Quite a well-marked central rafting group now, animals diving on periphery. It's in the rafts that one has the majority of head and nose outs. A maneuver of a quietly resting animal rather than an active swimmer. Another blow underwater, deep.

1147: Ed tells me he thinks he saw a spinner too Much more well-developed central raft now, animals lying more or less in same direction but some helter skelter, quite a few nose outs. Animals up ahead diving and maneuvering around. No bow bunches. Bunches by backdown buoy. No divers in water. Single spinner on periphery of school. Lots of nose out behavior in central group—these animals are scattered throughout the rear of the school. Mother and half-grown in rafting group came up tightly pressed together. I can see a rafting area which is fairly evident now. Looking it over many of the rafting animals seem to be unspotted phases. I see spotted phases next to two-tone juveniles. Could be mother-young assemblages.

1153: Net size reduced by very large stern bend. Net skiff piling on stern toward starboard bow. Net probably 100 m to far corks, 200 ft. long. Chance for net collapse. Bunches out toward backdown channel. I can see in the rafting groups, either juveniles with adults or unspotted two-toned with adults, relatively quiescently. Mother-3/4-grown pair, like that. Group below me of such animals and I can see speckled adult alongside two-tone, 3/4-grown. On margins are rapidly diving groups—let's look at those for a moment—speckled animals, so far.

1157: Rings up. Speedboat pulling at stern bend. Open area maintaining itself. Clean juvenile went over to side of accompanying spotted adult, to get on opposite side of us. Rings on ring stripper.

1200: Not especially notable structure, single animals scattered around, mother-young pairs scattered around near periphery. For some reason our divers have left the net without having gotten into it. Don't understand. School pretty scattered, not tight. Rafting speckled adults. Aggressive encounter between speckled adult and small . . .

1206: Great flurry of white water at school margin. Net rolling.

1208: Another chase at margin of school Thrashing around at margin near far side of school. Some animals come free of water. Three flurries in same spot. Tail socks free, very close to net—30 ft. Underwater blow, breaking water.

1211: Animals came to surface and thrashed. More aggressive encounters, racing animals, other parts of school resting quietly. Nets been rounded up by net skiff. Perfect shape.

1215: Animals alone at surface, school remarkably spread at this moment. School spread across $\frac{3}{4}$ of available net—120 ft. peripheral aggressive encounter. Light is difficult. Chase at periphery Another chase on periphery. Animals moving on margins.

1218: Fast chase on margins. Ed says he sees a spinner on school edge. Quite a thrash, another chase. Head slap some leaping.

1228: Obvious combination of formation swimming and rafting. Rafting groups fairly constant, lying continuously. Moving groups move more rapidly than before, continuously. Quite a bit of explosive breaths, tail slaps common. Nonetheless the rafters raft. Pongas attached to net. In backdown. Animals working toward backdown, many facing in the net. Is there a rheotaxis involved. A thrash amongst animals going over net. Net 35-40 ft. wide. Backward to backdown. A group swimming resolutely into net.

1232: More animals going over, some leaping away, herd leaping, leaping, leaping.

Fishing Set No. 20. It was decided that it was too late, and too rough for a data set. People weren't ready. So a fishing set.

1530: A lot of birds. The direction of these sets is always counterclockwise. Joe is getting on the microphone. The direction of the sets is done by both brothers—Joe and Manuel simultaenously, and always at full volume with face crammed right into the microphone. There is literally no crannie of this ship where one can escape the decibels. And the volume of each instrument is up full. Everything is in overload. Either everyone is chronically deaf due to all the winches, engines, etc, or it's just their nature. I'm sure it's the latter from watching Joe. He is the Toscanini of the microphone in a death grip next to his face, the other arm gesticulating in the air, stabbing the sky for emphasis.

I should mention that there are speakers everywhere—in the john, the engineroom, the shaft alleys, you name it. I never saw so many speakers. I tried up in the wheel house, for example, to get out from under one by running back and forth, and failed. There was Joe, overhead, exhorting Luish in the lead speedboat, now coaxing him, now calling him a dumb sonofabitch in both English and Portuguese for ruining the financial fortunes of everyone on board by letting some of the school get out to the side of his racing speedboat. Luish, by the way, cannot talk back, and one can see why. With two brothers at you there's no room in the first place. Three swear words superimposed might in some transform of heterodyning come out a love feast, and that wouldn'tdo. Anyway, it's noisy

Animals pouring from the water in droves now, quite a large school. The numbers in all of these schools is very much less than estimated by the crew, usually by a factor of 100% or more. A 1500 animal school has 70 animals or less when counted.

Sure enough the animals were turned by the wake, as they get within 400 yards or less of the wake they begin to slow and to be wrapped in a spiral of wake.

1546: Net skiff half out.

1547: Net's off the stern. Skiffs coming alongside the boat. Already the spinners are on the inside and spotters occupy much more of the surface area; can't tell what this means in terms of numbers, because spinners stay down.

1554: Spinners up. Bill Perrin and I will do a dive rhythm.

1557: I guess 400 animals. Spinners up 29 seconds. Spotter doing head over tail leaps, high belly flop, head over tail leap, great high head over tail leap. Another, another, another thwap, whap, another.

[List of dives]

November 2, 1976

Brisk breeze blowing today as we move into Experimental Set No. 14. Whitecaps on water—perhaps 15 kt wind. Bright and sunny, 5-6 ft. swell, rough set for anyone in the water. Not too bad. Photographers will be in water with acoustic people. The attempt will be to photograph an echolocating porpoise at the time it is being recorded. *Jordan* three miles on our port beam. Supposed to be a mixed school with, on the order of 15 tons of fish on it.

0812: In broad circling phase of set. Some birds over set. Low flying boobies. The *Eliz C.J.* has failed to follow the speedboats for a short time, leaving a straight wake, and going out of their path. Animals almost in the middle of the circle, with a smaller group further away from us. Abeam of lead speedboat. Animals moving along as a front, perhaps 500 yards from the ship's wake ahead of them. Their behavior relative to the wake impressed me that they are indeed echolocating the environment ahead of them, since they typically stop long before the wake would become visually visible to them, or are turned by it in a similar relationship. I have, however, seen them run right up and into the edge of the wake, and slide along the inside of it.

0823: Net skiff in the water. Porpoises are slowing down on the order of 350 yards from wake, but there is still some jumping on rear end of school, but the school as a whole has slowed and gone into their "Oh Hell, here we are again" phase. Well before visual cues could be used. I suppose the wake may bubble and hiss, so that some auditory cues might be involved, but the more likely modality is echolocation.

Now the whole school has slowed. Lead animals on the order of 300 yards from wake, directly ahead of them. There is a raft of boobies sitting 150 m inside wake. Porps almost in center.

0824: Half net. Cattle egret flying by.

0826: Porps in center of net. Maybe fishermen will [?] 5-10 tons of fish.

0840: Visibility is very bad. Chop, we are in the sun wake. Quite a lot of swell. Animals are silhouetted. The operations in a set that take longest are pursuing, and sacking up and brailing. Backdown is brief—a few minutes really, even for a difficult one, and a skillful fisherman seems able to perform it without significant loss of fish up to at least 60-70 tons of fish. Above that and I'd guess there would be problems just because the backdown channel would be full of fish jostling the porpoises and some loss would be inevitable. The entire *Jordan* contingent is out. One whaler and two Avons. Good to get some exercise. A rather poor day for work, though.

0845: Skiffs at backdown area, nosing over line, or going in the net. Animals over by backdown buoy. Typical position 60-70 m from far corkline.

0847: In the absence of spinners (the school is all spotters) I am going to play with this question of rafting, hoping to get some handle on age or sexual segregation. It's an inauspicious time, though, with the light so bad though, and the largely non-dimorphic spotter to work with.

0859: A very large stern bend which is causing a reduction in the size of the net available to the animals. A lot of folding of the net over toward the backdown area. One major bow bunch. Animals on port quarter about 70 m from corkline. There does seem to be a rafting pattern at the middle rear of the school. Swifter moving animals ahead and on sides, though the movement is not swift anywhere.

0900: A raft at the rear of the school. I can see animals staying for considerable periods at the surface in this position with occasional nose-outs, which are indicative of slow movement. Elsewhere, diving, throwing of the flukes, and sometimes rather swift swimming. A distinct raft now, in which sees consistent nose-out behavior, consisting of maybe ten animals. They turn as the school turns, and their rear center position means that they tend to wheel around slowly as the school turns without much forward motion, while the outer animals may be moving rather swiftly. The rafters on the other hand may simply move with their noses out, their tails slowly sculling around. But rafting group is obvious. Skiffs moving into net. Animals responding by moving toward the stern away from the boats. A rain squall sweeping in from the stern. A real wet one (but it largely misses us, driving me and Bill for cover briefly, while Ed stayed out talking into his beloved recorder.

0912: Rings up. Animals very close to being in the stern bend off our quarter. I'm going to try to describe animals that nose out, in terms of whether or not they have spots, are bicolor juveniles, or young. One young nosing out. The central rafting group around which the others have milled—I can't see spotting on any of the animals maybe because of the light angle. A two-tone nosing out, approached by another animal, who then thrashed at the smaller animal in an aggressive encounter. Active group ahead and rafting group behind. Very hard to see if spotting is or is not present.

Maybe later in set when animals are more below us we will be able to make better and easier determination of pattern (proved to be true).

0925: Divers in water forcing them over against the corkline, moving rapidly as if disturbed by this. One animal within a couple of feet of corks. The mesh is large, and hence dangerous at this point. Animals going around the divers, one rafting group astern of the others. Acoustic skiff cuts them off from others. Front animals rapidly diving. Rear animals traveling very slowly.

We can begin to see some pattern now, as the animals move around out of the sunwake. There are five animals in a rear rafting group, a mother-young pair, another animal that swims closely with them, and then another pair of two-tone juveniles. They are separated by perhaps 30 ft. from main group now, whose shape and movements are being influenced by the acoustic skiff. One of the animals in the outside two-tone pair is smaller than the other by perhaps 1/5, in length, and they stay quite close together.

Another slow-moving pair (than the five just mentioned) includes a speckled adult and a young with a few speckles. Maybe just entering the speckled phase. A mother-young pair astern of the school. The advance animals, the ones that move rapidly, as far as can see, are all speckled adults. The mother-young pair moves quietly, the young with its nose out, the adult wheels slowly as the school as a whole wheels, under the young,

bringing the young's snout over its back and pushing it up a bit, and sliding it off, as direction of orientation changes.

Now they slip back even further to the rear of the school, and both hang at the surface with their noses out. They are part of a six-animal rafting group. The rafting group close to acoustic skiff now, so close that the animals are actually on top of one another. The school is divided into three parts by the skiffs. One part dives, and comes up with one other part. What is left now is a single pair of juveniles—two-tone animals, moving along with noses out, a third animal, speckled came up near them, and the pair slid over on another, as if getting out of the way.

0932: Defecation in water, lemon brown cloud from adults. The diver now directly under two-tones, at rear of school. One two-tone in typical juvenile posture against a speckled adult at the surface, at the very end of the school. Going into nose up behavior, left first adult and went to another two-tone animal. This pair becomes separated from the rest of the school by the Avon.

End of Set 14:

The tape failed me at the end of the set. The final circumstances were that the juvenile pair continued to hang together, even into the backdown operation, and only when backdown was in full swing did they become invisible to us in the general melee of animals. Many of the animals went out of the set backward, and some hung for a few seconds facing the net, even after being out, and then turned and began the typical leaping away from the net. The population was not large. I doubt that there were more than 100 animals all told. 10 tons of fish taken.

After the set we packed our gear, took the sheets from the bed, and got ready to leave. Bill Perrin and I, along with the normal *Jordan* crew head for Manzanillo, where Bill goes to Washington, and I go home. George took us over on the big net skiff, because we had so much gear. A safe transition to the *Jordan* was made, one world to another. Leaving the predator's world of the relentless chase, the working for however long it takes, the dissatisfaction with routine, or even experiment if it clashes with the relation between predator and prey, the ethnic group, voluble, mostly warm and friendly, taking pleasure in the day's work, to the more structured world of the *Jordan*, used to research, helping and understanding it for the most part, but also good people—largely from the Anglo world, the perquisites of sea routine, two movie showings, linen call, water regulations, less powerful air conditioning, different food (more government issue on the *Jordan*, Portuguese-Mexican on *Eliz. C.J.*)

Two cattle egrets make the *Jordan* home—weak from flight, fed anchovies, with no Huskey to chase them away. Huskey, by the way, the Huskey dog of the *CJ*, who bites a lot of people, became my pal. He was a dog that wanted to preserve his individuality and dignity, and if you took him on those terms, and said hello when you passed, he would come to wag and lay his head in your lap. A dog with a lot of interest in life—sharks and speedboat launchings were times for barking and if someone came aboard whom he didn't like, he could get so agitated barking that he would snap at whoever was near, a line that slapped him, a person. Good honest hard-working dog. Ralph, his sidekick, a shepherd, a pale personality indeed, by comparison, but just a puppy. Maybe he'll develop prejudice as he grows older.

All in all I think we learned a great deal and that our report should be a useful one. It would have been more so had it been done three-four years ago, as planned, so we could have had it to think with.

November 3-5, 1976

Enroute, Manzanillo, Mexico

When we left the *C.J.* it was 56 hours by *Jordan* to Manzanillo. And we turned our nose north-northeast on a direct line. The *Jordan* rolls more—sandpapers one in the fore and aft bunks, and the weather was rougher. Enough so the normal routines of work become mostly snoozing on the bunk, shooting the breeze on the after deck. It was refreshing to find someone who cared about the national election, which took place while we were on board. The *C.J.* cared about football, but politics didn't seem to enter their concerns at all. Bob, the assistant engineer brought his radio up and we listened to *Voice of America* and heard Jimmy Carter win. I still have the same old feelings of concern about what kind of president he will be—he impressed me as full of heartless drive, like Tap Pryor, and in spite of the radiant smile, without essential humor. Nonetheless, he appears to stand for many of the things I do, while Ford, solid and likeable, seems to me so terribly conservative that fiscal concerns are all that drives him, while the country founders without energy or conservation thrusts, and with a foreign policy that aligns us with the worst of reaction in the world. No one, it seems to me, answers to the ecologic ethic, the systemic revolution through which we must pass. But then, no one ever did, since Teddy Roosevelt, so far as I know. And then he?

Not much happening—food, lots of it, people getting their gear in order, me trying to organize the report that must come from all this, trying to get films catalogued, and so forth. We did stop at a great coil of hauser floating in the water, and looked down at the glimmering mass of fish beneath it; clouds of small gray triggers at the surface, intermixed with young *Dermatolepis*, and other fish, a mill of 5-6 ft. sharks, and beneath in the azure, the flash of bellies of larger fish in clouds—probably tuna, maybe tons and tons of them.

We've seen a few porpoises. I descended to the bow bubble and watched a single big *Tursiops* as it rode in front of the window through which I peered. It rose and fell like a marionette on a string, spun slowly over this way and that, sometimes upsidedown, sometimes on this side, sometimes on that, its tail arched downward and its flukes horizontal with the line of the tail, but without any tail beat. One had the impression of a roller coaster ride in the undulating pressure wave in front of the bow. We weren't pitching much as the sea was pretty calm, but enough to generate these fluctuations. One can imagine what a whip it would be in rough water.

November 6-8, 1976

Manzanillo, Colima, Mexico

We pulled into Manzanillo in the early morning, after lying to all night off the entrance. The harbor is a lovely circular one, and one of the only truly deep-water ports in western Mexico. It is tucked in a circular bay, rimmed with green mountains, tier on tier back into the blue of the distant Sierra Madre. I understand up that way lies Patzcuaro, Lake Chapala and so forth. The town is old—300 years or so, and much is paved with artfully set cobbles. The town of maybe 45,000 people sprawls over the flats around the

harbor, up the hills and out along the graceful beautiful playas to the north of town. We tied to the customs dock not far from the Plaza. Our aim (at least that of Bill Perrin and I) was to rent a car and cruise the countryside, both north and south. We finally accomplished the rental and obtained a disintegrating American Motors beauty, which later collapsed on a lonely road far from town amidst a coconut jungle.

But first—we took people to the airport, passing the big mangrove-lined esteros north of town. Birds were everywhere—great herons—a white version of the great blue, spoonbills, ibis, ducks, olivaceous cormorants (a little stubby necked bird that is very common) and many others. I won't recount all our adventures. Suffice it to say that we explored some waterways near the airport where we found amis in abundance—lizard-eating blackbirds like heavy billed grackles, with big heavy bills, kingfishers (looking Irish), lizards, *Natrix*, which performed according to plan, biting Bill and slathering everyone near with anal secretions. There were armadillos, turtles, peccaries, lots of butterflies—a big white sulfur like a floating sheet of kleenex (we dubbed it the kleenex butterfly), *Heliconias*, and so forth. Up one canyon before we came to a beach named Playa del Oro we explored the jungle finding many new marvels. One big *Mimosa* tree, we find is protected in a beautiful symbiosis by ants. It has highly hypertrophied spines in pairs—big black fellows maybe two inches across. Each ends in a single sharp spine, and in the older ones, those not green but dried in place, nearly every one is penetrated by the ants, with a colony of them living inside the inflated spine. They reach to outside through a single artfully placed hole right at the base of the spine. These little black ants are literally everywhere on the tree—all up and down the leaves and veins. And they bite like fire. I wonder what the biomass of ants per tree is, for it must be large. Then I walked down a little jungle-shaded road to a quarry and found myself walking on oak trees—no more than 10 inches tall, with maybe four to five leaves, each five to six inches long—a perfect *Q. agrifolia* leaf except for its remarkable size.

At the end of the short road a small creek tinkled in a granite streambed. Up one wall, amongst the bromeliads I found a congress of harvestmen—dozens of these spiderlike long-legged creatures in an airy mass, all touching each other. They shook in a sort of wavering dance in their moist cleft. When I blew on them the quavering I created swept across the entire group—contagiously. Above us, in the nameless trees, tyrant flycatchers flew, down close to us.

Once on Playa del Oro, the day was hot and the winter sun beat down with uncommon force. Most of the folks trudged off down a long, long beach toward a distant headland. I chose instead to go less far and to take up station in the shade of a great rocky inselberg that rose from the sand, part in the surf, and part in the white strand below the berm

On the sand up the beach from me there were probably two dozen big *Octythoe* crabs (spelling?). They were feeding and posturing on the sand nearby so that my field glasses let me look closely at them. The beach in certain areas where the waves had cast a rusty colored material on the sand, was littered with the castings from these crabs. I watched as they made them—small lumps of sand $\frac{1}{4}$ in. long and $\frac{1}{8}$ in. diameter

The crab walked along across the sand, sideways, dragging the tips of its chelipeds on the sand, and then when some sensory signal indicated a good place it began to feed bits of sand into its mouth by probing at the sand with the tips of the claws, bringing it to the top of the mouth, just below the eye level, which was producing bubbles

in some quantities at the time. The sand, after several touches from the chelipeds worked its way down the groove between the mouthparts and became an oozing mass that dripped out onto the ground in the form of a casting. All the while this was going on the animal stood on the tips of its claws. But after 10 seconds or so, it usually bent the claws on one or the other side, causing that side to slant downward and to hit the sand. Usually it then made a couple of quite stereotyped wiggles that pushed that corner of its carapace a little way into the sand. In this posture feeding was often interrupted for a time—2-3 seconds, often with one claw continuing to bring material to the mouth, but then full feeding resumed while the crab stood slanted into the sand. This lasted five seconds or so, then the crab righted itself, and moved on. I noted them following strand wash lines—the little marks of the highest flood of a thin apron of water at the upper edge of a wave. I saw aggressive encounters in which the crabs seemed to attempt to intimidate one another, and spent much time making castings while they faced one another.

Well, after that we went to the airport and waited with no results for the planes of various folks to come in . . . some people from NMFS, and Karen Pryor.

So, we night-drove back, after taking a side trip up into Jalisco, past Cihuatlan, a fine little town just inside the line, and adjacent to an enormous coconut plantation down on the coastal flat. We found a streamcourse north of town—Arroyo Seco, and caught a cyprinodont fish and a shrimp with extremely long chelipeds. Nice jungly scene. Nice sunset and thence home. Bill Perrin jumped out of the car when I saw a snake, and announced it looked like a viper. It was—a big pichiquate or cantil, the Mexican dryland moccasin. It lunged at Bill as he attempted to keep it from leaving the road—3 times and almost ran between his legs. I uess it was 2½ ft. long—very dark, with yellow markings and a line over its eye—and also very fierce. *Hyla?* were everywhere, jumping in very high saltations in front of the headlights.

Back in town we were greeted by a biological phenomenon the likes of which we had seldom seen. The wires on the west side of the plaza were lined with swallows spaced inches apart—by the tens of thousands—all wires filled for several hundred feet, on both sides of the plaza, up the main street. Their positions seemed nearly random—that is two birds faced this way and five that, and nearly any combination could be found. They ended abruptly at a cross arm in one case. I never saw so damn many swallows and they were defecating over everything—cars, the street, etc. I tried to convince Bill Rogers to use it for his dissertation.

Today a trek south of town down the sand spit. Our car gave out, two beekeepers helped us get it running (the transmission was ausegeput) and then a soccer team helped us push it through a puddle. A nice swim at Karen Pryor's beach, back to the boat, and home, to the *Jordan*. Tomorrow, the plane to LA, then to San Diego, and then home on Tuesday night.

A nice looking Mexican guard on our pier wants work in the US, but needs a US sponsor. His name is Ignacio Gonzales Mantodecoca; Domilcilio Conocido Salahua Col., Municipio, Manzanillo.

April 5, 1977

Bunny Club, Granite Mountains, San Bernardino County

The fourth annual Natural History of California class arrived at the BC at about 1700. We had left Santa Cruz the night before, camped at Hart Flat, which provided us with its usual galaxy of trucks shifting gears, trains straining up the grade—but, a bit cold. I finally drifted off at about 1:30 AM. Then in the morning we ate our granola, powdered milk, and raising, keyed out a few flowers, and left. A really good group I think, with lots of skills scattered around. I'll append a list of everyone and something about their interests. Most have interests in outdoor education, field natural history, geology, and the like. Some are skilled with plants, others with minerals or birds. We have at least three capable guitarists and a closet harmonica expert.

We made stops near the crest of Tehachapi Pass, another in the Joshua trees to look at *Xantusia*, another at Barstow for lunch, and a final one at Pisgah. This was a great one—baby chuckwalla were out, we saw utas mating. Larry, our herpetologist, caught an adult *Uma scoparia*. The desert was carpeted with desert marigold around Pisgah, and across Broadwell Valley. But to the east the rainfall had obviously been less and fewer flowers were in evidence. Finally we cut off the Kelbaker Road to the Bunny Club road. The big bus was so long it dragged repeatedly and finally at the pond I had everyone dismount while Walt Ward drove it up empty. That relieved the situation somewhat.

We parked the bus at the top of the hill and because of the number of people all the gear miraculously arrived at the cabin in jig time. Bob had done wonders with the cabin. Windows now fold up out of the way of bullets. The new sink and breakfast table are in and beautiful. There are bunks, a nice pump, a propane refrigerator, and other goodies.

The weather is balmy—70 degrees or so, warm at night, and the nearly full moon lights up the sky while stars glitter. A good vegetable stew, some aboriginal history chitchat, a bit of music, and everyone faded out.

Brother Bob and Ginny and Maggie Fusari Asplund showed up and Jennifer. Nice to see them. Maggie seems to be running Prescott Center College. She's some species of

Dean or other. Her students do “solos” in which they may spend days alone in some part of the wilderness—on top of a mountain or on a sand dune.

Everyone is a bit tired I think and willing to relax a bit, play the guitar, and look at the moon.

April 6, 1977

Bunny Club, Granite Mountains,

What a grand snooze! The window wide open at my head, the warm breezes of the moonlit night came in and I drifted off, listening to a distant horned owl. I woke about 6:30 with the sun amber on the palisaded boulders of the Granites. The bluish hulk of Van Winkle Mt. rose off below us. People began slowly to stir and breakfast was put together. I spent my day taking groups out to observe at the pond. The first was a great success as we evolved some new ideas about the aerodynamics of small birds—is there a relationship between mass ...

The last one was less successful as we went in the afternoon to look at level flight in a couple of species of birds. The heat of the day had sent most birds in and we were interrupted right in the middle by a BLM truck driving up and Jerry Hillyer, Joe Gullickson, and a little round guy named Charlie Watson, a Nevada Conservationist, getting out. Needless to say, though I was very pleased to see the BLM guys, it pulled me away and disrupted the observation, which unfortunately needed attention. That is, the students were not ready for me to leave, and hadn't grasped what I was trying to say. I was very sorry to leave.

A nice dinner, Maggie and three of her students came up. Good music on into the balmy night.

April 7, 1977

Bunny Club, Granite Mountains

Up early and praises be, off to the dunes by 7, we were. That involved everyone eating breakfast and putting all our gear into the bus. Larry drove us over the dirt roads in a masterful fashion, balancing the big bus so it seldom scraped bottom. At the dunes we stopped near Parker's magnetite sand mine. (He has a new creeping magnetite sorter that looks like a bulldozer. I can't imagine that it isn't grossly inefficient, when boulders they throw away up at Vulcan Mine contain a ton of magnetite and they are scattered all over the landscape.) We set out for the high dune across the creosote flats. Larry Minden turns out to be a card-carrying herpetologist and proved it by vacuuming up everything in sight—a horned lizard, a leopard lizard, a tortoise, an *Uma*, and what else I can't remember.

Fortunately the air was cool so the hike up wasn't too arduous though I did puff a lot and have to stop every 40 steps or so. At the top Ken Hart gave us a good talk on sand dune history and structure, and we looked off across the desert to the north to see Soda Lake and the Mojave River that are the sand sources.

It had warmed up and various folks had shed various clothes at the base of the high dune. To shed a top seems a special joy to a girl who must wear it under most circumstances.

Then we lept off the dune and it hummed for us beautifully (actually I've heard it louder—there was a moist layer not far down). A lot of us slid down the hill with our ears below the sand, listening to the mountain boom.

Back across the sand we went looking at tracks, refrigerator plants (*Rumex*), termite nests, umas, and such.

Everyone was hot and sandy so the vote was to try the Vulcan Mine for a possible swim. Larry got us quite a long way up the Vulcan road before it disappeared under piles of cobbles and alluvium. The road is nearly gone undercut in many places and overwashed in others. We finally stopped $\frac{3}{4}$ mile below the mine—turned the bus around, and then hiked for the mine. It was a fairly brisk hike up though the air was cool, thank goodness.

Very few flowers are out here though the soil is wet and there is promise in a couple of weeks. Some things are in bloom though: *Phacelia campanularia*, *Castilleja*, *Sphaeralcea*, *Amsinckia*, *Lotus*, *Eriophyllum*, and many more.

The lake in the glory hole at the Vulcan Mine was as full and clear as I have ever seen it—deep, green, and mostly free of algae. Most of the bottom was water, except for a [?] of rocks and soil at the SE corner. The water was cold (15 deg. C.) but everyone enjoyed a good swim, a chance to cool off, and to get the sand and crud off.

We walked back to the bus, drove back to the cabin for another observation hike, and then dinner and reports.

It's a nice night, the group tightens, and gets to know and enjoy each other. The group is the most skillful I have ever taught and gets on very well together. Not a ringer in the crew

Big River, Mendocino County: April 15-19, 1977

April 15, 1977

Hopland Field Station, Mendocino County

This trip is to the Big River estuary that enters the sea at Mendocino. We will do some survey work in the area with Jim McMillan, his wife Valerie, and their crew of young people who are trying to save the area from decimation by logging.

I was very lethargic all day today—snoozing on the bus floor part way into Marin County and really never getting with it all the way up to Hopland. We had a brief stop at Pescadero Slough to look at birds. There were many—ruddy ducks, red mergansers, a single great blue heron, a snowy egret, pie-billed grebes, coots, and on shore beautiful little yellowthroats zipped from fenceposts to reeds. Dull metallic blue-backed tree swallows swooped overhead. Up on the dunes we looked at the strand flora—*Abronia*, *Artemisia*, dune bush lupine, and a good many others. The New Zealand dune grass is taking over however and seems to crowd out the natives.

At the Audubon ranch by Bolinas Bay we were able to sandwich our group in between a couple of school groups. It's an interesting place. A nice trail leads up through a hobbit forest of gnarled oaks, firs, redwoods, bay, with a quite diverse and luxuriant understory. Pretty big patches of Douglas iris were in bloom. Finally we came to an overlook with benches and a telescope where we could look down into the canyon in back of the ranch headquarters. Perhaps 24 great blue herons and one American egret

were nesting, their stick nests set on the pruned tops of a dozen redwoods. The trees were like big green platforms that easily allowed these big-winged birds to land without the hindrance of branches. The birds kept the platforms clear and may even kill the trees involved. Each nest tree had dead branches evidenced at its top and some had brown or dying foliage in its upper reaches. Why this should happen escapes me yet. But we did see birds pruning live twigs free and working dead branches into their stick nests. The nests were spaced—probably 8-10 ft. was a minimum distance between them. There were two or three nests set back in the side branches of tall trees well below the crown. All are open to the side so the big birds can easily fly up, fold wings, and land on lateral branches, but obviously these are suboptimal compared to those on the platform crowns. The birds were in several stages of reproduction from circulation of the big blue eggs through rearing chicks almost ready to fly. The egret was hard to see, being down behind another nest.

Down the Alice Kent trail we traipsed and had lunch by the lagoon, where we watched dowitchers, dunlins, turnstones, and sandpipers working the mudflats. I wondered how these flocks knew when to land, or how the information spread through the group in so doing. It wasn't easy to see, but some things became apparent. If a group flew up to an area already occupied by larger birds they sometimes swooped down as if to land and then didn't as one or more birds swooped back up. The signal was transmitted to the others and the whole flock moved off. It was sensory integration just as with a porpoise school.

At Santa Rosa we picked up Dave Hart at his parents' house. Nice folks too—we used up about 40 gallons of their water filling our water jugs. Finally we reached Hopland and turned off to the east toward the 5,000+ acre agricultural field station. It lies on the slopes of the coast range extending from about 600 ft. above sea level to 3,000 ft. It encompasses valley oak savannah, live oak, blue oak, and Kellogg oak forest on the lower slopes and chaparral on the upper slopes. Al Murphy, the manager, put us up in the bunkhouse (we cooked there) and slept under live oaks, outside to the music of a frog chorus down in the defile nearby. The hills are lush with grasses and the thousand or more crossbreed sheep look fat and lambs numerous.

Good reports and guitar music and then to bed under the starry night. It's a great group with amazingly accurate and extensive expertise, and much warmth and good spirits for each other. There are so many I've grown fond of it's hard to pinpoint them. And so responsible. No one is late. No one messes the camp or is inconsiderate.

Chris Brown met us and it was fine to see her. She seems to understand herself better than she ever has and to be more at peace. It seems that her teaching with delinquent kids at a nearby Philo school is proving rewarding. We talked of this and that and drifted off to individual camp spots.

April 16, 1977

Big River Estuary, Mendocino County

Up early for folks and a tour of Hopland. A very knowledgeable grad student from Davis (Mike) told us of their work on brushland conversion, stock culture, and predator control, grazing phenomena, and his own work on the utilization of oaks and their fate (most aren't establishing new trees, perhaps because of the pressure of grazers who eat the seedlings and acorns).

Bob Timm of Berkeley told us of his work with coyotes while we watched a young female pace in her cage. Delicate-looking, nervous animals they are. She shied at the wind passing through the trees above and paced in her path around the cage. They kill, Bob said, cleanly, by biting the neck of a lamb, and hanging on until the jugular is cut. Dog packs are messier and come up from behind usually. Most coyotes will kill even though full. Movement (running away) keys the coyote to attack. They account for about 12% of the local lamb crop, and maybe more. They dig under fences for the most part but may go through mesh as small as 6 x 4". Bob said he saw a coyote go at full speed through a 6x6" mesh. They can also jump, and electric fences, except the most high-powered, don't faze them. The most effective means of control seems to be chemical traps that are baited with coyote urine. The sniffing coyote tends to mouth the bait and a sodium cyanide pellet is popped out into the mouth killing the animal within a few feet.

On we drove through Booneville, past the Moonie Ranch, and finally to Van Damme St. Paul pygmy forest. We had lunch (splendid potato salad amongst other things) and heard about podzol soils, ancient beach dunes, emergent coasts, and the whys and wheres of Bolander's pines (a subspecies of lodgepole pine), Mendocino cypress, etc.

Then off to Jim McMillan's place out the Comptche Road that runs along the south [?] of the Big River estuary. His place is reached as follows [map].

Jim emerged from the scraggly pygmy forest to greet us, as did his plumber-man of all capabilities, Jim Naukunas, and his wife Valine. We never did get to their place or their glass furnace (Jim is a glass blower), but off we went to the estuary mouth to launch our flotilla. Jim said he had six boats including the *Naiad* waiting for us. Sure enough. There was a canoe, a paddleboard, two plywood skiffs, one with new pitch on the bottom to patch some particularly inelegant holes, and the *Naiad*, which is a 14-ft. runabout (fiberglass) with a little cabin and a fine vintage seagull engine. Then we had two—a two-person rubber raft and my redwood freight canoe. Gear was unloaded, great piles of it, food in boxes, our library parnassus, the cooking gear, collecting gear, and sleeping bags, guitars, and 28 people. The *Naiad* was crammed to the guards as was everything else and most people walked on the road that runs up the river canyon. Dave Hart, Valerie, Jim McMillan, and I perched on top of the *Naiad* and we pulled up, pulling one skiff containing Leslie and "the other Jim," a long, lanky guy full of good humor.

The canyon is steep walled, perhaps 30 degrees to the slopes 600 ft. above, and clothed with conifers—Doug firs and redwoods, some grand firs, while the river's edge is bordered with alders and bays that often sweep out over the water as limbs and leaves reach for light. The tide rises and falls 5-7 ft. leaving muddy banks often covered with a tangle of snags. Grasses clothe the banks above the tide, as do nettles, poison oak, berries, and many other herbaceous plants. Patches of horsetail rushes are common. There are some mudflats low down with pickleweed flats near the entrance.

The water is greenish and murky and somewhat saline quite a long way up the channel—at least seven miles.

Most people hiked the road and we ended up at a bend in the river where we could climb a 10-ft. sandy bank to a flat along the river in front of a second-growth redwood grove. Jim's crew was there—a group of kids from about 10 to 16 whom he is teaching about the river and attempting to instill with ecologic ideas. They were bright, imaginative kids, I thought, peering at shrimps under the scope and wowing at this and that.

As darkness settled, people chose places to sleep on the soft redwood needles under the towering second growth redwoods. Talks, including animal and plant topics were given—good too. Then some good music and off to bed under stars that just came out after a bout of mist that scared me a bit for fear it might rain. I drifted off quickly enough.

April 17, 1977

Big River Estuary, Mendocino County

Today we went off on various survey tasks, some of which met with success and some didn't. The group that had trouble was the water quality group that went upstream in the *Naiad*. The Hack kit for salinity testing works only in fresh water. Too much salt requires too much solution for titrating, hence they only did one or two stations. Then, my impression is that the *Naiad* goes mighty slow.

I guarded camp most of the day, but toward the end went upstream with Jim No. 2 in the redwood canoe (which we brought up suspended inside the bus from the luggage racks—a tight fit). It was a nice paddle. Jim is a boyish guy who laughs easily and has great capability. Up around the bend from the bridge to the south were cut banks in the mud with big redwoods above and bay trees hanging over the water reaching out for light, 200-250 ft. over the green water. When their leaves and branches touched the water it was as if poison touched and burned them. The branches were bare below water level and tufted with debris of the floods. Most were trimmed off as with a scythe, like a bobbed haircut.

We cruised along close to the mud banks in the dim light. A mink slid down from the grass to the mudbank at water's edge. This 15-20 in. animal was dark chestnut brown on its back with a somewhat tufted tail, a bit darker than the lustrous body. The little animal loped along the mud bank at the water's edge. It moved just like an otter, undulating along the bank, over snags, between branches, and finally after we followed him for 100 yards or so, it cut up into some debris and disappeared. Not long afterward we flushed out another one, on the same bank and chased it almost to the *Naiad*, taking samples way up the river, but mostly spinning around as various people tried to row in various directions. Not so coordinated, I'm afraid.

Those beautiful animals! So pursued! But still free, doing what they've always done. How many people in Mendocino, even, would want to kill them, given the chance. How much better to leave them alone.

We looked at a marsh back of a bend of the river—[?] by a mud bank from the river below with its tidal salt. It was fringed with cattails and filled with water lilies all in bloom. It was *Nuphar polysepalum*—bright yellow. Its pistil is remarkable—fringed and shaped like the head of a cold chisel, and ribbed with stigma tissue.

Back at camp—dinner, good reports, and talk. We heard some good talks about the local aborigines—Yukis to the south and Pomo here. The Yukis were pretty subordinate, without contact, except by trade, with the sea, and a very separate language. In fact no one seems to know where the Yuki language originated though Pomo was an Athabascan language allied to Navajo and others.

Things are goin' good on the creek side.

April 18, 1977

Big River Estuary

Today everyone goes out on his or her own. I went with Teresa, Vicki, Leslie, and Ken, down the creek to Mendocino.

We set off in the *Naiad*, stopping at various places to look at this and that. I pointed to an extensive pickleweed marsh, saying that later in the year it was alive with mosquitos and unlivable for a human, but we could go look at it now. We all trooped out, tying the *Naiad* to a snag. Not far out on the flat we came to some shallow salt ponds. I stopped to look at the life in one of them and found a microcosm of life and death and struggle for survival. The pool, perhaps 40 ft. long and 20 ft. wide, was matted with algal mats along the border, had a pink algal scum on the bottom, and was about 2-3 in. deep. On the surface film were hundreds of brine flies gathered in tight groups—dozens and dozens along the pond margins. As little gusts of wind whipped across the pond surface these groups would sometimes swirl out across the slick surface film only to pile up on another algal mat. Some stragglers would spin off by themselves. One impression was how terribly slick the surface film was for these tiny animals. It must be like the slickest ice.

Then we noticed spiders everywhere in the pickleweed and out onto the surface film. These very much heavier animals dented the film with each leg as they ran and seemed quite inefficient at movement, like a man running on a trampoline. Look, they're attacking the flies! Everyone was on hands and knees watching. A spider would race out from the pickleweed, rush toward a mass of flies whose members were so close they seemed in direct contact. An instant, and a fraction of an inch before the spider could catch a fly, they leapt into the air and descended after the spider passed. Not a fly was caught from these aggregations while we watched. Sensory integration at work!! But, when a spider spotted a lone fly that had been spun out over the film away from its fellows the spider made a direct dash at it, over it without the slightest pause, picking it up somehow as it rumbled over (under one or maybe several armpits?) and once on the bank bringing it out and feeding on it. How neat! The lone fly lacked the senses of his fellows and was easy prey if approached from behind. Even the waves in the surface film that must precede the spider seemed no warning. How does a fly sense them? What do they consist of?

One spider came up a branch near me and threatened me by rising up on tiptoes and walking stifflegged toward me, all eight eyes focused on me (or so it seemed).

On down the estuary we went to the flat above town where the houseboat *Ganymeade* sat stranded. Eric Erickson occupied this funky craft, with bunk and woodstove, pregnant cat named Bertha, nets and fishing gear, and various art objects. He was quiet, 30ish, perhaps stoned, I don't know, but hospitable enough, and a good friend of Jim's. He'd been on [?] to the flats eight years and had moved his house up or down a few miles at times.

I bought some groceries and then hiked back on the trail. The *Naiad* didn't arrive for a very long time. She'd broken a spring in the outboard.

I relieved Larry who went off on a hike.

April 19, 1977

Big River Estuary

We packed up in the morning and headed downstream. I was on the ragtag navy that hauled gear down and we were caught by the tide and unable to make real progress against it, for a long time. By shifting the load and hooking both powerboats together, we finally arrived, loaded the bus, said fond farewells including a hokypokey to the McMillans and left down Hwy 1.

Home at 9:00 PM or thereabouts.

VillaCreek, Carmel Valley: April 29-30, 1977

April 29, 1977

Upper Cruickshank Camp, Villa Creek

Here we are again at my old favorite, Upper Cruickshank Camp, this gentle, subtle, varied, and lovely piece of wilderness. And in the company of good friends, too. The mandolin and guitars sound under the bay tree over by the spring—the two Dans picking away. The fire pops and crackles amid the chatter of ShooShoo, Teresa, and Vicky sipping their after-dinner cup of tea. I cage a nice hot cup of tea from Teresa. The light fades after a fine day. Yesterday we came down the coast, stopped to see Margaret Owings, who told us of her history as a conservationist, fed us cookies, and showed us her fascinating house which perches on a fin of rock 300 ft. up from the crashing surf. Six gray whales appeared, gamboling in the kelp. There were at least two young, perhaps 22 ft. long, amongst them. That's clearly where they are on the northward migration.

On with various attempts to contact Patrick Cassidy who rents the Bateson's house below Villa Creek. No luck, so we simply parked up near the trailhead and trekked up the switchbacks and thence up the canyon trail. It's a dry year but many flowers are out in the chaparral. The old burned redwoods and some oaks have begun to swell in girth after the fire, producing long, vertical cracks in the bark with new clean bark underneath showing through. One could time girth growth or fire occurrence by learning about these fissures.

In the morning today we put up the sweathouse down by the creek. I wrote in my notebook and then Larry and I had a grand hike up the north canyon wall of Villa Creek and over into Alder Creek to the north, stopping when we could see the old mining district on its N. branch. (Krenkles Ranch, Los Burros Mine, Dulcimo Mine, Melville Mine).

We missed the trail where a switchback had been washed out and were forced into a bit of bush whacking but soon found the trail again. Deer sprang out of the bush ahead of us. One stood in the tall grass, its ears focussed on us and then sprang away, bouncing upslope as if on four pogo sticks. We passed through a copse of burned ponderosa pines with a forest of young trees. Judging by the whorls of branches they were six years old, or sprouted just after the fire. How does a ponderosa pine become potentiated to sprout by fire? Are seeds just devices that are ready for use in case of fire?

On up the canyon we went through little hanging valleys, where Larry and I dreamed of camping, raising pot, or setting up a still. As we approached the mining district we began to notice a tree we couldn't identify, all burned out and finally we found some new shoots that told us it was a golden cup oak, *Quercus chrysolepis*. On the way

back a purple martin female volplaned back and forth to the dead top of a redwood. Nearby was a single newly constructed hole in another burned tree. Do they ever nest alone?

Back at camp, dinner, and some fine discussions of what people had seen during the day. Foxes, yuccas (we have a *Y. whipplei* with a long rhizome here). We ate the new stalks—rather sweet and much like asparagus. Some were later steamed over the fire and they seemed even more asparagus-like. In the evening after reports, three of ours were still missing, but I wasn't particularly worried on their account since they were amongst our most capable and jet-propelled field folks—Bruce Stein, Helen Gibbons, and Brett Hall. They were trying to make a circuit up to the main ridge, along it to the north, and down Alder Creek and over. But they couldn't make it and ended up rock hopping down Villa Creek, which must have been a horrendous task in the dark.

Much steam, more rocks, cooking the sickness out of John Carothers who sat the whole time in the corner bleating for people to warm it up more. A bare hokey pokey, up the trail in the moonlight, filtered down through the tall spires of the redwoods. Then, a little quiet guitar and to bed, a bit sore but otherwise happy for my group was complete. Larry was a joy to hike with, gentle, full of pleasure at little things, caring.

Tuolumne River, Tuolumne County: May 22-, 1977

May 22, 1977

Tuolumne River, above early intake, Merced County

It's 6 PM and my last full day with Natural History Class 1977. We've just returned from a hike up the stream to a beautiful falls and an even more beautiful meadow and series of pools—small lakes really—all dark forest green in the deeps and amber over the granite boulders.

Somehow I haven't had time to write before on this trip. In part I was too concerned that it should turn out well for us all and in part there were so many questions, little tete-a-tetes on the ponderosa needles by my camp, or contemplation, jokes and warmth in groups hunkered on the trail in the dark sharing a joint and bits of chocolate, or just silence under the silhouettes of the trees, cliffs, and the stars.

How has it been? Rejuvenating for me, yes. Fun, yes. A chance to see and understand, yes. A parade of finding and discovering warm and loving experiences together, yes, most of all I think. And, no one, I suspect, has found more than I have. We're shared so much and our group is so rich, it's hard to tell.

Rich, that I can say for sure. Never have I traveled with a more talented group who knew, felt, learned, and perceived so much. There is no one who does not bring some special perspective or set of ideas or skills, or philosophical constructs, to us. No one who disrupts or must be compensated for.

What I have I've pretty much given, I think. Some ways of seeing, some scope and sense of time and pace in nature, spirit, belief in joy, belief in simplicity and the oneness in us all, and our oneness into every cranny, men and women. Some sense that in nature is not a chance for science, but also for philosophy. That true things are what matter and must for our ethics and our understanding of ourself. That being small and yet

part of the sweep of time, of the mountains, valleys, and forests, the creosote flats, the willing river dimpled by current, is magnificent beyond telling, touching everything we are or can be. That no person lacks something to say, whether it be through the joy of finding, like the children on the bank of Big River peering through our cloudy microscope at mysids bearing eggs, old Byrd and his bumper stickers, or that brave devout lady on her fin of rock down in Big Sur filled with indignation when officialdom dare to declare a bounty on her mountain lions, or her otters to whom she reaches out when they play in the kelp, 600 ft. below. Or to gentle Jim, Oxford scholar, artist, glass blower, fragile figure in the slash of the pygmy forest insulating his house with egg crates.

What did we see, hear, experience. So much I can't do more than draw a few examples.

Our group clustered on the Bunny Club deck not wanting to leave because so much remained to be discovered about everything. The peregrines, the *Opuntia* whose spines play tunes, the phainopepla whose adhesive shirt ties together two organisms so they cannot separate. The sand mountain that sends its Om out to us all and when we listen we hear a directionless throat of that mountain's being—constant, sending its vibrations into all of us.

Up to Vulcan, where John Carothers reveals his role as our resident gymnohiliophile, like I imagine Ishi must have been up in his canyons and oak trees.

So much, so rich, so scarcely touched by us.

The Big River, its ebb and flow, the history of exploitation, told in the layered muds of its banks. But out there on the pickleweed flat in that shallow pool where fat egg-bearing spiders thrash across the slippery surface film and through the massed brine flies all touching elbows and sending messages of fear ahead in the nick of time. But when the tiny eddy of wind sent a fly skating across that glassy, icy trampoline, it was caught in an instant.

Or Sandy, Larry, and Bruce's spiralling osprey. Or the trial by nettle train over which Dave Hart directed everybody to camp. Or the undulating little mink trotting on the riverbank and disappearing beneath a great redwood root.

Who could, for heaven's sake, forget that incredible ragtag navy, led by Teresa circling in lazy aimless vortices at the mercy of the silent tide? Pots, dipnets, one lone oar and faith in jet propulsion got it home, plus Leslie's attention to water seeping inexorably in through the tarry seams.

Or our group, ascending the switchbacks to the Cruickshank Camp, that gentle, sainted spot under the oaks with the indian shellmound meadow adjacent to the ruins of the Cruickshank house up the hill under the ancient apple tree.

Or Dan and Ken and Lori clinging to the cracked rock hillsides to psych out the yucca, taste its stalks, count its poker chip seeds produced in such profligate numbers, or its candles drifting their perfume in the passing air, luring the companion moth that is a part of the yucca as the yucca is part of it.

Or the crazy naked dance in the firelight around the roaring fire at 2 AM after watching the moon through the roof of the sweathouse.

Fog crashing in silent 400-ft. high [?] and pouring up through the canyon as quiet as twilight and then receding again.

Larry and I go off together to discover a hidden valley for a future camp, or a place to raise pot, a sequestered little eden of oaks, grass, and young pines tucked in the hills.

Larry, the gentle caring Larry, who means so much to us all but who did so much more than anyone knows when I couldn't and even when I could. Robert Redford to some, but better, a balance wheel, a spirit, a partner up to Tuolumne, after a beautiful, austere look at the scoured spine of the Sierra where we try to understand the things that happen to build a mountain or the things a tree does to live there when chilling winds sweep by, scalding the soft parts of plants as if by heat, the snow a blanket as surely as my sleeping bag, branches so pliant one can tie a knot in them.

Leslie and I talk geology, trying to understand in our own way, regardless of the conventional wisdom of books how this scape from the Colorado Plateau to the sea might have come about. I think we may be as close as anybody in what we concluded. Leslie, so inquisitive and full of ideas, it was fine, Leslie.

Then down to my gentle river. I hoped with Craig that it wouldn't be dry in the drought and it would be as I remembered it. It was. A lovely various parkland of oaks, pines, an alder-bordered stream, the towering cliffs above.

We pretended to be insects, or lizards and to try to see and sense the world as they do, with our thermometers or Ann Hoover's grass and hair wind gauge, or the light meter. It worked. Everyone perceived and then knew that there were worlds too tiny for us, of almost infinite variety within yards of our camp. An ice box at 12 degrees C. back under a boulder where only liverworts grew and 120 degrees or more on the soil surface. Trees emerged in terms of the strategies of leaves at using and transmitting light. They are stiff on their petioles or wave in the wind for reasons. Trees have shapes for reasons.

Shoo Shoo, Lori, Leslie, Carolyn, Bruce Stein, Paul, Steve, Nirea, Ron, and I went on a wild walk upstream that led to a percussion band being formed, aboriginal costumes of the most basic and incredible amounts of noise.

I don't want to be caught up in writing a salute to each of you for the good things I've seen and shared and gained. That's too fraught with the problems of comparisons. To chance that I won't be able to express the singularity, the warmth, the spirit, the insight I see and feel in you as individuals. It's too risky. So, suffice it to say, my love and respect and anxiousness that it not stop here to each of you.

Thanks, Ken

Magdalena Island, Baja California: February 5-13, 1978

February 5, 1978

Lopez Mateos, Baja California del Sur, Mexico

Here it is five days after we began this circus and we are still not yet on the island, nor are our tents set up, but instead we are moored alongside a disabled purse seiner at the dock. But, things are looking up. I think we will do those things in a couple of hours, plus most of the day to complete it.

It went like this. I flew in to La Paz, stayed at the nice Los Arcos, a couple of steps up from Las Perlas. I had a good marisco dinner, a bottle of wine, and Bernardo and William showed up, having driven over from the Universidad Autonmia de Mexico. Next

morning, we drove in their panel trucks to Ciudad Constitucion, and then to San Carlos. On the way we counted auras or turkey vultures. Pesticides are eliminating them from the mainland landscape, especially their near relative the sopilote, or black vulture. Here there were many auras, even around the cotton fields of Constitucion, where DDT use is rife. It may be too new a farming area.

At San Carlos we located a landing ramp, tended to papers with Sr. Armas (who was very helpful). We had one paper we had to call for to Mexico City—boat permission to ply the waters of Rehusa.

Our launch site was east of town near a little complex of cabins run by an American.

About that time the boat came in dusty but with a happy crew. They had come in after an uneventful trip down. We tried to compensate the compass (or Jim Christman and Bill Rogers did) and in turning in the soft sand got stuck. It was then I realized the weight of the boat and trailer—pushing, 10,000 lbs. (our boat, the *Naia*, is on her maiden voyage—she is a 25-ft. skipjack fiberglass twin-engine out drive). It was dark so we went to bed to wait for light.

In the morning we unhitched the trailer and spun it around on its caster wheel resting on one of our camp tables. It worked well enough—not nearly as difficult as digging the big truck out repeatedly. Then, launching was attempted, after completion of compass compensation. The wheels dug ominously in the low mud but the vessel was launched successfully. All hands were joyous at seeing her float and seeing the empty trailer pulled easily enough up the sand ramp. Nonetheless everyone, I suspect, certainly me, thought about the day when we will have to extract her to go home.

February 6, 1978

N. Tip of Magdalena Island, Baja California del Sur

By this time the Ruchs and Schevills had come in and joined us. They came in Jim's mighty Volkswagen, which for some obscure reason can not be shut off, so it putted away while we talked. They chose little hills to stop it later and each time it required a push and deft clutch work. Leaving them on the beach, William, Bernardo, Bill, Jim, and I set out for Punta Tosca and the Rehusa Channel to make the first camp run. My but the *Naia* was loaded, and my, but she was slow. Cut down from her majestic 20 knots on a plane (and 30 knots in the literature, which I suspect is performed on a specially flattened lake). We picked our way out of the channel by the anchorage, going south toward the entrance of Magdalena Bay, finally going over the shallowest place at about one fathom under the keel, and then into the deep basin of Magdalena Bay. It was duck at the entrance, and lo and behold the light on Punta Redonda, which is shown on the chart, was not lit, while one not shown on Punta Entrada to the north blinked away. Oh well. So much for the reliability of navigational markers. We turned past the half mile of rocks that jut out from Punta Redonda and slid down along the long straight shore of the outside of the Isla Santa Margarita. It was fairly calm, with just a long and rather flat swell, but poor William, who is terribly susceptible to seasickness, became whiter, then greener, then inverted, then horizontal, then fetal, in which shape he stayed until we anchored, and even beyond. Bill, who is also susceptible did well until just as we rounded Punta Tosca, and then he too succumbed with a vengeance, not wanting to live, and pleading to sleep ashore regardless of what it took to get there.

I spent some time trying to organize the incredible tangle of gear down below decks, and nearly succumbed myself, but was able to excavate a couple of usable bunks. We slid around Tosca at about 11 PM, and then up behind. There were four bait boats, their well-lights on, and crewmen jiggling over the stern. They had the only decent anchorage and shouted loudly that we should not come in. We chose a much less satisfactory anchorage 300 yards or so from the breakers crashing over the bar at the entrance to Rehusa Chanel. I could see the wind whip the crests off into long horsetails, and hear the mumble of waves coursing along the beach and rocks. Not good, I thought, maybe no chance to land. There was scarcely a place to sleep. I chose the cambered foredeck, propped my head up with a lifejacket, and picked up what I thought was my sleeping bag (which turned out to be Bernardo's), lashed a rope across myself, and tried to sleep. Some exercise! The boat swung on its anchor, sending the mouth of my sleeping bag into the wind like a wind sock in an airport. I rotated accordingly, attempting not to fall off into the water. It wasn't comfortable, but I made the best of it by propping my head up enough to keep the camber out of my backbone. Down below William and Bernardo slept, and Jim stood awake most of the night worrying about tides and currents. He did get a few winks toward morning. Nothing I seemed able to do induced him to have us stand watches.

Next morning William and I loaded the avon raft and headed for the beach at the foot of the place I had chosen for a camp. We made it OK, and landed a lot of food, but in looking back at the unfurling three-foot breakers I knew we would never make 30 such trips without misshap. It didn't take long for me to reflect on my team of folks, only a few of whom are young and resilient, to realize that it was a mistake to try to land. We pondered the storm offshore, the tides and wind, and a bank of fog pouring in and decided not to try to land on Isla Cresciente, because Jim was rightly afraid of the waters and didn't know them. So, reluctantly, I called it off and turned back up the coast, to try to make an observation post on the north tip of Isla Magdalena. Bernardo concurred in this plan, which helped, so off we went back to San Carlos. The uneventful trip took most of the day. That night the ship lay at anchor off the launch point, waiting for a full day's time to run Devil's Bend.

In the meantime we visited the local restaurant and had a fine meal of lobsters (some folks), shrimps wrapped in bacon, and other goodies. It took forever but it was worth the wait. I rented cabins for the night so people could shower and sleep out of the sand (we would have plenty of the latter later on).

Next morning we waited on the tide, letting it drop from a very high level down almost to low for running the channel. That way the channels would be easier to see—which turned out to be a very smart move as there were quite a few places else where the uninitiated could become lost (and we were uninitiated and in fact, without a decent chart). All we had was a mimeographed sheet of the general contours, given us by Fernando Armas. The ride up started near the entrance channel at upper Magdalena Bay with an encounter with a school of *Mobula*, or small mantas, all cruising along with the tips of their fins flapping out of the water. They were amidst a school of bait fish and birds and flotsam—eelgrass, mangrove seedlings, etc. Who was feeding on whom was hard to tell. The mobulas let us cruise over them and we could look down at them flying underwater, 18 in. across the wings to maybe 24 in., their blunt heads and palps showing on the heads. They dove and we left, cutting on up the channel between mangrove

swamps, the channel marked by shallows and a winding channel that wove back and forth between them. A couple of times we stranded on the flats and I am very glad we chose the low tide to make the trip as there were many false channels that were very evident at low tide but that would have led us off into the blind alleys of mangrove channels if the tide had been high.

Devil's Bed is a truly impressive bend, about ½ a mile across marked by white cans moored on the flat, with a channel that can't be more than 200 yards wide at the widest and I'd guess half that at the narrowest. How a 110-ft. ship makes the turns escaped us all.

On past Colina Coyotte. At low tide, as we knew, it would be devoid of whales, but just beyond we would see many in Bahia Grande. There they were. I spied a pink thing on the water and announced it was probably the whale placenta—as we approached closer it materialized into a mass of netting. I told Bill Schevill I'd surely never hear the end of it. And I suppose I won't (from him at least).

Finally we made it to Lopez Mateos to find the folks at the dock waiting. We told them we would go on and land on the island at the north shore of the Boca Soledad and Jim would return.

Off we went, and Jim balked at crossing the channel back of boca at dusk. I understand his fears—new and dangerous water, darkness setting in, so we turned back and found our people having loaded everything on the deck of a purse seiner. Jim Ruch was there gesticulating because he had just carried five 20-gallon drums of water across two boats to give us a place to load, and he faced the probability of taking them back. Luckily the boats were to be moored for two days due to mechanical failures and we could leave the stuff on the decks. So, we located places on deck to sleep and then went off to the Casa Dona Maria, a Casa de Huespedes in town down a couple of dark dusty streets. It was spotless but all they had was refried beans and chorizo (sausage and eggs) and vitas. Good enough, and then some sleep on the deck of the seiner. My ribs were sore from sliding off the roof the *Naia* and my back sore from lifting stuff. I had to turn myself over by reaching and grasping the sampson head of the winch above me and then flipping. If I dared to try it just by turning, my intercostals yelled out for all they were worth. But, I caught a few winks and was ready for the day.

February 6, 1978
Camp Sand Castle, North end of Magdalena Island, Baja California del Sur,
Mexico

The above name is no joke. This typewriter damn near fails to work because it is choked with impalpable sand that drifts in as the NW wind whips around our tents and fills our food shelter. I have to lock the typewriter away elst it get so full of magnetite sand that it ceases to function altogether. I work each key loose like an arthritic joint till it comes free and functions. I know when it is going to fail because I come upon a new key like, say, an "&" sign that won't work.

Anyway, came the day and we took off for the Boca, after quizzing the skipper of an adjacent vessel who gave Jim instructions about getting across the Boca (it's very straightforward). One goes up to the junk pile on the beach and cuts across to the inner sand spit all in water enough for a seiner. Jim was happier. Understandably he's nervous about working in waters without a chart, especially ones he doesn't know. It began to

show as he got more and more cautious, and I got more and more anxious to get at it—to begin paying the freight at my end. I knew we had to get on the beach and he knew it was dangerous and scary

We crossed the channel easily enough, cruised up along the inner side where we found a river of water pouring out, going so fast it stirred up great boils of sand up, discoloring the water brown. We tried to land alongside a steep bank and the current was so strong Jim almost couldn't anchor. It was fouled and kept slipping back. The bow swung in against the bank at one point canting the vessel over ominously. Not quite so scary from my viewpoint as from Jim Ruch's (who was leaning against the overhung bow trying to push her off) or Jim Christman's on board. Ultimately we turned down the site for a camp altogether (difficult landing, too far from the channel) and headed across the channel to the south side, where after much hemming and hawing we finally landed at low tide and hauled an enormous pile of gear up the beach to make a camp in the inadequate dunes at the north end. The wind whips right in from the sea, trails of sand snake their way among the dunes, and when the wind falls the mosquitos come in from the adjacent pickleweed marsh. Nonetheless we set up a relatively cheerless camp amidst the impalpable sand, that dusts into everything. We made windbreaks of sorts, anchored tents with deadmen (flat logs set horizontal in the sand), and cooked a meal. Next day we began observations of the whales that paraded by before us.

The new Celestron was set up and proved a jewel. With it we can inspect the markings of whales across the Channel, a mile away, and see birds on the beach a similar distance. It's sharp and clear and lightweight (12 lbs. or so).

We had taken a census of whales coming up the channel, and I'm sure it's a conservative one. There were something over 60 whales. At the point we began to watch behavior, and find, we think, tidal movements. At low tide only a few whales remain in the waters behind the Boca, and they have moved mostly out the channel, we think. Though I guess some must have gone back into the lagoon too, since at the turning of the tide the numbers increase again as the animals pour in from the sea and from up the lagoon toward Lopez Mateos. On our trip up we had the fathometer on and were interested to note deep ripple marks in the channel bottom starting at the shell mounds where both Ken Balcomb and I thought we saw the most frequent breaching inside the lagoon. Deeper in the lagoon the channel bottom is flatter. The ripples go on out into the entrance, where we are told they are quite extreme. A diver, Tim Means, had seen them when he dove in the entrance—a feat by the way that I would not like to attempt. The currents are almost always there.

It rained a little last night, and the tide lapped over the flats almost to the dunes on which our tents sit. Tomorrow I'll transcribe my taped notes on behavior and will likely move my tent down onto the flats behind the main chain of beach dunes. These dunes are a highway for blown sand that flows from one to another when the wind blows, erodes under our tents, fills our teeth, ears, clothes, and souls with drifting sand. On the beach it is so fine it looks almost greasy with glittering magnetite and garnet grit. Enough. Barbara Schevill ministered to a splinter in my foot tonight that she was able to get out much to my relief. I'll be able to walk again. Some illness is in camp. A bit of the eephus, but we think it will pass and we can eat our dehydrated hash browns and canned spinach with gusto. I like the lemons and virotes better, and the glass of sherry at dark. Off to bed in the drifting dust.

February 6, 1978

N. tip of Magdalena Island, at Boca Soledad, Baja California del Sur

1135: Tide is still going out. We have probably 5-6 animals over the central sand bar. On the Lopez side there seem to be a group that have come in that we didn't see before. The ones we watched go out of the channel have indeed gone out and haven't come back. The boats are still out in the channel. They are (the boats) coming in. All whales are down.

1610: We are taking a count. The tide is incoming low. I'll start making a count out in the entrance. We think we see a movement of whales into the area, after having had a dearth of whales during the low tide. They seem to be moving in, interestingly enough, from both directions. There's a blow out as far out in the channel as I can see (1), in the Boca Soledad channel before it turns south. Another blow (2) from an adult; it appears to be a big blow. The wind is high—25 knots and blowing sand. Partly cloudy skies. You can see the incoming tidal current. One more possible blow out in the channel (3). Tosscaps out in the channel sending their plumes up into the air. Another blow just at the entrance to the Boca Channel (4), a large one. No babies were seen. Very large whale threw its flukes just at the point of land at the end of north island (5) Both of the last two appeared to be coming in. Tursiops right abeam of camp. Cow and calf abeam of camp, just below the bluffs on the far side of the channel (6,7). Cow and calf on this side of channel (8,9), momma with great white snoot. Mother is throwing her head up periodically. Another off the cusp of the central bar (10), I have not seen a young with it. Central bar a blow (11); I can't make out whether there are one or two. Cow and calf this side of central bar (12,13), on the Lopez Mateos side heading toward the boca. Pitch-polling adult off pelican bar (14), next to median bar, two adults off little mangrove island across from camp (15,16) pitch-polling animal at base of bar (17), two adults and calf (18-20), Lopez Mateos side across from camp. Third cow and calf (21-22), all moving toward central bar. Five more whales back toward Lopez Mateos (23-27) apparently all moving toward the boca. At least into the embayment in back of the Boca. The time is 1630 at the end of count.

February 7, 1978

N. end of Magdalena Island, at Boca Soledad, Baja California del Sur

What a night!! It blew and blew and blew. The sand whipped along the dunes in a continual stream, insinuating itself into every crevice of everything. It piled over boxes in our little food tent, it came in the flaps on both sides of the tent, it gummed up my typewriter to such an extent that I thought it would never work again on this trip. The tide didn't quite make it over the crest, but came very close—lapping amongst the guardian dunes but sinking in and then receding again. We all awoke gritty and without any official word began to move camp down behind the dunes onto some flats that seem relatively safe from the tide. That remains to be demonstrated however. It took half a day to get everything moved, deadmen buried in the sand platforms leveled, tents moved, water barrels rolled down, and so forth. Barbara's tent was the last moved and we simply picked it up bodily, tent poles in place and walked to the new site (after, of course, moving the tents separately). All folks were in good spirits in spite of discomforts. Barbara and Sandy went for hikes today and came back with cockles and hachas (*Pinna*)

from the little local marsh. The *Naia* came in to check on us. She had made her census. I guess she'll be with us tomorrow at low tide for a new task and to unload people and maybe a bottle of gin to keep our spirits up.

I had a nice walk with Bill Rogers out around the point, looking to see if we could see whales in the channel outside (we couldn't), but we did pick up some lovely shells (the beach is peppered with them—mostly pelycypods of various sorts). Bill is a fine enjoyable companion and a dedicated naturalist. I think he is bound to go far in his field.

We cooked the shellfish and a great pot of beans and I tried a little surf fishing (unsuccessful) and then notes.

[Drawn Map—place names at Boca Soledad]

February 8, 1978

N. end of Magdalena Island, at Boca Soledad, Baja California del Sur

I'm sitting in my gently flapping tent after taking the high tide count in the Boca area. The sky is clear, pale blue and blown with what the Hawaiians call ehukai, or the mist of blown sea spray. Our count was, we estimated, as much as 30% low because we could not easily spot animals in the outer channel and the blows of babies tend to get lost, as do adults in the distance. The high tide brought sea swell crashing across the water bars all but obliterating the outer channel in breakers and tosscaps. On our dune where we stand to watch the sand snake by our feet in wavering sheets that coursed down the low places toward camp, making us careful not to shuffle our feet too much. In front of us the tidal flat swells at first, from a kind of low channel at the dune bases and then slants off to the channel 200 yards away. Now, with the tide high, some waves driven by the wind coursed up over it and sent a mass of pinkish foam (likened by Bill Rogers to the froth on the top of an A&W rootbeer float that is going flat) down amongst the sparse dune vegetation. Semipalmated plovers and sandpipers dipped and dabbled in it. We watched anxiously to see if the barrier to our tents might be breached and water enter camp, which is lower than the beach places. Insidiously, the water appeared not over the dune barrier, but from the south, up from the little lagoon where Sandy had located the hachas last night. But, so far, it has stopped some 400 yards away, sinking into the dampish sand, filling burrows. I set the main tent complex on a platform of sand I shoveled out from a dune, so my tent, the cook tent, and lean-to are up a foot or so above the low places. Only Bill, really, is in a true hollow, with his weird nudibranchish tent. I never saw such a creation. It is green and yellow with various cylindrical air vents, a wide open mouth, and a big high hump in the middle (where, I think, one stands up inside). We'll see. At any rate our NW wind isn't over yet. The *Naia* came up to check on us and we found that our walkie talkie is pretty much line of sight. They went off back down the channel, avoiding the swells.

In the afternoon low tide the *Naia* returned bringing the crew from the run down to Colina Coyote (Bill Schevill, Jim Ruch, Bernardo). They had made two counts and the largest was just over 100 pairs, plus a very few singles. They also obtained a complete fathometer trace along the channel. Bill Rogers and I jumped aboard since tomorrow we planned to observe at the second shell mound, where Ken Balcomb felt that an unusual amount of breaching occurred. Jim took us down to the little anchorage just south of Lopez Mateos where we tied up in the calm. There was enough wind chop that the boat banged loudly on the water, it being a resonance box down below. I slept in the forepeak

and hence was treated to the best chorus of gurgles, clicks, booms, and bangs. It kept me awake for quite a while, but finally I drifted off.

February 9, 1978

N. end of Magdalena Island, at Boca Soledad, Baja California del Sur

The morning was spent gassing the *Naia*, which consisted of hauling our 15-gallon drums to the local Pemex distributor, who features a shed with drums, a big plastic siphon hose, and a small boy adept at sucking without getting a snoot full. We carried our gas across the deck of a seiner to hold it up and sluice it into the funnel and thence the tank. Jim regulated the flow with his hand while I held up the barrel. The work got easier as the level dropped. We also picked up food and beer, and the about 1PM took off for the second shell mound south of Lopez. Bill and I put ashore while Jim took the *Naia* away to prevent disturbance. We were then treated to a procession of animals going by in the tide that must have included a fair part of the entire central channel population. Almost all went by from deep in the channel toward Lopez with the tide. Later, a few seemed to swim against it but in actuality were entering an eddy across the channel from us. They did not persist in swimming against the current but stayed in the eddy area, which came known as the pitch-pole place, because we so frequently noted animals pitch-poling out (what I used to call "spying out" but Bill Schevill tells me the whalers called it pitch-poling, so why not use the old term?). In this behavior the animal levers itself up slowly out of the water, its tail almost certainly on the bottom, and then subsides back, or falls slowly over. At any rate we watched from near high water to just about slack low tide. One gets the impression of the entire population in flux with the tide, sluicing back and forth in the channel according to the tide, sometimes swimming, with or against the current, and sometimes simply drifting. Often we could see the huge bulk of the animal only as a long low line of whale, which when viewed end-on showed the very broad arcing back of the floating whale. The little calves bounced around the mothers, often sliding over heads or tails, and sometimes taking little sorties away from the dam, only to return moments later.

Back at the camp we found the Ruchs had been out in the lagoon to the south of the mangrove patch near camp. Sandy, who is an excellent predator, had located both hachas and cockles in abundance. They came back with a great bag of the former (*Pinna*) and Jim set about preparing just the big adductor muscle. They have a lot of parasites in the guts, which thus is the most unappetizing part of the beast. So, just muscle. We also caught some good fish (sand bass and yellowfin croaker) which I prepared. We got the good cooking oil smoking hot, William made up a batter of eggs, bisquick, and beer, salt, and water. I dipped my fish in just flour and he dipped the hachas in his batter. Both were exquisite, I thought, and we ate until we burped in delight. Wow, what a feed. The vegetables came last and were cast into a shadow. So, off to bed, replete, with a good day's observations and a magnificent camp meal under our belts.

February 10, 1978

N. end of Magdalena Island, at Boca Soledad, Baja California del Sur

Today Bill, William and I wanted to work the outer channels, to see, if we could, what the whales do there. I lay in my cot, in the calm morning, listening to the clicking pots, the low conversation, smelling the wafting smell of coffee cooking, and finally

bestirred myself for a little breakfast—fried eggs, toasted virotes with ham, and such. Friend Barbara was at the helm, and a steady hand she is. She's such a good soul in camp, so uncomplaining about anything, so capable. She, Bill, and Bernardo will go off today to look at the whales at the shell mound, to see if they can see the pitch-poling whales that we saw. Only this time they will be on the dune side, nearest the whales.

They boarded the *Naia* through a little surf and succeeded in getting wet, but I gather not seriously so. Off they went, around the mangrove bend, not to be seen until later in the day. I spent an hour talking to Jim Ruch, about the Washington scene, should I be on the Commission. He knows a lot, having been an assistant to Nat Reed in USFWS. Then I trudged off after William and Bill Rogers, who had gone on ahead to set up a watching post at the Tent Dune. I found them perched up on top a bigger dune, William leaning back on a fine backrest board buried in the sand, Bill watching from the standing position. They hadn't seen anything in the inner channels, but had been watching whales outside the surf; they all went north. I relieved them and they went back to camp while I watched. I soon located two channels, one nearest the beach that I expected, but which did not prove to be the major channel, and a farther, almost-at-the-edge-of-vision channel, that bore most of the whales. I saw several and tracked some as the tide receded and the whales sluiced out of the lagoon and into the open sea. I was alone, on that island tip—nothing but sky with scudding clouds, symmetrical dunes, all swept clean by the wind, a broad expanse of beach in front, a gaggle of pelicans, royal terns, a few gulls, and some smaller birds. Beyond the tiers of breakers and channels intervening the sea could be seen, pale with sardine seiners pressing their proud way through the waters at their bows, the masts forking above and the stern down. Loaded with fish? I didn't know. Maybe. It's a long way to the cannery and the fish might be rotten ere they arrive.

In the farthest channel I watched a trio of whales drift out toward the entrance. It took half an hour or more as they drifted with the tide, blowing, pitch-poling, and spouting. One animal, in particular, bobbed frequently, passed along the channel, and finally with the current, I presume, turned north out what I had not earlier perceived as the entrance, but what I think was it. It was a low place in the last breaker chain and the animals simply bobbed and slipped out it to the north. My bobbing animal poked its snout up as it bobbed over the thin breakers into the open sea. If the channel I perceived is correct it runs out along the shore of north island, turns southward in a broad arch, and then when close to the outer breaker line turns rather abruptly north.

Bill and William relieved me and I trudged back across the broad shiny sand beach dotted with shells, the blue sea beyond and the tiers of parallel rows of breakers beyond. Bluffs of eroding sand to my right rising to clear dunes accompanied me as I walked along. Back at camp Jim Ruch and I rigged our poles and went fishing down by the mangroves, netting several sand bass (*Paralabrax nebulifer*) and a yellowfin croaker. Later we cooked these up in William's special batter along with some wonderful spaghetti and clams. After dinner Bernardo told us about the Mexican government and its role in wildlife management. He told us of the lack of understanding in the elected officials about wildlife problems, the problems of the ejidos and the land ownership. He then told us the almost heroic story of his becoming a mammalogist, and then the Secretario de Fauna Silvestre, and how he built up the collection and department at the Universidad de Mexico. He has risen from a barefoot country boy to a level next to the

President of Mexico and a person considered for the Presidency of University branches and yet he is a joyous and simple person, full of fun and pride in his country and his people. I look upon him with deep fondness and admiration. I watched Bill Rogers over on the sand dune by the fire soaking it all up, a real experience for him as he later told me. Bernardo addressed much of his commentary to Barbara, whom he had met years ago as mammalogists, and for whom he has such respect. Quite an evening, graced I might add by Jim Ruch slipping by my tent with a cup full 1/3 of good scotch. Hit the spot as I sit here typing.

The wind comes in from the SW now, for some reason, with a low [?] of broke clouds—hope it doesn't portend rain, but it seems clear.

Bill Schevill, Barbara, and Bernardo spent the day down the channel at the shell mound and did not see the pitch-poling play we had noted the day before. They did, however, have a good time observing.

February 11, 1978

N. end of Magdalena Island, at Boca Soledad, Baja California del Sur

Well, it did indeed portend rain. Not long after I turned off the Coleman the tapping on the canvas started. I lay there listening to it, trying to recall if anything sensitive had been left out that I should get up for. Then I heard an interior dripping, fumbled around and found a light and found the tent leaking badly from a dozen places, especially over the foot of my bed. By the time I got around to doing anything significant my bag was soaked up to about my knees. A pool of water was growing down along the front door. I wondered about the rest, especially Jim and Sandy in the abominable pop tent. But it was Bernardo and William who got wettest, and Bill and Barbara who had a lake on their floor. Not much to be done, except for everyone to fend for themselves as best they could. It blew so hard the tent bellied in like a sail in a gale but I slid back into the sleeping bag and finally drifted off, listening to the periodic sheets of rain that hit the tent. By morning it was pretty much over. Jim Christman came in early and took us out for the morning to see if we could get up on a pair of whales nursing, or mating, or whatever. The best we could do was to get close to whales who knew we were there. We saw one quasimoto style whale with a bent tail, a hump, and a very shortened body from knuckles to flukes. It seemed to go along OK, and was a smallish adult, so obviously it was on its own and surviving, and even migrating.

The channel was rough with wind and finally about 1:30 PM we landed again through the surf and went back to camp. Not long after our arrival a black wall of cloud swept in from the southwest and we all grabbed our drying bags and clothes and headed for various tent interiors. It hit as a gale, so hard I had to grab the front tent flap and hold on to keep it from slatting to pieces. The water came in again, but this time I was more ready for it and was able to keep most things dry. Having an uneven tent floor set on dune sand helps.

It went away after a while and William Forment and I went fishing, and I had the joy of watching him catch almost his first fishes—a couple of nice little sand bass. “Hijos, they're bigting,” he cried so loudly that Jim heard us over the mangrove in the adjacent lagoon. I had a nice time talking to him to see what he could find out about the gray whales of Sonora-Sinaloa as a project (he wants to work on whales).

Jim Ruch and Sandy went hacha hunting again, and came in with 12 big ones. One cracks a hole in the side at about the middle and can then reach in to slice the big adductor muscle and the shells fall open. There are two bits of muscle—the adductor which may be nearly 3 in. across, and two smaller slips that run longitudinally into the body mass. Quite a meaty beast, and delicious. Fish done in William's batter is delicious too. Our third meal in a row.

After dinner we had a few songs featuring me and Jim, a bit of memory teasing by Bill Rogers and droll comments as always by Bill Schevill, who never seems to forget anything of that nature, and who always has the viewpoint to see such things as they come along.

We are running out of useful things to do here and I think we will begin a phased withdrawal tomorrow. Jim Ruch and Sandy will leave on Monday, and we will be in La Paz on Tuesday, I'd guess. The weather has been pretty tough on us, but we have learned some new things of use, though not by any means all we had hoped we would. That remains at Punta Rehusa, and can best be reached by small boat from Puerto Chale, across Almejas Bay.

The wind whistles, especially in the tent poles of Bernardo and William and flaps my tent as it moans by. One wonders when it will come in carrying rain. It has shifted from SW to NW now, and may simply blow again. We won't be buried in dune sand this time, anyway, and I don't think the tide will wet us.

February 12, 1978

N. end of Magdalena Island, at Boca Soledad, Baja California del Sur

Nice calm day today. The Ruchs left to go look at their house at La Ribera. All of us enjoyed having them with us. Sandy is a kind of peppery little girl who had to get us all out to see her black cloud, but also stood for no garden sass from her Jim, who is nothing if not positive. He is a very bright, thoughtful person, dedicated to action, but in a political vein that is there are limits on what one can do, and learn to maximize the opportunities. A magnificent civil servant I believe, and a helluva nice guy. He and Sandy went with Jim and had a bottle of tequila with him. He came in the next morning a bit droopy but still with it. I typed on my plan for a field station, washed clothes, and spent a lot of time looking at whales. There were a number of old friends here, though not all of them by any means.

February 13, 1978

N. end of Magdalena Island, at Boca Soledad, Baja California del Sur

Today was kind of goofing-off day. I didn't think there was a lot we could do very productively here and thus spent my day leisurely writing on my Center for Field Studies proposal, and then washing shells, tidying up lines, and finally in a long, leisurely walk around the mangrove lagoon, and a fish to make fish chowder for dinner.

The day was calm at first and then the afternoon breeze came, sliding the dune sand in sheets over the dunes and into the channel across the beach. But in the evening the wind dropped a bit and it is breezy at this juncture.

We stayed here rather than leave a day early because nobody had hotel reservations and it is much more expensive in town than here. It was nice to have a slow motion day before the onslaught of packing, which begins tomorrow. We will try to take

out as much sand as possible, but it's in everything, especially this typewriter. I have no idea how it manages to function and will bet I get half a teacup full of sand when I clean it at home. I put the delicate gear on the boat today—cameras, night vision scope, etc.

The lagoon is a lovely one—banked with mangroves at two sides and sand dunes on the others, some spilling right into it. In the flats one could find dozens of scallops just for the picking, and I used a few for bait, to catch a mojarra, a puffer, and to lure a guitar fish up close. Lisas jumped often and I suspect ladyfish too, and I saw a couple of 8-lb. diamond rays cruising along. Across the water were rafts of brandts, scaups, and mergansers, as well as some egrets and others. Beyond, over the bar the main channel shone blue, with cruising whales blowing as they drifted by. Bernardo was there trying to master his boat pole, which has a standard old star drag reel. He is trying to cast with it. Later I gave him a little lesson, but it's not built for the task and the most he can expect is 50 ft. or so. I caught a half a dozen sand bass and one cabrilla (*Mycteroperca pardalis*) to make a casuela for dinner. Barbara cooked the vegetables and I supplied the fish. It was good, especially with a garnish of jalapenos.

So ends the effective time of the trip. I hope Bill Rogers comes out with a dissertation topic. I'm happy enough to turn over my work to him, and to sick him on Punta Tosca later for a real view of whale goings on outside the entrances.

Wonderful company this trip—though the weather has been tough and we didn't get to work where I wanted us to go. I think we've learned a good deal, but more awaits us, and more is needed. I truly don't know if we can hope to demonstrate much that will be convincing evidence for or against the necessity of lagoons.

**

Granite Mountains: April 8-10, 1978

April 8, 1978

Bunny Club, Granite Mts., San Bernardino Co.

Well, the Granite survey crew is here. They've vacated the cabin for us and moved down to Cove Sprig, where they had tents and the trailer all set up, plus the series of tents needed to accommodate 11 people. I spent a time with them trying to assuage their concerns about not having enough original work to do and what sort of collections to make. I tell them, "No worry, really." Just do what you can, to the best of your ability and the rest will care for itself. All in all they have really no problem—just do the best they can. They're so good, so bright, and so eager, and so special.

This day was spent with observation groups, three of them, all focused on the single male Anna's hummingbird. It sat on its snag of catsclaw, flying off to meet imaginary foes, or birds passing over hoping no one would rise to challenge them. But our hero rose up—vertically to challenge the intruder. Off they went in a wild arabesque over the swell of the hills, out of sight over the [?] creosotes and were gone.

I think the little bird was guarding his territory—perhaps five catsclaws—from all others, especially other hummers. Those he drove off violently, in long, low chases across the alluvial fans. Sometimes he would be gone for minutes on end. Sometimes we could see him rocket off and up and over the granite monoliths to disappear altogether in the sky. I wondered how he stayed warm, what ran his engine, what passions motivated

his breast. Who knows? I suspect that passion digs deep in history, far back in the dim recesses of time, into those early creatures that we scarce allow to be mammals, those nearly or wholly reptile. I don't see these things in reptiles. They seem mute and without essential emotion to me. What is it that governs their lives? A basic, unembellished urge it seems to me. The drives are there but the complexities of emotion are only alluded to. Even in lower mammals the skein is incomplete. Do they care, do they suffer deep pain, what is it that they feel? Somewhere the complexity rises. Is the sentient being an excrescence that uses essential talents for purposes that have little survival value? Who cares that an animal should care? And who does?

I guess that continuity will prevail and that a gradual change from the mechanism of lower reptiles to the choice-prone emotional life of higher creatures will be the rule, increment by increment. It's a source of wonder to me that people can expect otherwise.

April 9, 1978

Bunny Club, Granite Mts.

Today was dune day plus quite a lot more. We started our day with talks in the cabin. It was cold and bluster outside with a mist rain falling. I wondered that no snow had fallen on us but it was close as the upper peaks of the Providences, which were dusted with white.

The rain continued and even came harder as we drove over Granite Pass and down toward the Kelso Dunes all veiled with rain. One could hardly see the main mass of the Granites in its cloud.

Parker was at the magnetite mine and directed us outside his cable gate. He didn't recognize me, I believe. I understand he is making conciliating noises toward us now that our purchase is essentially complete. I welcome that. The mine machinery is freshly painted and the operation has a look of activity about it, though we saw no collection operation in action. It seems pretty clear to me that it is a stock come-on.

Up the dune we went and as we did so it cleared, and before the top was reached it was clear and calm. The sand was wet enough that our footprints dug steps up the knife edge of the dune, making it vastly easier to climb than in shifting dry sand. But, in compensation, the dune wouldn't sing for us—why does water make dune sand hard? I'd guess it has to do with the summation of the capillary forces that cause water to cling to surfaces. Around each grain these must exist, and when grains touch each other the sand might be tied to each other, and in aggregate the sand becomes hard enough to walk on.

Personalities emerge. The group is intent, responsible, eager to learn and experience, as yet a bit reticent, but that will come. Larry streaked the dunes coming down 100 yards away in the buff amid commentary about ogling at him. I guess he was loosening up the group. I didn't ask.

Louis is full of humor and we swap tales about San Fernando Valley. Susan is as bright and accomplished as I thought. Walter loves his music, builds his mandolins himself, and plays up a storm. Randy is a live wire. Mark Thomas brims with energy and goodwill, and so forth. All work with dedication. Couldn't ask for more.

At the top Charise gives a nice talk on dune origins which I adumbrate. Then we slide back down on the hard sand.

At the bottom we find Mark with a *Callisaurus*, which is a good topic for conversation. the bajada floor is a garden, beautiful flowering plants broadcast across the

washes and dune aprons. There are lovely large white *Oenothera deltoides*, *Abronia*, a great display of *Rumex hymenosepalus*, whose leaves, I find, are colder even than cool air. No umas are caught though I see occasional tracks.

We stack our food boxes on the road by the bus, slice cheese, break out the fruit and bread, lettuces, mayonnaise, and mustard on a fender and have at it. We were all hungry so a lot of provisions disappeared.

Then, tumbling back in the bus and calling for buddies (we divide the class into trios who watch for each other) and we are off toward Civia and Cedar Canyon. I took an observation group out on the hill below Hole in the Wall to talk about observations. we descended by rings set in the rock to a level below the camp—out on a magnificent bajada bounded by battlements of vertical volcanic ash cliffs all shot full of solution caverns. We saw a pair of nesting redtails, a beehive, and swifts rocketing by. Once again everything was verdant and moist from recent rains.

April 10, 1978

Bunny Club, Granite Mts.

Toda was individual observation day and our crew scattered like a covey of quail. They're a responsible lot, thank goodness, and wrote down their plans in the flight plan log. At the end of the day as the shadows stretched out across the east bajada, one group of five gals hadn't come in. We checked the log and found they had hiked around the toe of the Granites toward Snake Spring. I knew the hike and knew it is long and over swells and arroyos and congested boulder piles. So Larry and I went down to the camp of the Granite Survey crew at Cove Spring, borrowed a vehicle, and drove off down toward Granite Pass. There they were hiking up the road looking tired. We gave them a lift to the cabin and I had that glorious relieved feeling when all the chickens are in and safe. On this first trip one is never sure about people until a little experience builds up. Looks fine so far, and I know a lot of the folks well enough to feel comfortable.

As for me, I took a nap on the porch and dropped off in deep sleep quickly. I don't know, maybe I slept an hour with the balmy spring air wafting over me. How delicious!

Big River: April 23-26, 1978

April 23, 1978

Jim McMillan's Yard, Mendocino County

At 7AM the vans awaited us at the Barn Theatre, and then followed a bout of canoe tying and gear loading. Not long though, as everyone was quick about it and were off up Hwy 1. Larry detoured to Berkeley to pick up Dave Hart and to buy me a shelter.

We met at Audubon Ranch at Bodega Bay where everyone took the hike up to see the nesting common egrets and great blue herons. The treetops were covered with them but on the top of every tree trunk was a heron nest. No egrets occupied these much larger nests for some reason.

After lunch we drove up through Olema, along the trace of the San Andreas. I wasn't feeling too well and slept much of the way. Not much rest before leaving, I'm afraid. Larry gave me a very nice note from Craig Schindler thanking me for being

constant on his behalf. I have been and hope that lugubrious appointment matter is settled soon. It was part of my tiredness I'm afraid. I doubt that I'm really cut out to be a bureaucrat, especially when great dollops of inhumanity intervene. Oh well, it may come out OK. I feel confident it will.

About dusk we pulled into Jim McMillan's yard and were greeted by the boys and led through the driveway via nearby trails because it was a quagmire. The sky threatened so I chose to sleep in Jim's school, along with most others. It's a marvelous, idiosyncratic wood building all full of lofts, angles, little triangular windows, with Jim's pot farm growing upstairs and corners crammed with kilns and other projects.

We had dinner around a great, blazing campfire in Jim's newly cleared meadow. Dinner was cooked there and then we listened to a fine discussion of the pygmy forest by Louis and Teresa. Then Jim and John Paul led us on a tour of the pygmy forest about 100 yards away. There were clumps of bear grass in bloom (*Xerophyllum tenax*), their candles shining white in the flashlight beams, Ft. Bragg manzanita (a very small-leaved low shrub), and a larger more bushy one. Salal is everywhere.

Later we retired under gloom skies but no rain.

April 24, 1978

Big River, Mendocino County

Not for long, however, as after breakfast and by the time we'd reached Mendocino Woodlands it was drizzling steadily. Gear was stashed in a great pile under the old, battered, yellow tarp while we waited for everything to arrive. I spent my time loading all the food and camp gear in one skiff preparatory to launching. After a while we were off with quite a few people walking down the logging road to the crossing only 1,000 yards downstream.

Soon we were all there, the rain still coming down. Much scurrying around and tents went up under the redwoods on a flat 12 ft. up from the river level. The cooking shelter was a grand one, located on the top of the sand bar and covered by the big tarp. All stoves and similar paraphernalia were on benches in the sloping sandbank, scraped by hand. The guitars and mandolins came out (Walter is a real mandolin picker), dinner was cooked, eaten, and reports given. Then we wended our way to various shelters.

Jim's (McMillan) collapsed during the night sluicing water all over them.

There's a stomach problem going around, involving diarrhea and I've got it mildly. Some folks are really sick like Lisa and Dennis. Before long everyone had sampled it. Fortunately it seems to last only a day but it's fairly miserable for some folks, what with the rain and all.

April 24, 1978

Lilly's, Big River, Mendocino Co.

We divided into two groups—one of which I was leader, headed for Laguna Creek marsh, a 3-mile walk through a newly timbered redwood bottomland forest. Even though it was selectively cut the devastation was great. The other, led by Dave Hart, went off to look at stream and stream margin insects. They went off upstream all jingling with vials, nets, and bottles.

Our walk took us through the slash with lovely spindly trees standing up with just tufts of green at what had once been forest canopy level. Many had fallen, sprawled

across the littered forest floor after their equilibrium had been broken by the removal of surrounding trees. Those that were left swayed in circles, the dampening effect of adjacent foliage having gone and the wind now pushed them with its full force. Many more may fall, even though no logger touches them.

We could see the clay bands at the base of standing trees that told how high the flood waters had reached in Dec. 1964. On some it was 15 ft. above the ground and the whole valley must have been flooded.

Part of our crew went in a canoe. They were fortunate enough to come upon a pair of wood ducks cruising in the river and later, a pygmy owl setting on a low branch in a tree.

The marsh extends a mile up a south-branching fork of Big River and is the result of what appears to be a silt dam at the canyon mouth. It is choked with cattails (*Typha*) and with lilies (*Nuphar*). We found evidence of beavers—a dam, all patted with soft mud, a run with footprints here and there where the mud was soft, and a place where they entered the water under a log.

Seining didn't produce much, but the dip and zooplankton nets paid off with lots of small things. There were water fleas, whirlygig beetles, striders, *Daphnea*, and Charise had a leech latch on to her leg. It filled itself amazingly rapidly, and only when she pulled it off did it stop and then it pulsed red with her blood.

Back at camp the rain lessened and finally stopped. Dinner was begun, reports given. Dave's group had located a lot of streamside insects and a few things from the water. We all milled around looking at the collections. Mark Brown came in with a gilled Dicamptodon which he had caught in a nearby pool. Our group had located two species of *Taricha* (*granulosa* and *rivularis*) walking on a forest trail. I was surprised at how distinct they were. The *T. rivularis* was much longer and smoother with bulging eyes than the *T. granulosa*.

Someone noticed that we cast huge sharp shadows against the far bank and its trees, in the light of the Colemans. Kathryn said she always wanted to be a monster and so she was one—80 feet tall. By standing 10 ft. apart and fencing, death defying sword play occurred. Others pounded each other's shadows into the sand. Maidens were hauled off by King Kong and so forth. Finally, off to bed out of breath. No more rain but the dysentery and colds hang on.

April 25, 1978

7-mile Camp, Big River, Mendocino Co.

We loaded, sent a bucksaw team downstream to cut channels through some fallen alders and finally landed. Several folks went by car around and hiked up from below to aid the weight problem. I took the aluminum gear skiff this time accompanied by Kathryn who had never been on a river before. We sluice along, rowing to avoid snags in the olive water. Once we hung broadside on a snag but soon were off again without getting near to upsetting. On down the welling river between walls of alders, willows, firs, and redwoods. The current gradually slowed as we reached tide water and finally I began to row steadily. The last couple of miles was all rowing. We pulled up to the sandbank and most others were there arranging their gear or thinking about cooking. With half a day left we let people paddle—took the disadvantaged folks who had to hike upstream with the motor, which I got to run finally with starting fluid. Jim and Larry managed to get

them way upstream but broke a stem pin in the procees. So we had to go to town. Mark Brown and I said we'd meet them in the skiff, so together we rowed all the way, as did Priscilla Pattison, in a dinghy.

Soon enough they arrived with some rod for shear pins and we made the traverse up without a hitch. By that time darkness had set in and so it was dinner, reports, a bit of music, and to bed.

April 26, 1978

Home

Well, we sent everyone out for the morning. Most rowed on the river. I loaded my boat with gear and we did the same for Jim's big wherry. Nearly everything fit in and not long later we were off by outboard, towing the wherry. At the entrance we crammed the gear in one of the vans and set off upstream. Dave Hart and I stopped off at a pickleweed flat to see if the brine flies and spiders were still performing. They weren't. But it was interesting anyway. Two alligator lizards crawled along the bank of one catching some sort of insects and swam out to a big algal raft. We watched corexid beetles (whirlygigs) diving up and down and occasionally popping out of the surface, spreading their wings and flying away.

Jim talked to us about his trials in trying to save the estuary, a hokey pokey, and we were off. Lots of singing, dancing in the Cloverdale park (Walter lost his wallet and got it back later—cheers), a Chinese dinner in Berkeley.

The trip was interesting and aside from the rain and dysentery, fairly comfortable, but the information content was down and logistics up somehow. Both Larry and I spent most of the time planning, packing, worrying about who was sick and where folks were who didn't sign out. Kevin discovered a hewn tree on one of these unpublished jaunts (for which I chided him) back of 7-mile camp, on the north. I'm not sure about it. Jim's presence was a diversion. I'm not sure we needed that as it seemed to keep the group a little way apart somehow. I'll be glad when we are by ourselves at Villa Creek.

Villa Creek, Monterey County: May 5-6, 1978

May 5, 1978

Villa Creek, Monterey County, California

Another of my patented hectic starts. I had a meeting with the chancellor on a painful personnel matter in the board and then met Deni, who had a rather badly sprained ankle, Mark Thomas, and Mark Brown for the drive down. I had assembled the parts of a sedan chair to haul Deni up to Upper Cruickshank camp, but we had to buy two poles. This we did, and then drove off down the coast. It was a clear, blustery day, the ocean flecked with white and marked by tumbling breakers along the shore and great swirling boils of white water over the offshore stacks. The spring and winter rains had left the Santa Lucias clothed in green, while flowers of various sorts flecked the slopes with color—lavender hedge nettles, poppies, ranked sage bushes of white and blue, lupines, and much more. Skies were clear and bid fair to stay that way during the trip.

Dr. VanDenburgh put in a brief but heartening appearance as we were heading for the hardware store to buy poles. He was a dumpy little hobbit with his big belly sticking

out, a green t-shirt under an old reddish jacket, union army hat, and a fine tangled whitish beard. Green—that was the important thing!

Anyway, at the trailhead we met Larry, all alone, to help with Deni. I rigged up the sedan chair—an aluminum folding chair strung by nylon rope with two poles, padded for the shoulders with part of one of my old insolite pads.

Off we went, 120 lb. Deni riding nicely between us. We crossed the road as a motorcyclist buzzed by, turning his head in curiosity to see what it was that started up the trail. The first of the trail is a series of switchbacks that climb a very steep, soft chaparral-covered slope. My, was that a job! I finally relinquished my position to Larry about $\frac{3}{4}$ way up and stopped puffing and panting, my legs aching in oxygen deficit. I had my doubts that we could do it at all and then reflected about what we would do with Deni—she couldn't walk, and we couldn't leave her. Then I put on my gray heavy pack (extra laden with the gear of some of my colleagues) and realized that it was no better. I had made the hike before, heavily laden, so we would make it. On up we went. The poles make turns difficult, like the rear of a hook and ladder truck. Finally, my second wind began to come and the trail gradient eased as we trudged around the north shoulder and into Villa Creek Canyon. The hills were splashed with flowers and mats of wild strawberries in fruit. The poison oak, too, was lush. Long shoots with glossy green leaves ran across the trail in many places and while steering the sedan chair (the Big Sur Swaymobile) it was impossible for either Deni or the wogs driving the Swaymobile to avoid. Deni began to behave in a queenly fashion, urging us on to get to Cruickshank by tea time, and “would we move a little more smoothly so she shouldn't sway so much”—all in jest.

We finally emerged at Cruickshank to the clatter of pans and beating of plates in welcome.

Not much time left before dark but I set my pack down under the oaks up in the meadow and hied it for the creek and a wash. I sloshed my pants in the creek, soaped them, and then went fishing—not long before I had a nice 11-in. trout and one smaller one—enough for dinner. I cooked them, ate my dinner, had a nice set of reports on aboriginal history. Lisa's was a fine one.

Then, off to bed under the oaks, aching but happy. Owls hooted and some other night bird made its call.

May 6, 1978

Villa Creek, Monterey County

Well, today is niche day. Some folks had their act together early and went off up the trail. These were the Santa Lucia fir group. . . .

We've come to this mountain and together we've begun to perceive the almost overwhelming intricacy and variety of the natural life here. We see that every living thing has a story of how it makes its livelihood, how it reproduces, how it interacts with the life and the physical world around it, or even how it interacts with other life within it—for the surface we call our skin, or the feathers of a bird, or scales of a lizard, are the most transgressible of boundaries in both directions.

We see that time, the incoming energy stream from the sun, levels mountains, the sea floor itself moves, jostling continents like the pieces of a jigsaw puzzle, that streams

have life and that they somehow sustain those living things they ceaselessly wash toward the sea. We see that fire is as much a part of life as water. We begin to see that while questioning about the life on the mountain can often be done quickly, proving this or that about it, is much slower.

We have begun to tell stories, to weave relationships, to pose questions, but we are only halfway there because nature gives up her secrets grudgingly. A fact may be the most precious of commodities.

We begin to perceive that wresting these facts from her starts with a question and a test, and another question, and on and on, the wheel turns until our hypothesis, insofar as we can see, fits, and we are then halfway. Then comes the counting, the measuring, the pondering about what we *really* know.

And us! With our ripstop nylon, our osprey glasses, our Svea stoves that must be cuddled like an infant before their internal store of diatom digestate wells forth to cook our meal. Where do we fit? Why should we care? Doesn't the world always change? Are we part of this mountain? I'm sure we all have come to regard the lives and processes here and in other places like it as a central part of our being. To see them molested, scraped away by a D-9 blade, or forced to cope with foreign chemical sprays is saddening, even maddening, to see it die cuts like a knife.

I see a paradox. We grasp for contact with this world and engagement in it, but in many ways we fit incompletely and see incompletely. On a larger scale the rules of our world are no different. It is our power that is the problem and our understanding.

Tuolumne River: May 12-15, 1978

May 12, 1978

Tuolumne River below Hetch Hetchy (above Early Intake), Tuolumne County

The old blue bus picked us up at the Barn Theatre at 6AM. I had rather little sleep the night before and was recovering from the effects of a GI exam (Barium) which followed three days on liquids. All that left me weak so I was in bliss on the tarp, my head against a bedroll and a groundcloth over me to ward off the chill. I slept clear to Merced. We made our usual circuit into Yosemite and had the usual trouble rounding people up. I don't know why I let them talk me into that nearly meaningless jaunt composed of gift shops and grocery stores. If it weren't for the magnificent falls and rock faces and the nice indian museum I'd check it off altogether.

Then on up through Mather we went, cutting back to Early Intake. Quickly enough I shouldered my pack, with shears in hand, started off. Ted and I set about chipping away the poison oak.

The day was rather warm and clear. Winter rains had brought up a fine, diverse wildflower show. I stopped at the Big Pool camp and instantly later, with much whooping and hollerin', $\frac{3}{4}$ of the class was in the creek. Larry and I hadn't planned anything except a report or two and it was getting close to dusk so I just turned people loose and went off to set up my camp, which Larry and I shared. We were right where Annie Gottlieb and Don had camped the year before.

After dinner Walter and Larry and Teresa and I sang on and on till nearly midnight. Off to bed, the mosquitos having mercifully long since gone to bed.

May 13, 1978

Ponderosa Beach Grove, Tuolumne River

First thing this morning we dipped in the great rocky gorge pool, its black water rippling in silver and the walls echoing with joyous cries and splashes. It's a nice sunshiny day, bordering on the hot, glorious weather for a camp. I clipped poison oak branches from across the trail, mostly for Betsy who is so susceptible. It's a lovely hike up the canyon. The trail clambers up the great blocks of granite shed from the canyon walls to form a scree pile that sometimes chokes against the river and sometimes retreats up against the flanks of the canyon leaving grassy meadows undulating down to the alder and willow-bordered stream. In these meadows the footpath led between grasses and lupines in flower, and across occasional little crystal streams winding between banks of black soil and rushes, banked often enough by yellow streamside *Mimulus*.

Up on the rocky stretches birdsfoot ferns sprang from under boulders and more verdant succulent species such as wood and lady ferns stood on cool earth at the mouths of caves, their fronds athwart the sun.

Once the trail led up a sharp slope entirely of bedrock—a metamorphic contact with granite. Patches of the glacial polish were scattered over its surface, its striations still evident.

On one of the steep boulder slopes with a thin mantle of soil were several lovely mariposa lilies in full bloom. Down the throats of some, amid the retrorse mauve hairs were yellow and black beetles sucking at the nectaries at the base of the stamens. As the flower ripened the calyx split and the stamens unfolded outward, coming close to the walls of the flower. A beetle climbing out after feeding on the nectar came up against the hairs, scrambling to get up against them and between the anthers and the flower tube wall. Soon it was pink with pollen. Sometimes the hairs caused it to tumble over backwards, being daubed in the process.

Finally the trail dropped down to a sloping meadow of clustered buckeye, golden cup oak, and near the stream, stately ponderosas in an open grove. I knew there was a sandy bench amid the trees and at the water's edge. I soon found it, dropped my pack, and began to set up the rain shelter right above the water's edge. Once that was done I set off for the parking lot where I was to meet Phylly. She and I had resolved, if at all possible, she would come on this trip, in spite of the pull of caring for Grandma. More than anything else it's a burden because Phylly's freedom is cut down. Anyway, neither of us were sure she could make it and I was to call in if she didn't appear after a while.

Anyway, I had a nice brisk hike down and then sat for quite a long time carving on my new alder walking stick, and soaking my shirt in a little rivulet and drinking from a little pool, and swatting mosquitos. Finally, at about 3 she arrived, a bit frantic and hungry because of a late start and Grandma getting sick again. I don't know how much is worry and concern on her part and how much real viruses and the like, but I do know there comes a time for breaking such dependencies, hopefully with as little pain as possible.

At any rate, we hiked up with Phylly feeling the heat and trying to cast off the strain. She got better and better as we hiked.

At camp we cooked dinner and soon it was dusk and time for the aboriginal group presentation, a bear dance. They (Louis, Charise, Susan, Susan, Mark T.) had been

working for days on it. We sat around a cleared dancing ground of sand cleared of needles, and cones, with a fire in the center. Off to the side, under a big ponderosa about 100 ft. away was the dressing room. In it the dancers were preparing. When they emerged it was four girls dressed as men dancers, necklaces of shells, feather breech clouts, beautifully wrought, scepters of flicker and guinea feathers on sticks, bear claws made of digger pine bracts in their hands, and dangling jingling strings of shells held from a horizontal stick in their mouths. To the side were the drummer and the chanter. The drummer beat on a bongo that they had laboriously packed in.

Off to the side stood a squaw, he (his—it was Mark Levorsen) wrapped in a shirt in lieu of a kirtle. He kept time, and looked solemn. The dance was in sacred sets of four (as with the Miwok) and consisted of various evolutions in the sacred dance circle (kept clear by the jester with a stick who shooed people out of the path of the dancers). It was a marvelous performance, done very seriously, with every bit of integrity the dancers could muster. It gave, I think, a real sense of the entertainment and involvement of the indian with his dances, and a feeling for the movement, solemnity, and importance of such rituals to people who knew bears best, and who had few resources, except shells and drums and the like.

Phylly sat there enjoying it immensely, I thought, and not long afterward we slipped off to our sleeping bags under the tarp overlooking the shimmering water of the broad smooth stream and the cliffs above.

May 15, 1978

Tuolumne River, Tuolumne County

In the morning I led everyone up to a grassy field above camp where the sun shone down and the mosquitos were mostly driven away by the warmth and there we outlined the energy exchange relations of living things, Marc Brown doing honors on the Gates equation, courtesy of a long computer printout sheet on which he had printed the equation. I followed on with the black body radiation laws (Wien displacement) and then we turned people loose with temperature, wind, light, and current measuring gear to look at the little worlds of leaves and insects and lizards.

Phylly and I trekked down the trail and I finally left her at camp no. 1 and returned up the hill to work with my people. I wandered from one group to the next trying to help where I could, finding, for example, the light people in dismay over their instrument and its limitations, and the current people in euphoria over some peculiar discoveries they had made about surface vs. subsurface currents.

Later we gathered and had a good session discussing what everyone had found. As always, even though the individuals thought they found rather little, in aggregate many, many interesting stories emerged, and much enthusiasm was generated. People were tired enough that it took some doing to get a Virginia reel going around the fire. I pooped out after one set, wondering if I was losing my natural energy, but then reflecting that I had hiked about 10-12 miles farther than anyone else.

May 16, 1978

Home, Very Late

Up early and packed, while my bacon was frying. I'd been careful about cooking the stuff in the dark because we have seen bears three times, once right in camp. But they did us no harm, and most people hoisted their gear up in trees.

After some good reports around a little fire (the day was cool and overcast in contrast to the beautiful clear weather we have been having) and it took the fire to stay warm. Then, up with the packs and down the canyon. I hated to leave as folks are pulling together into a loving learning group. It's wonderful how trust opens people to share their thoughts and learning, and to teach each other. The collective capability never ceases to amaze me.

At the entrance we ate lunch and I read my little farewell statement that I had prepared upstream. It was met by thoughtful silence since I don't think most people suspected that this was my last trip. Later, as we walked on Hetch Hetchy Dam we had a communal hug and I was carried around aloft (this was after all our hokey pokey).

Then home with much game playing and singing on the bus, and much good conversation with individual students. I can help several of them in various ways, including some of them who have had trouble getting anyone to care.

Home at 12:45 AM.

Remarks at the end of the Tuolumne Trip, 1978

We've descended along the gentle lower Tuolumne, moving a little faster, I think, than the river. That might be a mark, that we've not yet joined the river or the land in its pace, nor become wholly part of the pulse of the land the way the ancients of this land were, such as those women who gathered around the grinding holes at lower camp. But we shouldn't, I think, denigrate ourselves, as we are wont to do, for this. In all men—Native American, Eskimo, WASP, or Oriental—lie the same potentials. It's not who we are but what we build for ourselves that counts. To build, however, we must have a dream, a vision, we must first see. To me the dream is to build consonant with nature, for, we all know, nature is paramount, and will in her own time, rule.

So our task is first to see, next to understand her patterns, and finally to build those patterns into our own lives and cultures. That to me is why we have taken these four glorious trips together. Parenthetically, I couldn't have asked for better, more joyous, or loving companions, and I must salute my wonderful, gentle companion Larry.

I can't list all we have seen and can only guess at what we have learned together. I only know that such seeing and learning at its best involves love and trust and collective wisdom, and the right of each, however private, to share thoughts, visions, and perspectives on the world with each other in the knowledge that all will receive, welcome, and understand in his or her own way.

We've been part of grandeur. What else would one call climbing among the soaring monoliths of the Granites and seeing far above you in the canyon an eagle soaring effortlessly tilting this way and that to spill the air from its wings as it banks in that walled canyon of air.

Or there on the cornice of sand atop the Kelso dunes, the perfect arcing slopes sweeping away from us, marked only by our transient footprints and below us a vast landscape bearing the marks of primordial time more than the marks of our own activity.

There have been gentle times too. Those flower-clothed hills at Villa Creek where one could lay naked in the meadow with lupines nodding in around you and the sun

shining down to warm, and the gusts to cool one's skin in an intimate touch with nature. Here the Tuolumne is another such wilderness, sand banks properly spiced with pine cones and oak leaves to prick the bare feet, the little wandering streams of the meadows whose interlacing currents are so mystifying.

And joy! Why not I say!! Katherine says, "I always wanted to be a monster" as she spied the giant shadows cast on the wall of trees across Big River, to be followed by those wonderful mask battles featuring agile swordsmen pitted against an 80-ft. high King Kong.

Or twelve steaming bodies running with rivulets of sweet, cleansing sweat, set in counterpoint by the phrases and thoughts of each of us and finally capped by Dennis's elegant couplet with its imagery of the wild woods.

Or who can forget, ever, the [?] duo of Nancy and Charise, man and woman for sure, introducing us to the vegetable world. Or the wondrous recreation of a bear dance here on Tuolumne's sands, its rhythms and costumes so perfect. Louis the jester, the fierce bears, the flickering light on the chanters and drummers, the fourfold repetition, the solemnity, the jingling shells, the fortuitous flicker feathers, so artfully built into scepters and wands. I shall treasure my four digger pine claws saved for me by Susan.

I know that together we have seen some of the pace and intricacy of nature, something of the worlds within worlds where to insects a grassy field is an endless forest whose borders are only to be dreamed of for the tiny beetle down there at the base of those green giants, feathery hands of lupine leaves far above and giant siliques hanging up near the distant grasstops, and the nodding seeds of grass only now and then visible as swirling gusts of wind sweep unseen across the forest top.

Or Becky, Nancy's, and my venture into those giant oxygen-filled vaulted algal domes, glistening with sheets of water.

Intricate, interlaced, all things reaching out not only to each other, but transgressing the barrier of body form into the outside world through odors, dependencies or water, heat, wind, and light. And all this is seen through time, as we contemplate the flux and flow of ice, origins of mountains, the unimaginable forces of colliding sea floor and continent.

For all intents and purposes I leave you here, though I may travel with you as a visitor later on. I treasure the journeys we've taken and shared, and our comradeship and loving company as we've tried to see into our world together. My deepest affection and thanks to you all.

Big Creek: July 6-7, 1978

July 6, 1978

Devil Creek Falls Camp, S. Fork, Monterey County

Yesterday Steve Strout, Dick, and I started out for Big Creek Reserve to do some trail reconnaissance. After stopping off at Roger Nevill's house for a potluck lunch designed to introduce our Big Sur interns to various resource people, we continued on down to the reserve. Roger lives above the highway near Nepenthe. It's a pretty spectacular place, hanging on that ragged slope. There's an old spanish house and a stone

barn. Fences cling to the slopes and then hang precipitously on canyon walls. These canyons are choked with redwoods and tanoaks and bays, all dark with only fallen fronds for a floor.

At the reserve we braved the big shaggy dog, obtained the key, and drove up on the south highland near Gamboa Point. On the way up we clipped poison oak where it has overgrown the road—a messy job, but the heavy rainfall has promoted so much growth that it scrapes the car top in many places and intermittently threatens to whip in the windows.

By dusk we reached camp at the old man's grave amid the live oaks. The air on this high ridge was at least 10 degrees warmer than down in the canyon where the air draws. I tested for mosquitos and found none. They came later at night and around dawn, when they troubled us enough that we arose with the dawn.

Steve and Dick are great company—helpful, fun, and skillful. No complaints about nasty jobs, just, “let's do it.” Super, I say.

Stories and jokes around the hissing stove and then to bed. It was too warm to creep down inside the bags but it wasn't until much later that the bugs found us.

On up the road to Gamboa Point and David's Camp (his tent is still up). We walked in and looked at the potential camp by the big Kellogg black oak. It still looks like a fine, sunny, but protected campsite, and I will move ahead to getting tables in place. It's so different from the river bottom, so open, grassy, and on top of the world. It does sit, just back of the main break in slope before the Santa Lucias plunge off into the ocean 1,600 ft. below.

Then we traveled up to the shake makers camp road and hiked down it toward Devil Creek to the north. One can see the remnants of the camp amidst the live oaks, madrones, and ponderosa pine. I'd wondered where he got shake wood, which I presumed must have been redwood. We poked around the old shakes and indeed they were redwood. Soon I found that the road went on north from the camp ducking down along the west wall of the canyon leading north to Devil Creek. It's a pretty gentle road and seems intact except for lots of deadfalls blocking it.

I found a midden of shells, mostly mussels. We were close to the 2,000 ft. contour. What a haul for those indians! [map]. After this exploration we donned our packs and set off down the Devil Creek Falls trail. We will tag it and straighten out switchbacks and clear what deadfalls we can, all prior to YCC coming in to do the final work. We hiked down the trail first, clipping poison oak and branches of bay and tanoak mostly to clear the trail. At the bottom, where the steep trail switchbacks onto a little flat along the south bank of Devil Creek sits the forest camp amidst redwoods (some towering old trees), very tall big leaf maple, bay and willow. The slope to the north towers to a rocky, chaparral-covered crag while the south slope is a steep one (45 degrees maybe), but forested and covered with duff. The boys ogled at the lovely greenish crystal pools and the perfect 75-ft. white waterfall. I declared a break and said, “Let's go fishing or we'll have to eat canned Argentinian beef.” So we rigged up and soon were on the creek. I'd seen fish last time so was not too surprised to have fish bite easily. I had seven fish on the bank in 15 minutes, the biggest was 11-12 in.—beautiful stream-grown rainbows all of them.

Dick had four nice ones and Steve was hooking them too. We stopped taking them at 15-16 fish, that being all I thought we could eat for dinner.

After lunch we took our machetes and loppers, plastic tape, and we went off up the trail. We worked four hot, sweaty hours and were able to fix up the entire lower trail which was where the bad sections were, mostly from deadfalls and people then making new trails. We went back down to camp, hot, dusty, and wanting to wash off. I washed everything including all my clothes and me. We snoozed, explored downstream, where we found a long procession of lovely clear deep pools, some fed by little falls. Such fish as we hooked we let go. This included some more 11-12 in. fish.

Just before dusk I built a fire, poured my oil in a pot, and soon began to fry our catch and some potatoes. What a delicious supper, we all agreed. It was spectacularly good, if I do say so myself. We could have eaten more, but didn't need it.

Notes and a fire along the rushing stream. The light faded that greenish cast it sometimes goes on clear days just before dark.

*

Magdalena Bay: December 31-January 31, 1979

December 31, 1978

La Paz, Baja California del Sur, Mexico

I'm back in my old cabin on board the *Regina Maris* after a rather hectic time getting free from affairs back at Santa Cruz. I'd been worried about Phylly and Grandma Jessie, and had resolved that to some extent by convincing Ginny Norris to come up for a few days in mid January. Not that I had to convince very hard. Ginny was very good and instantly saw the need. Then, there were myriads of things to do before leaving, trash to the dump, wood on the porch, new kindling, the sheep, and a bundle of grant matters to settle.

Then, last night, at a party, Gene Bolt, the Chancellor's money man, took me aside and told me there was suspicion of theft by my administrative assistant. He told me no more than that xeroxing was involved, how I don't know. But it was pretty unsettling to say the least and there was nothing I could do but write him a note and leave. The flight down was uneventful, if sprinkled with delays. George Nichols came into the LA Airport from Boston and so we went down together with Rich Mulla, the engineer. Rich carried a great raft of parts for the generator engine, which had crapped out. It turned out he had a little of everything else too, champagne and a new T-shirt saying "Chief Engineer."

The *Regina* lies anchored off the municipal wharf, and was easily reached by the inflatable that came in to receive us. Not too much longer afterward and I was aboard, putting my various gear away in drawers and closets and now I sit here typing by a bare bulb, with a little drip coming in on top the bunk I do not occupy, a new ribbon on my old Olivetti, and a full tummy from a nice meal whipped up by our bouncy cook (Pegeen), including pie and ice cream. Little Pierce (He's not so little, in fact he's a big big boy, all full of enthusiasm) wanders the ship, getting happily into everything.

Tomorrow we watch Rich fix the engine, take on water, fuel, maybe some more supplies and then on the 2nd take off on our ventures.

The trip is designed to investigate some unknown aspects of gray whale life. The first question is how do they traverse the Gulf to Sonora, the second, what is the group at

Cape San Lucas-Cabo Falso doing, and the third, is there any social structure in the groups at the entrances to calving lagoons? The latter is the most interesting question. I think it likely that we will find some such structure, and this may be important in showing why lagoons are crucial to gray whales. We'll see.

The *Regina* is improved in some ways, the new lab is quite nice and neatly kept, the field protocols seem to have been upgraded quite a lot. Plankton samples are taken and recorded with some care, and there seems to be some attempt at labelling, though I note that the author or identifier's name is left off on the tags I looked at. The new galley is clean and much better than the old below-decks catacomb. The student quarters are utterly minimal, with only a long bunk closed by inadequate curtains. I'm not sure what people do for space for socks and the like. One poor pair of folks who want to photograph the expedition were abruptly turned away by George with their piles of gear, all neatly boxed, for want of space. I'm not sure how much advance information they had been given, but I will put as much as I can in my bunk room, which is the most palatial on the ship. I at least have space to move around, and my own head.

All in all the ship seems in want of a lot of minor repairs, like bunk lights (17 out) and little deck leaks over bunks. The other bunk in my cabin suffers from one such, down a rusty vent that drops rusty sea water on the occupant (there isn't any right now).

Little Pierce, a healthy and good-tempered young lad so far as I can see, takes up a lot of space in the after salon, where ship's business takes place and staff meetings are held. This room is now littered with teddy bears and xylophones for Pierce. So, from the student standpoint it is extremely tight, and I think the ship would do well with about 10 less students, but then I don't suppose she could break even. The experience on board does have strong parallels to those of an old sailing vessel. *The Beagle*, at 90 ft. about, had a bigger compliment than we do at 144. What life was like on such a ship is hard to imagine, creature comfortwise. There must have been very little personal space around anyone on such a ship. The need for this, especially for permanent residents such as George and Annie, is severe, and one can see why arbitrary decisions come to be made, and why Captain Blighs arise. The essential person becomes invaded and strikes back, sometimes hard, to preserve itself.

January 1, 1979

La Paz Bay, Baja California del Sur, Mexico

We're still at anchor, with the NE wind whipping in the bay and the double anchor chain stretched taut. But the ship is still since there is no swell. Everyone is on board now, including the photographers who have everything stowed under my bunk (I guaranteed it was dry). One gent from Louisiana, a GP named Mayo Emory, lost his luggage at the airport and is hoping they will deliver it tomorrow. He didn't look too happy, somehow.

The conversation level grows around the dinner table as folks become acquainted. Names are swapped and professions exchanged. We've a bunch of doctors, one resident, an engineer, a bunch of students, and about 10 Earthwatchers, who are with us for two weeks. George gave us a really polished instructional talk ranging from how to use the head to the penalty for bunk swapping (banishment), to the penalties for drug possession (put ashore at once), to more mundane items like avoiding hanging skivvies over the dining table. I spoke a little about the scientific plans, about my hope that we might begin

to gather information that would allow us to convince people to protect the calving lagoons.

It was a quiet day. I went ashore in an attempt to locate the photographers who I knew were freaking out because George made them cut down on gear, but I couldn't locate them. Then I finished Harrison Matthew's uneven book on whales. We were given our safety harnesses, and the watches are being started. All in all, the act is much more together than on our other trip, and things are running pretty smoothly. I have a nice assistant, Karen Miller, a young gal from Connecticut College, who is to help with things scientific. Tomorrow we go ashore for cement blocks (as anchors), some floats, and lines to set up a grid. We'll use this as a base from which to locate animals as they move about the entrance at Punta Tosca. It should help.

Pegeen is doing a fine job as a cook. We are all stuffed. She's a very Irish, independent, dark-haired gal, very much herself.

January 2, 1979

La Paz Harbor, Baja California del Sur

The day, which was blustery and sometimes downright stormy (the sea was breaking ominously over the entrance bar) was spent doing little errands in preparation for leaving. I went off with Kay Miller, my lab assistant, to pick up materials for our work at Tosca. We will put out an anchored buoy line there, two lines actually, using painted plastic floats and cement blocks. I called Bernardo and he won't be with us this trip, but plans to be along on the trip up in the upper Gulf, praises be. He says our permit is sent.

People got their safety harnesses and mates circulated around in the teaching mode, telling people about downhauls, futtock shrouds and the like, and taking some aloft. Our grandmotherly types were right up there at the upper topsail with the rest, and I'd imagine will be so when the sails are to be set at sea.

January 3, 1979

At Sea inside Espiritu Santo Island

Various final details were taken care of, we haggled with the fuel dock and lost—they wanted to charge 3X for a US boat than they charge for one of their own (fuel is subsidized for their vessels), so George simply didn't buy any and left. I gave a lecture on the gray whale and our plans and Kay laid out fine-grained plans for a whalewatch as we cross the Gulf. She is very earnest and careful and nice to work with.

The water gurgles past the hull now, the sails occasionally slat as the wind shifts, but mostly we plod along at 4-5 knots in pretty calm seas, on a NNE course for Yvarros, where we will look to see if gray whales are still present.

January 4, 1979

Mid Gulf, Between La Paz and Yvarros

I've been going on the slow bell today, afflicted by some bug that seems to be with several others—perhaps a flu bug, or turista-weariness, la grippe a bit, and general inability to accomplish much or think very hard. We had lollygagged around and found ourselves off Espiritu Santo, and in the morning cut in toward a rock at the NW tip of the island to look at the sea lions there. They were clustered on the south shore and SW tip of

the sedimentary island (or is it layered volcanic rock—at any rate it has layers and is pink). There were between 150-200 animals there, including a great many males, but I saw some females and some small young. They yelped at us nicely, blew bubbles underwater, and milled around when we came too close, leaping into the water. Out off the tip of the island 3-5 miles we came into a small school of *Delphinus* that cut across our bow, ignoring us pretty full. The day has been quite calm, a bit brisk, with a few clouds but mostly clear skies. We have been moving along in the absence of a wind in the right direction. George says we will reach Yvarros tomorrow night. I spent a lot of time today peering at vacant ocean, and sleeping in between.

January 5, 1979

At Anchor, off Yvarros, Sinaloa

The eephus abandoned me largely this morning and I felt pretty good most of the day. Only an errant cup of coffee set me off a little bit. It was quite a day. Until afternoon we sailed through flat vacant seas, on engine. About all we saw were birds flying by us toward shore. Prominent were brown boobies. Some showed us their lancing dives, piercing affairs that drive the bird deep beneath the surface. Phalaropes were all around sitting on the surface and collecting along slicks. We saw a group of large, all-brownish black petrels that I decided were black petrels. They swooped around the stern for a time. California gulls, a few Heerman's gulls, pelicans, a Franklin's gull, and a couple of jaegers made up what I could identify.

On the last cruise the ship had encountered fin whales in about 30 fathoms up by Guaymas, feeding. So we kept a sharp lookout and sure enough, when we hit about 35 fathoms the call went up "Whale, ho!" Welcome it was too, since we'd spent a fair length of time without sighting much. The moment I saw the beast I was pretty sure it was a blue—the very long, arcing back, often without any fin appearing at all, and then, now and then, the ridiculous little fin. Finally we cruised close enough to see the motley gray color. There were two traveling together—one on the order of 80 ft. and one other quite a lot smaller. I think it could have been a cow-calf pair. Then, not too far inside we came upon two more groups of whales, this time clearly finbacks—the much bigger fin showing nicely, and the darker back. We weren't able to approach close enough to see the coloration at all, but on the blue we could see the huge ramp of the nostrils, and the spatulate head. What a sight. Our crew were pretty pleased to see these great creatures, and the blue such a rarity for any one, cetologists included.

January 5, 1979

At Anchor off Yvarros, Sinaloa, Mexico

Soon we turned for the shore, which now appeared in the distance; lumpy hills, a light or two, and prominent peaks behind, the outlyers of the Sierra Madre Occidental.

We came in closer and closer and found ourselves in a broad embayment opening south. The low landhills and playas stretched way to the west of us as we penetrated the bay, heading for the lighthouses. Finally, the boxlike houses and water tanks of Yvarros itself could be made out to the west of the town. Common dolphins began to play about us as a large school intersected us, going on its way with scarcely an animal taking advantage of our broad welcoming bow. At least I think the bow is.

George could see masts over the bar, of draggers, and I could make out the old pier and groin, only pilings and rocks remaining. George took the *Regina* in toward the range markers and buoys and rather shortly bumped a sand bar. He attempted to turn and hit on both ends with water in the middle. He worked her around but didn't know which way lay freedom. Finally a skiff came by and we hailed her. Her crew told us the tide was high and that the deep channel lay off to the south of us. George wasn't sure we could get there and when a dragger came by (drawing about 11 ft.), we convinced the skiff people to take a hauser over to her for a tow. Not long afterward we were under tow, with our own engine on full, and the *Regina* bumped and objected but gradually and fitfully made her way into deep water. Presents to our benefactors, the hauser drawn aboard the *Regina* made her way to about 10 fathoms of water, where a hydraulic line decided to break. This controls the winch and means the anchor has to be hauled by hand. But George cleared the dragger channel and dropped the anchor. I'm told it takes 1½ hrs. to haul 100 ft. by hand. Well, it's a helluva lot better than being on the bar, and I know George feels this.

By the way, we saw nary a gray whale in the channel as we neared the bay. Probably we are too early. But tomorrow we'll take a look inside and see.

The more I think about it the closer it was. The fishermen who towed our line to the dragger told us high tide was all day, and low at ight. That's not the time to run aground, even if it was flat calm. I know from trying to navigate in such areas that it's apt to be a trap since it's hard to find the deep water, though the fishermen knew where it was. One finds culs de sac, and bars rising up, and such. But we made it. One of the channel markers was a sunken dragger, on the tip of the rock jetty, not 300 yards from us. That gives you pause too.

January 6, 1979

In Bahia Reforma, Yavarros, Sinaloa, Mexico

This morning we put most of the people ashore to beachcomb for earbones and other mementos, hoping to find whether or not calving of grays took place in the area by this means. Ann Dow and I went in the Avon with John Harrar of the crew. John is big, raw-boned, bright guy from Massachusetts, who does a lot of things on the ship. Ann, who is a teacher of English to non-residents at Harvard, and chief editor for some publishing firm, speaks much better spanish than I do, so I thought she could help. Previous conversations with fishermen at the *Regina* in the morning had produced evidence that the large whales are commonly offshore, and seen by the colorado fishermen who venture 20-30 miles offshore for handlining. As for whales in the lagoons, there were no mention, though they did discuss the toninas there (*Tursiops*). The three of us ventured in past the channel markers, and into the bay itself, which we later confirmed was Bahia Reforma. It is a modest-sized bay, by the standards of the west coast of Baja. It stretched away to the southeast and northwest from the channel, blocked from the sea by hummocky sand islands on both sides, vegetated mostly by a low scrub of *Croton* and *Asclepias*. There were some larger bushes and some *Allenrolfia* evident too as well as what were probably low mangroves. The bay water was extremely dirty from a cannery on its SW shore, which was puffing away when we arrived, three seiners tied up alongside. The water was literally stringy with plant growth and waste. At times we passed bars tenanted by flotillas of birds, pelicans, cormorants, terns, one great blue heron, grebes in the water, a shoal of buffleheads. Once or twice we traversed water a

couple of feet deep and saw botetes scooting away. A dead young adult female *Tursiops* lay on the entrance beach, probably caught in a gill net, from the looks of her tail. There were at least four groups of *Tursiops* in the bay and entrance. They came rocketing over to us, and swam ahead of us for quite a time. In close to the cannery a group of boys and men were jigging for lisas (mullet) in the offal-filled waters near the cannery outfall. A long gill net was set around the area. We inquired of these folks and received no encouragement that gray whales entered the lagoon now, though they did know about the porpoises and the whales offshore. Since our group produced no bones in evidence of gray whales I'm reasonably sure they are seldom or never here now, in the lagoon. The channel is about 12 ft. deep and flat calm at our entry.

After a beach walk, in which I thought I saw sure signs of badgers digging burrows in the dunes and crabs on the beach. Big broad tracks and many burrows of badger size. We headed back to the vessel and began our traverse across the Gulf. We'll go a bit north instead of south to cover new 30-fathom . . .

After upping anchor with the newly patched hydraulic line (which had chosen to go out all over the deck amidst the problems about being aground) we hauled up the anchor. (Rich had done quite a job with tape, screen, epoxy and stainless fishing leader). We headed out northwestward along the coast, out on about the 50-fathom line. It was like a lake. Nothing at all, except flocks of phalaropes and other sea birds were seen until dusk when Carl Rand (a student of John Stevens at Oxy) heard a whale blow, turned, and saw what we think now was a blue whale (small fin, very far aft). Just before we had passed through shoals of *Pleuroncodes planipes* and had scooped some aboard. They seemed smaller than those I've seen on the outer coast, somehow, about 2-2 ½ in. length to the body minus appendages. They dimpled the water in broad areas, and occasionally swarmed.

In retrospect, I don't think gray whales go habitually to Yavarros (note spelling, which is on the chart, and is the way it is pronounced, contrary to the cetacean literature). They may occasionally come there, but it must be later, and very likely wholly sporadic. The badly polluted water might keep them out now. I wonder how long the cannery has been going? Were they chased out? Does water taste concern them?

January 7, 1979

At Anchor, South End Santa Catalina Island, Baja California del Sur

We transected the Gulf today at the level of Carmen Island, coming into that island at its northeast tip. It is a typical barren, reddish Gulf island, shaped a bit like a claw hammer with the head pointing north. It is composed of two ridges and a little graben valley, the longest ridge the handle, and the other the head and claws, separated by the little valley. The shore we travelled was composed of sharply faceted andesites, mostly, with the old erosional grade showing a bit more than halfway to the crest of the 600-ft. ridge, and below, steep fault faces dropping into the sea. The graben holds a salt deposit that had been mined since Spanish times, and which was once called "inexhaustable." I'll bet the pressures now from Japanese steel industrial needs alone, would exhaust it in short order.

The day was breezier than yesterday, but clear and crisp. With the ship going downwind George switched to sail and we set off silently, only the burble and hiss of water along the waterline and the pulling of the sails on lines and rigging. The watch

produced nothing until dark when, just as we were coming into the little cove a porpoise raced in in the dusk, leaped and stood briefly on its tail. We don't even know what it was.

The east shore of Santa Catalina, like Carmen, falls sharply into the sea, with faceted cliffs. Only Santa Catalina is at least half again as high. Rock exposures are of banded rocks, probably volcanic, some more homogenous and light-colored rocks, some fissured with thin dikes. In places the steep clefts are filled with scree right to the waterline. A fan just above water juts out at the northeast end of the island, and not until the south cove is reached is there a beach of prominent proportions and a good place to land. There, a light gleams intermittently from a sharp ridge to the west, a pocket beach circles along the shore, backed by a butt of low terrain before the ridge of the central island mass rises. I couldn't see much in the dark, but tomorrow we will go ashore briefly, before heading for San Jose and Bajia Amortajada.

The atmosphere on board is good—the calm seas have cut seasickness to a minimum, and only one of our people is sick, Mike of the photo crew, who was up today from a bout with the flu. He looks pasty but better. One person I have enjoyed is Bea Presky, the oldest gal on board—she could be in her '70s, but up the mast she goes, and stands all the watches. She was a Kaiser welder during the second world war and rose to do the bow work on the biggest tankers. She says it's like needlework, and that to choose good welders women who do needlepoint would be best. She's done some sort of social work too, and psychology and is really a level, low-key person who obviously lets nothing at all stop her.

My own lethargy is passing, and I did a little sewing on my old jacket today, putting velcro on the sleeves and whipping some torn places. Tomorrow the other sleeve.

Oh yes, I saw a red-billed tropic bird today, north of Carmen, and the ridge of Santa Catalina is thick with big cardons, and we understand there are fan palms and two little springs and some tinajas on the island. Where all this is, I don't know.

January 8, 1979

Santa Catalina Island, Gulf of California

After breakfast, and with a few looks at the lowering sky, we went ashore in the rubber boat for a short hike on the island. The wind was whipping whitecaps offshore, and big fronts of clouds periodically swept over the ridge crest. George thought he might possibly have to recall us so we were to listen for the ship's horn. But it didn't come, and the wind was no worse when we returned than when we left.

I was surprised to see the beach composed almost entirely of smoothly rounded granite cobbles, and all the land underfoot on most of our walk of decomposed granite. Here and there dike material of different rocks showed. One pale green dike transects the rocky headland to the west of the anchorage and other smaller ones, full of hornblende and quartz crystals were scattered about. The cactus were scarcely scarred, and fully expanded with moisture. I saw the sour pitahaya, achile, or fishhook cactus, the cardon, a staghorn, and a huge form of the barrel cactus. Jojobas were everywhere, and in places the ground was littered with their waxy beans. I showed those around. Palo santos, and a small elephant tree were there too, and I was surprised to see *Marah* vines growing, especially on the beaches at the strand edge. They were small leaved and did not send their vines so far as the California form.

Up on the bench, perhaps 100 ft. above sea level, were strewn various marine shells such as turban, limpets, and the like, gastropod opercula, sea urchin tests, and some very heavy shell fragments that were big enough to be from conchs. One gal, Denise, came up with a boulder of coral. How the shells got there escapes me. I saw one polished beach boulder nestled in the subangular boulders around it at about that height. There was also the petrous bone of a porpoise, very weathered, the bulla gone and no other trace of the animal.

Kevin had zipped up the mountain and came back with a handful of terrestrial snails—these long turrets with a very flat funnel at the opening of the operculum. I urged him to save them, as most of these land snails are endemics, and this snail is especially far off shore. Kevin also saw some small lizards that sounded about *Uta*-size to me, but he didn't catch them.

We returned to the ship, upped anchor and quickly set a few sails—upper topsail, topgallant, jibs, and set off downwind at a great rate, going inside Santa Cruz Island, a rugged, mountainous little place north of San Jose, and thence on to San Jose. The wind pushed us mightily and all around us whitecaps slid tumbling by.

The group of us hiked over the ridge from the SE anchorage at Santa Catalina, I forgot to note, and could see a SW anchorage that looked better than the one we occupied. The bay, with some stacks, is broader, a nice beach backs it and the land rises more gently in a northeasterly direction from the shore. At least two major drainages enter the shore there. One I could see, cut back into the main mountain mass, extending a long way north. At its mouth I could see a fairly broad sandy arroyo flanked by rocky bluffs. It may be up this arroyo that there are supposed to be tinajas and fan palms.

Santa Cruz Island is about four miles long, I'd guess, and is a tear-drop-shaped granitic mountain with big, faceted cliffs. At its south end I'm told one can land (to the west only) and there is an anchorage. Big whitish dikes cut the main gray formation in several places and one could see that large amounts of boulder waste had cascaded down the hill. San Diego Island, about four miles to the south, looks similar, only smaller. From the west it seems to be a single fin of granitic? rock rising about half as high (perhaps 600 ft.) as Santa Cruz.

As we cruised this coast what we think was a sperm whale blew repeatedly as it passed us to port, never showing anything except vapor. Then, shortly afterward, pilot whales began to go by us in tumbling ranks. One individual leaped free of the water repeatedly, not lifting its tail high over the water, but nonetheless clearing it—most unpilot whale-like in my experience.

Now we cruise with engines toward the anchorage. I've been working on the Hawaiian manuscript. Dull work, for the most part, and so distant that I lack the little nuances.

We anchored at the north end of the Bajia Amortajada on San Jose Island. A little rancho is to the north beach . . .

January 9, 1979

Bahia Amortajada, San Jose Island, Baja California del Sur, Mexico

A bright, sunny morning and the water flat calm. the arcing, sandy shoreline ends in little bluffs and rises behind to the 2,000-ft. mountains. Across is the magnificent Sierra Giganta scarp. Broad, u-shaped valleys cut into the structure in an east-west

direction, and are sliced as by a knife in the north-south direction due to a fault scarp exposing the broad-banded structure and producing a series of castle-like bluffs. One can see that the draws are heavily vegetated, and to the biologist, inviting.

In the calm water astern of the ship we watched a large group of diving grebes. They massed together in dense flocks wider than long and then dove in near simultaneity. Sometimes the group broke into three parts, and sometimes it dove en masse. The birds stayed under from 30-40 seconds and stayed at the surface from 15-40 seconds. Diving seemed to be signalled by the front ranks diving and a quick wave of diving followed, and all were gone in a matter of 3-5 seconds. I presume they are feeding underwater and the massed formation is used to herd prey, though of course we cannot see this. The birds are small grebes, dark in color above (dark brown, I believe though the light is wrong). I saw one rank of birds, about 6-8 deep and 30 yards long. [Drawing.]

When they dive there is a flurry of water, either from wings and in my impression, also webbed feet.

The anchorage of the bay is extraordinarily protected. To the north a spit juts out and overlaps the chain of the Giganta from the winds of the channel, and the same happens to the south where another, larger spit extends out, and once again locks the bay from prevailing southerly winds. A low, rocky ridge of reddish rock rises from the bay floor at the mouth there too. All in all it looks as if it might be protected in all winds, at least to some degree, though a secondary bar and strand line back amongst the cardons and mesquite make me think that occasionally it may get violent in here. Later I found a pilot whale skull up 10 ft. on the beach bluff, with cactus growing out of one nostril and a gecko (*Phyllodactylus*) in residence. It must have been thrown in there by the waves. The skull, a good *G. macrorhyncha*, was taken for Bernardo Villa.

The class went ashore toward what had been a sperm whale stranding. We had hoped to look at a skull and tell people about it, but it was gone, so we walked up the strand looking for less exciting things. Up at the north limb of the bay were a group of buildings on the beach, and then about a third of the way down the bay a small rancho lay nestled in the mesquites just above the strand, its thatched roofs and ramadas inviting one to shade. I'm sure that's especially true in the torrid summers of this place. The guide book says there's a well at the rancho and one can sometimes obtain a little gasoline when they have it. Boats lay pulled up under a ramada. Women and children went about their business under the thin mesquite shade, some brightly dressed. I'd guess the life there, though spartan, was not one of want. The sea is too rich here, and all in all it must be vastly better than life in the vast ghetto of Mexico City.

We landed a short distance below the rancho, at a very decomposed skull of a baleen whale, and shortly came upon 13 giant squid, lying scattered along about 100 yards of beach, newly cast ashore and still undecomposed. They were rusty red in color, the largest about three ft. long (mantle). I took the mandibles from two of them, big black parrot beaks, and cut away the hooked and stalked sucker discs from the tentacles. What could cause such a stranding puzzled us, since they did not seem to have been caught by fishermen. Then, over the VHF walkie talkie we heard that 50 sperm whales had just stranded at Mulege, about 100 miles to the north. Do the squid contain a vector that when fed upon by sperm whales causes the latter to go dotty? Who knows, but at any rate the presence of these prime sperm whale food here, certainly correlates with the presence of

sperm whales in the area. George saw them here on the last trip, and I think we saw one yesterday.

On down the beach we went, the slopes above rising to a rather low ridge clothed with thorn forest. Various flotsam kept us happy—sea lion skulls and jaws, the pilot whale skull, whale vertebrae. I convinced George to take one for Pierce's pottychair, which he can use when he gets out of diapers. Others had sunned themselves and walked the other way. The tide had dropped and the flat extended out a long way so we had to pick our way carefully in the rubber boat before deeper water arrived not far from the *Regina's* anchorage.

Soon we were up and off, cutting through the channel at the southwest corner where some isolated rocks stood a fisherman's camp that had been there for forty years or so. They bring in water from La Paz in barrels. How they get their fish out escapes me. To our port, on San Jose was the fine mangrove lagoon, filled with water birds, and I suppose, oysters and perhaps the wonderful hacha (*Pinna*). San Jose would be a great place for a camp some year.

At Sea, NE of Espiritu Santo Island

After leaving the island the wind fell, and at night we pottered along, under some sail, but making very, very little headway in these light breezes and with our grassy hull. Late, the engineer charged the batteries and started the engine toward Cerralvo, lying craggy in the distance, a piece of the North American plate pulled from the Balsas Basin in Jalisco, and taking with it some of its life—*Sator*, *Bipes*. So, to sleep. I'm getting bunk elbow—an affliction that feels just like tennis elbow, but comes from bracing oneself against the bunk with these angular protruberances.

January 10, 1979

At sea off of the Cape of Baja California, to the east

When I first came on deck we were somewhere south of Espiritu Santo Island, and Cerralvo was ahead of us. A good many times today I came up on deck to look at that fabled island through my glasses. It is a precipitous fin of rock, dissected by steep canyons that are not hanging above facets, at least on the west side, as so many of the more northerly islands are. Part of the island, to the north, looks granitic, part of darker rock fissured with dikes, and part volcanic. Toward the middle of the island there is a single tuff stratum, just above sea level, clean white, like a bank of pure abo, or Ajax Cleaner. The island is much less precipitous at the south where rolling terrain borders the sea, and where a pretty extensive sand spit, topped by a light tower, is located. I saw only one little cabin, on the spit, to indicate occupancy. Elsewhere, it was mostly clothed with mostly dense thorn scrub. I could see palo blanco trees up on the ridges, cardons, and in the canyons, mesquites. At a few places, as at Puerto Limon, near the north end, the canyon bottoms were green enough for subsand water, or tanques, or maybe even a spring. Across the channel at the south end there is quite a village, and some large buildings. I'm sure it wouldn't be difficult to reach, given a little patience.

Only one group of pilot whales was seen today—near the north end of Cerralvo. Brisk breeze today, with many whitecaps cascading by us. We're tacking toward the point, under sail, with the engine off.

January 11, 1979

Cabo San Lucas, Baja California Sur, Mexico

One baleen whale, with a pretty good-sized fin—probably a finback, was seen today. The sea flattened as we came into the lee off the Cape region, and it warmed up. People began to appear topside and climb the rigging in the warmth. Boat traffic increased as we came into Cabo San Lucas. The new collection of hotels, cabanas, moorings, and the like, lined the cliffs. Once in the harbor it was pretty vastly different than when I first visited there in 1948. Then it was a cluster of dusty little houses, a crossroads of dirt, and the empacadora. Now it brims with spanking new hotels and a population of maybe 1,000 tourists and a resident population about equivalent.

George and Annie laid out the Captain's party on deck—lots of rum and scotch and the like, singing, bird calls, and general merriment. I collapsed in the sack about midnight.

January 12, 1979

Cabo San Lucas

Well, some whales came in, three of them off the Hyatt Hotel just the east of the harbor, and others were seen to the west, so the little group is here again, and maybe we'll get some clues about it.

There is a single sea lion in the harbor too. I wasn't aware they came this far south, but there they are.

Today I called home (everything OK), did a little shopping, met some of the new people, and by golly, Jim Darling showed up, and is nicely stashed in the cabin with me, having left Hawaii to be on board.

Tomorrow we leave after the immigration matters are taken care of.

January 13, 1979

Hove to, off Cabo Falso, Baja California Sur, Mexico

After immigration and a few last-minute purchases we hauled up anchor and headed east out of the harbor of Cabo San Lucas. It is a bright, blue, calm day the sea almost glassy calm. The day was spent making a search of the Cape San Lucas-Cabo Falso area for whales. It is the same area we noted about 35 animals three years ago. It is perhaps three weeks earlier in the year this time and the animals are sparse, but nonetheless here, and all were over the nearshore banks, some right at the outer edge where the sea drops off into abyssal depths a short distance offshore. Jim was all over the mast and I made it up over the futtock shrouds on the mainmast for a session of watching. The day was enlivened by a floating, dead leatherback turtle, one flipper missing, a few sea lions, and a very large herd of common dolphins, plus at least one small rorqual that I suspect to have been a minke.

The entire exercise is nicely on paper. What it looks like to me is that the whales come down to San Lucas, and to them the cape is this underwater bank that juts out quite a lot farther to the south than the land does, and it was there the whales were concentrated last time, and are concentrated now. Too few this time to give a definitive picture though. We'll heave to tonight, and in the morning will make an attempt to photograph the grays here, for individual identification. Jim will probably work in the Avon rubber boat.

Not much else. I'm moving shelves in the cabin and fixing the damn light switch.

January 14, 1979

At sea, off west coast of Baja California, enroute Punta Tosca

Last night poor Jim succumbed to a combination of recent flu, two nights with no sleep, and a wallowing ship lying to offshore. He was really deathly ill, and when he began to bring up a little blood, along with problems at the other boca, I called George. Jim was to the stage where he had to get ashore, no matter what. It was life, almost. At any rate George gave him a 1cc shot of Chlorpromazine which stopped all the symptoms dead in their tracks and Jim slept the night and most of the next day.

We had drifted 20 miles offshore during the night and had to beat our way back in. On the way we picked up a drifting Avon 13-footer with a Merc outboard. George located the owner by radio and as we passed San Lucas a boat from the Port Captain came up and towed it in. We saw very little going across the banks—no gray whales, only a school of *Delphinus* and a small group of *Tursiops* that came to the bow. Up to the west coast, with only one gray whale sighting. I spent time making up a schedule of activities for Tosca. Now if the whales just cooperate. I'll attach the schedule for the record. It will keep us all busy, but will allow a reasonably long period for observation, and we should get quite a lot done, providing the animals are in, as they should be by this time.

January 15, 1979

Isla Santa Margarita, Punta Tosca, Baja California Sur, Mexico

The weather calmed even more so as we slipped through glassy seas on the way up the west coast of Baja. It isn't always thus. Much of the time we were 10 miles offshore or more, and encountering largely *Delphinus* schools, which were remarkably abundant. Most had totally dark dorsal fins, though Carl Rand reported one with a white center to the fin. I thought their dorsals were obviously falcate and un-*Delphinus* like. Jim, by the way, is up now. He's on his way to recovery after a really rough time of it, though after George's shot he was mostly just tranquil in his bunk sleeping.

As we neared Tosca we cut closer in shore and began to see whales. By the time we were five miles S. of the point or so I began to make out spouts against the cliffs, all along from outside the point to Isla Cresciente. There were whales inside the embayment, and there were whales over the sand bar outside Punta Santa Marina. The wreck, that lies inside Cresciente, shows over its top and I think will make a good range marker, but I'll have to calculate all the angles again.

We cut across the tip of the bank, as the fathometer chose to go out. George quickly got Scotty in the chains, and found we had only three fathoms or so, with us drawing a little over two. We worked our way into deeper water, anchored, had dinner, and here I am writing notes prior to talking to the new earthwatchers about gray whales, and then observations. A lecture, discussion, on observation, and tomorrow we begin to get our buoy line out.

We made it!! The place is full of whales—under the bluffs, breathing all around us.

January 16, 1979

Punta Tosca

As the day wore on our anchorage became rougher and rougher. The tide when it floods opposes the incoming swell, and if it is very high the result is a tumultuous sea across the Rehusa Channel. Two tiers of spilling waves and confused sea crossed nearly the entire entrance, except for very near to the Santa Margarita shore. I guess the breakers were low enough that one could take an Avon through with some chance of success, but going close to Sta. Margarita is much the better part of valor.

The day was overcast, with cloud banks, broken with some patches of blue, passing overhead. A wind eddy seems to exist near the surface at our anchorage, with the higher clouds coming in from the west or northwest. All day the sea was choppy and the boat rode up and down in the swell, making viewing a bit of a problem for me, especially any duration of looking through my glasses. Jim and Gregg went ashore to check out the possibilities there, and immediately fell in with the people at the lighthouse. They disappeared over the hill and as we learned later, they hiked a couple more larger ridges, and reached a sea lion beach all covered with bones. The ones they brought back were from sea lions. Then they clambered up the old road and watched the bay, and were delighted at the vista. They brought two folks from the lighthouse back with them, Rodolpho, and one whose name I couldn't catch. Rodolfo's father had been at the lighthouse for 38 years.

We placed buoys, with George and his deck crew doing nearly all the work by radar. I watched for the boat and buoys and more or less supervised them around.

Then, we moved the vessel and rather undid all my angles and mountain profiles for locating buoys and the like.

I made a count of whales from the vessel that I am sure represents a minimal count of animals in the area. Most of them are inside the first or outer breaker line.

I lectured on locomotion and then typed notes and planned for tomorrow. The ship wallows, but it's calmer in close to the lighthouse. George, however, is worried a bit about the wind and may haul anchor for the outside if it keeps up.

The whales aren't coming as close to us as I had hoped. Let us hope that a little acclimation will bring them closer. I've had several views of breaches today, none closer than perhaps 100 yards, a few pitchpoles, and a few apparent mating groups. But, it's too difficult to see much with the animals so far away.

January 17, 1979

Belchers Cove, Magdalena Island

During the night the swell came up, along with the wind, and after breakfast George took a look at the scudding clouds coming in from the SW and decided we'd better head for shelter to the north, in Magdalena Bay. Would I agree to changing the schedule, he asked? Of course, I replied, knowing we couldn't work and that the bay was getting dangerous, and also knowing George was going to do it anyway. (As rightly he should.) Anyway, we hauled up the anchor and made our way around the submerged rocks at the tip of Punta Tosca, then set sail with the wind behind us, and the rolling swells urging us up the coast in the gray mist.

Santa Margarita's windward coast loomed large and indistinct, a white line of breakers the most easily seen. As we travelled onward the storm closed in and rain came in gusty squalls sheeting across the deck and dripping from the now dark sails. The old *Regina* plunged into the sea, windening[?] waves contesting the regular swells coming in

on us, making tosscaps and cascades. Some, nearby, could be watched as they curled, emerald green and fell back in white and bluish drab. Somehow the storm petrels that had been missing came out, and now and then cut near us in their tipping swift flight, riding the pressure of air returning when wind hit sea. As we rounded Tosca a great flotilla of tijeretas, or frigate birds, rode silently and without wing movements, the flock extending from a mile offshore toward the misty highest peak of the point; hundreds of birds, all spaced in the rising air of the storm and riding it in silence. Later, graceful Bonaparte's gulls flew near, white and pearl gray, with a white margin on their tails. A couple of humpbacks rose in the rough sea, rolled, flinging their long, knobby fins into the air, and then breached, so all on deck could see their pleated throats. A few other spouts were seen, of southward-moving whales, presumably grays, even though we traveled about four miles offshore and in 50 fathoms of water for more most of the time.

After this the animals slacked off, and only a couple more were sighted as we changed course and headed for Belcher's Cove on Magdalena Island. This is a sandy hook of land discovered in 1602 by Sebastian Vizcaino, and then used later by whalers to work the whales of Magdalena Bay. The bay is so much easier to enter than Scammon's that many vessels worked here, and animals were rendered down at this station, which was used until the 1930s when the last whales were taken before being given international protection. Since then it has fallen into disrepair. We're told the old try pots are still there, boilers and the like, and a great pile of whalebones. It is mostly a camp for fishermen living in a row of shacks, with their nice fiberglass boats pulled up on the strand in front. The cove is flat calm and occupied by a mixture of small yachts and fishing boats. It is protected by the bulk of Mt. Isabela behind, and good for all north winds. We're told there is no water here but it can be had at Puerto Magdalena five miles up the beach at Man o' War Cove. Belcher, by the way, was a British Navy officer who did the survey of the bay. I'll bet he surveyed Santa Rosa Island, too, where there is a Belcher's Bay.

We had a nice meal of roast chicken and various fixings—beans, custard, etc.

January 18, 1979

Belcher's Cove, Magdalena Island

Not long after breakfast we hoisted anchor from the calm little greenish water cove, and made our way out into the bay and then ran a grid pattern across the entrance counting whales and noting the direction of the traverse. I climbed up the Jacob's Ladder on the foremast and watched from there. George put us over a number of whale groups, some very close at hand. I tried hard to see what was going on, but am mostly at the amorphous stage. Here is a distillate. I saw no actual mating, not even a penis, though two others reported seeing them. I did note that almost none of the animals I saw today were really singles when one waited long enough they usually resolved into duos and trios. The largest group I counted together was six animals, though I sometimes saw more spouts in a given area than that. I saw two whales swim toward one another and touch snouts. I saw animals tiered, on top of one another, or closely aligned side by side, with a third touching them at the region of the vent at about 50 degrees. I saw animals roll, and dive down together. I saw them roll and throw a pectoral into the air, or raise their tail, nearly to the level of the vent and hold it aloft for a measured five seconds before slipping back. I saw sideswipes with the flukes by an animal on its back. I saw one vent,

and think it was a male. I saw an animal change course and sharply approach a wuzzling group, joining them. And I saw two wuzzles approach one another and intersect and ignore one another. All this fits the mode of a female beset by persistent males, swiping with the flukes to drive the others away, and I did see a great size disparity in the animals involved. There were no calfs in the area. It's a start.

Then we headed back for anchorage and finally found it off the little village of Puerto Magdalena, which is a cluster of houses and boats in Man o' War Cove. All the lights in town are on even though it wasn't dark. I think they don't have a switch, but do have a generator.

Well, much typing, and now to sleep. Tomorrow we go ashore to Santa Maria Bay for a beach walk.

January 19, 1979

Puerto Magdalena

George and I decided that it was about time to let the students and earthwatchers, and incidentally us, take a stroll ashore. We chose the southern limb of Santa Maria Bay, on the outside of Isla Magdalena. Everyone took lunch and trooped ashore from the rubber boat at the base of the long line of dunes that form the spine of the island here. We traversed the island just above Howland's Lagoon, a little mangrove-covered inlet, and came out on the almost hemispherically curved Santa Maria beach, which extends about 10 or 15 miles north to mountainous Cabo San Lazaro. The day was overcast with about 20-25 kts. of NW wind whipping along. The dunes are low and hummocky here, covered with *Lycium* (with red fruits), *Abronia*, a couple of euphorbs, and a pretty evening primrose.

The beach on the outside was littered with flotsam, the way some of these Baja beaches are, including a note in a bottle, which seemed to be mostly swearwords, probaly put there during a good drinking bout at sea. Odd bits of manilla line, polypropylene (which lasts), timbers, and many animal remains; pieces of sea lions, a *Delphinus* skull, some bigger whale vertebrae, and finally the skull of a blue whale buried upside down in the beach. I paced it as 18 ft. long from occiput to end of the long, trough-shaped vomer, and about 8 ft. in zygomatic width. I can't think it could have been anything else at that size. Lots of folks dug away at it but when I left to walk back they were still digging away and were far from unearthing even the upper skull. I took my leave, carrying a few pieces of colored driftwood for a collage, and made my way across the dunes—twice as wide this time—to the Bay each. It is much cleaner, and the bay waters broke only in little running waves diagonally on the beach with the tide. A sand bluff stood back of the beach where the tide had cut into it waist high. I chose the hardpacked sand for walking, and shared it with busy fleets of little plovers, sandpipers, and sanderlings. It was a nice alone walk down about three miles of sand, accompanied by the wind, the sheet of blowing sand on the beach—whitish moving sheets of sand, hurrying and crossing into one another, so thin they had no dimension of depth. It is there, within a few millimeters of the earth that most sand is carried. The wind was on my shoulder, and blew up the backs of dunes ahead of me, sending little spurts of sand upward to plume out and blow away. The moving sand incised the still cliffs, channeling, slicing at bluffs, hollowing, sculpturing. For long stretches new drifts piled over the cut cliff onto the beach.

Once I came upon a little pillar of sand, five in. high with a narrow base rising to a three-sided hammerhead-like top. As I watched I wondered why it didn't fall, and when it would. I could see the sand cutting at its base, blowing behind it against the cliff face, and sluicing out behind, piling there, and periodically slumping. I timed these slumps. One came every 30 seconds while I watched, made of the hurrying sand stream. Still the balanced rock of sand stood. I realized that its top was being planed down by a sand sheet blowing off the cliff top, to facet it. The stream eroded and just beyond it piled on the cliff top, only to slump now and then to the beach. It did this nine times while I watched, and the little pulse of sand behind the pillar, uncounted times. Everything was in miniature and speeded up. Easy enough to imagine being a millimeter tall under that great balanced rock, wondering what equilibrium let it stand. Instead I looked down from above and wondered about the equilibrium. Why didn't it fall? How could it be sculpted in some unseen relation to the wind that gauged its weight and balance? I could see none, and yet it stood. I finally turned on down the beach. The sand sheet had frosted mats of purplish stringy algae across the beach, making pretty patterns above the sand. The sand cascaded into the sea to disappear in the clear greenish waters.

This must be the nasty season for sanderlings. One that seemed no different than the rest to my uncomprehending eyes, lowered his little black bill, hunched his shoulders, threw up a ruff of feathers and rushed at his fellows. Even I knew he was angry, though at what I could only guess. I seemed to the casual and distant observer that it was space on the beach. And it was just sanderlings, not semipalmated plovers who shared the strand. He raced between them dozens of yards toward an offending sanderling who ran in a blur of legs away along the water. Not enough. He was finally driven into lovely, sharp-winged flight, to alight 100 yards farther on. Not enough. Our sanderling, head lowered, flushed it again, and other ones two [?], running with great purpose between awed plovers who stopped to watch him go by. I say him because it was, to me, a himmish display. Later I saw another sanderling with the same attitude, and noted that they tended to be scattered instead of in their usual (to me) flowing groups, going in and out with the waves. One of the nasty sanderlings gave what I think was a consummation signal—a couple of ritualized probes of the sand after a chase, like a man dusting off his hands after disposing of a problem. A nice old osprey perched on a snag as I walked along and rose in their kind of loose-jointed flight, a fish in its talons. We waited a little while on the beach and Scotty the third mate came in to get us. Now I'm trying to clean up yesterday's notes, in preparation for the onslaught of tomorrow's, which are likely to be greater in amount.

January 20, 1979

At Anchor, inside Punta Entrada, Magdalena Island

We put a field party ashore at Punta Entrada, led by Jim Darling, to check on the movements of the entrance group. They climbed to the top of the little hill there, from a pocket beach landing, set up the telescope, and watched all day. They found that the group of whales spread out at times, but that it kept its basic station. The whales were a mile to mile-and-a-half offshore in 16-20 fathoms of water. Apparently they are using bottom topography in some way, perhaps because it produces eddies or upwelling, to stay there. Looking at the chart shows them to have been inside a sill that rises about 30 ft. from the bottom, to 11-12 fathoms.

On the *Regina* we tried hard to come up on wuzzle groups by pursuing them and had very little luck really. The groups dispersed as we came near, and then reassembled farther back in the bay. The effect was interesting. It broke the basic number down to groups of two and at most three. One could see them streaming toward the new aggregation spot, and beginning the courtship, if indeed that's what it is.

Then, later in the afternoon George asked me if I thought we should anchor, and I said sure. So he took her in to the place off Punta Entrada where we saw most whales and dropped anchor in about 20 fathoms of water. The result was dramatic. Very soon whales were drifting near us, and coming up alongside under the bow, and wuzzles were forming, and one drifted alongside for better than half an hour.

I had watched all morning from the after mast shroud and it was raw and cold, and by about 4 when we picked up the shore group I was tired and took a short nap before dinner. The meat wasn't done so I gave my lecture early, on phocid seals. Then, talk with Jim and Karen Miller, our fine lab gal, and did a little seamstress work on my old field jacket.

Notes (summary impressions):

The courtship, if that is what it is, is relatively languorous, and not at all like the high-speed chases I have seen between two animals and a mother with a calf back in the lagoons. There is no very evident avoidance but instead attraction. The pairs of animals tend to aggregate if let be, into wuzzle groups, usually within about 50 yards of each other, and these persist for long periods, presumably of courtship. It seems constant, and I saw one group engaged in it for 40 minutes non-stop. How much longer is anybody's guess. Jim saw extended penises and I sexed a female, so both sexes are present at least here. The groups do congregate in a given area, that we believe to be demarcated by a sill about 30 ft. high, on the bottom running between Punta Entrada and Punta Redondo. The animals gather back of it, at a place where there may be a significant eddy, right off Punta Entrada.

The wuzzles may be composed of 5-6 animals, but the basic unit to which they divide if harrassed, is two or three. Thus we have parced apart the wuzzle and find it to be made of units, the others are supernumeraries that probably come along for the excitement, like dogs around a bitch in heat. And they go at it for an incredibly long time of almost continuous courtship—perhaps a couple of weeks of it.

In assessing the reasons for these entrance aggregations one must not forget that gray whales have been shown to have most unusual reproductive resiliency, having come back from near extirpation twice in the last century. They are, in this respect, like no other whale. The compressed migratory path, in which whales are near other whales the whole way, the long testing and retesting of sexual readiness by way of prolonged courthip, must leave essentially every ready female impregnated. The separation of mothers and calves by exclusion of wuzzle groups to the entrances, and their departure before the females with calves leave the lagoons cuts down the wasted time when males try to mate with resting or nursing females. The difference in behavior when a male contacts a female coming to readiness and one nursing is so great it strikes a strong parallel in many other animals that have repulsion systems on one sort or another; aggression, development of male threat colors, flight, separation. Like most other biologic systems that of the gray whale is certainly stochastic. There will be a modal time of sexual readiness, just as there is of birth, and it may be necessary for the males to

travel with the non-parturient females the whole way to insure that all females are covered, to use a sheepman's term. The mean of the mode may hit at these lagoon entrances.

I'm impressed that the whales stop migrating at these lagoon entrances. They have reached a destination, and that's important. Like the females with calves they must be responding to light cycles on an annual basis. They must also be "getting their southing out," and very likely they are undergoing both a growth and recrudescence in both sexes for reproductive systems—testes and ovaries, ova and sperm, and associated hormonal levels. I would expect the male cycles to "cover" the females; that is to be ready longer than the female, to catch all members at their peak. And I wonder about sex linkage in the underlying genetic determination of these events. How much crosstalk is there between sexes that prevents the males from stopping short when their mission might be done, while females go on. If the females went on, one might have the spectre of only non-parturient females going without males to the lagoons, all lonely and non wuzzly.

Better, more likely and simpler for the sexes to travel together, and to cancel each other's variability by overlap and testing on a regular basis of the state of the other. After all, since both sexes have curves of readiness one cannot know the exact state of the other in advance.

Thus a long migration together, to the lagoons, is probably optimum.

January 21, 1979

Isla Santa Margarita

Today we made a tour of Almejas Bay and the channels leading it in search of the interface between the entrance wuzzling groups and the mother-calf pair aggregation in the back bays. We set off on an absolutely glassy clear day, the sea sparkling, and scarcely a cloud. Our track took us up in the east side of lower bay above California Shoals, thence down to the Marcy Channel and in past Puerto Alcatraz and Puerto Cortes, across Almejas Bay to the north, and around the shore and back across nearly to Puerto Cortes.

We encountered our first mother-calf pairs in lower bay over near the east shallows, and then a few more in the Marcy Channel, and occasional ones when we came close to shore of northern Almejas. There was overlap since we found a group of three wuzzlers in Marcy Channel, but the occurrence of either was very scarce for the three or four miles after we initially left the entrance group. They stay largely apart, and in this huge bay can do so pretty easily. My impression and that of George, is that the mother-calf pairs seek shallows with channels where they may swim, usually far back away from open water. For instance there were no whales at all in the major open water part of Almejas Bay, only at the edges.

I sewed today and lectured (I'm giving a marine mammal series). Slow day, but we did what we set out to. Puerto Alcatraz sits on a spit and is a cannery. Boats were on the south side, including a small freighter. Puerto Cortes is just to the south and is a cluster of houses and big oil tanks and shore facilities. It's a Navy base, and purportedly a nice, friendly place where one can buy some supplies. It looks a bit bigger than San Carlos, though the dock is nowhere so impressive.

I'm beginning to get the students coming in asking for advice.

January 22, 1979

On our way to Punta Entrada, but still in Almejas Bay

I've been pondering how the decision to go a given direction is imposed on a school of animals, like say, porpoises. It has been growing that democracy of a sort reigns in such groups. While watching a bunch of cormorants alongside I could watch it work. They periodically turned as a group. One could see individuals turn, and then the school wouldn't turn, and the individual animals that turned, turned back. But then, when the school neared the end of the ship such a turner turned the rest and back they came.

So, what I see is a potentiation of a tendency to turn depending upon either exterior or interior circumstances. The potentiation may come from learned circumstances or greater or lesser stimuli from outside. Let me amplify. In porpoise schools there is a hierarchy—older animals of both sexes, apparently can be dominant, and all juveniles and young, and apparently mothers with calves are low on this ranking. So there is a gradation of leadership with several or many leaders, and leaders of different degrees of intensity. Their decisions may come from learned patterns, like "It's the time of day to go feeding," or, "we are nearing that good rest cove." But all or most of the animals in the school will also know these things and be thinking similar thoughts with greater or lesser degrees of resolve. When one animal finally reaches its own threshold, it makes whatever signal it makes; a movement, a sound, it may be ignored if the thresholds of the remainder are too low. Those who do not turn will be reinforced by the others who don't. And nobody will turn and the group will go on as before. I saw this happen in the cormorant flock. But, if many others begin to feel it is time to turn, such an intention movement or signal will have widespread agreement and the group will turn. For instance, a feeding porpoise school has surfaced and stays up long enough for respiratory equilibrium, and maybe enjoy a bit of muscular rest. Each animal will feel this, thus when a signal comes from whatever animal has reached its threshold for change, the group will dive. The synchrony of a dive cycle will help insure this. That is the intrinsic rhythm of things will help, sensed by all members, whether it be a short rhythm as in dive cycles, or a daily, or even yearly cycle.

The signal may be learned, and only the older, more experienced animals know it, but they can turn the school, aided by their station in the hierarchy of the school. Thus old animals are invested with extra power to override the whims of youth, because they have had time for learned patterns to be assembled, and thus, in a sense, the school as a whole, behaves in a learned fashion.

And, exterior events, like the proximity of a shark, may raise the level of fear of all animals, and thus the "skittishness" of the individuals and the school as a whole. That is to say each individual is on the qui vive for signals to turn, or speed up, or dive.

As fear, from whatever source, rises in the animals of a school as a whole, the animals physically come closer to each other. Signalling between animals is more sure the closer the participants. And it may change mode too. At long distance the school may use "alert" signals, such as sounds, while close up, water pressure changes, and visual cues, or low-level sounds may mediate.

Thus we see that spread schools are always made of individually alert animals. But tight schools are where the animals may be individually resting, but the school as a whole may be more alert than in spread schools. Social behavior, which can take place in the envelope of a school because the school as a whole provides protection and thus gives

a measure of freedom to the individuals in it, only occurs in spread alert schools. Social behavior is, in a sense, a luxury, only available when others are alert.

So, decision-making is a meta affair, a systemic process that in a sense involves the physiological and psychological state of its component animals, their hierarchical positions, and their learned knowledge store. The school is both a sensory and a psychic integration system.

Fear responses may come first from the timid, while ones requiring thrust may come from the bold. School fear may override the bold and the timid will rule. But under other circumstances the reverse is also true. Fear thus may reduce the boldness of the normally bold and increase the boldness of the fearful.

Do decision makers tip on the knife edge of an equilibrium? Must of this is algebraic summation. Citation at Harvard [?] for Law Degree: "Those wise restraints that make men free."

January 23, 1979

Almejas Bay, Baja California

Today is reconnaissance day for the intrepid crew of Dr. George (at the helm), Karen Miller, Jim Darling, and Ken Norris. We had a visitation yesterday of the local Capitan and two of his patrol boat skippers, from Puerto Cortez. They rather quickly cleared our papers, having a copy of them at Puerto Cortez, somewhat to our surprise. Then they came out to the ship, with a storekeeper and two coxswains in a gig. We welcomed them aboard over the Jacob's ladder, showed them the ship, and then sat them all down for a couple of cups of coffee in the saloon. I had earlier explained to the Captain that we were seca, so his requests for a tot of rum in the coffee were in jest. His name was Capitan Luis Olguin Fernandez. He was a classmate of Jorge Lagos Kuntze with whom I had visited Scammon's Lagoon early in the 1960s on the *Sea Quest*. We both found him an urbane, almost courtly and humorous man. He told us a good deal about his post, the island and a miscellany of comments. Portuguese, for instance, was Castillian badly spoken. He said there was an oasis on St. Margarita, with palms and seven wells, and a few small farms, or gardens. It was in the center of the island. He said there were a few borrego on the island but no deer. His territory went from Abreojos to Todos Santos and included patrolling to the 200-mile limit. His two young lieutenants were bright young folks, speaking some English and giving the appearance of competence. All were nicely dressed in uniform; the Captain with three stars. When they left I whistled a bit of the bo'sun's piping for piping people aboard; the Captain smiled and they took seats inside the canvas spray cover and were gone. Afterward we cruised down to the end of Almejas and anchored for the night.

Anyway, we put teams ashore to walk the beaches and to look out over Almejas Bay with the telescope to see if they could develop a count of whales while the four of us set off in the Avon for Rehusa Channel and Isla Cresciente. We had a lunch, VHF (so much better than those damn walkie talkies) hand-held, water, charts, and spare gas.

Our track took us along the shore of Santa Margarita, thence around a long sand spit and into Rehusa Channel, across to Isla Cresciente, out the channel past the sunken freighter, over the bluffs of Tosca and back in for lunch on the strand and then back again to the *Regina*, anchored regally in the bay, towering reddish mountain behind her.

January 24, 1979

Puerto Magdalena

With little ceremony we hauled the anchor this morning and headed back out toward Punta Entrada. The day was gloomy and soon began to rain in earnest. By the time we passed Puerto Alcatraz we had some fine gusts of rain sluicing on deck. I stayed below mostly, getting notes in order, snoozing and talking to Jim and Karen about this and that. Late in the day we came up in the entrance, and I went topside in the beating rain to observe for a while. The whales were in their old stand off Pt. Entrada, and waves and wind were passing through. When the tide opposes the wind here it can get very humpy very quickly, and when the tide shifts it can lay down as quickly. I climbed the foretop in my foulweather gear to watch from the pitching mast. The tape I recorded sounds like it was made under a tin roof in a rainstorm. It was too rough to see very much. But we did note one thing. The whales were very much more active than usual. Some swam rapidly enough to have bow waves. Breaching was very common; we counted 11 in half an hour, and there were a number of surface flunders in which the water was beaten white without an animal emerging enough to call it a breach.

My impression was that the waves heightened the excitement of the whales and that this was then translated into aerial behavior of one sort or another, just as it is in spinner porpoises.

Not too long afterward I came down and we headed for anchorage at Puerto Magdalena. Jim Darling leaves us tomorrow to head back to Honolulu. He plans to get a ride to San Carlos at Puerto Magdalena, and then work his way home.

January 25, 1979

Anchored inside Punta Estrada

After a brief breakfast we put Jim ashore in the rubber boat. I went in to translate and asked some fishermen who were about to launch a skiff, "Hay personas van a San Carlos ahora?" "Si, ahorita," one said, indicating that he was going up right away, and Jim merely put his gear in and left. Excellent connections for Puerto Magdalena, I'd say. It, by the way, is a neat little place—the site of an old whaling station, and later a magnesite mine and orchilla gathering plant, its old factory stands back of the manager's house. Down the strand are about two dozen houses painted all colors of the rainbow. Almost missing is white. When we anchored yesterday the rain had converted the little draws around town into muddy rivers and it was divided into six pieces by five streams. Today they were all dry. The people seem extraordinarily friendly, as is everybody in this part of Baja, it seems.

After leaving Jim we shoved off under wet sails for the entrance. Everyone was a bit loggy from lack of activity back in still Almejas Bay, and the bit of hauling on lines, overhauling buntlines, and the like did everyone good, including me. I have trouble with the inactivity of a ship, anyway.

Under sail we moved pretty slowly so it was quite a while before we reached the entrance. Once there I had hoped to anchor but George decided that would be too rough; the swell was high and the wind likewise. So we sailed about, often far from the whales, and only late in the day did we spend some time hove to in the entrance group, drifting with them. The wind had shifted to northwest and much of the day whipped by at a smart

20-25 knots or so, and when the tide was ebbing, it was opposing the incoming swells and pretty rough.

January 26, 1979

Punta Entrada

We had anchored here last night in a little nook just inside the point, out of the northwest wind, and with only a relatively little swell to rock us. We'll duck into the same place again tonight, as it seems better than Belcher Point (which is only a low sand spit jutting out, and awfully shallow for the *Regina* on the south side), and Puerto Magdalena is ten miles away, and really no better, except that if the anchor drags there one drifts out into the bay, and here one has to contend with the rocks at the point. But George is a prudent mariner, knows his ship, and about such things as currents and anchors.

Anyway, today was probably one of the more remarkable days I have had as a naturalist. I went in with one notion about what was happening, saw my ideas change in the morning, made an hypothesis at noon, and saw it confirmed essentially to the minute in the afternoon. George, too, had an hypothesis confirmed today. What we have emerged with is an idea about entrance groups, why they gather, what they do, and when.

January 27, 1979

Punta Entrada

Well, now I know what it's like to be part of a communal love experience. Today we, and the *Regina*, were communally loved by as many as four whales, and they even got a little feisty over our attentions.

It was quite an experience. The first whale circled us and then stationed under the counter, its flukes shining greenish white off the pattern and barnacles. It began to surface, mostly along the waist of the ship, aft. People were clinging to the ratlines and standing on the sides of the ship, cameras clicking. I, alone, took 4½ 36-exposure rolls. The whale came up, a huge, huge bulk, right alongside the ship. One could see every spot, every barnacle, and practically every cyamid. It blew, and three people at least confirmed the blow to be sweet and salt water. They tasted it. If it does it again we will collect the blow and analyze it.

I have vignettes in mind of Annie clinging to a line partly over the side. I stood in back of her six ft. or so, and suddenly the entire viewfinder was filled with mottled graywhale, with neither head nor tail in my view, with Annie standing in front, so obviously so small in comparison. Then the whale took a sidewise, petulant swipe with its tail toward us, stopped before hitting us or the vessel (it did it twice, I'm told)—a gesture of annoyance, perhaps at the people (I doubt it), when the affair was between whale and vessel, the great bulky mother lying there, thrumming away placidly at anchor, and the small whale (it was maybe 35 ft.) rubbing against her, exploring transducers and underwater fixtures, barnacle coatings, with little response. The boat never once extended a flipper to the visitor, or arched her tail to invite a probe in the genital area, but just lay there.

Then, four whales came in, swimming rather rapidly, I thought, as if their alertness was up, coming in this close to so strange a companion. Mostly they stood off a couple of yards and circled their bolder companion. Finally, it was we that had to break

the encounter off because darkness was coming and we wanted to pick our anchorage in the light.

The impressions were of an animal orienting to a boat, seeking to get a response from it, of petulance, curiosity, but never outright anger. Also a little fear in the other three.

Were the animals relatively newly weaned young reverting to parent-calf behavior and thus seeking to nurse, or was it sexual, or both?

January 28, 1979

Punta Entrada, Magdalena Bay

I had kind of a lousy night; all stiff and a little hyped up, I think from coffee at dinner, and I didn't sleep worth a damn—had to get up and do exercises in the middle of the night. Amazing how stiff I am. I can't touch my toes, when usually I can put palms flat. George says it's probably the two foam mattresses. I took one off and it's a lot better, I think. But, man I'm sleepy today. I finished a biography of Lidberg last night, and found he was on my Oceanic Foundation Board, forgot about that. I remember him well—glittering blue eyes, unsmiling, terribly intense, his little wife a charmer, sweet, observant, smiling. He had wanted to know about whales and knew more than I about the Peruvian take. He was a flawed human—full of mechanical skills, but naive, humorless and difficult, and very, very macho.

Anyway, today we anchored again, took various observations. The whale population had dropped in number dramatically. This is the last day of a three-day spring tide series, and the flood almost didn't stop running. We almost didn't reach slack water for some reason. I worked below, wrote, had a snooze or two and came up for various observations. Brisk, overcast, blowy weather, as it had been most of the time we've been here. Our two "friendly whales" came over again. The same ones. They didn't give us such full treatment as before but did travel around under and around us, especially astern. Both are juveniles and the behavior seems to me juvenile, like teenagers relating to Momma, only here much is sexual. The orientation aft, under the counter, around the stern post, rubbing under the curve of the vessel strikes me that way. It isn't adult love, in my view.

I gave a bull session tonight for the people who are taking a final exam. They are to construct three marine mammals out of their imaginations, evolve them, give them characteristics, etc. Most are going wholly bizarre, but our discussion did give me a chance to talk about a lot of important adaptations.

January 29, 1979

San Carlos

We did another survey this morning, and boy, are the counts down. We can't have more than 1/3 the animals that were here when we arrived. We'll see. First thing, at the anchorage at the caleta inside Entrada we took a bottom grab, and it came up sand and shell, and bluish and intermixed. This certainly supports the eddy notion. I think Belcher Point has been built by this eddy and that therefore our anchorage is in much quieter water than out in the rip.

January 30, 1979

San Carlos

After the survey was over we headed for San Carlos. I spent most of the time below getting notes in order, packing, and the like. By the time I came topside we were in the channel and beginning to dock. There were two big ships alongside the wharf—an old Liberty ship loading cotton and a school ship of maritime students in Mexico that was loading ammonia from a local fertilizer plant. The Muelle was stacked with thousands of bales of cotton from the Villa Constitution area.

There was a little sortie ashore, for beer and camarones but I was so full, already, of dinner that it was more a burden than a pleasure.

To bed.

January 31, 1979

Bernd Wursig arrived today in a nice VW van that will allow us to take all the earthwatchers to La Paz, along with me and my gear. I spent quite a lot of time introducing Bernd around and orienting him to the work. The ship will go up into Devil's Bend, and with a bit of luck we should get some interesting data on spacing and nursing.

We engaged the local Miracion man in battle today and he thoroughly got his back up. It stemmed from Jim Darling's not checking in (we didn't ask him to) at San Carlos. Many things were found wrong with our papers, and renewals were impossible from here. George had to go to La Paz, it eventually turned out. What a damn nuisance since we knew this guy could do it, and had been told elsewhere he would. But I know we were wrong at the start and our language of apology insufficient and then George has a stiffness about him engendered in part from being a Yankee and in part from the confined life on a ship where one tends to slam the door shut on invasions of various sorts. Nonetheless George was the soul of patience with the man, and agreed to everything even though he must have been seething internally. So, he has to go off to La Paz to do what this man could do here, and no phone messages will suffice. He must pay penance. Later, the migracion man relented, and gave George his extensions here. We think he talked to Armas the Port Captain, who is a friend of ours, and knows we are not your typical arrogant gringo. At any rate, all problems evaporated.

A grand party ensued, with much singing on deck, etc. that went on for hours, leaving me with a bit of a rum hangover next day, but not too bad. I was only one of several, and not making excessive noise, but just singing good ole songs.

Many goodbyes, warmth from Annie and George and invitations to come back with a new program, many students with aspirations to do work like we did. Many had seen me and we had talked careers and schools and the like. Some will stand a chance, and some just don't have it. Most are going through both socialization and intellectual growth, and the two typically interfere. I saw family problems, people with hard-driving fathers in the way, people from the medical profession where so much can become so inhumane at times, and so on.

Anyway, amidst all this we cast off in the VW and had a nice drive to La Paz, where some left on the plane and Ellen Margulis and I who go out tomorrow holed up in the Perla for the night. My room had no hot water, but hers was apparently closer to the water heater and she gave me reports of hot showers. I went back and left my own water running for about 20 minutes and it too came hot, though La Paz's water supply declined 1/3 in the process. I recouped my snoozing, she circulated the town, a dinner, and more

snoozing for me anyway. Then, off to the airport for the flight home. I'm more than ready to be there. The trip was productive, hard work at times, and an interlude where I made a recovery of sorts from the pressures back at UCSC, and especially was able to do some honest consecutive science, which seems so hard to do in the face of other pressures.

Northern Gulf of California: March 2-10, 1979

March 2, 1979

San Felipe Harbor, Baja California Norte

The usual hassle has been traversed (not that other hassles may not lay ahead). The hassle I speak of is the border hassle. Bernd Wursig and Randy Wells towed the *Naia* down to Calexico in fine shape while I went to San Diego to pick up insurance, change money, and then I went across to Tijuana in a rainstorm, located Ben Lopez's house up on a terrace above Tijuana valley. That was not so easy. He said Londres Street and I found it, a deep ravine full of boulders, rushing waters, and [?] tracks. There were numbers on the houses, stilted to the steep banks in utter and insolent defiance of gravity. One said "Londres" clear as day, so down I went and never could find the number, as I dodged, slid, bounced, jounced, banged, and sluiced down the road, never knowing if I was going to make it. I made a great circle and finally found a little side branch with 447 on it . . . a neat house set amongst carefully trimmed trees and shrubs, and a rather formal entrance. Inside was rococo—high-backed, gilt chairs, marble fireplace, the only bathroom I've seen in which the bathroom, in addition to having gold fixtures, had the roof tiled. I met Benjamin Lopez, a handsome young man, now enrolled at U. Baja California at Esenada, and steered by Anelio Aguayo, who teaches there, toward a thesis on the Gulf of California harbor porpoise. He will accompany us. His mother and brother came in, and we sat down to lunch—beefsteak, clear soup, vegetables. Their father came in, a merchant here for 40 years—a dapper kind-faced man, obviously proud of son and house. We chatted and then left to drive over the Rumarosa—the grade that crosses the Sierra Juarez. Up by El Condor, near the crest it began to snow—big wet flakes that did not last on the ground. Ben had never seen snow before. Then down the old Cantu grade we went—a winding but good road. The Laguna Salada gleamed white below as we spiralled down under the clouds. I recalled for Ben old trips there, Manuel Demara leading us to his spring, coyotes circling my sleeping bag at one spring, and the hot spring.

Soon we were in Mexicali with all its traffic and bustle. Then the border in the rain.

I tried to reach the US side to see if we have any messages. One lane and traffic forced me to cross and Benjamin was scraped off, since he had no papers. I left him standing in the drizzle and went through. Finally I was able to park and sauntered over to the working agents at the border, to be greeted by greatest suspicion by the supervisor, who looked down his nose at me and said they discouraged such things as notes and contacts, but if one came in he would know and nothing had come in. I circled over to the Mexico side to find Ben, and did. Then I was greeted by Bernd who came joyfully out of the rain, saying they had been at the border since noon and he repeatedly left messages, the last about 20 minutes before we arrived. Damn those lying so and sos at the border.

We could have waited for hours. Bernd led us down through a lot of construction mud to a marshalling yard where the truck and boat were parked. Their trip down had been smooth and uneventful. The truck, however, was parked in a sort of pit in which the dust had turned to a sort of hybrid glue-grease in the rain. In short, the truck couldn't pull it out. I was ready to sack out for the night but my colleagues, who had been standing around the border since noon were filled with pizzazz and voted to try an extrication. About four hours later we made it, but first we pulled with the truck, the come-along, and the cable around a telephone pole for a better angle (which it threatened to cut in two). Finally with the come-along and cable clove-hitched to the phone we got the incredibly heavy *Naia* over the curb and then a straight shot by the truck pulled it nearly up to pavement—but not before the cable snapped, and Ben stopped the backward roll down a muddy road with a chock—just in the nick of time. It might have gained speed and crashed. Whew!

About 11 PM we hauled happily out of Mexicali and onto the San Felipe road. Finally about 1 AM I called a halt and we went off on a road for equipment for a gravel depot and quickly went to sleep.

March 2, 1979

Next morning, Bernd broke out some corn flakes, heated up a little water for coffee. Afterward we headed for San Felipe. Lupines lined the road—a magenta variety with occasional clumps of white ones—I suppose a mutant albino frequency phenomenon. *Encelia* was in bloom as was ocotillo.

At San Felipe we encountered the new town—about 5x my remembrance of it, then drove south to Club de Pesca where Trish Holt's (my secretary) mom and dad live. They were hospitable, feeding us dinner, and many margaritas. We launched at Rubens, the north end of town. We were towed out by a spastic old big-wheeled power wagon, but Randy was ready, started quickly, and was off through chopping seas to the new harbor south of town. Ben and I drove down and met them.

Later we clambered down the jetty boulders and to the waiting rubber dinghy. On board not long after we stretched out and slept. My space was the afterdeck, on a new backpack mattress. I slept hard.

March 3, 1979

Isla Montague

After a little rigging of this and that we left on a flat calm sea that never deserted us all day, except for a few light breezes in early afternoon. Our trek took us up the west side of the Gulf to Montague Island at the mouth of the Rio Hardy. We hoped to see *Phocoena* but didn't. Only 15 groups of *Tursiops* and two sea lion sightings graced the day. Most bottlenose were with otter trawlers, or fairly nearby, though we did see our biggest group by a channel drop off S. of Montague Island, and no boats very nearby.

The Gulf shallowed and finally about 4 PM we could go no further for lack of draft. The water was clouded with birds at times—mostly Heerman's and California gulls. Surf scoters were common—not a few Western grebes were seen, one jaeger and a few terns.

Right now I'm sitting in the helmsman's seat watching a magnificent Gulf sunset over the Sierra Juarez, and listening to tern cries and other birds over on the mudbank of

Montague. We are anchored at the southern mudspit in calm water. My fish line baited with elegantly odoriferous shrimp has yielded ziltch so far.

The *Naia* has done splendidly. On one engine she made the trip on about ¼ tank (70 miles), our chart table is great, our footrail greater, and I scrubbed everything down so she's pretty clean, too. Company's fine and detailed notes on porp sightings are in the Field Log book.

March 4, 1979

San Felipe Harbor

Sometime after midnight I awoke realizing that we were anchored where Francisco Ulloa (in 1510 or thereabouts) had a boat upset in the tidal bore, and later a Colorado River steamer capsized, killing more than 100 people.

I tossed a crumpled paper in and the tide still seemed to be going out. I could hear rushing and burbling water off toward the mudbanks. I began to worry a little about a bore of some unknown size and force though I knew we were past the spring tide and also that decrease in the flow of the Colorado River had drastically reduced the chance of such phenomena. Nonetheless I went below and shook Randy. He thought we should move. Soon Bernd was up and then Ben. Then, Randy pointed out a south course which looked north to me. I checked with Polaris and he was right. The tide was coming in. Even though by this time the anchor was up and the raft on the roof, I consulted Randy again. Better to anchor here than go off into unknown water he said. So, since the tide had shifted two hours before, we dropped anchor again and secured. So much for tidal bore drill. Back to sleep.

Montague Island rises dark brown with wetting from the tides, a long, rounded 30-ft. high mud mound, incised with runback channels where the tidal waters drain back. No features stand out. Only at night can one see the cluster of lights at El Golfo (Sta. Clara) or see headlights jouncing along the higher Sonoran bluff, as some unknown car makes its way along the rim of the Gran Desierto. Coffee-colored water merges with low tidal bluffs—only occasional tufts of saltbush relieve the monotonous landscape. Winds whistle in, unimpeded. This morning a short chop had built up from the 10 kt. wind.

Bottlenose porpoises puffed astern of us in the dark, the inspiration and expiration clearly separated—a 0.5 second expiration followed by a higher pitched and shorter inspiration. Does the change of pitch come from different velocities of air passage. I'll bet it does. But one would have to calibrate his porpoise to use it as a measure.

The trip down was uneventful except for a few encounters with *Tursiops* groups, a couple of jaegers, and much conversation of this and that. Randy's pole and nice reel, alas, went over the stern on an improperly set pole holder.

The *Naia* wallows in a following sea so we spent the day correcting course. We travelled on one engine, making seven knots or so, and made the roundtrip on less than ½ a tank of gas (50 gallons). Brown boobies became common as we approached San Felipe, and the water cleared a bit, but not much else happened. At San Felipe we loaded fuel. I designed a field camp for Hawaii (an assembleable house) [drawing] and later, cooked dinner, went shopping with Ben, and helped with rowing and so forth. Tomorrow we check with the Port Captain and then head for Puerto Penasco, and Roca Consaga along the way, there to count sea lions.

Good crew, good day, but no . . .

Today was Sunday and it proved impossible to phone home. The town phone was broken and the phone office was closed (it's Sunday). Nonetheless we obtained some supplies—fruit, bread, alcohol for the stove (pure cana, used to make vodka or dilute wine) obtained at the liquor store, “48 pesos por litro”), bananas, cabbage, mayo, and we try to see the port captain—no luck. To bed on board at the harbor.

March 5, 1979

Sonora, at anchor just outside Puerto Penasco

First thing this morning Ben and I headed for town to talk to the Capitan del Puerto and to call home. The Capitan was pleasant and pecked out a long document about motor numbers, captains (Randy), and destinations. Ben later said he was pretty bureaucratic and more or less asked for a bit of propina—100 pesos in this case. My call home showed Jessie better (a bit) and all well. Gasoline, carried in 15-gallon carboys took time to ferry, siphon, and buy. But in mid-afternoon we were ready and the wind had dropped a bit. I wanted to leave to keep on some semblance of a schedule, so off we went, planning to stay the night near Roca Consaga. The *Naia* bounced and [?] her way the whole 19 miles. She doesn't steer very well in a following or quartering sea. Anyway, toward dusk we pulled up on this sail-like rock. From any angle, it looks like a huge sailing vessel, with high schooner-type sails, all white with guano for whitening.

When we reached the rock, tidal currents ripped around her from the north, leaving lines on either side of roughened water.

The fathometer chromalled a steeply rising rocky bottom and no shelf at all where one could hope to anchor.

I asked Randy to circumnavigate the rock so I could count sea lions. In the late afternoon light and in choppy seas I made an estimation. On the main rock sea lions were around all sides. On the steepest slopes where cliffs slanted 80 degrees into the sea these pinnipeds were fewest. On the north rocky shore and a cobble spit to the west they were so thick as to touch in a solid carpet of sea lions most places. Groups of young juveniles barked in the water. On the western rocky outliers I saw only one, an old bull atop a 15-ft. stack. 326 sea lions were counted, no very young, but half-grown females and [?] males.

The rock itself is a precipitous fin or pyramid, the top a steep, fissured, and triangular pinnacle. Some faces are 80 degree faces, dotted at our passage with young brown boobies clinging to tiny ledges over it, while adult birds wheeled in a loose cloud around and over the pinnacle.

Both Randy and I immediately saw the hopelessness of anchoring and decided to head for Puerto Penasco, 40 miles distant. The idea of a nice navigation by compass exhilarated me. It is, as Randy points out, a simplifying experience. The world closes around in the dark to the compass, the rocking boat with all its sounds, and ultimately a light on the horizon, or a passing otter trawler.

Ben and Bernd, however, weren't up to snuff and went to bed so Randy and I took her in, and anchored outside the jetty at 1 AM. To bed.

March 5 [6?], 1979

Isla San Jorge, Sonora, Mexico

We anchored not far off the main channel into the harbor and were rocked by passing boats before we were up.

After pancakes, Randy took us in to search for gas. It proved to be fairly close near the south jetty. Ferrying worked OK though the little inflatable is pretty unstable. On one such trip I stayed aboard and not long after everyone left the trawler to whom we had a bow line secured threatening to back out, in fact from the snapping line and groaning cleat (which I thought would come out by the roots) I thought departure was in progress. My calls finally roused a deckhand and he said, yes, they were leaving. I told him we were tied to the bow. Then I learned they would be there two hours but then, in spite of asking to leave us tied, over came the line into the water. In moments, it seemed, we were drifting in. I tried to get the engine down and couldn't and then we drifted into some skiffs and lines. I tried to take the anchor up and row it out, and while in a snarl up came Randy to help and together we did get the *Naia* out but not before she dragged bottom, brought up an old tire on her outdrive and various other problems.

Gas, papers, etc. were finally completed with me forgoing Randy's name, as skipper, six times.

At sea we headed south toward Desemboque and Isla San Jorge. The coast is low alluvial plains rising to low hills some miles inland. An unbroken beach stretches a dozen miles back into Bahia San Jorge, almost due East. A 10-15 kt. NW wind kicked up a little swell but sailing was good. Finally when we were due N. of Isla San Jorge we turned out to sea and toward the island, 10 miles offshore.

Enroute various groups of *Tursiops* were seen, mostly in company with trawlers. One particularly large group—actually two of more-or-less 20 animals each visited us. They were heavily parasitized by *Xeobalanus*, especially on the rear end of the dorsal fin tip. Some had them on rear fluke margins and trailing edge of pectorals. Many had multiple barnacles of this sort in clusters.

I noted that when porps rise to breathe, they pause and glide up with flukes horizontal, breathe, arch the body, and beat the tail again. There is a definite hitch in their swimming. I wanted to see if I could discover any difference between the power of up and down stroke of the flukes. Purves, I believe, feels the downstroke is the powerstroke. If this happens the powerstroke should be quieter than the passive stroke. I couldn't see a difference in the time of up or downstrokes. They seem the same. Randy notes that whale and porpoise "fooprints" well up and out, indicating a power upstroke. I note that our fast swimming animal turned on its side and achieved power probably in both directions since the pressure exerted upward loses power and an animal on its side doesn't face this. I doubt that there is a difference.

At dusk we came in along the north side of Isla San Jorge. It's covered with brown boobies and has a compliment of barking sea lions. The island is a jagged, guano-covered fin that reaches about 250 ft. high on the south Islet. There is very little vegetation, the guano having buried most everything. The anchorage is a fairly good one though wind whistles through gaps and rocks us.

But if we drag anchor we drift out to sea. So, dinner, notes, and to bed. Oh yes, and I noted the *Tursiops* craning their necks a la *T. truncatus* . . . that is, turning them at 60-70 degrees to the side as they swim along, usually to peer at us, or something. *T. gilli* doesn't seem to do this.

Our anchorage was a blustery but OK one.

March 6 1979

Enroute, Desemboque

We made a count around the island first thing in the morning after I had caught lunch of *Paralabra nebulifer* (sand bass). Sea lions were distributed all around Isla San Jorge, which is perhaps 1/3 mile long. All age classes were present, many individuals had climbed high on the guano-covered cliffs, and there were several pockets with hundreds of animals piled all on top of one another. Bernd and I both counted and came up with counts as follows: Norris 2,274; Wursig 1,806. We can conclude that about 2,000 animals occupy its shores at this time of year. Such counts are rough with animals piled over one another and hidden in nooks and are apt to be low. Several species of birds were noted—nesting brown boobies spaced over the entire island mostly up on rubble and steep faces of rock.

We saw a few Heerman's gulls and California gulls on low cobble stringer, near the tide line. I saw a lone oyster catcher and a lone great blue heron, one group of a dozen or so frigate birds with red male throat pouches in evidence, a couple of kinds of cormorants, and pelicans in breeding color. One could see on the slopes where guano collectors had built trails, often with rock work supports in steep slide areas. No one was in occupancy and only a lone shack, its corrugated iron all but blown away, remained.

We left San Jorge shining that special tangerine shade of the Gulf light—in this case light because of the guano covering the island. On down the Gulf we went, the seas quite calm, almost glassy about noon and then picking up a bit in the 8-10 kt NW breeze. We cruised the shore, close enough to watch the beach as well as offshore. Only a few groups of *Tursiops* were seen at sea, and we saw five carcasses on the beach and rowed through the towering surf (six inches) to prove it. There was a skinned *Zalophus* and *Tursiops* and two *Delphinus* north of Desemboque. The latter may be a northern record for *Delphinus* in the Gulf, at least it's pretty far north for them.

The shore is a long strand, often topped with sand hills, and behind the bajada is a low sandy plain punctuated here and there with barren ridges of rock. Most are low but some are 3-4,000 ft. high.

Jellyfish were very common, of a single kind, sea blue in color with a very short funnel stalk protruding veined with pellucid fins that I assume can be turned to alter the direction of the jellyfish [drawing]. Certainly they were maneuverable and moved very rapidly for a jellyfish. One evaded Randy for a time when he tried to scoop it up in a bucket.

A long V of white pelicans flew north from the shore above Desemboque undulating over imaginary (or at least invisible) barriers in the air. Their slow, almost ponderous, wingbeat and large size set them apart from other birds, as did their immaculate black and white plumage.

March 7, 1979

At Anchor S. of Desemboque

Finally we located the mouth of the Rio Concepcion. It wasn't simple to see. A shallow, muddy area lies in front, out to sea. The shores are lined with stumps that have washed down the River. Ashore I could see an arroyo, the south bank cut with a braided channel, now nearly dry. Back beyond the beach bar I could see casuarina trees, the roof

of a quonset hut and thickets of desert willow (*Chilopsis*). To the north a few hundred meters was a cluster of houses on the beach berm, a gaggle of gill net boats and a number of people. I suspect this is the sea entry for the town.

Gill netting is still fairly intense in the upper Gulf though done entirely, so far as I could see, from open 25-ft. boats. We saw many of the nets set relatively close to shore as we travelled along. They were mostly flagged and set parallel to shore. What species they seek I do not know but the nets are relatively small mesh nylon—probably milled.

Bernd and I went ashore to look for *Uma notata cowlesi* and found it on the beach dunes just at sunset. I scooped one out of the sand where it had buried. Later we found a *Delphinus* and three *Tursiops* skulls in the beach wrack. No *Phocoena*, darn it.

Back on board, dinner, a spaceman's toddy (rum, sugar, water, and Tang), and dinner. We're fairly comfortable in a low swell coming in from the SW—actually we swung in the incoming tide and the swell continued to come from the NW. It was a wet night though the gnats blissfully enough retired at sunset.

It's a flat, rather featureless world here. All the relief is in the distance. We can see Angel de la Guarda Island in the distance to the southwest. I can make out Isla Mejia and where Puerto Refugio must be, and then inland to the east, those isolated Sonoran mountains.

I stayed on board this morning while Randy, Bernd, and Ben went ashore to look for *Phocoena* skulls. I spent my time scrubbing decks and cleaning the galley. They came back with a *Tursiops* skull.

We interviewed a couple of gill net fishermen who came alongside—boys really. They knew the chochito, and confirmed it had a snout and knew toninas, but they knew nothing of the vaquita and suggested that it might be a local name in Baja—maybe they are right. They fish for sharks—smoothhounds and said they caught as much as a ton a night.

When the shore party returned we gassed up and headed out on calm seas to the northwest. Last night had been one of wet decks and drips, soggy pillows and bags but withall dry enough inside for continuous dreams of this and that, of a garden belonging to a Mr. Rat who spoke the king's English and had subdivided his formal garden, where my car was parked, into districts—"Rosario, San Felipe . . . etc.," each connected by a gate to the outside. A remarkable contraption of levers stood at each division and off to one side an instrumentation panel. I read it and tried to operate San Felipe gate to no avail. The Rat came by and curtly informed me I was in "Rosario" and so I was ultimately released. Now what was that all about? The *Socialista*? I suppose, with an anchor foreward dragging as the *Socialista* nearly pulled the cleat off the stern.

There was also a colloquy about the Rat insolently informing me that of his two gold medals, as if I, serf, could never aspire so high, but I showed him some paper or other and we were again equals. I hesitate even to interpret this.

The *Naiia*'s a little tight for four. With the walkway (which works wonderfully well [?]) the foredeck area is available in inclement weather. Sleeping at night is a worse problem. There is so much gear there's scarcely space foreward and our crew seems not to relish such sardining. The bunk made by the table is the best in the house but also scarcely fits two. The afterdeck is ok when it's dry but with dew it's very wet, even under cover up by the helm. The solution is three[?], or more intimacy, or waterproofing aft. But all in all, we are doing fine, and are a good happy crew, full of jokes and songs and

poems (Bernd knows a lot of Hillaire Belloc's verses, amongst others). We kid Randy about fiddling with his "inflatable dinghy" and other bits of naval folklore in-the-making.

Random thoughts—seafarers must always have known the earth was round for they are confronted with the fact a dozen times a day. Each time a point of land or an island rises into view or a light breaks the horizon and rises as one approaches tells that story.

Right now for example, we can see the crest of La Providencia, the highest peak in Baja, nearly 12,000 ft. tall, and to us it is a low prominence of land not so tall as Isla San Jorge [?] our beam and 240 ft. tall. If porpoises talk might it not be that an entire school talks at once and that brain is devoted to making sense of the din. Our puny neural apparatus, used to one person *tete-a-tetes*, and boggled by cocktail parties, might make no sense at all of what may be a sort of "group speak." I'd guess such conversations would be incredibly banal, and instead of being devoted to timeless truths worthy of being said across interspecies barriers, they have only to do with relationships between porpoises. After all, that's where the communicants spend their lives.

The Sierra Pinacate has been a beacon all this trip, its double-tipped shield rising up to the north behind Punta Penasco. What interesting times I have spent in that mystical place. The sawtooth Hornida Range rising out of the sand to the west was too low for us to see but next we traveled up along the margin of the Gran Desierto to Santa Clara and maybe then.

This afternoon both south of San Jorge and Punta Penasco we encountered *Delphinus*—the farthest up the Gulf I know of them occurring. It clouded over but stayed calm on our 65-mile northwestward trek, which could have been miserable.

The *Delphinus* near San Jorge were feeding and generally avoided us. On one occasion about 50 animals came toward us in a slanted rank, and I cut the engine to wait. One could hear the rush of water along their collective bodies. As in other porpoise groups I saw ones with primarily adults and others with many young including very small animals. The other school Ben spotted in the dark just S. of Punta Penasco.

Tonight, courtesy of the Captain (Mr. Wells), who, bless his soul, I have a veritable palace on the stern. The canvas cover is up! I do not have to creep under the helm seat where I bang my head. I do not have to bend my body in the middle to take advantage of the companionway, which is the driest of the deck aft.

Our captain is a fine member of his breed, if I can include him with them. Randy knows a lot of seamanship and has excellent judgment. Best of all he is always thinking ahead, and that, to me, is the mark of a real seaman. Old Frank Brocato had that attribute in spades. Anyway, things go well with Randy in charge and we really let him make the decisions so that he can function—that being a real trap for a situation such as this where I have ultimate charge but must build a functioning team to work both when I'm here and when I'm absent. Randy amply fills the bill.

Ben is quiet, probably because of some degree of language barrier (we academics, particularly those who joke, use complicated language play on words, make esoteric inferences and references. But, Ben bears up and is gentlemanly. A thread of intensity shows now and then and he is very affable and helpful when we let him. With four people there's not all that much to do. We're having him fill out data sheets and go on beach walks and such.

Bernd is a joy, very, very competent, full of vivacity, humor, always ready for more, never ready to quit, a blithe spirit anxious to be a good shipmate.

March 9, 1979

Anchored in 3 ft. off coast 20 m. SE of Santa Clara, Sonora, Mexico

Today was a triumph of officialdom, though ultimately we escaped their uncaring clutches. We started at 6:30 with breakfast, then gassing which involved rowing ashore, toting 15-gallon plastic gas drums to the Pemex station three blocks up the hill, hailing cabs to drive it back to the ramp. The ramp, by the way, was where the gill net skiffs brought their catch in and the trucks backed wheels below water, to pick it up. I bought a nice halibut for dinner, by the way.

Then we attacked the Capitan del Puerto and quickly were sent off for four copies of our permit (five pesos a page at the local sporting goods store). The Capitan was pleasant enough but one of his type as you could tell three blocks away—unsmiling, a little moustache, about 40, a little flabby, not a working man, drives a spiffy car. He sent us to see the Inspector de Pesca, for a stamp and initials. That took half the afternoon as he didn't show and finally one of his secretaries took my papers and disappeared by car to return half an hour later with the stamps and initials. I suspect him of being holed up in some motel, but then my thoughts were oriented blackly. Finally, Ben and I bought bread and groceries and went aboard and we escaped the harbor at 1355. Whew!

We interrogated various fishermen and no one at Penasco talks about the vaquita. They know the chochita, and speak of it having a snout, and they know the tonina. But vaquita, no. But folks at San Felipe knew, especially one fisherman interviewed by Bernd who identified it very well without prompting, talked of three kinds. We had some unconvincing discussion today of our animal to the south at the midriff, LA Bay, and Guaymas. But here, it is either rare or doesn't come in now, it seems.

We headed out across Bahia Adair, the great bulk of Sierra Pinacate looming to the east and the bay stretching off to low shores backed in some places by strings of dune mountains. There were very few birds and very little life in general. We did see a red-billed tropic bird flying overhead. Finally we closed on the far shore—a low sedimentary bluff at the north end of Bahia Adair. After watching a spectacular carmine sunset with shafts of sun piercing the clouds and a kind of luminescent aura radiating over the land, we dropped anchor in three fathoms about $\frac{3}{4}$ mile offshore with a SW swell coming in enough to rock and slap us.

I cooked the halibut, we drank a ceremonial bottle of [?] de Jerez (Santo Tomas), with crackers and much conversation. About this time Ben faded out from a bit of seasickness while we ate till our bellies distended and our eyes bugged out. Good though.

Well tomorrow, a short run up the coast and thence back across the Gulf to San Felipe and then home while these devils continue their idyll on down to the midriff.

March 10, 1979

San Felipe

The swell banged at us all night, a mean little SE swell copping at us from the direction of Puerto Penasco. Everything slapped and banged—the rubber raft astern, the water under the chines, doors, pots, and I sluiced back and forth in the roll inside my sleeping bag, trying to sleep. I did doze off and in between got up to peer at the sea under

the flaps. There wasn't much wind, but we were in three fathoms (minus tide) and the wind, such as it was, had no fetch, so we banged.

No danger though, except that it might pick up and we had no real place to go from a SE swell. But it didn't.

In the morning, we rose before the sun peeked over the desert to the east, illuminating the Sierra Pinacate. I suggested breakfast would be easier if we got underway, so we hauled anchor and headed off along the coast, finding we were actually inside Bahia Adair, and had some distance to go to reach the western cape. Finally we did, after cruising through calmer seas and watching the terns dive. There were large numbers of Forster's terns, and what we think were gull-billed terns. The latter are supposed mostly to hawk for insects, but ours were diving. I dunno.

Finally we could see just the tip of Montague Island ahead and a little village of shacks on our beam so I changed course for San Felipe, as I have a long drive ahead of me. Almost immediately we ran into a good big school (100-plus animals) of *Delphinus*, feeding in small groups across a pretty wide stretch of sea. There were all age classes from very tiny young to adults. I noted a good many with the whitish flush in the center of the dorsal fin, a triangle of whitish that I've seen many times on the outer coast and wondered if it was a population marker. Now I wonder if it is age-related, and found only in large adults.

North of Consage Rock we began to see what we think were pretty sure *Phocoena sinus*. They were elusive in the extreme, but by this time the sea had turned glassy and we could see a long way. The animals were very small—five ft. or less, and often very close together. In all but one case their fins seemed fairly tall and gave the appearance of being falcate. When the animals dove they tended to come up in other than a straight line. They were in pairs and I think we saw about four such pairs the last being about five miles off San Felipe. One one occasion we saw the blunt snout twice, and I could make out the hitch in the swimming in which as the animal rolls it takes a hitch forward as by a strong tail stroke. Typical of *Phocoena* elsewhere.

Later we did see a small group of *Delphinus*, and they were notably different, breaking water, and finally coming over to the boat. I once saw what appeared to be a fairly low, triangular fin on the *Phocoena*. All in all, I'm essentially convinced we were seeing *Phocoena*, though because we never approached closer than about 100 yards our data do not firmly stand up in court.

At the same locus, in a slick area, we came across three or four minke whales—not very big ones but clearly minkes, with the fairly large fin, small size, and lateral pattern marks. I'd guess the biggest at about 25 ft.

Then we went in, landing in front of Bud and Helen Neal's place, and wading ashore across the flat. They were gone, so after some searching I went out for a meal and then settled down in their living room. Finally they came in and we had coffee, said our goodbyes, and I was off. I drove straight through to Indio, slept in a turning circle in an uncompleted country club, and then over Cajon Pass, up 395, across Tehachapi pass, over to Paso Robles, and home. A long drive, but glad to be back. The boat should be well on its way south on the midriff cruise by now. I think it should be a marvelous cruise and I envy those guys doing it.

Tuolumne County, May 18, 1979

May 18, 1979

Tuolumne County, Camp 3 miles upstream from Early Intake

Larry's and my journeys with you are at an end. I lie here on the pine-needle-strewn sand looking up past three ponderosa spires to a domed and scaling granite giant across the stream. Wind flickers the alders and the sun glints and runs along the stream surface telling of a powerful current. Tomorrow we will gather our gear, swing our now light pack frames onto our backs and head for the blue bus. Then we will go home to other streams of life and other styles of doing things, but I hope some of what we have seen and done will stay with each of us.

There's much love here, of the caring kind, and maybe if we knew how it came to be we might recreate it at various other places and times. It grew, I think, in part because we 25 found places and times to let ourselves unfold, each at our own pace, away from the tug and haul of modern life, and we've come to trust one another in this relatively simple and enclosed world. Trust, that's it. That and its permutations, of tolerance for the paces, foibles, and needs of others. Our little world has been simple enough that we could attend to such things.

How else could we have been as silly as we have been? Mostly, the child in all of us lies boxed and hidden beneath social forms that we cannot drop easily—the cost is too great and too many faceless people would disapprove.

How could we afford to embrace one another, man and woman alike, in camaraderie, if it were not for trust in our little world?

Released in each of us in this way is the chance to unfold, to reveal, and to learn. No sham has blocked awe. No sham has blocked the child's curiosity, and no sham has blocked our mutual and deep desire to know how we might fit into the interlocking warp and woof of life that clothes the earth.

It's easy to mock a person for asking a question as profound as that, yet to us, in the alchemy of these times together, such discourse has become as natural as amber dawn's light on the mountainside.

We've talked a lot about seeing, perceiving in nature, and yet I think that some of the constructs I have presented have been more landmarks of my own history as an unfolding human being, and a naturalist, than something universal. They were some of my few windows to the world, in a house made mostly of glass. For instance, I remember with great clarity the first time, I combined notebook and direct observation. It was atop Mount Pinos, under the gentle eye of a great naturalist, George Bartholomew, and I watched a nuthatch drinking from a faucet and climbing a tree trunk. For the first time I tested the iteration of small hypotheses winnowing and refining ideas and observations. And my eyes were wide because I had seen so much I had never seen before, or even suspected was there. And I told you of my excitement in defining the lizard's world using David Gates's marvelous little book *Energy Exchange in the Biosphere*. From that came the clear understanding that the boundary of our bodies is the most evanescent of barriers, and we are linked, like every other living thing, to the physical world.

But in all this I do believe that one cannot really see if the internal ego predominates, and I do think guided curiosity unlocks and reveals many, but not all things.

More recently in my history, on these natural history trips, as a matter of fact, I've come to know that quite visceral feelings count profoundly too. Beauty engages our kinship with the wild world. The sough of wind in the treetops and the lonely owl's call, the cold creek on our skins—these are windows, too. We must feel with our senses and care with our deepest being to truly spur our curiosity about how things work or we could not engage ourselves with these trappings of notebooks, hand lenses, and India ink.

Seeing the intricacy of life in this canyon, sensing its quiet perfection, we are apt to denigrate our own chaotic human constructs of cities, laws, relations to the land—yet I believe they are one. Those extremes are merely processes near or far from equilibrium—the laws are the same. Yet, what none of us can yet do is simply to be of this canyon world, or of the desert, or of the river. Our beings are too much in evolution for that. But I'm not sure it makes me unhappy. I savor the engagement, the hope and the mystery of changes as great as these, in which every aspect of our lives is being reassessed, and given birth again. What a time to be alive! And, what a time to quest together.

What have these times meant to me? In the collective sense, everything. I've had the rare chance to drink at two wellsprings of understanding—my own, stemming from my experiences and mullings during wide wanderings; and yours, where I can draw from your fresh wonder, strengths, hopes, and timidities, and especially from your new perspectives of the world as it is and will become under your hands and those who follow.

We've shared a lot. We've felt puny at the base of those awesome monoliths of granite, and yet we knew that they too, in mountain time, will tumble and dissolve, like sugar cubes in tea. We've listened with all 14 danger points to a mountain sing. We've run for the blue tarp together up on Villa Creek when the mist sifted down, and we've viewed, and even spoken to the most magnificent Dr. Van Den Burgh I've ever encountered, and then heard him sing. We've had fashion shows on the gravel banks of the Matolle, and stomped the old bus almost to a pile of spare parts while Fran's family looked on in disbelief, following our ice cream binge. And we've shared our times and insights with some of the most talented and marvelous colleagues a person could have: Dan Warrick, Stephanie Kaza, Jim Pepper, Roger Samuelsen, and now Craig Schindler.

To you all, Larry's and my fondest and deepest feelings of camaraderie, gratitude, hope, and love.

(The reading of which is to be followed by a second ice cream binge in Sonora, in honor of Pamela's 22nd.)

April 13-16, 1979—Granite Mountains

April 13, 1979

Bunny Club, Granite Mts., San Bernardino County

It's a fairly warm night in the Granites and I suspect we will have a warm day tomorrow. We're arrived with the class of '79 Natural History of California in the old blue bus. Good group, appreciative, expectant, dedicated, a lot of joy, learning to know each other. We had a delicious [?] and apple sauce for dinner.

The full moon rose, amber and huge over the Old Womans, and now rides high, smaller, shining white and cold. Stars shine against the granite monoliths above the cabin. Toads trill in the moonlight down in the wash, short bursts interspersed with silence. The air is still and the voices of singers and guitars float off the porch. Our windows are open and a fire gleams in the hearth and Dan Warrick stirs it. The gear lies about in heaped disarray but no one minds. People are perched on rocks and the porch, bunks, writing notes.

Tomorrow I start a round of observation studies . . . , always a hard-working and rewarding day. I'm mildly weary, finding it hard to break away from the routines on campus.

April 14, 1979

GMBC

Today was observation day for me. I took four groups on the little walk to the pond and back, laid my assorted prejudices on people, and then watched various beasts—butterflies possibly drinking from the moist sand at the pond edge, water striders, fringillid flight, toad swimming. The latter was the most successful, surprisingly enough. We could see it easily and we could prod our charges back into locomotion whenever we wished. I was amazed to see the proguinal leg segment held nearly at right angles to the body in the swimming stroke with the lower leg and foot doing most of the movement. I made a fairly complete description of the patterns in my species accounts. The bird flight was not very satisfactory. We couldn't see it over and over and I couldn't seem to keep people from looking at other things, but the others were good. The little walks added, too, I think, though, this group is so skilled that much of what I know was old hat. But by being socratic one can draw information out to add to the group experience.

Back at camp, we watched the great, yellow moon rise, had dinner, a little music and sleep. I was tired but not so seriously as not to enjoy a song or two.

April 15, 1979

GMBC

Dan Warrick led a group of us on a walk up the draw north of the cabin above Cove Spring. It was one of those fine clammers up a rocky slope and canyon to a divide where we could see the world. The day was absolutely clear and only gentle breezes abated the heat. It's spring. Little green swords of fiddlenecks and grass and tender hydrophylls made gardens of little hollows shaded by pinon and junipers. At these places a few granite boulders leveled the ground, pine duff made it springy and tufts of *Hilaria* grass were tastefully planted about.

We threaded our way up, alternately taking the creek bed and the rock hillsides. Much of the way a little crystal creek flowed through, rocks bordered by stream monkey flower (*M. guttatus*) in banks up the sandy shores or covering the rocks under big boulders. Back deeper in crevices, ferns poked their fronds out for sun and the *Eucrypta chrysanthifolia* twined, green with little white clots on its fernlike leaves.

Up the banks the rains had sprouted banks of *Amsinckia*, the blue-purple bells of *Phacelia campanularia* under bushes. A few chicory—*Rafinesquia*—threaded up to white flowers. The soil of slopes was moist and at higher elevations one could see how it had expanded under snow. The clinking of the stones of the slopes was muted by this moisture and our footfalls were quiet.

Up we went, clambering up alongside the long cascade where the slight flow of water was guided by an algal meshwork—orange and brown, and then in the slopes amid the cholla and catsclaw. I drank often from the little cups of clear water on these cascades, knowing that arid slopes lay above. As we treaded our way up past cholla and yuccas, we heard a buzz and saw a big rock rattler (*C. mitchelli phyrus*) in a catsclaw, testing the air with its tongue, in a striking coil, the body inflated so that scales were separated by stretched skin. We left it to deflate and wonder at its fear.

On up we went to the ridge, Dan a compendium of names and information. So much he straightened out. Randy, Larry, Pam, Susan C., Sue, Steve, Jody, Don, Dan, and Wendy were companions and good ones, too, passing the water flasks around under the pinon when we had lunch, threading our way over rocks and meadows and finally converging on a rocky promontory where we could see Granite Peak across the central valley to the dunes, [?] Dome, Ivanpah Mountains, and the faintest outline of 8,100 ft. Clark Mt. to the northeast. We shared landmarks and surveyed our world.

On the way down I heard a whoop to the left and two of those with me came up with a ram's head and horns and then a whoop came from the right and Dan had come up with a manzanita in full bloom. No member of the Ericaceae had been found on the mountain. It proved to be *Arctostaphylos glauca*—known nearest from the Little San Bernardinos to the SW. A real find!

The manzanita was at about 5,200 ft., in a rocky cave. It seems to spring from many branches, some only partly alive, a thread of life running and twisting along branching to the flowering tip. There seemed to be no basal woody portion from which these branches sprang. Leaves were smooth, and light-green and pink bells hung down from branch tips.

Back at camp some went swimming and some sat on the porch and wrote notes, as did I, enjoying the waning day, and the quiet scene.

April 16, 1979

GMBC

We went to the dunes today and once again I made it up the slope, though this time only one was slower than I and she didn't even trip.

My, but it was beautiful out there. We arrived early, about 7:30 or so and made our way across the sand at horned toad time; we caught two and the *Callisaurus* and *Dipsosaurus* weren't yet out. I went under forced draft up the serious[?] with Dan Warrick. He soon enough left me to take my 20 steps, puff, and come down to some sort of equilibrium before going on again. At first Dan stepped on the ridge, one footprint on each side and that was fine. I liked it. I could walk in the steps, and it was very measurably easier. Then, Dan switched to one side and I slogged and struggled against the soft sand. But finally I made it to the top. We talked about sand and playa lakes, buried ourselves in sand, and wiggled our toes before jumping off for the descent down the singing slope. Some tumbled, slid on bellies or rolled. Most of us put our ears below the surface to listen to the mountain sing its low, vibrant song. I lay fascinated as people slid past me or took giant steps near me. Each set the mountain humming. Each step gave out a low note—the lowest of the complete chorus of sounds I heard. A slide of someone passed me on his or her belly. Deep throaty thrums came in cadence with footprints, the sliding sand two or three steps higher. As I lay here the mountain continued to sing even though people apparently lay still or were distant. This sound crept higher and I could hear little thrums in a kind of counterpoint. It was nearly directionless to my single, buried ear, except that one could detect where footprints or slides came from, more or less. But the steady hum of the mountain came from everywhere, and I thought I could feel it on my cheek which was laid against the sand. Strange earth music that reached into one.

Two or three of the men ventured to run the dunes naked but some timidity held the girls back, a timidity that left them when we later washed the dust and sand off in the pond below the cabin.

That mountain! Such strange inchoate emotions as I lay on the steep slope halfway down, clasped by a thrumming mountain. So beyond imagining, insignificant on my part, as I lay there listening into the depths of the dune.

Dave Sofer was pretty sick so we headed back to the cabin, had a dip in the pond, and then most of the group went off to the Hole-in-the-Wall and the petroglyphs, and a few of us stayed at the cabin to laze the afternoon away. I snoozed and walked down to Cove Spring to look at the cottonwoods. I counted eight alive from a distance (I may have overestimated—there was one dead sapling still with withered leaves on it).

The bus came back just after dark and we had dinner, songs, dishes, talk, a fire, and such.

Right now a group of maybe 10 people are clustered together on the front deck singing to Kathy Clark's guitar.

April 21-28, 1979—Mattole River

April 21-28

Mouth of the Mattole River, Humboldt County

A long van drive up to the Mattole River. I slept a fair bit of the way, having had close to zero sleep the night before. So it all seemed short even though it was 4 PM when we reached A.P. Way County Camp, about 6-8 m below Honeydew on the Mattole. Honeydew sports some nice shady oaks, an old gas station, general store, and a ball field. Nice folks, too, who sent us down to the County Camp where we spent the night. It threatened to rain off and on, but an old white-bearded man, Hawkeye by name, said he personally entreated "J.C." to keep the rain away. It was clear to me he was Dr. VanDenbergh, and I knew for the first time his line of communications and source of Power. He was a splendid Dr. VanDenbergh and it was one of the few times I've spoken to him directly.

Good reports, in the morning, a wonderful one on shamanism by Mike Fink, and then we were off to launch off boat people about five miles below Honeydew at a metal suspension bridge. The river is a reasonably big and swift one, running through mountains logged nearby clean of forest and now left for sheep. The river itself cuts in a fairly broad bed through these mountains, winding and bending, its banks of extensive sand and gravel bars or cutting close against banks, sometimes banked with tangled willows and alders.

Much instruction and off we went, one boat right into the willows. We watched them out of sight and then headed for Honeydew to buy gas and milk, matches, etc. and then off down to the mouth of the Mattole. It broadens to a wide floodplain with the river slipping along, a bit milky and pale blue in the deeps. We drove out in the cobbles across from Joe Goff Gulch, where a midden of the now-gone Mattole Indians has been found. There were once about 1,200 of them on the Mattole, Bear, a bit of the Eel, and down to Spanish Flats in the King Range. They lived largely on fish and were done in by the settlers who systematically killed them and cheated them out of their lands.

Our camp lay on a grassy, willow-clumped bench across the stream. Many trips by boat and paddles, and we had set up camp under the sloping hill, with the river [?] by and off to the west, the boom of surf. Fog came and went, the sky tunnel snapping bright with stars and our folks came in from their drift, canoe far in front, cold and wet. Apparently it was blowing hard upstream and they were constantly wet.

We sat in camp contemplating a big, black-spotted banana slug named Stanley, observing how he moved. I suspected him of laying down a slime trail and somehow liquefying it at his body surface. It was interesting to see how he lay the mucus trail with his mouth, in synchrony with the peristaltic pulsations of his belly.

Dinner and a few notes and then off to bed.

April 29, 1979

Same Camp

I took the river trip today and quite a trip it was. After breakfast and some presentations on geology we packed the canoe and the rubber boats and drove to the suspension bridge south of Honeydew. Things were readied and I launched out in the canoe with a crew of Doug, Pam, and Leslie. We had only begun when we snarled in the

same bush that nailed Merry the day before. We broached and blipped, emerged, dripping and full of water. Well, so much for arrogance.

(Some of our crew—Larry, Stephanie, Randy—are out screaming and swimming in the Mattole. It's morning and overcast, glum and nippy, and they're welcome to it.)

Anyway, we started off again and mastered the tippy little craft and the willows overhanging the swift waters at the inside of bends. These can be mean places if you swing too close. The water sluices under and often enough leaves little other river in which to navigate.

In the upper river run there were just a few rocks and not many real chutes to run, but snags keep us entertained. We ate lunch on a bar, lizarded on a rock to warm on the bank out of the wind. We changed boats. In the middle of the run I went with Greg, David, and Randy—what a rum crew. Greg, who could handle the boat very well when we wanted to, lapsed periodically into cackles of laughter and ended up in the bushes. Once we ran into the worst snag I'd seen, the raft swung sideways, and we damn near swamped. But by brute force we pulled ourselves out and slid around. My main worry was for punctures from the old broken branches but somehow that was avoided too, and we slid out into the current again, sans two oars, which we later retrieved. We had to pump one section, but it held OK. Everything, needless to say, was soaked. Not long after, I changed to a boat with Brad, Sue Sanford, and Jody. That was a singing boat and we stuck together to the end of the 26-mile drift.

It's hard to do much natural history except in a gestaltish sort of way, when one is so preoccupied with rapids and snags, but we did see some things. The hills changed and became lower and finally we were on a flood plain of gravel and cobbles, across which the river swung. Upstream the hills were desolated by logging, probably with conscious purpose of creating grazing land for sheep. Sheep were everywhere—far up the slopes in steep fenced pastures amidst the burned spikes of old slashed trees. Some knolls were clotted with black stumps. The trees that remained were tattered flags of trees, forlorn and alone, a battered remnant with no attempt at reforestation. Down by the mouth the forested slopes returned a bit, even though second growth. We could at least see a whole spruce.

A white-fronted goose stood on the bank, orange feet and bill—a magnificent bird, especially when it flew. A great blue heron, likewise, flew ahead of us. Mergansers, too, flew close to the water and many vultures tipped and swooped.

The lower river had tiers of bars that produced clusters of 4-foot drop or so. These were exciting to enter, the peaked caps of water and standing waves undulating the boat, as it slid down at 5-6 mph. or so.

Finally, in late afternoon, we nosed the bar of camp and came ashore.

Dinner, talk, much laughter, and then late at night, bed. I was only moderately stiff about the shoulders from the day's row.

April 29, 1979

Mouth of Mattole River, Humboldt County

Last night I could hear the breakers pound and finally they faded away. I was a little sore but that's about all; so it was a fair night.

This morning after breakfast we listened to various presentations around a daytime fire and then set out about 10:30 for a hike down the beach to see what we could

see. Steep hills rise on both sides of the ¼-mile-wide river entrance. The river moves back and forth over this gravelly bed, leaving some banks on each side. Our camp rests on one. It's hard to see a road from camp, but depredations in the forest are clear enough. I wanted to explore south toward Pt. Gorda so we crossed in the aluminum boat and hiked the Lighthouse Road to the entrance.

There is a camp area on the dunes at the S. entrance but it's not for open camping, unless you're up for wind. It's better for the trailer set. The beach hummocks against a steep bluff, clothed with bluff flora—*Iris*, *Ceanothus*, poison oak, *Erysimum*, *Platystemon* (a beautiful one with yellow tips on white petals), *Lathyrus littoralis* (on the beach)—a gray-leaved, pink-flowered one, a yellow *Abronia (latifolia)*, and *Garrya elliptica* (on the slopes).

We walked the beach under clear skies, finding two middens in the sand, mostly filled with cracked mussel shells, and sea urchin spines.

The big event of the day was that I packed my lunch in a plastic bag with bobcat scats in it (used in last night's presentation)—egg, orange, apple, banana. The apple wasn't too good. General hilarity followed when I discovered it as I was peeling the egg—last item. Hard to believe, but true.

Then a group of us left the beach and went up a zigzag trail to the top of the bluff—some 600-700 ft. up, maybe even 1,000. It was a long trek that put me into forced draft ventilation—one-foot-in-front-of-the-other, Ken. Cathy Clark and I came over the top first to an old sea terrace—grassy, dotted with *Iris* and occasional clumps of *Ceanothus*. The grass was dotted everywhere with beautiful little purple-blue violets (*Viola adunca*). It was cold. We'd come up from the sunny beach to the base of the cloud hanging stuck on the mountaintop.

Some cheviot sheep baa-ed and hurried away. Five deer bolted from the brush in a little watered draw. On over the undulating grassy hills we went, stopping now and then to examine a flower or bird. We kept moving in the cold, topped a knoll far above the Mattole and could see clear up to Petrolia. Our camp was a bright patchwork of tents and tarps on the opposite bank. The stream braiding was especially evident.

We tried to avoid a house and came close to another, where a man stood patching a corral, his hammer blows echoing against the bowl of hills. Finally we passed through a gate and looked back at a big "No Trespassing" sign, and another proclaiming the fields to have poison trays set out. Presumably these are the cyanide traps set for coyotes—the ones that spring into the animal's mouth when he mouths it.

Back at camp, we traded stories, talked about animal consciousness, animal rights, and death . . .

May 16-19, 1979—Tuolumne River

May 16, 1979

3.5 miles above Early Intake, Tuolumne River, Merced County

My last class hike of the spring. Nice warm clear weather, we've had so far. The stream sparkles green against the rocky cliff across from our camp. The group is off on various quests—a light group, a couple of temperature groups, people in the river, etc. I gave a good lecture this morning and Larry followed with a fine description of gear and

what the groups should do. We'd plunked down on a grassy hillside under a big, platy Ponderosa pine with everyone in a semicircle, and I talked about radiation and heat budgets, etc.

The hike in yesterday was one of me trying to break loose into second wind and finally making it halfway up. Good sweat, good breathing, and the old pack creaking back there out of sight. My, I was tired though from pressures at home and lack of sleep. But last night Larry, Craig, and I lay our bags down on the sandy bank at the stream edge and had a grand sleep. I slept hard, loving my little double mattress. I'd called off presentations because many people felt like I did, and everyone seemed grateful just to crawl in and drift off.

It is a warm, hardworking group, many fine folks. I'll have a cup of coffee now and drift around and see how they are doing.

Next morning—Yesterday, I'd walked all the way down to our camp by the pool to find people. They'd all gone upstream, so I trudged along alone with the meadow and the *Mimulus*, the bird's-foot ferns peeking out from under boulders, the roaring stream, sun hot on my shoulders.

Back at camp I found Larry circled by the students discussing their findings. He was afraid many were frustrated and was giving them a chance to be helped by others who had succeeded. Nice going, Larry.

In the evening, we had a dance—Indians coming hooting out of the woods, painted from head to toe; many of them had made instruments to keep time. I had made a wooden drum, burned out a punky log and slotted it to knot holes to make resonant slats, and fire hardened. It made a nice Quok Quok sound and a good rascado, especially in Craig's talented hands.

The dance itself was good; this time the men did most of the dancing and the four women stood by dancing lightly and circling the male dancers around the fire. All were decorated from head to foot with both grease paint and water-soluble body paints. The men wore breech cloths and carried fans of pine needles which they virtually burned. Chas Salmon was the drummer on a pair of small bongos. The girls wore nothing but paint and carried scarves. The flickering firelight on the tense muscles of the men and the silhouettes of the girls moving by made a scene of artistic power and grace. I played my drum and generally kept in time, and learned quickly to be quiet when the lead dancer grunted out his command for the beat to stop next sequence around. Mike Fink, our Native American Studies major looked uncomfortable on the sidelines, though he did join in a bit when called upon. I, like Mike, I suspect, hoped the dancers would have told how their recreation fitted the old reality, but they didn't, leaving us to wonder if it was concocted or real. It turned out it had real parts, and the dance group did know, but they told us little.

At the end Mike interjected and told us of the Tuolumne—the cave people who intermarried with the Yosemite, who even now cannot use this, their old sacred valley. But they are organizing all 300-400 of them and may win the valley sometime soon. Mike then read an interminable speech by a Ms. Pinetree, given to a group of medicine men in Seattle. I was irked by its length. Mike doesn't gauge his audience, but speaks from internalities—good, facile with words, knows an amazing amount, but he has that to learn yet.

The dancers stood around the fire and finally the group broke up. I, for one, don't know how to make small talk or to stand next to a naked woman. So, I left, and, I think others did, too. Dancing and swimming, or even listening to a lecture in a grassy field is one thing, but singing around the campfire is another. I find clothes provide a nice shield that lets one sing old songs, dance, and be silly.

I spent a somewhat restless night at our new campspot. Craig, Larry, and I had moved because of rising waters, and are now up the hill on a sandy slope under big old ponderosas.

This morning, after breakfast, we talked about integrative mechanisms, about the past history here, about how long a chain of interlocked organisms one could expect in nature and how they could move together. It was good. Followed by some presentations, including one by Mike on trout, in which Larry had to cut him off. I hung behind as various groups moved out into the valley for various escapades. Merry and Dan missed the morning expedition as they were out on a hike and did not return on time. Are they back yet?

May 19, 1979

Musings at the end of Tuolumne, 1979

We've talked a lot about seeing, perceiving in nature, and yet I think in a real way these methods have been more the landmarks of my history as an unfolding human being and a naturalist than something universal. They are my windows to the world, in a house of glass. I do, however, believe one cannot really see if the internal ego predominates, and I do think guided curiosity unlocks and reveals many, but not all, things. But less intellectualized, almost visceral feelings count profoundly too. Beauty engages our kinship with the wild world. The sighing of the wind in the treetops, and the lonesome owl's call, the cold creek on our skins; these are windows, too.

We can appreciate in our intellectual ways the quiet, slumberous, yet perfect interlocked community of life in this canyon, and we exult in its intricacy and perfection and may then denigrate our own chaotic human constructs. Yet I believe they are one. They merely flow at different paces.

What none of us can yet do, is simply be of this canyon world, or of the desert, or the river. Our beings are too much in evolution for that. But I'm not sure that makes me unhappy. I savor the engagement, the hope, and mystery of a change as great as this, in which every aspect of our lives is being reassessed, and given birth again. What a time to be alive! And what a time to quest together.

What have these times meant to me? In the collective sense, everything. It gives me the rare chance to drink at two wellsprings of understanding. My own, stemming from Larry's and my journeys with you are at an end. I lie here on the pine needle-strewn sand looking up past three ponderosa spires to the domed and scaling granite giant across the stream. Wind flickers the alders, and sun glints and runs along the stream surface telling of a powerful current. Tomorrow we will gather our gear, swing our now-light pack frames onto our backs and head for the blue bus, and then we will go home to other streams of life and other styles, but I hope some of what we have seen and done will stay with each of us.

There's great love here, of the caring kind, and maybe if we know why it came to be, we can recreate it at various other places and times. It grew, I think, because we 25

found places and times to let ourselves unfold, each at our own pace, away from the tug and haul of modern life, and we came to trust one another. Trust, that's it. The key is trust. That, and tolerance for others paces, foibles, and needs. How else could we have been as silly as we have? Mostly the child in all of us lies boxed and hidden beneath social forms we cannot drop easily—the cost is too great. How else could we wander naked through camp, have all embrace each other in camaraderie, men and women alike, if it were not trust?

Released from each of us in this way is the chance to unfold, to reveal, and to learn. No sham has blocked awe, no sham has blocked the child's curiosity, and no sham has blocked our mutual and deep desire to know how we might fit into the vast interlocked warp and woof of that which clothes the earth.

It's easy to mock a person for asking a question as profound as this, and to us, in the alchemy of these times together, such discourse has become as natural as amber dawn's light on the mountain.

My experiences and mullings during wide wanderings and to be with you where I can draw from your fresh wonder and hopes and strengths and timidities and especially your new perspectives of the world as it is and will become under your hands, and those who follow.

We've shared so much. We've felt puny at the bases of awesome monoliths of granite, and yet we knew they too in mountain time would tumble and dissolve like sugar cubes in tea. We've listened with all [?]. We've run for the blue tarp together up on the Villa Creek meadow as the mist sifted down. We've viewed and even spoke to the most magnificent Dr. VanDenburgh I've ever encountered and then heard him sing. We've had fashion shows on the gravel banks of the Matolle, stomped the old bus almost to a pile of spare parts while Fran's family looked on in disbelief as we boarded following an ice cream binge. And we've shared our times and insights with some of the most talented marvelous colleagues a person could have—Dan Warrick, Stephanie Kaza, Jim, Roger, and now Craig.

To you all, Larry's and my fondest and deepest feelings of gratitude, camaraderie, hope, and love.

August 2-September 13, 1979—Kealake'akua Bay

August 2, 1979

Napoopoo, Hawaii

I came in to Hawaii two days ago, spent the night with the Coryells. Grand folks. Carol was there and about to go off to Whitman to college. She wants to be a vet, and is one of the nicest, most stable young ladies around. Roger took me all over Honolulu to look for video parts, and then out to lunch with Cissy Lucy, my fine Hawaiian friend, who has become an authority on ancient Hawaiian dance. Roger thinks she's about to pick up the fallen mantle of Kapiolani Iolani, the great dancer. Wouldn't be surprised. Cissy's obviously now a purist and has little patience with those who tinker with it. Rog took me to the airport, and I flew over here this morning to be met in our little Datsun pickup by Shannon and Melany. We shopped for various things and gradually wended our way to Napoopoo, where we found Bernd and Randy just in from a cruise around in a

rented Zodiac to try to net porpoises with Bernd's porpoise-catching device. "Net" is really a misnomer here. His gadget is a tail-grabber made of a motorcycle spring, a shovel handle, some tongs rubber and pins. [Drawing] It clamps on the porpoise tail, which then swims off with this heavy gadget weighing it down. Bernd says it doesn't seem to injure animals, and because it slows them so it makes them easy and quick to pick up.

It's pretty hot here—sticky—and Polynesian paralysis is setting in. I get sleepier and sleepier. Bernd and Randy have landed and we toured the Manini Point site—a beautiful place on the southern limb of the bay, a little inlet in the lava, a small grove of coconuts, and behind a dense thicket of huale koa and trees, which is the state land we seek to use. My crew has picked out a place for the collapsible house back by the road in—crushed lava and negotiable by most cars, I think. The tent platforms have been built closer to the sea under some trees, within a few yards of the water, probably illegal but certainly beautiful.

Shannon and Melany had told me about it, and they weren't wrong, a lovely place. Right now I'd guess the mosquitoes will come out of the huale koa in droves when the sun drops down. But, it'll be a nice camp, though pretty tight for all the people involved.

August 2, 1979

Napoopoo, Hawaii

We are staying temporarily in a house being rented out by Bob Leslie (he doesn't own it), right down near the beach park. It's a palace—baths and bedrooms and kitchens and places to launch and all. Seven hundred a month.

I'm trying to grab a hold of what is going on. Bernd and Randy are doing fine things, monitoring from the cliff, scars and marks, surveys along the coast, and so forth. But there are pieces we'll have to get at—the sounds, the social behavior, and all our gear is not yet assembled.

The videotape, by the way, does not yet work. It may have the wrong number of lines.

Anyway, after a fine meal of eggplant parmigan and lilikoi chiffon pie and stories, we are off to bed. Randy and Bernd try for porpoises tomorrow. We hope the Zodiac works. If so we will be able to obtain one from NMFS and Warren Stuntz. Off to bed, a bit sticky, no sheets, just a pillow and the air.

August 3, 1979

Napoopoo, Hawaii

More time spent trying to gather all the strings together. I climbed up the pali to the tracking site and had Melany show me how to use the Nikon theodolite. Chris Johnson also came along and stayed to tinker with the instrument after we left. The post is 250 ft. up the steep pali trail, that climbs up through the loose lava and grass, hale koa, and other trees at the N. end of the Napoopoo beach.

A metal suitcase is chained to a tree, unobtrusively tucked out of sight in the bushes. One extracts the tripod, levels it, then puts the instrument in place and does fine leveling, and then zeroes things on the tip of Captain Cook Monument. One can see essentially the entire bay and the accuracy is really quite exceptional. Bernd and Melany

have taken calibrations from the long dimension of the heiau, and back-sighted, and the error was bits of an inch. Commentary is taped as the instrument person talks out the sightings in terms of vertical and horizontal angles, time from a little Casio timer taped to the tripod. These little digital quartz crystal-operated devices can be used as elegant little stopwatches.

Then the behavioral person can talk into the same recorder and later the tapes transcribed. Nice. And Melany is so good at it all, after only six man years of doing it in Argentina.

Bernd and Randy are out trying the capture technique from a Zodiac, and came back at noon, without success. The animals don't seem to ride close enough to use the tail grab. I'm sure they will, though, at the right time of day, when the school is in the right mood.

It's muggy today, and now overcast. I've been calling various officials to get papers expedited, and calling home to get motors sent out, and to talk to Phylly.

Maybe a swim in a little while, to wash off the perspiration. A school of porpoises, of maybe 40 animals in the bay, patrolling back and forth as expected between the boat anchorage and the Monument.

August 4, 1979

Napoopoo, Hawaii

Bernd got up at 4:30, blessing, to run a track on the cliff with the theodolite. Randy, Jody, and I went off in the *Nai'a* to look for spinners up and down the coast, and to add to our store of documented sightings of marked animals. The day was calm with the dark-blue sea rolling and slick and the sky clear until late in the day when the clouds came down from Hualalai and Mauna Loa and covered the nearshore with dark gray and veils of rain.

The *Nai'a* is in quite good shape, though dirty from some sort of soot gathered during the trip over. She also had a portion of one dive step broken off but it will be glued and screwed back in place.

Down the coast we went, and our first porpoises were seen at Hookena, a small cove just before the coast becomes a steep lava flow dipping into the sea as it is clear to Milolii.

We found two marked animals there; one, Floppy, with the top of the fin folded to the left (about 3 in. folded over) and another unnamed one with a slash at the base of the trailing edge of the dorsal, in about 3 in. The latter animal was very shy and stayed with the school well away from the vessel while Floppy seemed always in evidence. There were perhaps 30 animals there, including several young.

Back up the coast we went and about one mile off Palemano Point we came upon seven *Mesoplodon densirostris*; there were two young, one very small, some middle-sized ones and one old animal that was maybe 15-16 ft. long. It had clusters of *Conchoderma* barnacles from its enlarged teeth, that trailed like pom poms as it swam. Its teeth were quite obscured. These rare beaked whales were quite scarred, had a distinct beak, and a rather lumpy melon. The color was a moderate gray, and not the fawn color I remember so well on *Hyperoodon*. As these animals swam they threw their beaks free of the water, and I was clearly able to see the arched margin of the lower jaw, and perhaps a slightly protruding tooth on one. I saw no blows. The animals were simple to approach,

and we were able to motor within about two meters of one or more. They evaded us slowly and once dove for a few minutes before rising again 50 meters away.

I did not get the impression of flight or any great fear of us. I never saw a fluke thrown, and their dorsal fins, as expected, were quite far back on their backs, and very small. I was also impressed with how variable they were in size and shape, as if dorsal fins didn't matter much. Maybe they don't. They dove again and we left.

After gassing at the new harbor at Honokahau we rounded Keahole Point and inspected the reef flats there for the Keahole school. We didn't find it. The afternoon waves had come in and big blue swells swept across the sand and coral, breaking in places. Finally, not too far south of Keahole we turned back. At Kealahou we landed in the rain, had a nice dinner and a drink, and then slipped off to respective places to write or read.

August 5, 1979

Napoopoo, Hawaii

Sunday, and off we went today to try to launch the *Maka Ala*, or the new viewing vehicle. First, we cornered Shannon, who had made up the name—the watchful one—to christen it with Primo, and due ceremony, and to have our pictures taken. Then we hauled it away to Keauhou with the little truck, which was all laden down with the lead ballast bars. Chris, Randy, and I went down in the *Nai'a*, and arrived before the truck. Then, followed one of those sagas that are so typical of field work. We couldn't get to the hoist in the Sunday traffic, had to jimmy a guy's window (who had left his locked truck in the no-parking zone by the hoist), and then once we got the hoist working, the hoisting line broke and fortunately didn't drop the craft very far or on anybody, but such good luck. Bernd was close to being hit, but escaped. We replaced the line with a piece of my old nylon whale line, and had more trouble getting the thing high enough to slide off the trailer and over the rail. But finally, with some windlasses we made it, and then the front port leaked pretty horrendously, and we had to take it out for repairs. That pretty much shot the day up to about 4 PM, and I had signed up to cook dinner so Mel and I went off to the store to buy various goodies like salad makings, and dill. I cooked some mampacha and taapi (looks like a little snapper) and made ice cream with cherry and peach sauce, salad with lime and olive oil dressing, and Mel made nice sticky rice.

The boat stayed offshore with a spinner school until dark and then came in. The school spread as advertised but seemed not to spin as much as I had suggested they do.

A little music and then off to notes and bed. I'm busy editing the *Big Creek Resource Survey* for the last time.

August 6, 1979

Napoopoo, Hawaii

A lot of phone calls today. I made arrangements to go to Honolulu to pick up Phylly and to see Earl Murchison at the Marine Base (where the Navy porpoise work is done), and then called our favorite bureaucrat, Roger Evans of Land and Natural Resources, and lo and behold, he damn near told me outright to set up our collapsible house. He said neither he nor the land board would be here in the foreseeable future and our permit was approved in substance, but the matter of procedure had yet to be completed. So, tomorrow we put up the house to keep people from taking pieces of it

while we wait. Then, we went shopping, buying lumber, water seal, and two dozen other things. Tomorrow we get the house up, I hope, providing nothing has been lifted. Bernd and I walked over to the site and met the Walsh's from whom we will obtain electricity and water, and the native guy who lives in the next cove over, and who, I'm pretty sure was making serious eyes toward our lumber. Jody swam with her porpoises for the first time today, and had some come within about six ft. It was fairly murky, though calm. I think she hoped for more, but to me it seems stellar.

Chris cooked a nice dinner and I built a ladder for tomorrow's work, and now it's note time, and time for a little reading and then sleep. Much talk about food finances comes from the gals, Shannon and Melany, in the next room figuring out shares.

Good day, all in all.

August 7, 1979

Napoopoo, Hawaii

Today we worked on putting the building up. It was beastly hot, and the site is back of the beach, behind a screen of head-high vegetation, haoli koa mostly, and still as a pocket, the black aa[?] radiates fiercely and the sun was unmerciful. We leveled the floor, got it in, put up the studs, and then took a break for a swim. Blessed cool water. Then back for copper plate installation and finally the roof trusses. The siding and roof sheeting remain for tomorrow. I achieved a pretty fair sunburn, but the others only got headaches or lethargy. But, it's going to be nice. I cleared some vegetation away to let in the sea breeze and it did come in a little. We'll have a nice place to store gear, park the car, launch our boat, and we'll be able to run water and electricity from the Walsh house just in back of us. Only things like bathrooms and showers are as yet primitive. We have a lua in the woods, but it's a pretty fair trek and full of bugs. I bought a shower head so we can get washed off, but we'll have to get it in soon. Then, too, the house will be small for all of us, and as yet, pretty open.

No porpoises in the bay today. We keep the scan constantly, which pleases me.

I'm pooped, but tomorrow we pick up Phylly at Honolulu, and I'll spend some time with Earl Murchison. Randy cooked a wonderful dinner of spags, bacon, eggs and garlic, good salad, and wine. *Hydrophorus* came in.

August 8, 1979

Honolulu

I flew to Honolulu in the morning, and visited Kaneohe and the porpoise work being done there—elegant—had dinner with Earl and Sally and then picked Phylly up at a bit after nine. She was surprised and delighted that I had come over.

August 9, 1979

Phylly and I went shopping this morning at Ala Moana and then boarded the Aloha plane for Kailua-Kona. Shannon picked us up. We shopped a bit, picked up a motor for Jody's inflatable boat, ate lunch, picked up mail, and headed for Napoopoo. Then, in the afternoon, I worked on the house with Bernd, Randy, Shannon, and Chris. We got two complete rolls of tar paper in place, and I cleared away enough brush in front of the house to let the breeze come in off of Kealakekua Bay. Never mind that one can

see the house a little as a result, and that is not what we are supposed to do, but it was just too stuffy for life back there and the view will be very slight.

Nice dinner, and then bed. My arm is all puffed up with heat rash and bothers me a great deal. I wonder if I will sleep tonight.

August 10, 1979

Napoopoo

No, not much. First we had a wild wordless party out in the park. People were drunk but they didn't seem to use words, they only yelped and yipped. It went on long enough to keep me from drifting off and by that time I was wide awake and itching. Then the rat got caught on the kitchen sink in a big rat trap and I watched him thrash his last, all buggy eyed as only a rat in extremis can be. So I read and slathered my arm with this and that, and finally drifted off. The crew worked on the house and nearly finished the roof and I don't know what else. I'm up in the hospital trying to get some proper goop to cure my arm and save my disposition.

Kim has a crush on Phylly and in one day only. Wow!

August 11, 1979

Napoopoo, Hawaii

My birthday. Just right having it out in the tules like this. But no little ceremony this! I spent the day shopping for hardware, wood, and heaven knows what else, and ate my cortisone pills which did marvelous things for me arm. The Doc, Jim Erickson, who knew me and my work, and in fact knew Chris[?] Varez from Sea Life Park, and had swum with the spinners there, told me it would take a couple of days for things to calm down. But I must say the first day's calming is a thing of joy. Blisters subsiding and arm depuffing, and sleep!! I seem to have to go through one such exercise ever time I come to a new tropical land. I swell up somewhere, take two weeks at it, and then my skin comes into equilibrium, and I begin to pick up energy.

I had the first of my meetings about the program—this one about sounds and sound analysis, upstairs in the solderatorium, which is the Wursig apartment (we put Kim upstairs so her occasional wails don't disturb the others). Bernd is doing wonders with our gear. We may be able to photograph from the TV screen after all, though my instrument camera won't do it, I'm afraid. We need a wider-angle lens.

Then came the party. A cake with rafts of candles (all Captain Cook had, and still not enough). I mark 55 today. Actually, it was a lilikoi chiffon pie, a taste sensation created from lilikois snitched, primarily by Bernd, who ascends trees like an aborigine, and who rummages in the brush for lilikois. Then we had lasagna, salad, bread, wine, and such. The Walsh axis (Lorraine too) came over. He's an ichthyologist, and she works in the local bookstore. And together they make lovely painted t-shirts with authentic fishes on them very nicely painted. His house is back of ours and we will get water and lights from him, hoping against hope that we will not blow out his fuses in the process. His house was wired for one light in 1908, I think. Nice folks. He told me about trumpet fishes probing their long snouts down in the bellies of moray eels, and at a certain point the moray no longer can bite, only gape, and the trumpet fish eats what's in the moray's stomach. Now, how did evolution arrive at something like that?? Anyway, nice time, good sleep and such.

August 12, 1970
Napoopoo, Hawaii

Oh Frabjous day, my arm is near normal and my disposition has returned to near-normal crochettiness. I held a meeting, but schedules and plans this morning that went on most of the time till noon. It was good and we settled a good many issues. I had a feeling we were on our way with various parts of the program beginning to jell. It's a complicated one, with a lot of diverse parts but its do-able, and we should learn a good deal.

In the afternoon we shopped for bits and pieces and then did a bit of carpentry, and picked up Jody who had spent the day at Hookena. Hookena, a cove about four miles down the coast seems like a zoo. Fights, stolen cars, people living in a cave, and in the midst some nice old Hawaiian types that are born there, and a lovely little bay backed by a lava cliff pierced by lava tubes. The porpoises come in fairly frequently and because the bay is small, it's a place where Jody can expect to contact the animals easily. She wants to live in the cave, and I guess it's her business, but I'm worried about the peculiar fauna of the place. I wouldn't be able to cut it though maybe she could sweet-talk people into it. If she takes a man down, as she plans, she is taking him into a violent situation in which he is apt to be challenged, even if she isn't, which I told her.

Good work on the house this afternoon. The darkroom is partly up, the dining table is nearly up, and other stuff was done.

August 13, 1979
Napoopoo, Hawaii

Shopping this morning with Jody for wood, various small things, food and so forth. Then in the afternoon Phylly and I, Bernd and Melany (and Kim) went to the house and worked. We got a lot done in spite of not having enough tools. The darkroom is up, the sink is up, the electronic bench is in, the shower duckboards are in, the shutters are all hooked together, and I started on the wires for the curtains that will block off the sleeping area. Nice Hawaiian dinner. Tomorrow we go out to Keahole Point for sound work, and for identification of porpoises by photography. We'll try to catch a typical resting school up there, and maybe a feeding group, or one on its way to the feeding grounds. We'll see. Phylly, Shannon, Randy, and I will go.

August 14, 1979
Honokohau Harbor, near Keahole Pt., Hawaii

At dawn Phylly woke me, and we were soon rummaging around for breakfast and piling our gear down by the landing. Bernd came out with us to clue us in to the mysteries of the Lockheed tape recorder and our set-up. Phylly, Shannon, Randy, and I will try for the first recordings of our trip up near Keahole, and at the same time attempt to typify the animals there by photography. We will be able to listen through a cassette recorder and record at 15 ips (about 60 kHz top level) with a Navy hydrophone rig good to about 80 kHz.

We loaded a little food on board, soldered some connections (Bernd did) and then headed out at about 8:00 AM.

Some small schools of spinners were located below Keauhou, and S. of the Kona Hilton.

We rounded Keahole and found a quite large school of spinners in the little bay just N. of Keahole Pt. It was very quiet and little was heard from it save a few squeaks and quiet click trains. We were able to make some nice tapes with modest water noise, and vocal commentary on one channel, on which I described animal position and behavior, while the other carried the taped animal sounds. Phylly, who had been feeling a bit off when we bobbed at the mooring at Kealakekua, was feeling better, and taking in a little sun. I decided we should go back for gas at Honokohau—so we did, being filled from a small tanker at the clock (water also available). Right by the green channel buoy outside the harbor entrance we came upon a 15-animal school (including fore-nip) that was spending nearly all its time down. We made another recording, also largely quiet, and headed north around the point. The day was hot and sunny with a cloud bank capping hualalai and only shading the land. There was little wind and only a modest swell rolled in from the Alemuihaha channel. A trip north to Kona Village produced no more schools. On our way back we circled offshore of Keahole Pt., and made a circuit around the Mini OTEC (Ocean Thermo[?] Energy Conversion) a mile or so offshore—an experimental barge testing the use of cool water from below the clines to boil the surface water under a vacuum. Hank [?] of Mokai Range, I am told, had a part in its design. It works. Whether a larger model would be cost effective is the major consideration, I'd guess. At any rate, it sits on a double-[?] barge, about 120 ft. long, all colored pipes and at the stern bobs a tine-capped pipe down to thermocline 600 ft. below and through into cool water. I can't understand exactly where what goes but two pipes emerge onto shore at Keahole Pt. and there seems to be minimal shore activity.

Back at Honokohan we tied up at the fuel dock and decided about dinner. It ended up hash and sausage and tea and lemonade and crackers and peanut butter. Not long after this repast was complete and we were beginning to think about bed, who should come down the dock but Nell, Bernd, Chris, and Jody, with ice cream, Phylly's pillow, rum, coke, lemons, and heaven knows what else besides. So there, tied to the fuel dock in funky little Honokohau, we partied it up in the gathering darkness to nobody's dismay that I detected.

Bernd, who turns in early, finally called a halt and they trundled off in our little blue truck, and we turned in—Phylly and I in the bow and Randy and Shannon on the stern. In spite of an open hatch right over me and Phyl, I never did retreat beneath the covers.

August 15, 1979
Napoopoo, Hawaii

Phylly tapped me at dawn and after a little coffee and cereal we left the harbor and made our way in calm seas around Keahole Pt. In the cove just north of the point, we encountered a big school (70+ animals) coming on down the coast, traveling resolutely. To me it was obvious that the animals were on their way to a resting spot and still traveling inward. They moved quickly, mostly at the surface, and there was some aerial behavior that Shannon documented. We stopped the boat ahead of them and made a nice tape of them approaching us and passing the ship. They were remarkably silent just as

resting animals are. They traveled very close to shore, a matter of a dozen meters in some cases.

Then, obviously, we were bugging them as they failed to settle down and then turned and began to go north with increasing activity level. We finally reached extensive flats at Makolea-Makalawara; the animals spaced out over the 20-25-ft. deep water slowed and let us travel right with them for more than half an hour. What a lovely place and how magnificent were the porpoises there! The reef flats bow out from shore 500 m or more and then drop abruptly into azure water of the deepening slope. On the flat is turquoise water over white coral sand, but here and there rocks and living coral turn the bottom dark and blotchy. In the glassy, clear water our porpoises hung suspended and their body pattern shone brown, pinkish, and white. Interestingly, over this rather shallow flat the animals spread and slowed. They did not bunch as Kealakekua animals usually do, but swam separated by 3-4 meters from the next nearest animal. They flickered as they dove down over the sand and one could discern their fragmented shapes now in the wavy light as they raced along near the bottom. Randy photographed and photographed, taking 13 rolls I think, of fins and backs for identification. I piloted and was able to maneuver in close for good photos.

We watched them meet, but not join a school coming down from the north. Randy watched it closely and reported that the two groups of animals maneuvered around each other and did not seem to coalesce at once.

We left these, encountered another school northward toward Pau Alu, a paired cinder cone before Kona Village is reached.

On we went, but saw no more porpoises to the north. At broad, shallow Koholo Bay no animals were seen, as has been the case in the past. The porpoises stay well over toward Keahole where access to deep water is at hand (I think) and where nice shallows can be found.

We turned out to sea, but encountered only wedge-tailed shearwaters and slicks.

Gassing at Honokohau (\$140 worth for the trip), we continued S. and reached Kealakekua at dusk.

A nice welcome, a nice meal, a swim, notes, and home.

August 16, 1979

Napoopoo, Hawaii

Look, look, a new typewriter ribbon courtesy Oshima's Drugs (one can build a complete battleship with parts on stock in that store). I also bought two colors of paint—all they had. Ballet Blue and Nugget Yellow. One for the electronics bench and one for the kitchen sink. The main problem is splinters and the paint will help the poor ole wood that is drying out so much. After a morning of letter writing to various people, I totted up bills and went over to the house to do work. I painted and built shelves. The porps came in, and the folks up on the cliff had a good time tracking. Tomorrow, Phylly and I go off on a little trip around the island, to visit Hilo and the volcano and then back. Phylly goes home on Tuesday. Shannon's friend, Dave, a bacteriologist, or is he an algologist, comes in tonight. Bernd drove down with her to the airport because Winifred the Datsun pickup is acting in need of new points and distributor cap. But running. Our tapes from the trip seem OK, though we did have a mistake on how the tape was put on the machine and

there was bit of cross talk from my voice channel to the data channel. Bernd quickly saw how to fix it by adjusting the roller. He's amazing. Everything works in his hands.

August 17, 1979

Hilo, Hawaii

Phylly and I set out to circumnavigate Hawaii for a couple of days before she has to go back. I decided to take the time off since these chances don't happen very often and we hadn't really been out together since last summer. Bernd planned to drive us to the rent-a-car place in Kailua, but Winifred (the Datsun) was feeling out of sorts and we only made it to Kealahou when she refused altogether. New points, condensers, plugs—nothing satisfied her and there she sat looking cross, her mag wheels all muddy, and her wide-track tires pooching out. Finally, I called a cab and we left Bernd in a light drizzle looking quizzical, the hood up. At Kailua we transferred to a Mazda—a nice little peppy car with good gas mileage, but some one's cat had decorated the interior somewhere. It wasn't till Hilo that we counteracted it adequately, first with a lavender gizmo that made a noxious effluvia called Eau de Cat and Lavender. Sears provided us with a pine-scented little vial that I hooked under the dash. That helped.

We headed up Kamuela way, crossing the lava flows of the saddle, passing the PuuWaaWaa ranch at mid point, and then down onto the long, sloping plains of Kamuela. We stopped at the Parker Ranch museum, and enjoyed it thoroughly. It told the tale of an early Yankee coming to Hawaii, marrying a Hawaiian gal, becoming friends with Kamehameha I, obtaining land, and then starting the dynasty that goes to the present, and Richard Smart, the present lineal owner at 60-some. They invented a way of life, the paniolos, the various attempts at diversifying—each time they came back to cattle on the vast land that finally stretched across the island—325,000 acres now. We saw some of the best on Kohala—a relentlessly green land, of grass overwhelming the lava beneath, eucalyptus windrows that divide pastures, Herefords grazing with their simple mechanical gazes, not asking for more. Even the bulls have a plasticized look, as if aggression from them would hardly be pure, and maybe stop in mid expression.

We traveled down the slope of Kohala-Mauna Kea to Honokaa, where we visited the macadamia nut factory, amid cute signs telling us things were nutty and we were getting closer. There a glass-walled sorting plant let us look at girls doing awfully boring tasks (sorting out dark pieces of nuts) and being given high-flown titles (assistant cook) after 14 years apprenticeship. The owner's lady, a comely Italian lady, was pictured using macadamia nuts for everything. They were immolated in various jams, looking out of place, there were bars of chocolate with a single nut embedded, there was soup. We liked the brittle, an honest use of a very fine, tasty nut.

On down the coast we purred, or hummed, as Mazdas are supposed to do. It did. Nice car, except for the cat, which we can hardly blame on the maker. Fields of cane cascade down the slopes to the sea, and I guess the windward coast keeps the clouds coming and the rain sifting down. We stopped at Akaka Falls, a 400-ft. clear drop of brownish volcano slope water, pounding into a pool below, where the mist rises so continuously that nothing at all grows for dozens of yards from the place where the water hits. Not far to the south we topped a rise and could see Hilo Bay.

The walk at Akaka Falls was notable mostly for the array of moisture-loving tropical plants through which we walked. Banked ginger made the air sweet.

Phyllodendrons, ferns and vines were everywhere amidst the trees. Down below a stream glistened over brownish rocks and I wondered if any fish could be this high, above the various low falls, or shrimp, and I saw nothing amidst the bamboo-shaded pools.

It was especially pleasant being with Phylly, who is so filled with pleasure at these chances to walk in the tropical places where her plants grow in such profusion. I was fascinated, here, and elsewhere by the array of reproductive means shown in the flower types we examined . . . from the strange, glutinous conjoined anthers of some primitive flowers, making me wonder if the sperm swim free in some of them, as they do in ginkgo trees.

We stayed at a Travelodge on the hotel strip, went to dinner, a hula show, just like good tourists, except we knew the Hawaiian words to “Pearly Shells”.

August 18, 1979

Napoopoo

After bits of shopping we headed up the Volcano road, visited a lovely Hawaiian 20-acre garden (Nani Mau) filled with a bewildering array of wonderful tropical plants. They seemed to have burst into bloom for us. There was an *Anthurium* forest, with hundreds of these plants in sawdust on the forest floor, acres of orchids, a fine arboretum, and more. They fed us exotic fruit—a *Eugenia* relative in which one eats the flower, and which one of the gardeners said was better as a pickle, then something like a cherimoya, and some sweet pineapple

It was interesting to see how Kilauea had changed. One had to hike a long way to Halemaumau, but the white-tailed tropic birds were there circling in the fumes and steam. We drove down the Chain of Craters road, took off to the side, going through gnarled ohia forest to a kipuka (nene) and down to the escarpment to the Ka’u desert coast.

We went around the southwest tip of Mauna Loa, up into dense ohia rainforest, past lots of nice grassy ranches to the kona area where coffee took over—growing on bare lava slopes, apparently a continuous crop.

Because we hadn’t wanted to drop in, in the midst of a prepared meal, we stopped at the old Manago Hotel (established 1928) and had a marvelous \$4.50 meal of ono, rice, Japanese cabbage, and vegetables, tea, etc. It’s a wonderful funky old place. Then home again, to the place where our compadres had finished a session with some TV people who sounded nearly incompetent to me. It was a fine two days with Phylly, and we both enjoyed it.

August 19, 1979

Napoopoo, Hawaii

Jody did a swim with the porpoises in Kealakekua Bay today and seemed to have been drawing them in. Bernd was impressed with her success yesterday, and she did it again today. I answered letters and tried to take care of problems long distance, and then worked on the house, painting blackboards, installing sinks, drains, projection screens, front porches, tables, and a lot more. Shannon worked on screens, and then she, Randy, and Mel worked on the porch. It’s up now, and is a nice open place to sit in the afternoon, though a little hot right now. I also dug lava out of the road at a place where we had to take evasive action before.

I was a bit grumpy from a belly ache until late in the afternoon when I began to feel better. Nice spag meal by Randy.

Napoopoo, Hawaii

Good day today. The morning was spent fixing the house—setting the darkroom sink, putting in drains, showers, painting the porch. Then in the afternoon, Randy, Bernd, Shannon, and I went out to record the exodus of a spinner school out of the bay. We chronicled zig-zag swimming, and then followed animals offshore, making a series of recordings on the way. It was a large school, maybe 70 animals, and when it reached a mile or so outside the bay it literally split up and went in spread formation both north and south. We finally lost it, and then picked up a spotter school from the very high (in excess of 20 ft.) leaps without spins, falling back on flanks. Bernd, Randy, and Shannon had never seen a spotter before so it was a good time. The school was very large, and very spread over a wide area of sea, and I cannot really estimate numbers very well. It was huge—maybe hundreds of animals though we never saw that many. We followed them down to beyond Honaunau, and at times they approached within 100 m of shore. It was getting dusk by this time. Do spotters come ashore at night?

If so it is the reverse of the spinner, who rests ashore during the day. I would like to track some of them to see, and will likely apply for an exception to test it. We could catch them from the *Nai'a*.

Today is Phylly's last day. She and Mel had a good time at Honaunau, looking at plants and talking to rangers. I'll go to the airport with her very early tomorrow morning, and then a month later go home myself. It's been grand having her here.

August 21, 1979

Napoopoo

Mostly housework today after taking Phylly to the airport early. She seemed so happy and pleased to have been here. I loved it. She's *such* a wonderful gal. How lucky I am!

Afterward, Jody and I drove north to look at Makalauena beach as a place for her work. We walked 1½ miles on a nice road across the Paholhoe, but the second locked gate stopped us. Later we learned that it is Bishop Estates land and we hope for permission. The reef flat offshore houses Kona's largest porpoise population, has clear coral sand beaches, palms, and [?] and maybe water. There's a house there.

In the afternoon I worked on the house, putting in shelves and running the water line through the haole koa amidst myriads of big garden spider webs. It didn't reach by 150 ft. or thereabouts. Then, we are getting ready for tomorrow's flight—we have to be in Hilo at 8 AM. God help us. To sleep!

August 22, 1979

Napoopoo, Hawaii

Flight day, and a long one too. We were up at about 4:30. I never did know really, had a cup of coffee and a bowl of cereal, stumbled out to Winifred, waiting patiently in the port cochere (or however one spells that!), and off around the south end of the island. It was a nice drive with much discussion of this and that. We pulled into the Hilo airport about ten minutes past 8:00, and our pilot, Sam Jones, was there, as was the Cessna 172

we would fly. After a bite of breakfast we boarded and took off to the south. Sam is a burly contractor who flies for the Civil Air Patrol and who is volunteering his services to us, with just plane rental being paid. Nice guy who seems a good pilot, though I expect not deeply experienced at his craft. At least he hasn't had to ditch yet, and that's good. No hot dog, he, but just a guy trying to be careful and conscientious. He understands the gobbledegook they put out from the towers, and that speaks well.

Anyway, off we went to the south, along the Kumukahi coast, around Kalapana, below Kilauea, to Ka Lae. I saw a tight school below the surface at Kalae, but we never could find them again. The wind had picked up from a dead calm to a whitecap-dotted sea with foam trails by the time we rounded the point. It soon became calm again as we went up the Mauna Loa shore, passing Milolii, where there is quite a little village, with what look like house lots north of town and a decent paved road in down the face of the lava flow. Here and there up this coast are little coves with sand, a few palms and kaiwes, lots of old stone walls, house foundations, and so forth. The glassy sea failed to yield up anything until we reached Hookene however. There we saw a few spinners and one big manta ray.

Up at Kealakekua we found our school back against the bluff, Mel and Chris up on the tracking station. We talked by VHF, and Mel came in loud and clear, but apparently Bernd was less clean because of airplane motor noise, but he could be understood, and maybe with an adjustment about how he talks it could be good. As we circled, Randy said: "Let's take another look at the Temporary shelter and the tent sites." When we did so it became apparent that the tent platforms were gone. Cockaroached. That was about 500 dollars worth of wood. Then I noticed a pile of plywood and timbers back of the Iolani Waihi house, which looked suspiciously like our stuff. We flew over again, and the others were in agreement. No, our work was cut out for us. Off we flew, seeing *Tursiops* at Keahole, headed for Keahole, and just as we were in our landing pattern (for gas and lunch) Bernd called out "Porpoise" from the cove just north of Keahole. But we landed, had a sandwich, and then looked at the animals from the air—a group of spinners in very close to shore. Right where they're supposed to be. On up the coast we looked at Jody's chosen site at Makalawena. There's quite a camp there; for tour busses that come in a couple of times a day, and the old house is to the north under the Kiawes and palms. Jody found out that it was once occupied by an old guy who kept goats, and that the goats come down there still.

As in previous tries, not a porpoise did we see to the north along the whole lovely bight—Koholo, Mauna Kea, Kawaihai, until we passed Mahukona. There we could see the house walls of the old settlement, all cleaned and explained for the tourist. Just south of Opolu airstrip we came upon two groups of *Tursiops* lolling along.

On around and into the Alenuihaha we went, being buffeted by the turbulent winds that sluice around the tip of the island. Soon we were traveling along the Kohala coast, which is a lovely escarpment, plumed with long waterfalls and cascades, most falling into receiving pools not far above the tideline. It is very much like the north coast of Molokai really, with the long, deep, flat-bottomed valleys, all lush and green winding back into the clouddeck that caps the Kohalas. In some, wide streams wound to the sea.

No porpoises, though, either there or along the Hamakua Coast. I was having trouble with attention then, and found myself drifting off for a few seconds at a time, to catch myself, screw up my resolve, and then slip again.

Nothing in Hilo Bay, and we landed, did a bit of shopping, headed up the coast to Waimea and around to Kailua and home after dark. A long, long day.

Then, we skulked over to look at the plywood situation, and indeed it was gone, slick as a whistle.

August 23, 1979

Napoopoo, Hawaii

Well, with fear and trepidation, Randy, Bernd, and I, first thing after breakfast (our last) advanced on the old dancer's house to confront the plywood cockroachers.

Instead of some big Samoan, we were met at the front door by Mrs. Prim, a smiling, 70-year-old Hawaiian lady with scant few teeth. "Aloha," she said, greeting our intrusion into her front yard. Later she explained one could call her Mrs. Primo by adding an "O," but she didn't drink.

She called her daughter, Fern, over from the opposite house to join the conflagration, whose origins and aims she didn't know, and didn't press. We made light conversation. I let them know about my time in Hawaii, and that I had seen and admired Iolani (Iolani is Mrs. Prim's sister). Like her mother, Fern had a nice, open face. I then launched into our project, explaining what we were doing, and then around to July, the rains, and the tent platforms. On and on we went, until we had to leave them because of the state and Roger Evans, the bureaucrat, and that we were going to have to go back, to them again. "Oh, you wanna know about the plywood," said Mrs. Fern cheerily. We got it out back. Some guy down at Honaunau told us it was left by some hippies from the Bishop Estate. Mrs. Prim pipes up—"It's all out back except for the three sheets I got uppa my bedroom." "Mrs. Prim," I interjected, "I give you those in honor of your sister whom I so admired." More conversation, not refusal, not agreement, but the ownership changed from them to us, somewhere in there.

About that time, down the steps comes Jerry, a giant Hawaiian marine on leave, six ft. three of chisled bronze in a crew cut. He joins the conversation at the listening end, volunteering very little. I'd of had trouble with him if he'd been the first out the door.

We leave, inviting them over and proclaiming that if our plywood has to be cockaroached we'd rather have them do it than anybody. We will invite them over for the dedication, and I don't really mind them taking the stuff very much (except it cost us \$500, and we could scarcely afford letting it go). It was out lying in a clearing for a month, and the competition between cockroachers gets fairly tense—who's to get it first, so you gotta move quickly—ownership becomes subordinate to competition. Anyway, we got it back. I'll leave it there for a day or so, and then retrieve it. By the way, both Fern and Mrs. Prim were Prison matrons, or police matrons, which they laughed about.

Then, we'd been turned down for a gas allocation on the grounds that we weren't old customers. The station told us to get turned down again by someone else and then make our case to the head office in Honolulu. In view of the fact that it took a month to get turned down the first time, I said, "To heck with that." I called Honolulu, wondering if I'd meet another vintage bureaucrat like our Roger Evans, but no, Al Harris was a comfortable old shoe, even if head of the state's energy allocation program. He said even if DOE was incredibly fouled up, miraculously they did handle for FEI 15, or whatever it was, rapidly, which would put us on the list, and in the meantime, he could make emergency allocations month by month for us. Furthermore, he'd send us the forms right

away, and we could return them directly to him. Now, that's service. Crowing over two victories, I launched into more amorphous crusades, like getting the final water pipe for the house, the wire to hook up to Bill Walsh's ancient electrical circuitry (his plumbing is equally ancient . . . there's one valve in the entire thing—at the main shutoff). I bought Jody a nice floating dive flat, got aluminum wire for half price, made a very reluctant salesman roll me out 140 ft of water pipe (saran black, ¾"), and then home to cook dinner of omelettes for all hands. I took the stuff over to the house and tried to figure out how we could run the electrical wire unobtrusively. Not easy. Tomorrow we retrieve wood, try to catch porpoises, and put in the water system, and maybe the electrical system. I'll build the screen around the shower. Then, we'll be pretty close to ready for a move. Oh yes, I also found us a refrigerator for \$100 bucks that should do us—a far cry from the rinkydink little one for \$395 just because it was propane, over in Hilo. Bernd solved that one by upping the electrical load we will take from Bill's circuit, hoping the entire thing doesn't collapse in a cloud of pulpy wood, cockroach wings and termite scat.

August 24, 1979
Napoopoo, Hawaii

I worked on the house today, running water lines and power lines through the haole koa to Bill and Laraine's house. It was sweaty, spiky work, hauling the line up in the trees, and braving the spines that are *all over* the kiawe trees, trunks, and all. Getting up and down one of them is an experience. But, we got water to run through the pipe, and electricity is yet to come pouring out of the line, but we do have a fine telephone pole, and the wire ends reach in both directions.

August 25, 1979
Napoopoo, Hawaii

In the morning I made a trip to town for various bits of pipe. I want to finish the water system, get it hooked to showers and the like, and I almost made it except for a few miscalculations. With the system we will have hot and cold water. Bernd, meanwhile, worked on the electricity and came close to finishing that, too.

Gordon Leslie came in, all full of swagger and accusations about the evil things we had done. Our house was too grand—seemed the major problem. It, of course, is exactly as advertised. Actually, he was feeling ignored, I think, and was probably also probably on the take. I'll resist that. He also asked if we might be interested in writing a little piece for a newspaper that his association puts out. Sure, I said. I think he thought I'd refuse. He picked especially on our water and power supply and may make a fuss, which will make things a lot more difficult for us. We'll see. I'm perfectly prepared to collect all effluent in barrels and dump them in the dump, and run a generator, however inconvenient it might be.

Damn nuisance, especially when we are trying so hard to get our work done, and want no trouble from anybody. He seems also to be spreading the rumor that we might be chasing the porpoises out of the bay, which is not at all true.

But, in matters such as this, egos are important and truth isn't. So, we must assuage the ego if we can, without losing our own footing. We did join his Community Association for 10 bucks.

Anyway, Bill and Larraine came over for dinner, and have just gone home.

August 26, 1979
Napoopoo, Hawaii

At about 8 AM we headed for the *Nai'a*, Randy, Chris, Shannon, Dave, and I, and spent the morning making recordings of a large school (50-60 animals) of spinners in deep rest. At times the animals reacted to the boat, even though we might be 300 m away, by edging for deep water. Rather seldom did they come very close to us as we recorded, though once in a while they appeared within a dozen meters or so. Shannon kept aerial behavior, I made comments on the comment channel, Dave deployed hydrophones, Randy drove, and Chris looked for marked individuals. The animals were very quiet, both in terms of aerial behavior and sounds. Chris said there were whistles, but I only heard breezy click bursts and occasional chirps. Mostly it was snapping shrimp and outboard motors.

We had lunch, turned back to the mooring, and went ashore. A calm, lovely day it was, and we did obtain some good recordings. Dave was able to cook his lily-white body while telling me his interesting work with a parasitic bacterium that lives on an alga. All scanning EM and nutritional work. Very interesting stuff, and I like him a lot. He's bright, balanced, and broad in viewpoint.

Back on shore I set to the business of adjudicating with Gordon (if I can). I prepared a little piece on our project for his consideration in *The Native Hawaiian*, a tabloid about native Hawaiian affairs. He's ticked off at us and though he isn't even an elected officer of the Napoopoo Association, he has the title by default and as such can dream up endless things to plague us. I hope we'll soon be boring to him, and he may turn to other novelties to occupy his paranoid and befogged mind. He thinks he wants us to look tropical by putting palm fronds on the roof—we'd be the only house in Napoopoo thus decorated . . . but I said, "Great, it'll make it cooler for us." I worry only that people may sidle up and order maitais from our front porch, thus disturbing our work. He's a case—dark, very Hawaiian, full of internal evasions about others lying, while he, himself, is uttering the blatant falsehoods to us, which are utterly transparent. We know, but I truly doubt that he knows—his evasions are so deep that he mustn't admit to himself his status or he'd lose everything. He hates his Uncle, Bob Leslie. They had a fight at a luau, and because we rent from Bob we are unacceptable. He hasn't succeeded at anything. He can't even get us to kick back to him. He owes everywhere, but his parents take him in at the age of 31-34, and hope for the best. He has "secretaries" in his grandmother's house, when in fact he was told to leave those precincts. He has a restaurant at the dock, when in fact the planning commission has refused permission. He has school groups he is training when in fact they are illusory. Dear dear, and to be his pet. I'd rather not. I've made my obeisance and will make no more. It's better to let him turn to other things. That's life in Napoopoo. Sounds like Kaunakakai, where we had to find local entre to work at Alii Pond. Tonight, Manago Hotel for dinner.

Ooh, good opelu and rice, with pineapple shake afterwards at Sandy's and then a slide show of dorsal fins by Chris, Very nice.

August 27, 1979
Napoopoo, Hawaii

Gordon's at it again and bitching to the Walsh's about our water and electricity. Bill thought we ought to see Ms. Kakakau, who is a relative of Gordon's and secretary of the association, so Bernd and I did. She lives in a lovely, glassy house full of koa wood. She was reasonable and pleasant and spoke of the energy of her young people and how her job was to keep them on an even keel. We showed her our plans and left much calmed because somebody of her intelligence and probity was on the Community Association.

Other than that saga, still no final permission from the state over occupying the conservation district. I put in water pipes and worked on showers and the like. It's nearly done.

Jody swam with porpoises today and is getting closer and closer. Mel was her tender. They work very well together.

August 28, 1979

Napoopoo, Hawaii

Gordon ruined my sleep last night. Apparently, he's angry because, in part, in my book *The Porpoise Watcher*, I mention historical records of Capt. Cook being cooked and some eaten, and the long bones returned to his shipmates for burial. I think I took that out of a history of Capt. Cook, though Dawes only mentions dismemberment and burning of the flesh. At least I'm suspicious this is part of the problem of continued harassment and attempts to find anything to pick on. More, though, I think it is a simple Anti haole paranoid personality given a little power. He's angry that the County didn't give him copies of our submission and approval, and I can understand that—though he is so troublesome. I understand they don't want to deal with him. We may lose our power supply but I'd guess the water is OK.

Gordon had his picture in a native Hawaiian paper and he hands out copies like business cards. Well, I think we'll weather it OK, but it is annoying and he can cause us trouble.

We recorded today in Kealakekua with Jody in the water with a very quiescent school. We could hear her call clearly enough in air, in water, I don't know. Our audio feedback amplifier is weak.

Then Bernd and I went up the hill and found that our refrigerator seems OK—it shocked Bernd as he opened it in the rain—the plug was wet. But now it's OK and we loaded it up for \$100 and headed home. I set up Makalawea for Jody through Roger who knows Dick Lyman, the head of the Bishop Estate Board of Directors. She's ecstatic. My, my but life is complicated.

Jody's animals were remarkably quiescent some of the time. She and Mel followed them clear out around Keawekaheka Pt. Their behavior changed dramatically, as I expected, and they began to bow ride and place[?]. Torn-hip came in and rode and other marked animals did too. Pretty clearly there is age segregation in schools, beyond juveniles and young. There seems a preponderance of marked animals that swim together and that have tall fins and big bodies. They may have had time to become scarred.

August 29, 1979

Napoopoo, Hawaii

Bernd and I were up at dawn (before), had a bit of breakfast, and made our way through grass, garden spiders, and haole koa up the steep ridge to the theodolite station. Bernd set up the gear, leveled and zeroed the instrument, and we were ready. We didn't have long to wait. About 50 animals came quietly in from the north around Cook Point. They were soon deep in the bay. The yacht fleet began to wake up, Francoise on a ketch emerged (I was looking elsewhere) in the altogether and another regular too. Then another school of perhaps 20 animals came in across Paluau Pt., making directly for the school already in the bay. My impression was of somewhat increased aerial behavior on both sides until merger, but I can't be sure. At any rate they approached directly and when 100 m apart the moving school partly veered away but then kept on and merged.

I stayed on post for three hours, went down to make phone calls, and then drove in town with Shannon and Dave.

We bought (I bought) a propane stove for the field shelter—in a second-hand store for \$90. It has burners and oven and broiler and works. Will get it hooked up.

Then I searched out a minister for our spiritual dedication of Hana Naia (our project name, which means porpoise work). First, I went into the old Kona Congregationist church in search of Rev. Boshard. Instead I found his tight-jawed secretary, who wanted to know why I had parked in the church parking lot. I explained. Kahu (Boshard), she said, was in Honolulu but could talk to me when he got back. I mentioned I'd been given Leon Sterling's name.

She allowed as how he did a lot of such blessings, but wasn't ordained. I didn't mind. She said I could call him. Apparently he works for a competing church (a sort of stringer, I guess). Anyway, I called him and he agreed.

Napoopoo, he said, was a heavy area, the cliffs, the heiau, etc. He knew instantly that I was a haole and he knew I wanted peace with the Hawaiian community. I told him our animals were special, too. Anyway, he'll do it. I'm setting things up with Roger Coryell. He'll fly over, maybe with Cece and Lehua. I invited Jim Simmonds, our mechanic. I'll invite others here. So, those wheels are turning.

We cleaned the stove a little, set it in place, put on the last pipe fitting—spag dinner a la Jody and now notes and a John O'Hara novel. It's hot!

August 30, 1979

Napoopoo, Hawaii

Today we launched the *Maka Ala*, up at Keahou. Randy, Chris, Aaron (from Bill and Laraine's) and I drove the *Nai'a* up—a nice flat-calm day while Bernd drove the *Maka Ala* up with most of the ballast in Dave Coder's VW, so poor ole Winifred wouldn't have to strain. At any rate we all arrived together and this time backed the trailer in and attempted to float the ungainly ole *Maka Ala* off. We had Winifred's tires in the water and still she wouldn't come off. Finally, we had to do it by hand and off she came, all imbalanced and tippy. We loaded her with lead bars and only once did she seriously threaten to turn turtle. We didn't have enough ballast—she needs perhaps 400 lbs. more. Then the windows leaked about as ferociously as before. Oh woe, woe!!

I hoped the water would swell the wood and seal it, but an hour or so's watching didn't bear out that idea.

Bernd suggested underwater epoxy, and soon enough was off to buy some. I went to buy supplies for our Milolii tomorrow, and Randy took off for gas in the *Nai'a*—I saw him planning straight as a die across Kailua Bay.

Bernd's putty largely worked when gooped over some exposed screw heads. It collects only an inch in the window overnight now. It was quite a grampus-ish job putting it on—taking a big breath, submerging, and then surfacing for a blow.

Chris and I decided to drive the *Maka Ala* back. It took three hours or so; she's slow with a 20-horse engine, and cranky. It was a wrassling match keeping her going straight. It was dark before we came in and 9 PM before we had her boomed away from the moored *Nai'a*. Cold spags and a lilikoi pudding on the beach and then to sleep.

August 31, 1979

Napoopoo, Hawaii

At about 8 AM everyone was aboard the *Nai'a* and we headed off S. toward Milolii. It was a nice calm flat day. Bernd and Mel, Jody and I were crew. Our hope was to find and photograph spinners at or near S. point (Ka lae) where they have been reported. A group of seven spinners came in just as we were leaving, including a fairly young animal and some adults. Two were marked—one by a nick at the base of the trailing edge of the dorsal and one with a rounded nick in the middle of the dorsal. Bernd photographed them.

We saw nothing until south of Kookena at Lepeamoa Rock, when both Bernd and Jody saw a single animal a few hundred meters offshore. It was wary and we could not relocate it. A single animal, so un-cetacean like.

The sea was vacant and calm as we cruised along the steep slope of Mauna Loa. Rivers of aa[?] streak the slope up into the clouds where lava cascades have poured down out of fissures and vents high on the mountain and cascaded to the sea, leaving their trace of rock.

I slept and finally at Milolii we decided to see if gas could be bought.

But first we went to Kamoi Point looking for spinners. It became rougher and rougher as the trades whipped over Ka lae and finally we turned back. Just then, a big brown-backed shark was seen over against the lava bluff, sailing along. We couldn't see its head but its fin was rather high. I fully mistook it for a marlin [drawing].

It was on the order of eight ft. long, and I'd guess a bit awesome to Jody.

At Milolii, Mel and I went ashore. There's a dock and a couple of buoys for 25-ft. craft. Children were leaping off it, about eight ft. , into the turquoise water, including a little girl, flaxen-haired, who looked no more than five. She was eight, her mom told us. Milolii is a grand, funky little place—palms, kiawes, lava-rubble streets (except the main paved thoroughfare), a tiny steepled wooden curch, a general store that only opens when you ask the lady swinging in a hammock in the house next door. We found one could buy gas from an old hand-operated pump, providing you have gas cans.

At Lepeamoa Rock the lone animal was sighted again. It's very deep there, 600 fathoms or more in places. The animal surfaced in a line four times, disappeared, and was seen again and disappeared for good. It seemed *Phocoena*-like and may have been a *Kogia*—small, fairly high fin, elusive, alone, in deep water, small . . .

Nothing more, We anchored and cooked a good meal and sent Jody ashore (seasick, a bit)—actually she swam.

That's it for tonight. Tomorrow we try to catch spinners coming in.

September 1, 1979

Kealahou Bay, Hawaii

The swell came in all night long, rocking us, but not so violently as to be uncomfortable. I had a nice sleep up in the bow, with the hatch open and the breeze blowing by—enough so I put on pants and shirt (in lieu of a blanket, which I didn't have). Before dawn Bernd was up and stirring. Soon I had water heating and some pancakes in the making. We cast off, and moved out of the bay in the dim light. I guessed they'd come in in the northern sector so we stood off Cook Point, about 1/3 of the way to Palemano. While I was sitting on the afterdeck on the waterproof box I spotted a school of maybe 40 animals coming in from the sea, but in the northern sector, and moving toward us, ultimately to pass not 30 m. off our starboard. We quickly tossed the pickle in and made a short recording before they had gone and then moved in ahead of them, and at about 1/2 way in the bay were able to station and record again, this time a good session before they reached the back bay. Then they moved into the little cul-de-sac between the moored boats and the cliff just below the Pali Transit site. We lay off the white band and recorded. Later, Melany and Randy, at about the same time, spied another school of maybe 20 animals coming in very close to the south shore. We saw them when they were somewhat outside Man-- Point. We ran over a little closer and then decided to make a recording while we were still 200-300 m away. The porpoises already in the bay had done the following very clear thing. They left their little cul de sac and for the first time this morning, moved around the boats and toward the incoming animals and inside, by us. They moved toward the incoming animals directly, and merged with them. The recording we made was full of squeals, whistles, and click bursts. Aerial activity was not, however, at a high level, though perhaps up from the previous level while in the cul de sac. It seemed an obvious swimming to meet the incoming school, and a greeting. The sounds will be interesting, though I wish we could have been closer.

I went ashore shortly thereafter to call Mom on her 88th birthday, got through, and had a nice talk. I talked to Phylly and she told me Tim Brown had died on Santa Cruz Island, possibly of a heart attack, and Pat wanted me to speak at a celebration for him. I'll have to leave right after our little ceremony here, probably going back to Honolulu with Roger and thence to L.A. All so unexpected. Tim may have been close to 50, but no more, and seemed healthy. He'd had one attack a week before, but nothing was found, and then came this attack with only Pat present, and by the time she knew something had to be done, he'd died.

So far, nothing has been found wrong with his heart. How strange. And how sad. A real field man, whose head and heart lay in the land, in the desert whirlwinds, on the remote islands, and with his animals for whom he cared so well.

I've changed reservations and will fly to L.A. from Honolulu on Saturday the 8th, attend the service on the 9th, and go home that night.

This afternoon, prodded by the need to get things done, Bernd and I went on the *Maka Ala* and tried the video camera. It works OK, even if the eye sees vastly more. We will be able to do things like sex animals if they come within 12 ft. or so. I could tell Bernd's sex from that distance. It does work in very low light levels. We had two stops left, and it was an overcast and dark afternoon. One can adjust it easily. It has stop-frame

capability. I think the motor is going to create interference of a serious port. It puts lines on the picture every time a spark plug discharges, I think. Not sure what to do about that.

We just missed the porpoise school, which left as we were getting underway.

I tried my plumbing and it was full of leaks. Oh my. Even half a dozen in the plastic fittings—now, why? Tomorrow is a holiday and I doubt that I'll be able to fix it, but I must by Friday.

September 2, 1979

Napoopoo, Hawaii

Bernd and I decided to try to get some video with the *Maka Ala*, and so we took her out after lunch. Just as we loaded up, the porpoises drove out of the bay to the north. But never mind, we photographed each other, and at various distances from the viewing port. Then we took pictures of tropic birds, told risqué stories into the microphone, posed and acted generally silly. This, of course was translated into a hit production back home, to cheers. Everyone decided I looked like the Emperor Claudius.

The pictures came out quite nicely, even though the light level was low. We had about two stops left on the camera, which indicates we can take pictures in very low light, and that definition is acceptable at some distance, depending on the clarity of the water. We'll keep at it. The ole *Maka Ala* rides very far too high in the water and needs ballast badly.

After that saga I went over to the house to work on the plumbing. Much, much to my surprise I had enough parts to do something to every leak, and with a little luck we may have solved some of them. We'll see. It was all I could do to restrain myself from turning the water on before the various cements had stuck.

Good raucous dinner, with a session after scheduling things.

Sunday is schedule night, and we talked about days off, scans, and the like. We developed a matrix for time off, some folks take Saturday and some take Sunday. The cook had plied us with wine and only Jody, who doesn't drink, was able to make any sense out of the whole thing.

September 3, 1979

Napoopoo, Hawaii

Today was joy and woe day. It's hard to tell which overrode the other. Bernd and I took our notices of our open house around Napoopoo, visiting various people and telling them as we came in the yard that we weren't salesmen, but that we had an invitation. We were greeted by fleets of dogs of all dimensions, including steely eyed ones that dared you to come on the porch, little yappy sausage hounds, many German shepherd crosses, some terrier types, whose grungy dispositions showed in their wiry hair and surly looks. But the people were nice. They listened to our tales, were interested, said they would come see and listen to porpoise sounds, and their kids perked up. We met the cross-section of Napoopoo, and what a cross-section it is. Herb Corneulle, the President, or ex of Dillingham Corp, out slaying crabgrass on a lawn that looked utterly crab-grass free, he looking like a Boston Brahmin with immaculate white hair, looking like he was ready for tennis; Koiko Andrews, a powerful hapahaole with his pregnant blond wife, who runs the canoe team locally. He asked us if we wouldn't please, tie a rock to Gordon Leslie and sink him. So much for that relationship.

Then we saw Mrs. Kamakau, a handsome Hawaiian lady in a lovely house, who welcomed our invitation, but said she would be on Kahoolawe. A large group, she said, was going there to work toward making the place a park. It's a Hawaiian thing. They still carry the kahili of the island in celebrations locally, even though it has been a bombing range for years and no one lives there. It is an aina, or one of the islands of Hawaii, and thus a member. I understand.

We asked her who to see. We saw a family whose head is a King Crab fisher out of Dutch Harbor. You can see why he is here. We talked to the wife who had gone around the top of Alaska with him, to the Mackenzie and Canadian Arctic Ocean. Then we saw the paddler; then we saw Mr. Johnson, who was actually a Johnston, or a Scotsman who traced his lineage back nearly to the birth of Christ, a mormon, whose floor was strewn with pictures of deceased relatives, busy on a genealogy. He waved us in, and for three hours we sat listening to him. He had been a hydraulic engineer at Cal Tech and Hughes. He had worked on two aircraft and had been here since the end of World War II. He had been on a troop transport just like me, urged prayer on us, talked about Yuri Geller, and was a sidekick of Gordon's, and then he hauled out *Smithsonian* of all things, with my article on the tuna-porpoise problem in it. Now that's validation of what we are doing!! He discussed the pics, the scots, the link between Japan and the Basques, and on and on. I can't recount it all, but after we had left, Bernd encapsulated it all: "He's absolutely brilliant, and absolutely bonkers." He did, however, tell us about Gordon, whom he describes as honest, a thing we found hard to countenance, and told us of his sensitivities.

Then we went down Leslie Row, where everyone was named Leslie—the women flaxen-haired and slim, the men darker, hapahaoli. All except Mrs. Henry Leslie, who is pure Hawaiian. She came on somber, and gave us a radiant smile for our invitation. Then we saw Mr. Shutte, who runs the Holokahana, which he had bought from Bob Leslie. He was a pleasant, rugged, haole guy who flinched at our mention of saving porpoises—he'd had too much trouble with the stenos, whom he called by name. They stole him blind for bait. What had been a profitable flag-line fishery was marginal because these porpoises wouldn't leave the fishermen alone.

We walked back, to be met by Mr. Johnson, who had been in consultation with Chris. Chris explained she was a Johansson and Scandinavian, so that was that. But, not before we were met by Gordon, and laid on with five violations of the building code where we left. Johnson urged prayer. He said one could turn on the shower to drown out the prayer, but that before we knocked it we should try it. Gordon's gig was with the assistant planner in Hilo, and he said it rather smugly, I thought, and then gave us a lot of sass, about the fishermen not giving a damn if the porpoises were saved since they stole bait. This in the face of taking the opposite tack yesterday when he was accusing us of chasing the porpoises out of the bay. We counter with a blessing and an invitation to everyone in the town to come see what we are doing.

Kim's typing. Quite a session, and maybe not yet done. [Kid's typing].

It was an experience. Gordon's bomb means that the planners in Hilo, who had wanted to help us, are now restrained by the rules. I'm not sure what it means but we will go to Hilo to find out. I'm morally certain that Gordon will be on our case, in any event. It keeps the days interesting when there might be only science to deal with.

In the afternoon Bernd and I took a nice swim and tested Jody's tape recorder case under pressure. Bernd had smoothed the O'ring and it worked fine. I had a face plate for the first time and enjoyed the swim greatly. I called Phylly and enjoyed that immensely, as I miss her, and changed flights around. I'll now go back on the 15th, since Pat has changed the date of the memorial service to the 16th.

September 4, 1979

Napoopoo, Hawaii

Well, Gordon lied to us, as usual. He seems to prefer that mode when dealing with us. I called Hilo and we have not been cited. They only want information. Bernd and I will drive over in an hour or so to see Bill Moore. And then I called Roger Evans in Honolulu and he tells me our Conservation Zone permit has been recommended for approval. And, out in the bay, Shannon and crew have been waiting for the porpoises to come in. They finally did, around Cook Point. Shannon missed getting right in their path. It takes alertness and speed, and luck. I think the latter was missing, but she did get into the school as it was subsiding into rest. So, things seem to be shaping up a bit, moving toward some sort of operational mode that we can live with. If we just keep doing our work while all this mayhem swirls around us, we will make progress. Otherwise it defeats us. We are working hard, and only occasionally does the frustration of bureaucratic problems sneak through to disrupt things. Later in the morning Melany and Randy will head out to attempt some video recordings.

Poof, I'm back from Hilo, all bushed from driving entirely around the island this afternoon. We had a nice meeting with Bill Moore and Wayne something-or-other—a very taciturn Japanese. Moore is hapahaoli, the other half Chinese—very big and tall and affable. We discussed what we had done—set the house up, get electricity and water at Gordon's suggestion, and then be hit for these things.

I laid out everything, including the gauge of wire we had bought, and they will check into things and give us a reading by Friday, when, incidentally, our permit for the Conservation Zone is due for approval. It seems that the two offices are not hooked together and what happens in Moore's office, which has already given permission, is not likely to mean much in the other office. If anything. Bernd drove much of the way, and wow, he drives fast and swervy. I was tired just from holding on. But we did the right thing, and the final disposition is ahead on Friday, I think. Randy and Mel hadn't gotten out because of rain, and then the porpoises left around 1 PM. Bob Leslie is sort of due for dinner now. He may or may not make it.

September 5, 1979

Napoopoo, Hawaii

We went out in the *Maka Ala*, Mel and I. The weather had been bad yesterday so no attempt had been made. It wasn't bad when Mel and I went out. The ole *Maka Ala* needs ballasting pretty badly, but she worked, and we were able to obtain some interesting videotapes of animals, and to begin analysis of wild school structure underwater. A school of between 50-60 animals was in the bay, usually broken into three groups. There were many young animals in evidence, some with presumed mothers. From below the surface we saw a few groups, two mother-calf pairs, and a couple of identifiable males. Our best runs were at quite low speed and especially in shallow water

where the animals dove and drifted below us in full vision. I have no doubt we will get plenty of value if we keep after it.

The evening was spent in going over the tapes frame by frame. Luckily the machine has a counter, and a stop-frame arrangement. The latter isn't too good in that the picture becomes vague when on stop frame, but usually we can make an approximately count, and can determine dispositions. We've a grid work that goes over the screen that will let us calculate inter-animal distances, and positions of snouts relative to one another. There are many problems, but we are begun.

I made a run up the hill to get some materials to fix the sunshade on the *Maka Ala*. At present it is propped up by two wooden slats held together with latex rubber tubing. I'm afraid somebody is going to be hit by flying slats or snapping rubber tubing. Then, too, we will build a little slate to photograph for each reel at its start, or for each new day and sequence. Just like the professional types do to identify their tapes or films.

We had primordial ooze casserole (quite good, I have to admit—broccoli, swimming in cheese and over rice).

To bed late, with Chris, who is an utter night owl, still looking at the first tape.

September 6, 1979

Napoopoo, Hawaii

Well, the saga continues. If we were only working on sociology, we'd have three or four dissertations already. This time our Avon 12-footer was cockaroached during the night. Taken off the dock, the anchor neatly removed and left, and spirited away, probably by water, and probably to the Napoopoo dock, and thence to where I don't know. But gone. It is a grievous loss in that Jody uses it all the time, and it's best for hauling heavy things. We prepared a report on it, including identification marks (there were many) and took it to the police. They seemed confident of finding it, but if it was taken in anger, I doubt that. It may never be used again. I called Warren Stuntz about it, and he seemed unperturbed, but didn't offer to replace it.

There are so many thefts, I'm doubtful that it was directed at us. It was big, available, and not tied down in any way, and could be taken by water without disturbing us. Bob Leslie had his house broken into last night, too, he says, by some young guy out of work.

The house is cleaned, the gals have made a lot of sushi, and will make haupia pudding, a punch, a fruit dip, and lots of cut vegetables. Should do. I called Leon Sterling and he will be here a little early on Friday to talk to me. Then we go over to Manini. I hope my friends Lehua and Ceci make it over. I dropped up to Sherwood Greenwell's office in the Kealakekua Bay Center and left him an invitation. I hope he comes. Jim Simmonds, our mechanic, will come. He's such a nice guy. That'll be enough by itself.

Warren, by the way, bless his prescient soul, set aside funds for seven months rent here, should we need it. Wow. We probably will.

What I figure is that we cheer every day we get our data, and every day get closer to our scientific goal. Damn the Gordons, full speed ahead. Bob Leslie, by the way, is very sure Gordon, or his pal, are behind this, though I am not so sure. Well, who knows?

I took Jody's cast-off mask (which works fine) and had a second lovely snorkel time around from the front of our house to the Beach Park. It was raining, chilly getting in, but once there, all one did was hear the patter of rain and feel it a little on shoulders

and back. The bottom here is rich with fishes of many common types. I saw several butterflies—*C. lunula*, *corrallicola*, no *miliaris* though, and some others, yellow tangs everywhere, olive tangs, and some others. *Gomphosus* of both sexes, lots of needle-nosed butterflys, and just outside the entrance we came upon an 18-inch flatfish, which was capable of flashing out dark spots in an instant. It swam quite gray, and once it landed it instantly chose a level of spots to shine out. The spots were composites, including some iridescent blue subspots. I suspect it is *Bothis*. Then we came upon two *Naso lituratus* swimming parallel almost eye to eye, vibrating the posterior body. The vibrations were not wide excursions, but just that, vibrations. The fish swam from us, and fled to another rock in deeper water, and when I went after them to look again they fled inshore, following one another. They led me over to the side of the beach at Napoopoo and there I saw two eagle rays (*Aetobatis narinari*) flying in the sandy turbulence of the nearshore waves. They blotted out, then faded into view again. I swam quite close as they rather majestically, with slow beats of their wings flew over the terrain, rising and falling in the waves. I approached closely enough to see the rings on their dorsal wing surfaces, typical of the species. They were perhaps two ft. wingspread, not large but beautiful. Shannon and I both enjoyed the scene.

Then we wandered our way over toward the sand again. It wasn't long before three magnificent awa swam in front of us—big milkfish, 2½ ft. long, powerful silvery bodies, strong forked tails, big eyes, and black pelvic fins. I followed them for quite a while. They never spooked, but stayed just ahead of me.

Well, the house is all clean, the sushi made, the gals are making leis out on the porch, and most of spent some time up the local *Plumeria* trees picking flowers. There are, I find, several kinds of white plumerias, and the rotate ones last longest. There was a rush on to get red ones so I scaled a local tree all full of orb spiders to pull down some prizes.

Bernd is down picking up Randy and doing errands. Pancakes for dinner. Seems appropriate and is clearly all we need what with the other tasks that need to be done.

September 7, 1979

Napoopoo, Hawaii

Well, it was a nice party and quite a few of the local folk came, though almost none of the Hawaiians. We did have some of Leslie row, who are married into Hawaiians, and Ceci came over with Roger, and Jim Simmonds came down the hill. It went like this.

First thing, I drove off in Winifred to pick up Roger Coryell and Ceci Lucy. They arrived in good time, were properly draped with leis by me, and off we went. Roger had brought along maile, and Ceci some ti leaves for serving platters. But my gals had all that together anyway. They had even made pretty new dresses for the celebration—nice flowered dresses in the Hawaiian style, with bare feet. Shannon, especially, was in her element. She knew all the proper forms, and how to make leis and haupia. Jody whipped up a very tasty dip for fruit, and we had a great bowl full of melon slices and pineapple, and then another of watermelon slices. The sushi was sliced and was very tasty. There was plenty, in spite of my usual worries.

Randy and Bernd assembled the electronic gear and all this was duly hauled to the field shelter. It had been cleaned within an inch of its life, and covered with pictures,

many of them Bernd's lovely photography. There were maps, diagrams of the *Maka Ala*, and a slide projector had been set up, and about 20 slides chosen of marked animals, transiting, the *Nai'a*, the *Maka Ala*, aerial behavior, and the like. We hung blankets over the two windows and used our new screen on the wall. It is really nice, and the pictures just fit when projected across the room. When 15 people crammed in, it was hot, steamy, and limited discussion and dawdling over the pictures to a minimum.

We had a sound station and a place where we could play our one roll of videotape.

People began to straggle in about 11 and continued all day. About 11:15, the kahu, Leon Sterling, showed up. He is a shrewd-eyed hapahaoli, but quite Hawaiian appearing. He used to be a cop, is mentioned in Mami Stover, lived in southern California, became a Baptist there, and is a quick man with a quip or a leveling remark to regulate the emotional flow of a conversation—very much in charge. About noon we gathered everyone together in the erstwhile bunkroom.

Sterling, a burly man, draped in maile (I had one and so did Bernd) spoke to us first of our responsibilities to the earth and to make our information available to everyone, especially Hawaiians. I suspect he may feel we are on some mission where this might not be so. This was good, and he spoke of a two-sided contract, of which we had as much responsibility as the local residents. Then he offered a prayer, his face fervent, his eyes closed. He spoke of this Friday as an auspicious omen, and of the wind as another omen. He mixed in the scriptures, and held a tiny bible or phrase book in his hand. He spoke of wilderness tabernacles with altars of dolphin skin. That made me think of the Ark of the Covenant and its dugong hide. But I forgot to mention it to him.

Then, after the service, I found him staying with us, long after I thought he would have left. He told me he liked the feeling of the place and the people. He told me of his attempts to steer young Hawaiians into education and jobs, when they told him it was easier to rip off a haoli now and then—no jobs, few opportunities, an alien culture forcing them away. [Invitation to event enclosed]

Though some thought he was probably opportunist, and all of us saw a way with words, a capability at manipulation of the social situation, I saw instead a very shrewd and perceptive person capable of bridging two cultures, and capable of seeing deeply into the psyches of the people around him, and further capable of asserting some degree of control through asking of those to whom he spoke for commitment. I saw a person who had seen very much of human nature, of trouble, and whose religion was a way of ordering the chaos in lives around him. He was facile, and to me, fascinating as a person of depth and great skill at treading a very difficult line. His job was to bridge the almost unbridgeable gap, and he did it with grace, and deep skill. It is easy to see how hard that might be when the anger of the Hawaiians against the haoli and Japanese is so deep. They are put down by us at every turn, by every evidence of educational advantage, by every little gadget we understand and they don't.

Anyway, I can't imagine having had a finer person come to grace our morning.

I took Roger and Ceci back to the airport, bid them fond farewell and returned to Napoopoo after buying a little food—some nice opelu, but everyone but me had been feasting on sushi and didn't much want a full dinner, so I cleaned and split them, and shoved them in the fridge. Several more folks had come after I left, including Mr.

Anderson, who went on and on about various things, and a couple of groups from Leslie row. All in all a full and a good day.

September 8, 1979

Napoopoo, Hawaii

Warren has guaranteed our rent here until the end of February, so no one can get at us—the state, or Gordon. Our permission from the state arrived today with a few codicels, and dated September 14th. We have to discuss with the Forestry Department a plan for fires, and the land folks may want to charge us rent. How much they didn't say. But now we may just leave the shelter up for a while using it as offices, and then ship it home. If we do that I'll try to raise money to have the Environmental Field Program buy it from us, for costs.

Anyway, Bernd and I went out with the video today. The swells were running quite high and the water became very murky before long. Even animals looming large were just in vision. At first we saw pairs and slow-moving groups, usually spread, in pairs or threes, and then when the animals began to move faster, we began to notice sexual behavior. Animals were seen belly-up, swimming slowly in company with another animal above. I saw a genital probe by one of another belly-up animal, and I suspect I saw intromission. Even as late as about 12:30 I saw a defecation and several times I saw us passing through trails of loose feces. There were several marked animals in the school—fore-nip, deep notch, and others. [Drawings]

Bernd took many pictures. There was an animal present with an open cookie-cutter wound in this position. We saw finger-dorsal. There were very clear groups of young, including quite small ones, and some traveling with adults. There were also adult groups. I saw fore-nip in a group with mostly juveniles.

September 9, 1979

Napoopoo, Hawaii

This morning Jody and I went out for a row-swim. That is to say I rowed the Metzler and she swam and made her noises to the porpoise school. A huge school was in—75 animals, I guessed. It was composed at least half of juveniles and young separated off into their own groups, usually with a scattering of adults. Fore-nip was one of those older animals typically with the younger animals. Female? Then there was the old-boys group, those with tall dorsals, finger-dorsal, flopper, an animal with the sawn-off fin and deep notch, and one with a lunate notch on the rear margin—all noted yesterday. I should note that after this group finally left the bay in mid-afternoon, another group came in not far from sunset, and swam around right off our landing, inside the boats. That's the first time I've seen that!

Anyway, Jody and I set out a'rowing. She had gone before in an outboard-driven tender. But that boat had been stolen so we had to settle for the little one. My main problem and only objection was the problem of a place to sit and row. I ended up doing most of it on my knees, facing the bow and rowing Portuguese style. I did have sore knees for a while, but that's all. Just outside the boats to the north we came into porpoises who were milling in the cul de sac below the Pali Transit site. Jody was at once amongst them and they cruised right by and under her within feet. My little presence didn't seem to influence them much at all, and I had them near me several times, too.

Then we skirted down the cliff and once again came into the school. This time I watched a group of animals, mostly juveniles, go by Jody on both sides; then the animals nearest on boat sides, perhaps 30 ft. away, turned toward her as she made her warbling, mewling call. They came in from all directions and seemed to stop when 10 ft. away or so, and dive. She said they zapped her with echolocation trains, and one came within 6 ft. She reported seeing a nursing young. Then, the *Captain Cook* came in and thoroughly disrupted things, running through the school and dragging them into her tumbling wake and taking them out past Cook Point. They finally came back but we never again had a really good session. Twice I had seen the animals attracted to Jody, and it seemed pretty clear. At other times segments of the school simply went by and under her as if not disturbed at all, and then later I wondered if the reason the school tended to stay far offshore, was avoidance of her. I told her she had achieved about the maximum she could expect when she couldn't keep up with the school. She had attracted them momentarily to her, she had not ever spooked them, and they had reacted to each other as is to be expected. They are schooling animals and ultimately will give way to the urge to follow and remain part of a school. What complexities must arise from being schooling animals and at the same time being of highly complex mind? That is a major puzzle.

At any rate we rowed back about noon, full of pleasure with the morning, and not at all scornful of the rowing mode—if only I had a better platform to row.

I snoozed, and wrote a eulogy to Tim Brown for Sunday, and laid plans for the week. I cooked dinner tonight—tuna noodle casserole, with some more broiled opelu, rice, salad.

We'll probably go the super 8 route for the *Maka Ala*, I'd guess. We are missing so much data. What we can see with our eyes is vastly greater than what appears on TV.

September 10, 1979

Napoopoo, Hawaii

The porps came in early, perhaps 75-80 of them, all the old actors and also the juveniles and young. There was fore-nip, deep notch, finger dorsal, the cookie-cutter-scarred animal (whose other side was grievously wounded with a huge, six-inch-scooped-out and tattered place on its tail stock). One with a bent fin (flopper?) was there, too.

Chris and I went out to the *Maka Ala*. After some hitches (I put the gas hose on backward and we forgot things—it's awful to be expecting this and that to be done for you and suddenly it isn't). Anyway, we went off in gin-clear water with Chris making happy, incoherent noises up in the bow. Her pictures weren't all that good but she saw a lot. At noon, when the porpoises are waking up, we saw mating again. Do you suppose porpoises were so civilized that they mate only when wide awake? Looks that way. There seems to be an absence of mating and/or sexual play after first arrival in the bay and then it picks up after noon, before the animals leave. Zig-zagging must be contemporaneous.

Anyway, the school went very close to the cliff at times—5-6 ft. offshore, swarmed all around two swimmers. It was easiest to cut up near a school where the shore or the boats were in the opposite side and gradually got closer.

I really don't think TV is going to do it—too poor resolution. Everything else is grand, except stop-frame, which wipes out detail badly. Of course, our old rig could be part of the problem.

Anyway, we were out until 2 PM—dry, hot, sunburned, and then came in to a new mooring, praises be. When the first storm arrives we'll bless that arrangement.

September 11, 1979

Napoopoo, Hawaii

Another day on the *Maka Ala*. This time I stayed ashore in the morning and sent Randy out. He, who did all that work on her, and her trailer, had never been on board for any length of time, and had never seen a porpoise from her. They took most of the rest of the movie films with a little rented super 8. We'll buy an underwater version and substitute it for the video. A roll of film, processed, is about what a roll of videotape costs, and we should get a lot more detail. There is a new camera, the Nautica, that lets one work just like with a Nikonos. Just jump in and photograph, surface, and reload with magazines that cost 10 bucks. It should be possible to get footage at various places in their activity patterns—including offshore, incoming, etc.

I couldn't stand it and went out after lunch to work with the porps and had the pleasure of watching quite a lot of sexual behavior, which seems to spring up about 11:30 or so, after a period of pair and trio swimming without overt sexual behavior. The sex seems to come with increased aerial behavior, too.

I was pooped and hot and didn't sleep much somehow, but I do feel the *Maka Ala* is going to do some important things for us.

September 12, 1979

Napoopoo, Hawaii

The aerial team went off and had an eventful day. Chris got sick over Mahukona and had to wait to Keahole to get off, a mess I guess without airsick bags. The plane, by the way did not have its generator fixed yet. I told them not to go up again until maintenance is in order. I don't like that outfit. It's set up for a snotty son, who hasn't a clue how to run a business. The pilot is nice—Sam Jones.

They saw *Tursiops* at various places and spinners clear down to Opoe Bay south of Milolii. Hurray. Saw them spinning.

Bernd and I went out on *Maka Ala*. He finished the movies, and then took a long series of motor-drive stills—it took nine seconds to do in a roll when the action was continuous. Then, about 10:30 I went below and simply observed and noted things into the tape recorder. It's not easy stuff at first—the language of dimensions and interactions has to be learned. And timing. But, we did see the switch from pairing and trio swimming in the rest period to sexual behavior in zig-zagging at 11:30. Aerial behavior was also a correlated with the rise of sex. Much caressing, probing, and belly-belly swimming. I saw the water just after a series of tailslaps. Each blow had driven a cloud of bubbles into the water that was 1½ ft. long and perhaps a ft. deep into the water. It occurred to me that these would be echolocatable, and that an animal wanting to know school dimensions could not only hear the sound but zap it with clicks and get a precise range. Spins and other aerial behavior probably make much larger targets of this sort. Since they are well below the sea surface they should be easily locatable.

I wonder if the tiering I see in the school is a direct result of viewing cone of the animals involved. They are staggered, and in echelon in such ways that animals can keep

contact visually during rest periods. Thus, the use of sound for school cohesion is obviated. It needs more observation.

Chris came in in late afternoon, still feeling a bit lousy and the others made it after dark for a chili dinner. Tomorrow is my last day here, and I'll take it on the *Maka Ala* trying to see if focal animal methods seem useful. I think they should be. I'm anxious to go home, but also pleased that data seem to be coming in now.

I'll go to Honolulu with Jody, see Lou Herman about my chapter, buy some clothes, and head for L.A. for the Tim Brown memorial on Sunday, and then home Sunday night to my FAMILY. . . Wow, that'll be nice.

September 13, 1979

Napoopoo, Hawaii

Last day here this time. The porpoises came into the bay twice and left, and right now it looks as if they won't be in. But if they do arrive, I'll go out for some single animal tracks. That is, follow a single animal in the midst of a large number and watch for interactions of various kinds. I'll pack. The heat is still here so I'll simply leave some clothes out, and then Jody and I will be off tomorrow morning for Honolulu, where I have a car waiting and will meet with Lou Herman about my manuscript in his book. I've had to revise in various places, because it has been nearly five years now that he has had my manuscript. What a nuisance. A good paper with things in it ahead of their time is caught up with by other work, diluted by chapters written by Herman himself, etc. I hate these edited volumes.

Anyway, I leave the project going pretty well. I do have concerns about their capture plans and have discussed them with Bernd. Mostly I want the work done without any public knowledge. It's a terribly touchy issue here and we mustn't be connected with any public view of it, especially here at Napoopoo.

I'll buy a few clothes for Tim's celebration, eulogy, or whatever one calls such a conclave in honor of a person recently passed on.

Then, Sunday evening, home.

February 9, 1980

Metaevolution began with learning. It allows the animal to respond to the environment, but regardless of the direct dictates of the underlying code. The response is to environmental variability too variable for the code to respond to. The end products between selection and behavior are congruent—individual survival.

Further, this frees the code of needing to respond to minutae. Such minutae, hard-wired, are constraining, and dip down into the noise level of environmental variation. Optimum fitness is achieved when a broad genetic plan, responsive to the broadest variability in the environment of the organism, is matched with a fine-grained response system.

What remains unpredicted are the longer term or broader controls that intersect into the ecosystem of the organism from beyond its range and beyond its lifetime, i.e. beyond its direct individual experience.

Enter conscious awareness. With it ultimately comes the ability to assess to some degree at least ecosystem state.

Our society now spends a large part of its activity in such assessments in the attempt to inject findings from them into societal direction. It is, at the moment, the ultimate extension of the organism and its code beyond that set of basic patternings. But, it has not in any sense escaped the code. The tendencies that allow us to reflect and act on our own fitness spring directly from the code. Determined there are the basic emotional features of socialization, of the associations that let us look at the domains within which our lives are played, that let us look off into the intricate murk of the intermeshing systems that form our world and that represent the ultimate restraints upon us.

March 25-29, 1980—Mojave Desert

March 26, 1980

The Bunny Club, Granite Mountains, San Bernardino County

Dick and I are wandering the desert during spring break, visiting mineral and fossil localities and laying plans for a new University Center at Snake Spring. Tomorrow we'll head north to attempt to line up a lot of materials for the construction at White Mountains Station, where our intelligence tells us lays an enormous and incalculably valuable junk pile.

We started out on Monday (it is now Wednesday), drove across the Paso Robles-Wasco Road and across Tehachapi Pass. We camped north of Hinkley in the Lynx Cat Mountains—a nice *Larrea* bajada but blustery and cold. We both had to come to terms with mummy bags after long absence. In the morning we whipped up elegant collision-mat-style pancakes and bacon over *Larrea* twigs. My, how I love that smell!

We drove N. into Black Mountain to look for rocks. Opal Mountain is banded with pure white tuff capped with volcanics. We had a couple of grand hikes and found a little opal (none with fire) and headed north again for Murphy's Well and Coolgardie. The latter is a mass of small mine dumps and tunnels in bouldery alluvium. Why, I don't know. There were quite a few shacks about, some with highly unfriendly signs: "Trespassers will be eaten"; "Honk three times or we shoot", etc. We ended up in the Superior Valley, an area of giant Joshuas, creosote, and grassland. The road finally took us full circle up against the boundary of the China Lake Navy Base (jets arrowing past) and then down to the Ft. Irwin Rd. We cut off to see Rainbow Basin, a varicolored badland of banded and colored sediments, some full of mammal fossils. We didn't find any but had a good hike.

Then Barstow—lunch, shopping, and gas, and on to the Granites. We arrived not long before dusk, cooked a nice meal of lamb chops and fixins and then to sleep. Felt good. Better than in a long time. Nice traveling with Dick, too. He's up for most anything, has quiet humor and lots of energy, and loves the desert.

March 26, 1980

This morning after Bruce Jenner-encrusted Wheaties, we headed for Snake Spring to check out the potential for a University Center there. I want to build one of stone that will take the pressure off the BC and provide more room.

The creeks there were flowing with clean granite water over green algal-covered stones and cascading out of north spring into potholes in the granite and sliding in long, dark bands down the naked rocks.

We traced pipes up North Spring, past the golden cup oak clump and the willow thicket, all yellow-green with new succulent growth. Probably 75 ft. above the oaks, the pipes went under a big, house-sized boulder under which the stream ran. It would be easy to dam. There's lots of pipe—hundreds of feet—1/2-in. black iron in fair condition, 1 1/2-in. galvanized in good condition, and 1-1/4-in. black plastic that seems OK. Enough here to plumb any new house we build and to bring water in.

We then traced the South Creek and went into a 15-ft. high grotto as big as a big living room. The stream bubbled crystal on the floor over phenocrysts and orthoclase. We found two petroglyphs inside—one the ladder-like motif, pecked in the rough granite.

Then, just east of South Spring, up against the granite face of the mountain, we came to a fine site for the center.

69840 Granite Mountains Bunny Club Mileage on Way Home

Dick and I went north and in the Mescals found a fine sandstone quarry—unsigned. One drives up an old road past a plastered shack, two Bonny and Clyde cars with their doors full of bullet holes, and up a steep, rocky hill toward the west and a mountain from which very regularly bedded sedimentaries jut. It's a quarry with no signs and wonderful flat red sandstone, some in sheets six ft. long. We'll use it for the Granite Cabin.

Then up past the Mountain Pass Mine. The road emerges there—then up to the Kingstons. I'm always amazed at the lovely nolinias, the talc mines splashing the hills with white. Up past Horsethief Springs we began to see the crest. I guess we were at 4,500 ft. and the crest, lined with trees and rocks lay two miles to the south and 2,000 feet up. Beyond what we could see apparently lay two to four miles of rolling ridge to the crest. At any rate it'll be simple, relatively, for our crew to reach the upper mountains. We cruised on down the rutted dirt road to the iron mine, on the north side of the road—great piles of talings cascading 800 ft. or so down a steep slope—magnetite we found.

Then at Crystal Spring we saw the University van stopped and walked up the hill. Out came Steve Raneau and Brad Bush. They thought we had come to chase them out! Together we went up the creek to explore. There is a talc mine as a series of levels and tunnels up the hill to the east. Three houses sit in the streambed and a flowing clear stream. Trees (cottonwoods and locusts) grow in the canyon.

We found a nice 12 x 5 cement tank overflowing with clear water (what a place to swim when it gets hot). One building had been built athwart the stream and a storm had filled it with mud. The other was in better shape. Up on a mine level we found nine 8 x 10 beams, maybe 20 ft. long. Great for the Field Shelter.

On down the road we went to the Smith Mine cutoff. We rocked and thumped up the entry road in the wash to the two houses sitting amid locusts at a little spring. There was Valerie Sumida, the planner of the group. I really liked her. She is so acute and bright and concerned. She saw many problems of BLM management that I had painfully come to.

Anyway their house is a galvanized roofed house with windows out but the roof apparently intact, a good kitchen and a couple of bedrooms. We cooked outside, Dick and

I, over a nice *Larrea* fire—broiled lamb chops that we shared, potatoes and onions and soup. I slept on a tattered old couch kind of leveled alongside the fire.

In the morning we headed out up through Shoshone, lower Death Valley, Bad Water, Stove Pipe Wells, over Tomues Pass to Keeler and Lone Pine and up to Bishop. We arrived at the White Mts. Station at 4:15, introduced ourselves to the caretaker, Don Boozer, and asked about possible supplies. What a treasure trove—weasels, trucks, aircraft tanks, wire, jeeps, and heaven knows. What a suspicious pack rat—not that I blame him. We *were* trying to get his goodies. But his junk had put the University in a fix with the forest service. I looked, was past everything and out. Dick and I made contact through Phil Pister with Rob Rainer and Joanne Kerbaraz, who were out catching wild sheep at Sawmill Creek. It was a circus. All sorts of uckymuks. Dick Weaver of CF & G and 20 more. They caught 20+ sheep with cannon [?] and apple pulp.

Dick and I had dinner with Joanne and Rob and then took a motel room in Big Pine, nearly fell out of our bunks at a Peter Sellers movie, and went to sleep all clean for the first time in days.

We traversed Saline Valley, pecking at formations and dun--- mines, met a colleague of Bob's, Jim Cushin? Hayward State, a grand-looking geologist with a flat tire, then headed up Grapevine Canyon toward Cerro Gordo Mine. We were stopped by snow at 8,500 ft. or so, and hiked nearly to the ridge, found crinoids and brachiopods and some other fossils in the [?]. The mines lay above us and I had to pry Dick off the mountain. He's so enthusiastic. We made it to Olancho after dark, called home, and headed across Walker Pass, up Hwy 5 to Pacheco and home by 3 AM or so.

Wonderful trip. Wonderful being with Dick and grand sights.

April 7-13, 1980--Granite Mountains

April 7, 1980

Upper Rich Bar, Kern County

The spring field quarter starts—30 of us—in the Blue Bus. A quiet crew, sleepy and trying to catch up. Down the road at dusk for dinner at a greasy spoon in Moss Landing and on to Paso Robles and over to Wasco and Bakersfield and thence to camp at midnight. Some sleep and then up.

Granite Mountains, San Bernardino County

We looked around us at the canyon, the trembling brown river, the bending willows and up the hill to the leaning digger pines—their delicate silver needles trembling in the breeze. I tried to recast the flora in terms of times past—sycamores coming from the south along with Fremont cottonwoods.

We watched the desert [?] long before we reached the crest of the pass. The Joshua trees came fairly early and way west of the crest. Junipers came in even earlier, near the lake as did *Artemisia tridentata*.

It was a fairly quiet crew all the way out to the Granites—it takes a little warm-up.

We caught our *Xantusia* up near the crest and talked about that for a while, keyed out plants, and drove on down to the desert. A stop at Barstow and then at Pisgah. The chuckawallas were out in force in the warmish day. I caught a big male and one of the gals caught a *Phrynosoma platyrhi*— and talked about color matching. Things are out. The air is dry and warm, but not hot. Otherwise, no horned lizards would be out at 4 PM.

Cheese fondue tonight and we got our musicians up in the wind scoop—a guitar and banjo. Don Usner on one and Tom Curts on the other. It works great—it projects the sound out and envelops the whole cabin. Tomorrow, observations. I'm a little low and hope the voltage picks up.

April 10, 1980

Bunny Club, Granite Mountains, San Bernardino County

Well, it's been a good day! As dawn streaked the sky I could hear the kitchen group up, stirring around, setting out the breakfast. I took out three groups on walks today and all were successful. The walks were leisurely strolls through the wash community, asking about this or that plant, peering into pools—the stream runs clear in some stretches and gurgles nicely in the jumble just before the pond. The weather has been spectacular—clear, blue, and warm days, with some times a little gusty breeze to stir the air. We inspected woodrat middens, peered under rock crevices at ferns and poured water on black patches of moss.

Moss is so amazing. I wonder if it doesn't promote dessication by the places it chooses on exposed rock surfaces. It must get very hot, probably well up over 180 degrees F. at turns. It seems like a pretty efficient black-body radiation trap—blackish fronds pointing upward toward the sun like a deep-pile mohair. I wonder if the strategy isn't to dessicate way down to the bound water level in dry periods. Somehow in such a state it is relatively impervious. Maybe it prevents a vapor phase from occurring—no gas can escape, or little from the free water, as the plant heats. Somehow, I'd guess the vapor disrupts cellular processes.

At any rate, in ten minutes after we doused one patch, it was gleaming yellowish green.

Then we crawled under a long north overhang, just high enough to accommodate me on the phe— roughened flat boulder that formed the floor. Back six ft. where the cap rock and the floor joined was a vertical wall of soil, dark with moisture. It was green with liverworts, golden-backed ferns, and the delicate little hydrophil, *Eucrypta*.

We sat and I talked about observation. One group clustered in the lush green grass beneath a spreading pinon.

One group tried to psych out ant mounds down in the arroyo below the cattle ponds. They are geometric structures with a smooth, equal-angled (or sloped) inner surface that I wonder about. Do ants respond to the slope angle? If so, mine were about 20-30 degree jobs. It looked good. When an ant bearing a little crystal found a depression in the inner slope of the mound it usually filled it, but if it reached the top it just dropped it, often on the steeper slip slope. But affairs were far more complex than that amongst the ants, with social interactions, and other ants wandering long distances on other missions that I could not penetrate.

The students are a warm, attentive lot with many individual talents—quite a special group, I think. As a group they're responsible, too, back on time, ready to go

when you ask. Larry and I sigh in relief when this emerges. The two or three ringers one usually gets are absent.

A little music and to bed with the spotted skunk pattering busily around the cabin. Once the cacomistle stuck his head up just below our banjoist, Tom Curts, who was up in the wind scoop. Cacomistles eyes are huge and glow from his tapetum.

I'm up on the upper bunk with a few students down below. Melanie Seacat is below and the skunk just ran across her and her pillow. "What was that?" she says. "the spotted skunk," I replied, but in 10 minutes she was asleep, unconcerned. Such savoir faire.

Soon enough, me too.

April 11, 1980

Granite Mountains, San Bernardino County

Today was Kelso Dunes day. We were up very early. Bets Norris had dropped in last night and accompanied us. We arrived by perhaps 8 AM. Clear and calm and with the bracing freshness of early morning. Not too much was out on the walk in but emergence was well underway on the return trip. For me it was an odyssey of hyperventilation. I was last up this time but not by a long stretch. The crew was largely out baking in the sun sans clothes when I crawled over the crest.

We assembled at the top while I caught my breath and then Tom and I regaled folks with the wonders of sand dunes and then the inevitable tumbling, sliding descent began. The mountain sang nicely indeed and we headed back for the bus. On the way we came across a sidewinder track. I tracked it the right way, all the while wondering if I remembered (J crosses—the mark of the rattle forward). We found him under a *Petalonyx* bush, coiled in partial shade, with sand over part of his body. I fished him out and demonstrated sidwinding. Then I tried to pin him down and missed one [?] jowel. I was able to retreat and do it right but it was closer than I like—once a year is all I'll do this. His venom dripped yellow to great intakes of breath by the students. I showed them accessory fangs (he was shedding and replacing both front fangs), and then the loreal pit. Then, I put him back in his bush. He crawled off yawning at all the sand in his mouth.

Larry took us to Kelso so he could make a phone call. We lounged on the lawn and were served at the Café—I'd thought they were closed to the public.

Then back to the BC. After lunch I took out the last group. Maggie Fusari had sent a message of triumph for my ascent of Kelso Dunes "Pretty good for an old geezer in the age of Philosophy."

The cook group went with me. We sauntered along the wash at the base of the mountain looking at this and that. Then we sat under a pinon tree in a copse of green grass with the desert breeze rustling in and out. We had a nice talk and then moseyed off to the pond and down to look at a rather reluctant male Anna's hummingbird. It did three courtship flights and then we watched it on a *Yucca* perch. It was probably frightened by this invasion of intellectual talent. But we had a nice time, and I think everyone felt good about it.

Square dance tonight. Hard to do, but successful. A few boxes and tables, orchestra in the windscoop.

Two skunks got in a tiff and one became stuck in a cardboard box. Each time they squirted a little—not a full-fledged blast but a petulant puff. It wafted out soon enough though and it was strong at the start.

April 12, 1980

Granite Mountains Bunny Club

The cooks were up at dawn—the red light lit up the deck and tinged the beams. I didn't want to stir. Sleeping inside means one is last to have the light out, so it was late last night.

I was sleepy in spite of two cups of boiled coffee and slept in the bus after we checked out the UC site (for the field center). I woke up about the time the trash was dumped at the Kelso Dump, and again, when we entered Cedar Canyon. At one point San Geronimo loomed up 100+ miles away with the entire Kelso dunes in the middle ground.

Up at Hole-in-the-wall almost our first sight was of three bighorns—a ram, a ewe, and a lamb up on the top of the lava mudflow deposits watching as warily. The ram stood up and never took his eyes from us. The lamb is very different from a domestic lamb—very wild-animal-like—long, boxy nose, and very pale short fur. They finally sauntered off along the mountain slope unhurried and unfrightened.

We hiked down the Hole-in-the-wall trail (I'm writing this with the spotted skunk under the opposite cover of this notebook eating falafel dressing off my plate, not eight inches from my writing hand—then he came over and smelled the tip of my pen and went off to the sink—he has such a flat weasel head and little black button eyes).

The hike at Hole-in-the-wall was rather uneventful other than the desert bighorn—we looked at *Ferocactus* trying to understand how it defeats predation from rodents, climbed the chemehuevi trail and came down the other side and then went off toward the petroglyphs at the road that cuts along the south side of Hole-in-the-wall.

Janey Belknap badgered me to go for a hike locally and I had demurred because my knees were sore. I finally capitulated on a shorter outing, and six gals decided to come along. After breakfast and after Larry had gone off to scale Granite Peak we headed over the fault valley that slices west just N. of Cove Spring. It runs up a boulder-choked canyon and slopes to a saddle where the boulders became more scattered. We followed a clear, gurgling little creek up under the boulders. It nearly reached the saddle and way up there in an alga-streaked pool was a red-spotted toad.

As we climbed we gradually changed the flora—*Garrya* came in, its tassels not yet out in flower, and *Quercus chrysolepis* came in.

I think I saw *Amelanchier* but am not familiar enough with it to be sure. *Pelaea* forms were common under rocks as were golden-backed fern (*Pityrogramma triangularis*, and the hydrophil *Eucrypta*.

Out away from the mesic boulder-stream area we began to see mound cactus, fishhook cactus, and more common species. I ate the chile off one fishhook cactus. *Eriodictyon angustifolium* became common—an almost chaparral-like element.

All along the upper third of the climb we followed a dike of quartz and fault gouge. The crystals gleamed and glittered and we couldn't resist putting this or that bit in our pockets. On over the crest we went—me, Julie Perrochet, Joan Beatty, Janey Belknap, Judy Ward, Trevelyn Houdi, and Sandy Perscheid—a fine crew. We had a lot of fun along the way.

Beyond the saddle lay the upper valley, an almost rectangular depression fed by two streams from the palisaded rock cliffs above. Down into it we dropped, stopping to munch apples and oranges while sitting on the pungent duff of pinon, a circle of green succulent grass. Down we went to the clear gravelly stream. A bobcat had walked the creek, big-footed, and we argued if it might be a mountain lion.

Carex lined the creek before it narrowed into another boulder-choked canyon, opening again below in a beautiful little valley before largely disappearing amidst boulders as large as small houses.

It was rock-hopping all the way to reach the alluvial apron near Granite Cove. All this is on the University Section 17—a kingdom of little hidden valleys, great towering palisades of smooth and fissured granite. At the bottom we drank from a clear pool, inspected both petroglyphs and pictographs and trekked for camp.

Not a snake did we see, aside from a cast racer skin. Birds aplenty, though, including Sandy's first *Phainopepla*. She, by the way, is now Sondra. She had told me to fall into her arms when I was having trouble on a rock. You can image what I did with that—a towering continental affair between us two.

We took a quick cold dip at the pond and thence to camp. Then Glen, Tom, Julie, Janie, and Joan helped to empty the outhouse pit and bury it, a noxious task, but not as bad as might be imagined. The biggest problem was to keep from tipping over the full wheelbarrow on the way down the trail. We made it and balanced the house again so its door opened.

A few others were back but Larry and crew straggled in around dusk. They had split up, dammit, and gone various ways. One group of Don, Kim, Dennis, and Gretchen took another way down and came in after dark. I told them I was glad to see them but ticked because they had broken my rule about not changing hiking plans beyond what is needed for safety. Then I told them I'd stay mad three minutes. So we went on to nature notes. Pat Murphy came out with a few needles of what is almost certainly the first white fir seen on the Granites. It came from about 6,000 ft. near a ledge with a pinon tree alongside, on the Cottonwood spring side. Pat said it contrasted strongly with the pinon and was six ft. high with branches only two to three ft. long and only tufted with needles. What a find!

Dinner, notes, and everyone is off to bed. We leave early.

May 6, 1980--Big Creek

May 6, 1980

Big Creek Reserve, Monterey County

Off to Big Creek for niche hunting. The blue bus appeared about 7 AM at the Barn Theatre and packs and all we crammed in and were off. I was mildly dazed from too much paper work and jammed schedule. But the trip will revive me. They always seem to.

The weather is beautiful, clear and mild, and the hills still clothed in green grass and the flowers are out in some splendor.

With Larry at the helm we bumped along, stopping only once for a sermon on geology. It wasn't too lucid, I'm afraid. We loaded the jeep with willow poles for the

sweat, and a lot of other general camping gear. Then we swung our packs on and hiked the 1+ mile to Redwood Camp. It's so clean and nice and handled our 30 students easily enough.

I released everyone to find a critter for the niche hunt.

Larry and I went up to the University Center to pick up some tools and cabinets for Boronda Camp. The cabin was occupied by two girls, Laura Patty, and a gal from Sonoma State. They were watching gray whales from a grassy knoll S. of the cabin and maybe a few dozen feet lower on the slope. It was a great observation post. One could easily watch them come into the kelp beds below. Two mother-calf pairs came in while we watched. Laura said they had come inside the kelp and that they had seen a baby mouthing kelp. They thought they had seen nursing and perhaps adults mucking in the bottom. We warned the gals about fire. The University Center is deep in grass and the road centers, too. Fire hazards are rising. We close the reserve in three weeks. By that time it will be dry as a tinderbox.

I worked on clearing for a sweat lodge our aboriginal groups wanted to hold, down by the crossing and next to a deep cold pool. I ate early and they sat at the fire circle by a fitful blaze. Our wood seems wet and the soil is soaking. Then off to bed alongside the rushing waters of Devil's Creek. I'm atop the old debris pile from the shake makers who once worked this grove.

Once I was arranged in the crannies I slept hard and long.

May 17-18, 1980--Matolle River

May 17, 1980

Matolle River near mouth, Humboldt County

All arrangements are made. Larry called New York and finally obtained permission to camp on our little bench by the N. mouth of the Matolle. I took my truck so we could haul enough boats for this big crew.

The trip up was through uneventful sunny weather, except that the truck brakes got hot above Ettersberg and they had a fairly close call stopping, I am told. I was pottering happily along in the little truck, away up ahead.

The trip across was made easily enough and camp set up by dusk. Offshore, a bank of fog ran down the seashore, standing threateningly and up on the wooded mountains across the stream a cap of swirling clouds moved over the hidden peaks. But, it didn't come down. Instead it dissipated and the entire trip here has been beneath clear spotless blue skies.

Everyone was tired so we didn't do any presentations but merely gathered around the campfire, gabbed, and went to bed. Stars!

Three Dr. VanDenburghs had graced our arrival, each more magnificent than the last, and finally an anticlimactic one in Petrolia with a tiny white beard, a Chairman Mao hat, and blue mechanic's clothes on. We figured because he had a tan truck it would be dry, his magnificent white beard—protection, and his blue clothes, a fine time on the water.

May 18, 1980

Larry and I escorted the first party up to the bridge below Honeydew. The river was a bit lower than last year and will take longer, so Larry and I decided I'd meet them at the Petrolia bridge if it passed 6 PM and they weren't at camp. They weren't so I drove up, almost to the launch point, and finally sighted them on the way back, above Petrolia.

They were ready for a lift, all except the big, 20-ft. canoe that went on. The dinner was ready—fondue and fixins when we waded across to camp, and a nice big fire.

I'd spent much of the day snoozing off a kind of flu that has me aching and logy.

My turn on the river, this time we cut it a little short by starting at the A.W. Way Camp. My crew was Julie, Flora, Judy, Sandy, Amy, Carol, Roy, Don, Alisa, Joan, Megan, Rena, Dawn, and Glen—a rum crew. We had a fine time, in the sun all the way. A blue heron paced us, we swam, banged into cobbles, went in circles with inexperienced oarsmen (and oarswomen). The blue raft dragged beyond the others—it can hardly be rowed at all. But we won out, over songs, swims, conversation, occasional flashes of tension and fear as the rocks or trees loomed up ahead and we seemed so close to being unmanageable.

I rode the last stretch from the Petrolia bridge with Judy and had a grand time on the river down. She's a good person with the oars even though inexperienced. We popped an oarlock but converted to a steering oar, which actually worked better!

Our crew caused quite a stir in the Hideaway bar—Petrolia—Roy and me and about 10 gals. We were invited to a dance (I was an accessory to the fact) and general good feelings abounded, plus free beer on the house. The dance we will pass up because people are behind on their presentations. Julie explained the geology, though, and I gave a thing on rivers and their wisdom, point bars, gravel riffles, and the like.

We tried a new thing this time—looking at physical processes. It worked well, the structures of streams, bars, sand, mudcracks and mud. People really did well, trying to psych out how these things work.

June 5-8, 1980--Tuolumne River

June 8, 1980

Thoughts on the Tuolumne

One knows one has arrived at trust when people begin to sing girls' camp songs. None are sillier, and when they can be sung one after another in perfect security that no one scorns, then that is trust.

Hiking concentrates attention on one's feet, on the trail just ahead. All sorts of otherwise unnoticed things go on there. Tete a tetes between tiny wasps, a magnificent gleaming metallic-green bee startles and bumbles off sleepily as if flying with only one arm in his flight jacket, running into a grass stack. Ants cross, one nearly obscured under its treasure of a whole caddis fly casing.

What *is* butterfly business, anyway?

Digger pines are leaners. One of my students called them "drunken pines." I thought they might do it to avoid shading as very young trees, but no, I found a leaner growing from a crevice in a huge boulder where it could never have been shaded. No, I think they probably avoid shading themselves.

. . . all innocent, a lustrous poison oak frond leans over the trail bending it in a sharp U. . . .

June 5, 1980

Rules for Modern Field Class leaders (cont.) [the beginning comes later!]

11. Lovers get in trouble.
12. Lovers pay no attention.
13. Groups need, at first, to be alone to find out who they are, to dissipate fears.
14. Care for the individual process of enlightenment not some goal.
15. All water is one inch over your boot-top (Backer's law).
16. If you have time, build your group as a place, an entity to which people can belong. In time it can become a bulwark against the placelessness of the outside world.
17. Jokers are good in modest quantities.
18. Trust unlocks the heart and mind. For a person to know his or her personal space, integrity and ethics will not be affronted, allows them to release themselves tentatively at first, to the trust of the group. Then unburdened of such fears, the mind opens to all possibilities.

. . . a fat utilitarian robin flaps by. Somebody seems to be shooting down deerflies this morning, like Messerschmidts over London. I've seen three that couldn't fly including one grizzled old giant with one front leg missing. He climbed the tip of my walking stick and then fell heavily into the grass.

At noon, under arcing oaks, the trail is dappled with light and shade and shingled with tan leaves.

Life is made of interludes, of streams that swell and then usually wane, or spread like spreading rivulets on a delta. Our group this spring has been one such. Tentative at first, it grew in trust, and then, in anticipation of an end, each turned a bit inward in wordless sadness that this precious place, this trusting enclave, was to reach its delta, too.

June 5, 1980

Early Intake, Tuolumne River, Tuolumne County

Time, this spring, has passed like the swift Tuolumne. I guess we all wish we could wander another few thousand miles together. There's so much to see. Being a naturalist is one of the most fulfilling of occupations since there is no place on earth without fascination.

I know without being told that most of Larry's and my hopes for you have been realized. We wanted to parade the natural riches of California before you so you could see firsthand, and examine in your own terms the remarkable diversity of this most diverse of states.

We wanted you to have fun doing it. I know that joy and the child's playfulness are keys that can unlock the mind. Part of seeing is caring. No person can really be successful plodding away at the edge of knowledge as a duty and a labor and at the same time expect fresh insights to come. What could be more fun than floating belly up in a cool cauldron of finest Matolle mud, slathered from stem to stem with glistening inches of greenish brown gooop, with only eyes showing!

What could be more fun than slurping barefoot around Boronda meadow in the rain, singing and digging tent trenches.

We have, it seems, run to mud as our official substance. Then, think of that delicious day on the Matolle, with Flora (or a reasonable facsimile) at the helm trying the wholly new rear arc approach to snag passage.

Or why does just hiking with or listening to Sondra make you silly?

I wanted each of you to surrender to that best-of-all educational adventures, letting the length of personal intellectual passage measure the worth of experience, rather than setting up some concocted standard to be sought by all.

Each of you, I like to think, has been taken along a trail of some personal realization, some unfolding of mind or spirit in our intimate encounters with nature.

I wanted many windows to glint in on your minds, not just the structures of science. To look through just one leaves a person one-dimensional. Some scientists I know are so solemn and self-deluding about their work, that they live with the delusion that no emotion touches their productions. Foolish folk I say!

Surely they must see majesty in the insects or flowers they study, the perfection and economy of design, the fittedness of color.

Who could view the lichen-splashed boulders of the Tuolumne rising like schools of whales and porpoises through the sloping grass fields and not see the consummate artistry of form, shade, and texture?

Who could cling to a narrow perch on a granite wall and watch swifts arc and oolplane down those towering airy gorges of apricot morning light and not feel a little less arrogant or omnipotent?

I wanted you to glimpse the overwhelming intricacy of nature and by mind alone sense the thrumming wholeness of life in this canyon.

I wanted you to know how little we really knew, and perhaps to reflect that the Miwok before us knew about flower landing platforms and bees, of afternoon canyon winds, and felt linked to all that was around them.

About all of deep importance they may not have known was the land beyond their tribal holdings, the spinning globe in its wholeness that adds a new dimension to how we must think about ourselves.

For me the journey has been rejuvenation, a glimpsing of many things I've never thought or contemplated before. As by a projector being adjusted, you have all come into focus as caring people of remarkable and varied talent. Larry, all spring you and I have traveled in the company of princesses and princes. I put the princesses first because there are more of them, and we have to watch our step.

I know I am deeply fond of you all. Hit the road and wallow in the lake mud and climb the plateau and then help me build the tree house, a motel 80 ft. off the ground with no visible plumbing.

June 5, 1980

Thoughts on the Tuolumne

The resonant drum of my boots on the dark forest trail.

Water sapphires lined up in a leaf fold.

Gray-green lupine stars.

Out from a dark crevice a fern bends and reaches for light.

Spilling cascades of auburn lichens on the boulder face.

The life on the ancient manzanita pours, flows, and twists in mauve streams around the ancient dead and silvered arms. The living river branches to pass on both sides of a long dead limb. It piles in wrinkled folds like syrup over partly hidden burls. On each branch the silver is edged with black strand lines of the retreating living band.

A boot propped in a low crotch for support peels the mauve away revealing a glistening, moist, yellow-green patch.

One cannot look at a buckeye tree in bloom without thinking of a candelabra. Each is set with fifty or more white and yellow tapers curving up from the canopy.

A great somber Goya boulder rose along the rocky trail, painted in black and gray with splotched lichens. Dark clefts sliced along its face and beneath it a stone-roofed cave led inward to blackness.

Why do lupines balance rows of water sapphires in their folded leaves? Why does the dew gather there in little shining spheres?

I should think that digger pines would drive fire lookouts wild. They look so much like plumes of insubstantial gray-green smoke rising from the hillside.

The trout riding the bow waves of submerged boulders, or gathering in thin rear eddies like boys riding bicycles behind a truck.

Watch the world slide by, swirling patches of foam casting moving shadows or focusing little playing beams downward through curved bubble surfaces.

Twigs, alder cones, little insects caught in the film move by. The movement is ours and the trout's, but does not belong to the insect being swept slowly, twisting and turning along.

Where the slabbed boulders jut out over the stream, waves of reflected light dance and intersect like smoke blowing away.

Manzanita sets its leaves on edge. Out there in the high light it's probably important not to provide canopies for the rising heat.

The slanting sun sets the forest alive with light. A clear yellow coreopsis nods brilliant heads against the dark rock. Alder leaves look as if lit from within, hanging over the olive stream.

I lay my fresh-caught trout on a rock. Ten minutes later the bag was swarming with ants hurriedly seeking ways inside the bag. Such imperative message there must have been, sending ants pouring in hurried ranks from their underground works. No single ant rushing back to tell the others of this giant windfall could have roused the rest as they obviously had been. No, more likely a message on the wind swept over their coned entrances and many were set in motion at once.

High cirrus passes in diagonal rows athwart the wind. From my east-west cleft in the Sierra, they slide constantly overhead. Below them, and not far above the craggy canyon rims, gray and white cumulus, trailing veils, swirl in the opposite direction, probably driven by winds that catch and swirl around the [?] peaks beyond my view.

A cracked, diked slab of gray-banded gneiss forms a stone platform along the dark, deep river. For river and stone to meet is the most immediate of newness. That stone had its genesis unimaginable millions of years ago in some sea and sliding beneath a continent of lighter rock condensed and pressed into those bands and only now, have winds and water stripped down to it, so that in its ultimate moment of existence water

insinuates into it, pulling it apart again to tumble in chaos to the river floor, to be rolled, ground and tumbled till it's no more.

So many adaptations are deeply systemic; so few, on analysis, seem to even approach being unitary acts in nature, conferring this or that specific advantage to a plant or animal. Each change, instead, finds itself in an almost infinitely complicated sea of interlocking relationship both within and outside the unsubstantial boundaries of the organism. Doctors with their specific pills for specific symptoms could do well to ponder this.

The digger pine across the grassy field in front of me looks like a column of unsubstantial blue smoke. Why bluish? It's like so many desert plants. Bright-green chlorophyll partly hidden beneath a lighter bloom of cuticular waxes or other compounds.

A balance has been struck, here in the Tuolumne and also on the desert, between racing the sugar machinery and how much water it costs. Diggers opt evolutionarily for a slower food production to conserve water. With this option comes a color that prevents the digger from living in shade. With it comes the need to deploy foliage so as not to shade needles farther down the tree. It becomes wispy, and light filters through almost unimpeded. Its needles and branches are constantly mobile in slight winds, shuttering the falling light through the plant. It has taken a systemic path and can now find a modest place in hillside and canyon. The silver or gray plants of the desert are no different, except in detail. They too have struck balances involving a profligate light source with side latitude for evolutionary play, while to them water is a precious resource to be fought for, traded for, and sequestered like the most precious of jewels, and given up with deep vegetative reluctance.

Mosses and lichens amaze me. Many choose the most exposed situations to live and then taunt nature by being fuzzy, textured, and in shades of black or gray.

To be black and fuzzy on an open rock face is to trap the maximum sun in a place of great heat. Rocks in summer, after all, may grow so hot, one can cook an egg on their surface. Then, the moss, crisp and black, breaks off brittle on one's pants and socks, as apparently dead as any fallen branch beneath an oak. Not a bit of it! Pour a cup full of water from your canteen on a moss patch and within a few minutes the fronds have swollen, beginning to curl outward like huddled Bedouins after the sandstorm has passed. Emerald green is revealed from somewhere in the black mat.

Is it that it is dangerous to be partly moist? I'll bet so. I'll bet the plant must pass as quickly as possible from one metabolic state to another and that whole circuits of machinery must shut down in minutes or hours as the plant crouches again, hides its emerald, and goes black. Then, its internal machinery in a new state, it crouches again and waits.

What is the transition about? From what to what? What part of full life lies in slow process in these black, crisp fronds? I'll bet it has to do with free and bound water. Free water is a mixed blessing. At its lower temperature it turns to ice, spearing and swelling cellular parts, rupturing walls and delicate intracellular strands, bodies, and chemical chains.

At the upper it boils more and more rapidly to vapor. Such vapor may be as destructive as ice. But some essential water may be bound chemically and cannot at rock temperatures be converted and lost very fast.

I suspect that transition is involved and that the moss promotes crossing the barrier as rapidly as possible, shunting then to a new state, marking metabolic time as the slow processes allow when water mates with other molecular things.

Norris's law: Pay attention to the state of your ass, I tell my students. When it goes to sleep, it's time to move. The moral is to observe well. Your body should intrude its messages as little as possible. Be comfortable to see best.

Rules and Observations for Modern Field Studies Leaders:

The slightest girl—the one you worry about, is apt to be the strongest.

Drinks on the ground always come to grief (after Ferrisy's law).

- 1) Never embrace a girl with her clothes off unless yours are on.
- 2) Sex divides.
- 3) Little and big kids both have attention spaces.
- 4) To see out one must be in inner peace, both emotionally and physically.
- 5) Nature could care less.
- 6) Embrace both boys and girls.
- 7) Take the rain with as much pleasure as the sun, but to do this Law 4 applies.
- 8) No one can stand being profound more than 20% of the time, nor can anyone stand a person who is profound more than that often.
- 9) Say thanks for back rubs, but don't rub back right away.
- 10) Orchestrate chances for people to see for themselves and not [?] for you to tell them what they can see?

August 11-September 1, 1980--Kealake'akua Bay, Hawaii

August 11, 1980

Kealakeakua Bay, Hawaii

How does one learn about the social relations of wild porpoises? The chances one has of seeing anything are fleeting, little camera flashes of animals swimming. Usually there are so many animals that one's attention is torn apart, just as fishes in a fish school tear apart the attention of their predators. We are predators on understanding, and mostly we starve. Well, two major things go on. First, one learns to push aside the confusion by looking at one thing, seeking answers to one tiny question amidst the jumble of events. Do the resting animals travel with their bodies staggered or are they abreast? Thus armed with a question a tiny fact emerges. Nearly always their resting groups are in echelon, staggered, snout tip to eye. Ah, but when they arouse this pattern changes. Many times, these animals travel abreast. Then we ask another tiny question. Do resting animals touch one-another? Aha. Mostly they do not, but often they swim with pectoral tips inches apart. Do waking animals touch?

The second thing we do is be cautious opportunists. Not having clean sequences to deal with, we gather hints from anywhere we can find them. The captive spinner porpoises at Sea Life Park Oceanarium are a rich ground for us in spite of our clear knowledge that, much, even most things in the lives of these captives are warped by their confinement. At any rate, the three animals no longer on public display occupy a big

disc-shaped tank with an underwater viewing room on one side. We watch. Sure enough during midday, these animals swim in echelon, mostly not touching and later they arouse and move into caressing patterns. For much caressing, especially mating or pseudo-mating (for much apparently isn't directly reproductive), animals abreast, nose-by-nose fits together better.

Question by tiny question we tear at the chaos and the regularities of these porpoise lives begins to emerge. Cautious of the circularity that threatens if we move too fast, we begin to recognize "rest" in an instant; one of those little camera flashes will often do. The guide posts have become slow movement, echelon, not touching, a general lack of sociability with no, and almost no sounds. We learn they rest best in shallow water over clean sandy bottom, and always near midday. A step has been taken, a block has been laid down. The tiny questions focus more tightly. We see descent into rest as gradual and awakening as rather abrupt.

In like fashion the sophistication of other parts of the lives of these porpoises builds. School geometry emerges as a fluid system providing a place for all things in a porpoise life—a dynamic and subtle geometry quite directly molded by events. Fear coalesces a protective structure as we learned from swimming with porpoises in tuna nets, but mostly in the calm bays where we encounter them most that structure is not very evident.

The rules of this circular observational game are 1) watch the chaos at first until you begin to suspect regularities. 2) Then ask a small question. 3) Check that question with nature because she holds the truth, and no matter how much we wish, or how hard we imagine, we don't. 4) Probably this new look will modify the original question. 5) Look again. 6) Then, piece by piece, a turning of the observational wheel [?] regularities will begin to emerge that we can count on. 7) Then we go back and ask how we can demonstrate this or that regularity to our colleagues. What table or graph will show what we have seen. 8) Often enough such pointed quantification will in itself pose new questions or reveal new things.

All this is well and good, but as my colleagues, Chris and Rachel gently point out, the glimpses we get are so fleeting that we must modify our observational process a bit. Instead of a single question we must carry with us a number of questions simultaneously, so that we do not waste all our days waiting for a chance to check a given idea. When babies are in view it's perhaps best to have a baby-related question ready to ask, and then, once the baby has disappeared be ready with questions about spacing, or sensory geometry, or turning. So, the process I see, and what I've been following pretty much is first to frame observations in terms of the cycling daily pattern and then be ready with a series of specific things to ask. That is, most everything seems to shift according to the time of day, a time for feeding, one for traveling, one for descent into rest, one for rest and wakening. Then in that frame to ask things about, for example, relationship.

The process of discussion here at camp becomes important. It's where we transmit things to ask to each other. So we talk over the dinner table and frame new questions and talk of mini-triumphs.

Even though we arrived (Phylly and I) on August 3rd, I've not gotten organized enough until now to begin detailed daily notes. I've been tapering off other duties—Maggie Fusari's dissertation, student papers and notes and other concerns. The boats haven't been wholly ready nor my use of them, nor have I or Phylly been able to take the

full sun. So we expose various coated parts, learn to use the Zodiac as a photographic platform (I've fixed a line on her side that I can hang onto.) Randy prefers the bow but that scares me. I worry about sweeping into the screw. We've been putting acoustic feedback apparatus on the *Maka Ala*—a small hydrophone in a plastic conduit, bolted onto the false bottom of the vessel. It is shielded from the rear to cut down motor noise and the plastic greatly reduces water noise over the receiver itself. [Drawing.]

The *Nai'a* is out of the water. Randy put a coat of paint on her bottom today and she has her engines tuned tomorrow. One of our outboards is out of commission (off the Zodiac) so we use a spare 15 hp.

Phylly, Paula, and I took the Zodiac south today in the morning, hoping to find a chance to photograph with the Eumig in clear water. The clear water was there. I think I could see 100 ft. down, but we saw only five porpoises. They were all adults and were skimming around Palemano Point into K Bay as we went south. We photographed them. One had a subtle but clear fin mark. No other animals appeared save a beautiful 7-8-ft. span manta ray in Hookena Bay. We slid over its jet-black shape in maybe 60 ft. of water. It flew beneath us maybe 6-10 ft. down and then tipped and flew away. I had several extended views. I could see its palps reaching forward, lined on wing margins with white. A magnificent animal. Before I could ready the camera it was gone.

Both Phylly and I returned a little cooked but not seriously so. We slathered ourselves with aloe cream with Vitamin E, which works wonders. My birthday today, complete with wine, a real coconut cake, a nice dinner (chile and salad), and two gifts—a walking stick for my collection of coffee wood, and a cap with ram's horns. If I can control my horns all will be well—they flap a bit.

Tomorrow we're off—one group in the Zodiac, another in the *Maka Ala* and Randy to stay home and tinker with the decade[?] attenuator and our Sony tape recorder and to hope for a check.

August 12-15

We've settled on a schedule now and go out in either *Maka Ala* or Zodiac to make recordings of behavior or film from the side of the Zodiac. It goes pretty well now; quite a number of films have been made, the best down by Hookena where crew including Phylly found a school that then encountered another school, and they were able to record it all. On *Maka Ala* we have some good sequences now on various behavior during descent into rest. Long tapes have been made in commentary, including stories about mother-young behavior, interanimal spacing, the reasons for frequenting sand (dark sharks will not be visible even far above dark coral).

Paul Breese and Mary Lew have been here and we had a grand time with them, then Pat Brown and Bob Berry, and Pat's mother and daughter Cathy have been in and out. We went to a luau with them up at the Keahou. There were some evident stresses in that group—Cathy not happy to be out here with grownups and wanting to find some good boys her age. She did too. Looked happier.

All in all, through the flights of visitors we do seem to be producing some good usable data and I'm much more satisfied with what's been coming out of the underwater than I expected to be. With a few more shots at it we should have a lot of stuff. There are more than 50 rolls of film now, and 120 hrs. below water in *Maka Ala*. And all of that is

something no one else has done before. I'm also enjoying my literature review too. It makes me probe into a lot of people's ideas and think how they apply to this work. Fine.

August 16, 1980

Kealakeakua Bay, Hawaii

Nice day today, breezy around noon, but calming in the afternoon, though big squalls trail veils of rain down to the southwest. Randy, Shannon, and Rachel went up in the plane today, to fly over schools along the Kona coast until dusk, hoping that they will be able to see aggregation and travel to sea.

My task for the day was to take the Zodiac out to follow schools as they woke. It looked rough and Phylly thought better about sea so Paula, Chris, and I headed for the Zodiac at about noon, wondering if we would be blown back. We weren't. It calmed. The plane told us there were 15 porps in Kealakeakua, but we never saw a fin, even with three observers and binocs. The plane also mentioned a group of five just south of Honaunau, so off we went for that group. We arrived about 1330 and found six animals, including a small baby and one about a third larger and four adults. They were in the bay south of Honaunau, right in against the lava bluff. They circled in that area until we had to leave at 1600. I'd promised Phylly I'd either reach her by radio or come in at four. So, come in it was.

We spent our time timing the dives and surfacing in this little school. It was amazingly regular—dives were between 3:30 and 4:10 long, and surfacings were a bit more than 20 seconds, or usually five blows. The most interesting thing was that a number of times the baby surfaced first by several seconds, especially on long dives. It seemed pretty obvious that a four-minute dive was a bit more than the baby could do, and probably was limiting the diving of the adults. This baby was small enough to throw its snout as it swam.

Once the school lept in a rank unison. Beautiful arcing leap it was, too, directly after a thrash in the water. I don't know if they crossed a shark, or what, but they quickly settled down.

The trip back was slow, with the little 15-hp kicker for power and us afraid to run it flat out because of water supply problems at that speed. Its shaft is short.

Tomorrow I want to go out on *Nai'a*, which is now back at anchor, after Randy had its engines checked, seals and the like. I want to go out to the feeding grounds, and see if we can watch underwater.

Well, off to forage for something to stay myself till dinner.

I had an insight today while reading. Why, I wondered, do males often harass mothers and babies. Often they bite and scratch both, especially the mothers. They will try to mate and bite and prod the genital area of both. Both are unreceptive and frightened and death can issue.

I wonder if in an oestrus animal if sexual advances and reception of this sort are accepted in season and if in other parts of the year, especially for mother-calf pairs they become aggressions focusing on a very sensitive portion of the body. In other words, isn't it still possible that the males are driving mother and young, in nature to a safe part of the school and in captivity without a place to go this will cause injury and death at times.

In the school ringed by adults in times of stress, this places a ring of aggressors around and under mother-calf and secures[?] position. How does Male know when to stop driving them in nature?

August 17-18, 1980

Kealakeakua Bay, Hawaii

Yesterday we took a long trip up to Keahole Pt. in the *Nai'a*, finding a school just north of the point at about 4 PM. It skirted the shore, close in, nearly to Homokohan anchorage and then readed[?] sharply out to sea. In 100 fathoms or so it dove, subsynchronously, spread over a fair stretch of sea, and was not seen again, even though we waited until dusk. The impression of the animals heading toward the setting sun was unmistakable.

I took a reporter, Ron Kruise, from the West Hawaii News, out on *Maka Ala* with Chris. We [?] in perhaps 30 animals, much of the time in the cul-de-sac and he got super shots. Thirty seconds in the pit were all he could take. But we did him good service, and I liked him.

In the afternoon Rachel, Paula, Randy, and I followed the school out to sea on the *Nai'a*. We were on the school at 3:00 PM and by about 5 they headed resolutely out to Captain Cook Point. Once outside, there was a sharp turn, the animals porpoised, in beautiful clear ranks of smoothly leaping animals, back into the bay. They arched over past the anchorage to Palemano Pt., milled, went very close, within a half dozen yards of the lava bluffs and milled back and forth between Maniai and nearby Palemano for hours, with bursts of activity and periods of quiescence. At after 7, as dusk was falling, they headed out, cutting away from shore directly toward the largest light patch in the sky. Leaping increased dramatically, until we lost them in 75 fathoms of water and turned back in the mist.

It occurs to me that the way a school led by an age-related hierarchy but no one leader, decides, is by a shifting equilibrium. Zig-zag swimming is a perfect case in point. One can see the group will oscillate. These group animals decide everything by oscillation of one pattern and the next. Bouts shift that way, and the decision of when to go to school is made that way too.

September 1, 1980

Kealakeakua Bay, Hawaii

I have written for a while, being busy with the book, various bits of field work, and summary papers of a conceptual sort that follow.

Phylly and I went north, met Paul and Mary Lew Breese near Hawi, on the Kohala coast, where Mary Lew has a little woodworking shop—she makes hair prangers, combs, mirrors using native Hawaiian woods. We stayed there for a long and sodden evening (Paul and to some extent me, anyway) when I listened to the incredible complications of Paul's now bachelor life and tried to enjoy the relative simplicity of Mary Lew's work.

Next morning we headed for Kamuela, picked up Roger Coryell at Hawaii Bound and took off through the gap road. We stopped at the Nene-rearing project at Pohakuloa, found Ah Fat Lee there feeding his birds—some Laysan teal, two Mariannas ducks (2 of

only 20 in the world), and a pair of Hawaiian crows (of about 50 alive). These are lovely birds, with rather soft, gray, tufted heads and curious crow dispositions. They've had some reproduction, but not ultimate success yet in reintroduction. Ah Fat's wife is Paul's favorite sounding post, and I don't what it bodes for that relationship.

We went on down to the Mauna Kea road and up to about 9,000 ft. to a cinder cone Roger knew about where one could find olivine crystals inside volcanic bombs. We had a grand, panting climb and found lots of the bombs. The crystal masses are sharply demarcated and usually triangular in outline, corresponding to the outer shell of amorphous material that much congeal first. Then we slipped down toward Hilo, named the venture "Cockamamie tours," holed up in the Hilo Hotel, a grand businessman's hotel for about 2/3 price. Nice place and all we needed. Then we relived Roger's past out on the point near Hilo Bay where he used to go wading in ponds. We did too, ending up waist deep, laughing and catcalling at our tour director. Then we hit Akaka Falls, for the lovely walk, the plants, and the pretty 700-ft. falls.

Back to the hotel for a nice Japanese dinner. Next morning we were off to the south where Roger regaled us with tales of his proposal to Earnie, their churchmouse early life and then his reporterage of the volcanic eruptions down at Puna.

Wild rides in the middle of the night with loaded newsmen running out of booze, Roger finding a bottle, put out for Pele, in the dark in a tree hole—instant hero. Then his mother in law who thought Pele had drunk it told the story for years, Roger too meek to tell her, but he finally did, to gales of laughter.

On to the volcanic park, to steaming vents (big joke)

September 2, 1980

Kealakeakua Bay, Hawaii

This afternoon, John Hickey, Rachel, and I took off on the *Nai'a* to follow a school to sea. We worked our way north all the way to Honokahou Harbor, where a good group was coming down the coast toward Kailua Kona, and we turned and followed it till dusk at about 6:30 PM. It did the following—it speeded up to 1400 RPM on our engines (a pretty good clip, I'd guess five knots or more, then slowed, repeatedly). At the same time it changed course, going out, coming in, mostly following a bottom contour, I thought, about ¾ mile offshore, some course changes were reversals. At changes, aerial behavior would pick up, and as the animals speeded they were often dotted with leaping animals, many headslappings in lunges in the direction of movement. Then, offshore a little, they began some tentative and very short dives, often leaving a few animals on the surface. Then they spread over at least a mile of sea, along the general line of travel. We left them in order to make it back to K Bay before utter darkness (we didn't make that). The total impression was of great fluctuations in speed and aerial activity, starts and near stops, with some milling, fitful tentative dives, as if getting ready for the real thing. In fact, the whole pattern was a long, 2½ hour zig-zag swim, as the animals worked toward the feeding grounds. We never did see a full-blown synchronous dive.

The first time I'd done it, coming into the dark bay following lights, full of pleasure when Cook Point light came up flashing and we skirted to the south, shone the big spotlight on the boats and buoys and finally made our way to the proper one, fished it up after only three tries, unraveled the incredible snarl of line provided on it, shut off switches and stuff, and made our way ashore. I can't think of anything I forgot.

Summer 1980

Decision Making in a Spinner Porpoise School

No single discernible leader of events seems to exist in a spinner porpoise school. Instead, age seems to impart tasks to porpoises that may be carried out at many places in a school by many animals simultaneously. That is, both adult males and females may herd young, or mothers and young in times of stress. And both probably are involved in the changes of direction that take place in a school. From captive observations much and perhaps all turning seems initiated from behind (probably anywhere in the school, and often perhaps from the periphery of a school). If a school contains a mixture of ages throughout its breadth, then nuclei within the school, of older, experienced animals may probably also initiate changes in direction, and probably also of activity, though such activity change may not require leadership, only group response to environmental change.

We note that in paired behavior patterns there is a clear oscillation during the course of such a pattern. Onset may have certain precursors, and then may become rather intense and exclusive of outside influences, except those of the strongest sort. Then the pattern may wane, the partners separate further and further, outside influence may intervene more and more until the pattern ceases. But in the cessation one can see an oscillation back and forth between the pattern in which the animals share, and its absence.

Animals who have been caressing, and who have drifted out of pectoral touching distance, may come together again, briefly, drift apart again and come in for another even more brief touch, before separating again, perhaps finally. An oscillation is involved in which one pattern shifts to another. Onsets are sharper than terminations.

We see the same kind of oscillation on the group level in the pattern zig-zag swimming. The race out to sea ends in a turning back to rest, and to the rest location, and the oscillation can be marked by the fluctuations of aerial behavior. Finally, probably in concert with physical factors such as light levels, scotopic changes, etc., the school as a whole moves, with great vigor and high levels of aerial behavior to sea.

Thus each animal in the school is engaged in shifting modes of behavior whose changes exhibit oscillations that clearly indicate the dual nature of motivation in the animals involved.

This is unlike a fish school. How? It seems clearly mediated by activity level. It seems as if the oscillation observed leads to unanimity and that high activity is also a marker of concerted action by the school. Once each animal is brought to a level of alertness and is in concert with the pattern being reached, it can occur. Previous to that, oscillation occurs. Each behavioral shift requires a pep rally.

(The effect of disruption of rest groups is instructive. What happens is that the activity level rises and shunting from this pattern to the next occurs. "Animals are driven from the bay" may be the same thing as saying rest cannot exist with active participants who[se?] use of sensory modalities are incorrect. A pep rally has been imposed from outside.)

The fish school seems to be the primordial sensory integration system. That is, members are receptors of environmental information whose intensity affects their behavior directly. The waves of influence of Radakov may sweep across a school, causing it to turn, or compress. Nonetheless there is also, in the fish school, influence

between animals that must be modified by such waves of external influence. These are the countervailing forces involved in spacing and positioning of fish in a school. These, for example, are the responses to marker spots on the sides of fish, which when an animal turns, swing across the visual field of an adjacent fish and are picked up, perhaps by edge receptors, causing an adjustment in the receiving fish, to bring stability between marker and fish again. These are the forces that regulate interanimal distance; perhaps the reception of flow fields in the head and lateral line canal systems of schooling fish.

Are there the beginnings of volition in these schools? I don't know, but would not be surprised to find them in view of the fact that learning is a considerable component in the behavior of many fish.

But, volition isn't very evident in polarized fish school affairs. Mostly one seems to see structural internal relationships mediated by sensory relations between the school members, modified by environmental information from outside the school. All this occurs in a dynamic equilibrium.

In the porpoise school, one seems to see almost the exact reverse. Internal patterns seem muted and flexible, at least until stimuli from outside become very strong. One sees intraschool events, and school decisions mediated by alertness states, and features of the diurnal cycle, light levels, sleep patterns, and the needs of social communication (caressing bouts), rather than preponderantly by stimuli from without.

But, in two conditions this is reversed as porpoise schools seem to revert to a degree at least, to the status of the fish school. The first is during rest, in which the quiescent school tightens, becomes more clearly polarized, individuality is muted, movements become much less individualistic. The correlates are seemingly a complex of the dropping out of the acoustic mode of surveillance of the environment (echolocation effectively ceases), and a strong lowering of activity level.

Concurrently, the school becomes much more wary of outside intruders. It is harder to approach and enter a resting school than an alert one. This I lay at the door of the oppression of individuality, and partial reversion to sensory integration. The second is during threats of one sort or another to the school members. In the tuna net we saw the tea cup formation, and a rafting center core of animals. When the school is frightened it tightens and its activity increases. Usually a frightened school flees in waves of simultaneous arcing leaps. A rifle shot behind a school will create this, or release from a tuna seine will do likewise.

The individuality of the alert porpoise school is the gift of the large and complex brain and the consequent intelligence. The function of the sensory integration system of the fish school must be assumed by some members of the porpoise school, probably the echolocation guild, and as a substitute for the waves of information of Radakov, it seems likely the porpoise has substituted acoustic assessments of the status of school safety, from these guild members. Much of the time there is no need for the fish school in a porpoise's life, and there is only a skeletal structure of it left, but the signaling allows it to be resurrected in moments if it is needed.

One has the picture of a very intelligent zebra herd wending its way across the veldt (the sea) with a retinue of predators (in this case less capable mentally) at some distance beyond the escape distance of the porpoise school, waiting for that signal, that opportunity that allows successful attack. It comes, too, as we can tell by scarred animals and the many reports of porpoise remains in shark stomachs. The ancient still wins over

the refined new animal enough to matter greatly; enough to modify the entire course of evolution of the porpoise, enough to retain in times of stress the old, tested methods of tight synchronous swimming, almost instantaneous information transfer, probably confusion effects produced by numbers of animals sweeping across the sensory field of a predator, even by sensory illusions. In fact, the evolutionary battleground between porpoise and shark may lie, ultimately in a battle of illusion; the school deluding the shark, and its sensory system refining to reduce the delusion. I suspect that's where this battle is with all groups and their predators. (Shark threat behavior mimicked)

But, most of the time, the porpoise school can spend its time in the multet of relationships between individuals—the greetings between schools in the morning, the reaffirmation of relationships in caressing, mating, birth routines, the growth, play, maturation, and role assumption of the young.

Yet, not all odontocete schools seem to behave this way. It seems that a basic schism exists, a basic tipping of the evolutionary-ecologic balance that sent some taxa down one line, and others down another. One route, that taken by the spinner porpoise, is to make use of the very great resource of small prey (that, in this case, form the deep scattering layer—the halo of small squids, shrimps, fish, siphonophores, octopi, and larvae), much smaller than themselves, which do not require strength to kill and subdue.

The other route uses larger prey, larger fish, larger squids (some even 50 ft. long), or even other marine mammals.

The one route, the spinner's route, leads to dependence upon the integrity of the school, and its sensory integration system, and with it the decision-making system that relies upon members who are true schoolers—decisions are made by the group, by the oscillation of roles and tasks in times of little stress, and by sensory integration in stressful periods.

Whether the spinner has defense other than the school isn't clear to me. I wonder if the aggressive sound of the adult porpoise can be a weapon.

The other route is that of the large toothed animal capable of its own direct defense. In its polygynous schools defense may fall upon leaders, which mostly falls on the males because of the great disparity of size that polygyny often brings (though note that in nursery herds of sperm whales the females are quite capable of their own defense).

Leadership in the truest sense seems to exist in such herds, and this I suspect, is why their members often strand alive around such a leadership structure that for one reason or other has come to grief.

But, note that even in polygynous schools there is tightening of the school under threat. I've seen it in pursued killer whale schools, and it occurs in sperms. The ontogenetic groups in these schools still require protection—the young, the suckling mothers.

So, I think no open water animal at sea escapes the need for the school in the sense in which fish use it, but that the high order of intelligence of porpoises, and the larger toothed whales has profoundly modified it much of the time.

What might be the consequences of geometry in porpoise schools?

We assume that the geometry of porpoise schools is less rigid than that of fish, and we assume that this is due, in part at least, to the higher evolutionary level the porpoises represent. Part of any such difference, however, might come from the sensory modalities

that fish and porpoise use to regulate their relations to their fellows. What follows is an attempt to reason out, from what we know of porpoises and fish, what to expect from these relationships. First, let us look at the senses each critter is thought to use.

Fish have good vision, and color vision at that. They apparently have the attributes of vertebrate vision; the diversity of receptor kinds in the retina, an eye capable of accommodation (at least some seem to). Their lens is spherical, and some can move it back and forth. Like the porpoise the cornea may be covered with an irregular surface—in the fish an adipose eyelid, in the porpoise a flowing mucal secretion. Both are close to the index of refraction of sea water, and in both we assume the cornea is unimportant for this reason. Porpoises see well but not in color.

Fish have the *ferntastsinn*, the distance touch receptor system of the lateral line and head canals (*campullae* of Lorenzini), sensitive to sounds as low-frequency as swimming motions.

No one knows how a porpoise senses pressure fields around its body, though from watching them assume places at a ship's bow, and other observations, they seem exquisitely hydrodynamically aware. It is probably tactile.

Fish hear, but only low sounds to perhaps 2,000 Hz, and even then there are questions about directional sensitivity. Obviously fishes have this capability to some degree, but how precise it might be, and how intense sounds must be to be heard is another matter. Only some fish have Weberian ossicles, the body chain that extends from skull to swim bladder. Many schooling fish such as the half beaks schooling in front of the house, do not. The question is, even with a single chain of bones and a median swim bladder, how are directional sounds discriminated.

Porpoises are exquisitely acoustic. Most genera hear at least to 50 kHz, and some to 150 kHz. Sensitivity is great. Better than man, and they have biosonar, which may be extremely sophisticated. They certainly can search the environment 1500 m ahead of their schools. Their sounds are highly directional, as is their hearing, both directed predominantly forward. Their sound pickup is likewise directional ahead. There is no question that they can detect predators and food by echoes, and they can hear other social signals. They have refined directional hearing.

Porpoises have no sense of smell; fish can smell down to nearly the molecular level. Both have a sense of taste. Fishes may sense electrical fields; porpoises probably do not.

It is perhaps very refined in both cases. Of these senses sound and light reception are probably predominant, though the electrical sense of fish may be important in transmission of the waves of Radakov. And the sensation of turbulence, of differential water flow, is probably crucial to both. Both probably regulate geometry to some extent in relation to flow fields. After all, a 70% saving in energy expenditure may accrue to the animal capable of playing the hydrodynamic game. In either case, fish or porpoise, they swim all their lives and such a saving is not a trivial aspect of their energy budget.

So school geometry should reflect both sensory and hydrodynamic concerns, and sensory concerns involve both sending and receiving signals.

From the standpoint of each sense involved, what school geometries would be expected.

The predator avoidance strategies used by the animals involved should be reflected in school structure.

Let us look first at vision: In the sea, for a small fish, it loses definition a significant part of the time within a few cm. One fish could not make out the pattern components of another very far away, assuming that these are used in ordering of the school and in regulating differential movement. And in the dark it won't work at all. The cut-off point, at the latest, should be the photopic-scotopic interval—the time when eyes that are predominantly using cone vision switch to rod vision. Rods have much less definitional capability than cones (each serves several neurons, unlike cones). This will hold for both porpoise and fish.

For these reasons I'd expect school structure related to vision to be a daytime thing. If a porpoise wants to assume the visual mode it better be done in the day in reasonably clear water. Is that why our porpoises rest during midday and why they leave when the bay becomes especially murky during or after a storm?

The visual mode for a small fish might require fairly close packing; for porpoises less so. There should be a direct relation between body size and packing in a visual school, and between packing and the size of pattern components used in visual orientation. The 5 mm-diameter black spots on a sardine would be functionless on a porpoise which would, instead, use pattern marks of similar relative size, or several cm in one dimension.

Pattern components related to disposition of schoolmates for porpoises should be

- 1) Beak tips
- 2) Eye patches
- 3) Stripes
- 4) Dorsal and pectoral fins (you can learn a lot by looking at your neighbor's control surfaces. Especially pectoral fins are important. Is that why many are dark and armpits are white—so that tiny rotational movements become obvious? Is that why the inner margin of flipper has a right angle bend over a light field [drawing]?)
- 5) Longitudinal pattern gradations arranged in steps, from dark to light, which allow precise rotational information to be transferred. If, for example, one looks diagonally down, can only the dark cape be seen? Then the partner is in normal orientation. If the mid-lateral gray panel shows, the animal is rotated toward you at 10-20 degrees. If the belly white shows the rotation exceeds 20 degrees.

Note that bottlenose, living in murky water, grade only from gray to white and that belly flashes of white tell even us when a porpoise is engaged in courtship or mating, and the information comes in from approximately the limits of vision.

- 6) Dorsal fins are usually dark triangles, good for close-up assessments of horizontal turn angle. As the fin turns it changes to a vertical dark line.

The visual field of each animal needs consideration. The fields of most schooling fish are predominantly lateral and eyes tend to be rigidly fixed in schooling fish?

The eyes of porpoises are highly mobile, and are on the widest point of the head and furthermore, because behind them lies a pad of cavernous tissue, they can be pressed outward even further. Some porpoises, at least, can look binocularly backward over their

tails. All can look forward binocularly over their own snouts and both up and down binocularly.

The binocular field may be relatively narrow. If vision was mediating school deployment, I could expect partners to stagger in three dimensions.

Key features could be:

- 1) Pectoral viewing. Note that the *viewer* would thus be a *receiver* of attitudinal information and thus secondary (if not even subordinate) in any turns. Of course, in an echelon, a viewer is also viewed by the next animal in the staggered formation.
- 2) Viewing of longitudinal pattern divisions, i.e., dark cape, lateral field, belly white for roll information. Note that viewing down at midbody or head provides the same data.
- 3) Only equals look each other in the eye. (Izzatso?) Thus mostly I'd expect porpoises to avoid utter equality in fore-an-aft position unless ranking made no difference in their schools (one seldom sees them eye to eye). I think ranking probably does make a difference.
- 4) Viewing out by individual animals. As large a field, both fore and aft, above and below, should be available as possible.
- 5) Since the animals are moving forward all of the time the section immediately in an arc in front, at the limits of vision carries the highest degree of unknown. It is there that predators might most often be first sighted.

Predators coming in from behind can be countered by repeated and frequent reversals of course, so that vision sweeps in effect, a safe area, on a repeated basis.

If the water column is kept shallow and the bottom without ambiguity where a dark predator could hide (i.e. sand), security is greatly increased. Note that viewing down against a dark bottom allows a predator to hide even high in the water column.

- 6) By the way, rest in porpoises might be importantly a time for the biosonar apparatus to rest. Recognize that each click contains energy not far from the threshold of tissue damage and only because it is brief is the reason the animal not hurt. Restitution on a daily basis may be needed.
- 7) School speed is important. In the visual school slow speed allows careful assessment of new features coming out of the murk ahead, and at the same time it allows predators to move in from behind. Thus, shifts in direction are especially important. It is likely that a safe area will be "swept" during rest, i.e. covered in all directions. The threshold of danger might be expe-- . . . School ordering for maximum defense should take a finite amount of time t . But this time should vary according to how spread and heterogeneous the school is; when in closed rest-formation it should be faster to reach defense posture than in a dispersed traveling school. This might be expressed by r , which equals the degree of defense posture in %. The sensory modalities used have different characteristics. Vision is highly dependent upon water

- clarity which is variable. In the rest area it seldom reaches 100 ft. and usually is half that.
- 8) In the faster-moving schools danger often approaches from the rear and should lessen as speed increases. But such danger should continue to exist, unless scanning (echolocating) animals also scan astern.
 - 9) The total school should be in visual contact, at least on an animal-to-animal basis. More secure by far is viewing of the whole school by all or most members. The Radakov wave of response to a threat signal should be speeded if animals can see several of their members and sense from a distance a coming wave before it arrives adjacent to them. Forewarning of this sort enhances individual safety. Uniform surfacing will keep the school together and allow them to deploy as they dive, to the limits of vision.
 - 10) In rest most threat is likely to come from below. The visual scanning of the entire water column The best sensory protection would seem to come from a tiered school, with some (the carpet) patrolling the bottom and with others above, watching at various angles and levels.

Now let us turn to own produced sound and echoes as the main sensory modality. Note that this is not available to the fish. Their schools become random at night, members spread, as if when a predator found one member it could not easily find others. How does the night-time school stay together? Do they, for example, emit sounds that no one has, as yet, listened to? . . . ranges than are usually allowed by vision.

Perhaps the acoustic school can be spread because its members have not reached the Distance of School Closure?

What do I mean? The distance of school closure is either the distance between porpoise and predator where active threat is deemed to exist, or the distance to sensory uncertainty within which threat might exist. Either failure of sight, for example, due to darkness of sensory incapability (murky water) or the actual location of a predator, could set off the reaction.

What good is school closure? Do the waves of Radakov speed up with closure? In other words does intraschool communication become faster, more precise, or of better discrimination the closer the animals are to one another? Can slighter movements be perceived? Can, for example, a turn of 10 degrees be discriminated at 2 m than requires 20 degrees at 4 m? If the relationship of distance is not linear it may speed the waves to close ranks.

[Graph]

What I am trying to evolve is a formula defining the point at which, in the absence of predation, a school should assume the defense posture. The same formula should define the point at which the school reacts to a predator closing upon it, by a change in structure.

Terms: t =time required to order school (including reaction time); s =Closure rate upon predator; m =minimum allowable predator distance. This will vary with speed of closure. Effect of multiple predators should be to increase m . Then one should be able to plug in figures for the visual situation and the acoustic situation.

What do we do about predators fore and predators aft? Closure rate from behind should be less (predator speed minus porpoise speed) than turn in front. A vector should be used to account for closures from sides in same term.

Back to sound as a mediating agent—as the sensory modality. Its range is much greater than vision, perhaps 1800 m. With excellent discrimination capability—not as good as close up vision, but better than vision near its limits. It is independent of time of day. An animal in the water column cannot hide (or is it possible to hide under temperature stratification. It is highly directional, both in sending and reception, however, moreso than is likely for vision. Can we put figures on these things? [Drawing]

My impression is that in acoustically mediated school all sounds cease as they move by: clicks, whistles, and burst pulses. If some clicking continued it might indicate the presence of a cadre of animals periodically echolocating behind as the school as a whole passed by. It would be especially suspicious if all one heard was clicks. Clicks are known to be highly directional (the evidence is less clear for burst pulses and whistles) so it will clearly indicate some animals facing away from the trend of the main school.

It may be that because of the velocity of the moving animals and the great range of echolocation clicks such a rear guard is not needed once the school is underway and has traveled some distance. The assumption is that no predator could or would swim fast enough to close on the school from the rear because it would previously have been detected from the front. Within a very wide column.

Nonetheless, chances for a predator to rise from below and behind exist, especially over moderate depths and rough bottom where a predator might hide and slip in undetected while the schools attention was ahead. Periodic reversals of course would sweep an area and it make it safer with each pass.

All this assumes that the porpoises swim in shark-free seas in their immediate area. Like zebras on the veldt this is probably not true. More likely a game of cat and mouse goes on continually, a game of flight reactions and escape distances with both predator and prey present much of the time, swimming as a group.

Within the restraints of certain rules normal behavior by the porpoise school goes on in the presence of sharks. Philippe Cousteau reports such shark-porpoise assemblages every time he dove into feeding aggregations. This seems normal on the yellowfin tuna grounds, too.

The most vulnerable place or situations would seem to be

- a) wandering young who forget the rules
- b) sick animals
- c) when attention is riveted on a catch of fish or squid near or at the surface (a dimension of maneuvering or escape is removed by the proximity of the surface)

It seems unlikely to me that sharks will engage in cooperative hunting, as for example, some predatory jack schools do. I think we can deal with them as individuals, a much simpler problem for the prey species. Nonetheless, having multiple predators is a disadvantage in that it reduced the available flexibility of response of prey. As a school you should not avoid one predator by flowing toward another.

It is more efficient energetically for a predator to swim with a prey group, just out of the flight distance and wait for the misstep than to pursue a prey animal relentlessly at high speed.

This is a function of the power curves related to locomotion velocity and the odds of success.

What defenses does a porpoise have?

- i) Flight, certainly; rapid porpoise locomotion by tight schools does two major things
 - a) it provides much in-air time when drag is greatly reduced
 - b) it reduces in-water drag by formation swimming where close proximity is required for maximum effect
 - c) maneuverability
- ii) Confusion effects. A tightly maneuvering, fast school takes advantage of confusion effects. It may be that this is a function of the differential receptors of the eye (edge receptors, bug detectors, light-shadow receptors) that require “attention” to be focused on their individual effects and only work optimally when there is a one-on-one situation.
- iii) Possible overt defense. Can a porpoise “zap” a shark with high energy clicks sufficiently intense to cause disorientation in head canals (including ampullae of Lorenzini) and lateral line? Is the tail a useful weapon? For a spinner, teeth seem of little use. Does the field of predators shape the porpoise school or does the porpoise school herd the predators (sound?)?

Probably, a porpoise school going to sea accumulates a retinue of sharks, through the offshore time at night, and shucks it off as the school comes ashore and fragments. Probably, at first as a school begins to travel offshore, there is a time without sharks. Maybe we have two stages of predator relations.

- 1) When none are detected;
- 2) When they have accumulated and begin to travel with the school. There could be degrees of freedom of school response involved. Young porpoises, for example, might be allowed more wandering room within the school when “no predator blips were on the radar screen,” than when they were traveling with a feeding school with sharks in attendance. Are schools coming in the morning different in disposition of individuals than those leaving at night? When and where does the school encounter and leave sharks?

Observable Stages of School Structure

- 1) *Tight unified school.* In fright situations very tightly bunched ranks of animals numbering in the dozens of individuals have been seen leaping in near unison (does echelon swimming persist?—I suspect so). The only leap or animal behavior seen is the arcing leap. Locomotion is very rapid, at a near top speed. Such unified arcing leaps also typify the period when clear decision has been made by the school to go to sea, though in such schools other aerial behavior is also seen—spins, head-slaps, tail over heads! Thus we may be able to discriminate fear and excitement without fear.
- 2) *Rest schools.* Tight, slow-moving, daytime schools, diving in unison and spending ca. 5 min. below the surface. Largely but not wholly silent. Only seen in shallow water and usually over sandy areas; polarized.

- 3) *Feeding schools*. Widely dispersed, polarized schools. Sub-synchronous dives, ca. 4 m. Divided in subgroups. Deep water _____ to _____. Noisy, with all classes of sound present.
- 4) *Zig-zag schools*. Schools in transition from rest to travel to feeding grounds. They oscillate in activity. It may take a long time, and one wonders if the shaking off of hemispherical sleep might be involved. At any rate the oscillation between the active state of going to sea and the deep rest is clear. A plot of aerial behavior shows strong peaks and valleys.
- 5) *Going to sea*. A very active race with much aerial behavior, especially the head and backslaps directed along the course of travel.
- 6) *Coming ashore*. In one radio tag track this was observed to begin as a back-and-forth excursion along the shore coming ever inward. It finally ends in a rapid swim into a bay, or a landfall and a working alongshore to a preferred rest spot. There is activity and some aerial behavior.

What does information transfer include?

- a) Does the sound include descriptions of situations, the predator, etc. Analogic signals? . . .

Thoughts at Grandview Camp, White Mountains, at the end of the 1982 Natural History Field Quarter

In a few moments we board our blue time capsule and head home. There her doors will open us back into plans, hopes, and uncertainties that typify our various lives.

We have together been part of a rare odyssey of exploration that has all but closed out that other world.

The great patient beast has contained us all this spring and at its wonderful pace taken us the length and breadth of our magnificent diverse state. In the process we have been transformed from a shy, expectant group to one of growing camaraderie. We have all come into focus like slides at a show. We have found much diversity in each other. At the same time we have felt, rather than stated, the strands that have come to tie us tightly together. I will return to these things in a moment.

Another thing has happened. We have evolved in trust toward one another, finding that essential dignity of belief can remain intact in spite of our diversity. We have found that such dignity has nothing at all to do with clothes, or their absence, or layers of dirt, or language, and everything to do with respect. Each of us, I find, has much that is worthy of respect. We are no longer cardboard cutouts to each other.

We can even know and love Andrea, even when she paces in back of us like a caged panther, prattling on and on interminably about the moon, while the cold night creeps deeper into our bodies. And when she is shown to be wreathed in a chlorophyll-impregnated afro we even have the strength to laugh.

It hasn't fractured anything important because Sarah inverted her day-glow buns to the world, shining like twin red searchlights at a Pizza Parlor opening. We even cheered her as one as she floated toward the Matolle River mouth.

But the strands that tie us are made of other things too. They come, I think, from the essential human quest for underpinnings to personal philosophy. We all feel intuitively, I believe, that such sources must come powerfully from nature.

I perceive that one such strand is aesthetic, and needs no latin names or equations. I've wondered about it for a long time now. Why should we feel such peace and such a sense of attachment out here in nature? Why should we think of devoting our lives to her protection?

That perfect cream-colored cup of *Lewisia* that we found up at Sierra View, has, we intuit, much to tell us. There is a *rightness* about it, as it thrusts up through the *Eriogonum* cushion, and sequesters its fleshy root close under a warm slate slab. To dig it up, as I did, was to defile that rightness.

Later I think I did it again, as Gary gently and wordlessly led me away from cutting dead limbs off pinons for our fire. He took me to a downed log whose severing

did not leave the live pinons bereft of their long scaly dead limbs, which are so filled with “rightness.” I don’t know what was on Gary’s mind, but it doesn’t matter since the conflict was my own anyway.

On the hike up the Methuselah Trail I fell to thinking about this “rightness” and what it might mean. I concluded that it is the shape of our connection to the natural world, and that it is the essence of our aesthetic understanding. It is a manifestation of our experience with nature and it involves form, pattern, color, energy in all its forms, and even a broader conception of how the world must work even though we cannot see more than a bit at a time.

That wild clashing of wind, river, stinging sheets of windblown sand, tides, and waves raised by distant storms far away from the Matolle River mouth was perfect in its “rightness.” It drew me to it until I could stand no more.

Yet, to many of you the Matolle and its enclosing hills was sick and very much “unright.” It’s splintered trees cast a pall which many of you were never able to shake away.

Our common sense that nature’s patterns are “right” reach deep into most, and maybe all of us. They are our windows to the world against which we measure the flawless beauty of an etched and fluted bristlecone trunk, the shining sweep of Mono, or the shimmering leaves of an aspen in all its exquisite geometry.

Many of us wonder whether our modern contact with the natural world can ever match that of aboriginal humans who were, after all, of the land. We watch with deep guilt as their torn and fragmented peoples struggle to regain the dignity of that connection. In my view we can, but the pieces and paths are inexorably different, but nonetheless, valid. We know both more and less than they. Our view extends to the cosmos, while the much more restricted “window” of native Americans produced a world view of much less detail. In effect it verifies the statement that “humans, whoever they are, will explain their world whether they can or not.” Our explanation may be merely more intricate than theirs. Boundaries beyond explanation sweep away from both of us.

We can never fit in the Tuolumne as a part of that system as those patient Indians did, who talked and ground acorn meal in the bedrock mortars above our camp. But, we know much beyond too, such as the sources and sinks of their river and its part in global balance.

But, I perceive that our sense of “rightness” comes closer and closer to theirs, however different our windows, or our means toward understanding. In both our worlds this rightness comes to encompass our faith, our dignity as a people and our ethical foundations.

Very much more than most things in our littered society, my wonderful colleagues Steve and Larry are of this rightness and so are all you newly minted friends, my fresh-minded colleagues on this odyssey.

As Richard would say, “I’d hug you all if my T-shirt weren’t so dirty.” (I will anyway.)

With great fondness and respect,
Ken

July 18-30, 1982 Australia, Queensland

July 18-19, 1982

Cairns, Queensland, Australia

George Hernsohn, Phylly, and I drove from Townsville up to Cairns, leaving about 10:30 and arriving 5:15 PM. The drive was a fascinating one through wetter and wetter areas until just before Cairns when we entered again gum tree scrub. By Tully and Babinda the vegetation was true gallery rainforest, some coming down on both sides of the road. At Bartel Frere we turned west through cane fields toward Josephine Falls on the SW slope of Bartel Frere (5,322 ft.) the highest mountain in Queensland. It is a granitic peak entirely clothed in dense rainforest. At a small camp at Josephine Falls we hiked a short trail (1/3 mile?) to the falls, a series of cascades and low falls running from pool to granite pool. A young man rolled rocks looking for freshwater shrimps while his girlfriend looked on disinterestedly.

The forest is magnificent. The understory is a bewildering array of ferns (some like banked bracken), ginger, "celery top" (a dicot tree), ti plants, lawyer vines (a palm—the longest in the world), hoyas, and unidentified vines. The buttressed bases of 150 ft. trees appeared here and there, rising to crow's way up above, most festooned with mosses and especially ferns in huge clumps. Some strangler figs in the vine stage were seen hanging like giant stiff ropes to the ground.

We were warned about leeches but saw none on our nice trail. The day was shining sun and no rain, but I guess it's seldom this way. Babinda, George says is the wettest place in Australia (150-200 in. rain/yr.) and it shows it as trees are festooned with ferns and old roofing soft with moss.

Old style Aussie hotels attract us with their broad upstairs verandahs all around, and grill work. Many were plain, however, looking like they belonged on the frontier as I guess they do. John down the hall, and all.

At Cardwill by Hinchinbroo Channel and Island, where we had lunch by the road, the low tide exposed a broad shallow reef flat simply alive with *Periophtalamus*. We watched them wriggle at each other in territorial disputes. The big ones erect a peculiar flag-like dorsal fin from time to time. Both George and I mistakenly thought it was pectoral until we saw the two eyes in the right place. The burrows are spaced but many are within a foot or so of the nearest other burrow. Many pictures and on to Cairns where we holed up in the Golden Key Motel and Caravan Park (you can rent trailers or rooms). We rented a room with 4 beds and a kitchen and went off to find Ray Oke. He lives just up the hill but we found him at his coral shed downtown where he was working on his 21-ft. inboard (Volvo) boat (fiberglass with a sun shade and cuddy cabin full of a welter of drive gear).

Arrangements made, we had a nice seafood dinner at a "bistro"—an a-la-carte salad bar, pick up a ticket, cheap by Aussie standards.

To bed.

At 5:30 we arose, had a bit of breakfast and made it down to the town launching ramp where after [?] Ray appeared with his partner Peter Escreet of Melbourne. Both are young men in late 20s I'd guess, low-key, outdoorsy, full of good humor and at home on the water.

Once launched Ray suggested we go north of town at Trinity Beach about 12 km N of the harbor at Trinity Cove. The shores are gum tree scrub on granite headlands and long, arcing, sandy beaches. The bottom is a rather shallow sandy flat, averaging perhaps 30-40 ft. deep. The day is clear and calm. The temperature is about 65 degrees F.

Orcaella is reported to swim more like a dugong with very little show of its small dorsal fin, than a porpoise.

Trinity Bay is about ½ a mile of good sandy beach bounded by granite headlands. The south limb has dirtier water than the north. Some galley forest occurs in canyons surrounded by gum scrub. Kawara Beach: Fair amount of offshore breeze has sprung up.

Clifton Beach: A small group of *Sousa chinensis*, water calm, starting to [?] to, low dorsal fins, brownish back and lighter sides. They swim slowly and not much different than a bottlenose. Their low fin is the tip-off. Its margins are sometimes whitened as if by abrasion.

At least four animals—perhaps more. One rather smaller one. Largest is about size of a moderate-sized bottlenose. They seem to be feeding, or chasing fish, in a circular mill. I saw fish. I saw one throw his flukes out and his body sideways so his flukes were “flat” to the direction of movement. the flukes are fairly large and rather often seen. I saw them give “hitching” locomotion like a *Phocoena* with the flukes held below the water. The “hitch” if from a fluke stroke given as the animal rolls at the surface and dives.

As we approached, cut our engine, the sousas very soon began to maneuver offshore and to dive and evade us with underwater traverses, once again reminiscent of *Phocoena*.

We lost them.

We saw them breach twice, with two animals leaping in a crossing pattern directly aside one another going in opposite directions. Just like at the oceanarium (after six months training).

Phylly saw them split into two groups, one of two and the other of four to five, 20 ft. apart.

Ray says the bay water is usually murky and the sousas were right in the middle of the murkiest part.

As we move up to Palm Beach the water clears significantly. Hightide was early this morning, and it is on the receding tide now. Ray says they move offshore at low tide. He says his dad caught *Orcaella* with a round haul net maybe 8 ft. deep payed off a sterntable at 20 knots in a circle around the animals. They worked quickly to get the net into water shallow enough to touch and beached them.

He says offshore captures of spinner (he had a captive for two months) were made with a tail grabber that stitched a loop of rope around the tail stock and fell away. He says the light model was best. His memory was uncertain—he said the orcaellas might have come out of shark nets. Most of the time nothing alive comes out of the shark nets.

North of Double Island: a band of sousas 300-400 yards offshore in murky water.

Phylly tapped hydrophone twice for this [?] of tape, through preamp.

A couple of channels of tape with four taps, no preamp at [?] start.

Sousas 100m off starboard bow, 4-5 animals, back to preamp at 5 taps. Max sensitivity.

Lollygagging, in a mill, one rolls upside down and bends its neck and head back toward water as it dives (seen often). Only dolphin I've seen do this.

Very flexible necks are evident in these animals. They can move their rostrum almost out their chests when in inverted position.

Back drive seen again. In last couple of bands of tape 1 the animals were close by, playing with one another. They are not nearly so spooky as the Clifton Beach school. We could beautifully see long snouts of the animals. Sousas for sure. The melon is rounded and prominent.

A school of sousas playing off N. shore of Double Island, we will make tape No. 2. Two *Tursiops* seen, they travelled right with *Sousa* for a couple of minutes and then moved off in opposite direction. They were as if a part of the *Sousa* school (but occupying a distinct sector). Three sousas, 2 *Tursiops*, 50 m off stern.

Tursiops leave to north as sousas lollygag to S. toward Double Island.

100 m. off port beam facing away, moving slowly, pure *Sousa* school now. Band #2 milling off starboard quarter 150 m here they come, arcing inside our bow. A large animal has whitened margins on its dorsal fin.

Hydrophone is 3 m down. Animals are still moving slowly at surface. Band 3 off Ellis Beach, N. of Double Island, animals very close into boat when hydrophone lowered. Another tape was made on a [?]Recorder and a home-made hydrophone.

We are recording with a LC32 hydrophone, a Lockheed Instrumentation Recorder at 30 ips (1/4 in. tape) plus a small preamp. The record level, even so, is faint and the ???meter seldom budges. I worried that its battery wasn't good, but it proved OK. While we were at this Ray tried to start the boat but it wouldn't kick over. He traced it to a faulty coil and quickly produced a spare which when installed, worked. He's a good guy to be with, calm, with a lilt, and with common sense. We headed back after photographing the last group for a while and worked on gear all afternoon.

July 20, 1982

Cairns, Australia

We're back on board the *Cilla*, same crew and this time we will spend a little time exploring the edges of mangrove swamps and rivers to see if *Orcaella* might not frequent them. North of town mangroves line a giant shallow mudflat only traversable at high tide. We began before the tide had peaked and ran over this flat, only now and then stirring the brown muddy boils of water in our wake. Though the water lapped among the prop stems of the mangroves no animal greeted us.

Still further north we rounded a headland and entered the mouth of the Barron River. It drained a large mountain area behind Cairns. Here it is mangrove banked broad and curving, with occasional gum forest coming to the cut bank.

Flocks of Australian pelicans stood on the flats in one place. We left the river and headed north. South of Yorkey's Knob, about 300 m offshore we encountered a relatively fast-moving school of *Sousa*, a couple leaped out of the water. Our first band, for some reason seemed overloaded. One 1/2-grown young is in the school. Moved into Kawara Beach under clear skies. Nobody home at Trinity Cove we encountered five *Sousa* as the S. breeze began to blow up and make whitecaps not far offshore.

We now tried to move into a group of three farther offshore. These animals did not show the play behavior seen yesterday, only just relatively slow surfacing. They stay

under water from 30 sec-1 min. The water is rather murky—in fact we have never found animals (*Sousa*) in any other circumstance. *Sousa* seems to be a murky water animal, slow, probably always pinging when it is on the move, and nearly always moving very slowly—a knot or two.

Finally, on down the coast about two miles S. of Unity Reef we turned for Cairns into an increasing head wind, and then pounded on our way back amidst great sheets of spray from the bow.

Back near Cairns we took a little detour up the estuary to peer at a Chinese (Taiwan) clam pirate junk that had just been impounded. I know I wouldn't like to head for Taiwan in it.

At about 7 we located an Italian pizza maker and had a beer and a very tasty, hot pizza.

Then Phyl and I went off on a tour of a local sugar mill which was very interesting.

Then to bed. I was pooped.

July 21, 1982

Cairns, Australia

Started off from the harbor and cut S. along the Cape Grafton Peninsula south of Cairns. It is a series of sandy coves and rocky headlands and it is washed with the shallow mudflat from Cairns Estuary until one nears the Yarrabah Aboriginal Community (a reservation for Aborigines). We rounded False Cape and then turned north across the harbor mouth. It was funnelling an offshore breeze out to sea and a vicious little beam swell and short chop soon sent sheets of spray over us. I called a halt to protect the recording ear which we had resting on some rubber diving suits on deck. That done we bucked our way up the coast past the mangroves. Our hope is to arrive at the northern beaches before the tide begins to recede.

The northern bays are not so shallow and at any tide 20-30 ft. of water can be had 100 m. from shore.

Our compliment this morning includes Victor Jacobs, an amateur naturalist and teacher from near Birmingham, England. He is Ray's father-in-law.

Off the N. end of Half Moon Bay two sousas 350 m. offshore, however the animals were largely silent.

At Buchans Beach (Clifton Beach) we took a control band in the same place we saw animals yesterday. The water is very very quiet. Band #3 taken astern of a traveling drag boat where two sousas (an adult and a closely attending calf) swam and dove in the wake. There was much motor noise.

The sea is picking up. We'll have to go into it.

At Cook Hwy Lookout we turned back—in the far distance we could see the plain on which Port Douglas sits and Thornton Peak (4500 ft.) the third highest peak in Queensland. From here its bulk could be an island.

We headed for Nudie Beach (Buchan Point) for our coffee and a biscuit. A welcome relief in the calm bay, its rocks festooned with several kinds of fauna. Off Double Island, Ellis Beach 500 m, we encountered a pair of *Sousa*, calm and clear and some breeze.

It's a mother-young pair. Later we spotted a *Sousa* off the coral reef at Double Island but we could not sight it again.

I should note that we've taped two bicycle tire inner tubes on our hydrophone and it does wonders for the water noise. The hydrophone slides up and down in the swell rather than dragging the hydrophone forcibly up and down

In the afternoon we visited Ray's dad, Victor Oke, who had set up the Cairns Oceanarium from an old swimming pool. His garage was full of things from his museum including a plaster cast of an *Orcaella*. It lived three years and may have died of *Ciguatera* poisoning.

He caught it in a round haul net very near shore. He said the animal was very flexible and might be able to take its flukes in its mouth. It was capable of a powerful bite he said, but it was very affectionate and a pet of all. It would not leap free of the water but learned quickly. It has a big pectoral fin shaped this way [drawing] and very broad flukes. Its dorsal fin, 2/3 aft, is well formed and not so triangular as *Sousa*'s. It's still small for an animal so large (6½-7 ft. I'd guess).

The narrow neck is clearly obvious and Victor said it could and did turn its head sideways to look at you instead of moving its body as other dolphins do.

Victor had never seen them more than about 500 m from shore and had seen them in mangrove channels near Cairns before boat traffic got so great.

I like these Okes a lot. They are direct, honest, capable, and friendly.

After that soiree, we visited the Queensland Fisheries Lab down by the harbor and I psyched out why my volume is so poor on the tape recorder (problems with use of the preamp). I have about 20dB more now. We'll see what tomorrow brings.

We reached the dock at a quarter to 7, with newly found knowledge about our preamplifier. I was able to get about an additional 20 dB out of it.

We headed out the shipping channel from Cairns Harbor—a dredged waterway through the extensive mudflats. Yesterday the big dredge chugged along low in the water, its spoil bins nearly full.

We headed out along False Cape over ever-deepening bottom, cutting close to shore to make a good inspection of every bay and headland.

We skirted across Mission Bay on the way out. This bay has an aboriginal community.

Of perhaps 2000 people set along its back shore (Yarrabah). Normally the bay is closed but we were told that nobody really minded if we traveled through.

We rounded Cape Grafton into a moderate S. breeze. The currents and funnelling of the water in the passage made for a bouncy sprayed passage but beyond it was quieter so we continued on down past a long, sandy beach, turned and headed back, looking hard at the band of water from surf-line to 300-400 m offshore. Not a beast did we see. Then we rounded the Cape (Grafton) and entered Mission Bay from the east. [Map of Mission Bay]

We touched bottom a couple of times on the south limb of the bay, and aside from a few birds—egrets mostly—we saw nothing except possibly a turtle.

On back to Cairns Harbor we went, passing among the anchored, moored boats to the inner mangrove area at the head of the harbor. It is extensive—perhaps four miles of swamps and channels in one dimension. Our track wound around in the curving channel. The tide was up amongst the prop roots and no more than a foot of mudbank remained. It

was honeycombed with crab burrows from which we could occasionally hear loud snaps or clicks. Listening to the mangrove banks one could hear such clicks every few seconds.

At one point we recorded a short band as a control and the waters proved to be terribly noisy with muffled clicks or bangs.

The main channel through the mangrove swamp circles a large island. Into the opposite bank dumps the series of smaller drainage channels. [Map]

The channels were generally quite deep in most places and the banks an impenetrable tangle of prop roots, mud, and fallen trees. One can image what an ordeal it would be to try to traverse such a forest on foot if one's boat failed for some reason.

Up one such channel we tied up to an overhanging branch and had our morning tea and rolls. Then up another channel we passed the fallen-down camp of a man who tried to build a boat out of mangroves to sail overseas to visit his son. He never made it and died some years ago, his boat now rotting in the swamp. George said the mosquitos are fierce in summer in these swamps.

Up another we wound around and finally came to a house and dock to which two large trawlers were tied. We asked if dolphins had been seen and one man said no, but he was only a visiting mechanic and probably knew nothing.

Lyle Squire of the Queensland Fisheries Department had been up one channel last week and had encountered dolphins. Though we searched hard we saw none. But they could have given us the slip by being amongst the prop roots or up the very extensive upper channels where we did not go.

My impression of *Orcaella* is of an animal that habitually frequents restricted water situations. Its very flexible neck and body, its big paddle-like pectorals, its little fin, and its large flukes, and finally its light color all suggest this. It may, in fact, be a mangrove-adapted dolphin. I believe extensive mangrove swamps occur throughout its range. It is reported to eat crabs and have a very strong bite. All in all such a habitat would make sense as an important habitat for our beast, with riverbank situations and the back reef shoreline another.

But all this is speculative and we need to see it.

Ray took us across a mud bar in which we became stuck. We were able to wiggle off but very soon the motor began to heat up and he stopped it to open a filter on his cooling system. It was crammed with mud. It took three iterations before it came clean and the engine could run cool.

Shortly afterward we reach the launching ramp and our trip was over. Goodbyes were said, invitations to visit us in the USA given, and we left for Mission Beach, about halfway to Townsville.

As for *Sousa* it seems also a murky nearshore animal and in several ways a precursor to *Tursiops*. That's one reason it was so intriguing to see them school together. *Tursiops* is much more of a generalist than *Sousa* but it inhabits *Sousa*'s habitat, except the rivers, if one includes *Sotalia* in *Sousa*. The places we found *Sousa* were murky water areas, especially where tidal rips and roil were prominent, and never very far from shore.

Did *Tursiops* arise from something like *Sousa*, and did *Steno* also come off such a stock? Do all three hybridize? Certainly *Tursiops* and *Steno* can.

Where did *Tursiops* arise? It's cosmopolitan in tropical-temperate environments. Might it have arisen along tropical shores from an earlier more restricted estuarine-riverine stock?

As for *Orcaella* it's a creature of the Indopacific heart and a creature of restricted habitats, especially, I suspect, mangrove swamps and their channels. Mightn't it have come from a warm temperate belukha ancestor, perhaps in the western Pacific. Though we only know of fossils from the eastern Pacific, of early belukhas there is no reason to exclude them from the western Pacific. Fossils simply haven't been found. But even in Japan proper a mangrove differentiate could have been developed and then moved into the Indo-Pacific proper.

July 23, 1982

Mission Beach, Queensland, Australia

Our day started out by awakening at 7:00 at a motel at Mission Beach. We had driven down yesterday afternoon to this place very near where we will go to the Barrier Reef. It's a nice but somewhat seedy motel right on the shore of Bingil Bay, just to the north of the little pier. At the pier we paid our fare and were soon on board a cruise boat that packed perhaps 60 people aboard. The voluble skipper welcomed us aboard and soon we were headed directly out to sea in a nearly flat calm. Rain squalls, however, darkened the horizon. Aside from a single *Tursiops* that came to run our bow not long before we reached the reef I saw nothing of much interest on the way out. About 10:45 the tiny little sand cay at the reef came into view as a shining lozenge of brownish silver dividing the sea and sky. It grew larger and we began to see the reef itself, making the water greenish around the little cay. The cay became a mound of bright coral sand with about five rather sickly looking young palms on it—they had been planted.

We sneaked into a little sandy bottom reentrant in the reef and dropped anchor in perhaps 40 ft. of gin-clear water. Immediately schools of fish converged on us. There were three major kinds—a snapper of about three pounds, brownish and faintly striped, a jack of golden yellow color and much smaller, and a single great seven-ft. hulk which proved to be a groper (*Promicrops*, I'd guess) weighing 400 lbs. They had all been tamed by a skipper of the boat and came alongside to receive gifts of bread and fish. The jacks and snappers ate bread with great gusto while the grouper held out for a ration of fish. The skipper said he'd learned by experience how much he could feed the groper before it was sated and wouldn't return on the daily cruises. This time he received about five gar fish (halfbeaks). This halfbeak would run about 3-4 to a pound, I'd guess. This squares well with my memory of gropers eating once every two weeks, but then of a considerable amount per sitting.

George and I decided to go snorkeling, while Phylly and Ann went for the glassbottom boat and a walk on the 100-yard long sand cay.

George and I donned our gear and slipped over the stern into the 70 deg. water. On either side of us, 50 m away, were reefs with the living ledges about ten ft. below the surface. Leaving the powdery white coral bottom, we entered the reef area. Its edge was tiered with dish corals, great shelves spreading out like platters from a rather small central "stalk" that we are told it is easy to break, tumbling the coral down. Green Island we were informed has none of these dishes left because divers have tried to walk on the dishes and broken them off.

Staghorn coral patches were frequent, and often brilliant dark blue with almost iridescent blue tips. If one looked closely it was possible to see the polyps of the living

coral animals dotted densely over the coral arms. The name staghorn is apt because the branching of the coral is very much like that of a staghorn.

Now and then large brain corals rose up, massive and rounded. These are basement animals in reef formation we were told. Soft corals were especially prominent. These often assume the shape of giant anemones, but at once can see that the basic structure does not move, only the surface which is waving with polyps like a shag rug. These came in tones of browns or green usually, some light apple greens and some pale lemon yellows. Sponges were also prominent forms, mostly tans, yellows, and browns.

Now and then I swam over a giant *Tridacna* clam, some a meter long. Their mantles spread out over the prongs of their shells in waves. The mantles were deep bluish with bright iridescent blue spots, and others of emerald green. The two siphons were open and water was being pumped through, allowing one to look deep into the flesh-colored interior of the huge clam—strange stationery molluscs that had apparently lived or a hundred years or more in a single place. The Taiwanese junk we viewed at Cairns was apparently poaching these ancient giants and had a hold full of the meat.

Some of these soft corals were so long and flexible that they had received the name “spaghetti coral” from the locals. Indeed it did look like a patch of brown spaghetti waving in the undersea wind. Now and then, small patches of bright green grasslike algae could be found, long and soft. It was surprising to see how circumscribed these patches were. They only seemed to occupy holes in the reef a few inches across. Perhaps if they are any bigger grazers, which are dominant reef forms, can kill them and only in pockets of small size can this be avoided. But the story shouldn’t stop there because why don’t these same grazers simply eat the waving ends of the grass?

Fish were everywhere. I could take most to family, but the species were all new ones to me, since I’ve had no experience in the giant Indopacific faunal area. Pomacentrids were very common, whole schools of them flashed and flowed in front of my mask.

Wrasses were common too, including parrot fishes of a couple of species at least, Cirrhitids were there too, and in the sand pockets, lizard fish. Most fish were small—less than 10 inches, I’d guess. I saw one classical cleaner fish (*Labroides*)—yellow, black, and violet.

Later, I took a run on the glassbottom boat and found that the skipper was really quite knowledgeable about reef animals. He was able to point out clumps of dark wine-colored “feather stars” which were crinoids. These were especially attached to vertical walls of the reef where it began to drop off into deep water. He showed me a great spreading, pearly white-colored anemone accompanied by 5 or 6 *Amphipriod* fish of a form I’d never seen before—perhaps five inches long, with the diagonal white bar through the eye and a bipartite body color of red and deepest blue on the belly and after back.

We looked at places in the reef where the coral had been killed by crown-of-thorns starfish. The skipper kept this reef clean of them as well as he could. He said that reefs farther north were 80 percent destroyed by the stars and he laid the cause at the feet of those who had cleaned out the helmet shells, which eat crown-of-thorns.

We swam back on board after our snorkeling, and then spent a fairly abortive time fishing before heading back with a quartering swell following us and causing the *Friendship* to roll mightily. Phylly and I had been wearing our Transderm patches and they stood us in good stead here with us only feeling lethargic and sleepy.

Ann who is a very interesting gal, doing the history of the Northern part of western Queensland, whipped up a dinner for us, and then we wandered off to our room and sleep.

July 24, 1982

Townsville, Queensland

Because we were going to visit some friends of the Heinsohn's down a country road, and because Phylly and I were still a bit nervous about driving on these narrow roads on the wrong side, we split up, Ann and Phylly, George and I, and set off. The roads are just wide enough for two cars and when passing in opposite directions at 100 km/hr it's invigorating and the edges of the shoulder are rutted with the wheel tracks of thousands of cars. It's a way of life to drive partly on the shoulder.

And then the bridges are too narrow for modern semis and there are signs for one lane to wait for the other on some of the narrower bridges, and that's exciting too.

Anyway, not far from Cardwell we cut into a dirt road leading toward the sea. It led to a small National Park that included some of the mainland rain and mangrove forest and what seemed to be an indeterminate amount of Hinchinbrook Island offshore. At a sign that said "Private Road" we turned into the forest down a long winding one-lane path. The forest here is a mixture of rainforest elements, gum forest, *Melaleuca* scrub, and occasional patches of marsh. Later we learned that this road is underwater at the time when the rainy season comes in full flush. Rainfall exceeds 80-100 in. a year here we are told.

Finally, we came to a clearing grassed and dotted with trees and walled with forest. Set on one side were some ramshackle buildings, one of which turned out to be the house of the Thorsbournes, Margaret and Arthur. The place was called Galmara and it was on Meunga Creek.

Arthur came out—a leathery stubby little man with tufts of hair whispering up over his freckled pate, no shoes and feet as tough as leather, a handshake with the rough hands of a laborer. Behind this lay a sharp mind and a compassionate one, his compassion directed mostly at embattled nature in northern Queensland. His wife Margaret looked like a proper little British lady (she wasn't I don't believe) (she's an Aussie from, I think, Melbourne) but it was she that would have nothing to do with electric lights, favoring Alladins (kerosene) instead. Her pale hair done up in a bun, dressed in a light frock, her usual comment to any sally was a broad "Yaas." She is an artist of delicacy, making cards that are works of art to be sent to ones that need to be brought into this or that cause. Together they protect this park, along with a local ranger named Sav, to whom I will return.

Their house is all open doors tending into verandahs and the forest. In back they have a screened bedroom wing and bathroom with a giant tub, where they find surcease from the mosquitos in the dry season. Right now only a few fly but it gets thick I gather when the rains come and one's arms get black with them. Arthur says one becomes hardy to them and they no longer sting much.

They've set garbage can lids around the forest near the house and every day Margaret fills them with water for the forest birds to bathe in. And bathe they do. All sorts of entertaining critters come out of the woods to partake. As we entered, three species of honeyeaters flashed down out of the dense forest to splash in the water and

take off. These little birds are miraculous flyers, being able to negotiate the trees and vines that crowd the forest floor with such agility that they can quarrel with one another in flight, tumble and chase all the while avoiding the numerous obstacles just as if they weren't there.

Not long after we settled on the verandah for tea and scones (biscuits and honey), we noticed a rustling in the leaves and two jungle fowl, or scrubfowl, bobbed past, kicking leaves aside just like banty hens. They, we learned, are megapods and build communal leaf nests deep in the forest. These are heaps of leaves that may be three ft. high and as much as 15 ft. across, usually started around a pile of rotting logs. The fowl lay their eggs down in the leaves and then tend the pile, testing it with their beaks for temperature. They are reported to hollow out areas on the surface to catch radiation so the eggs may incubate. Later we saw several of these mounds. In use the hens keep the surrounding forest free of leaves which are scratched onto the pile.

Not long after, a grand brush turkey came sauntering up, a glossy black feathered bird like a small turkey, it sports a narrow, rounded tail flattened laterally, deep with a rounded tip, like the rudder of a boat. The turkey's neck is yellow and its head is brilliant red. We had two about the house, and were told they could become a great nuisance, picking out new plants and walking in the house to take food. It also kept the pitta away. This little hopping forest floor bird was a favorite and would come up on the back porch for a bit of ground meat. The Thorsbournes didn't feed any other birds, but they lost their resolve with this bold gaudy engaging little bird. It is a beautiful creature—crimson, green, emerald-blue rump and wing coverts, brown throat, and head with a red nape. It is supposed to feed on insects and other bits of food it can find on the forest floor and not to fly long distances.

About this time, big, hulking, kindly looking Sav Mostecetti drove in (he too was barefoot), the ranger assigned to the park by the Queensland National Parks and Wildlife Service. He had abandoned a job as owner of a cane plantation to work for the pair. He lives at Bemerside, Ingham.

He and Arthur fell into discussion of the doings of the park—the problems with motor bikes and minor vandalism. My impression is that they don't yet know what vandalism is. Margaret took us on a walk down to the river identifying plants as we went and looking at orchid and fern clusters up in the trees. We ended on the gravel sand and mud bar of a slow moving stream that a mile below led into the sea. It had had crocodiles in it at one time was probably had none now.

Then we went by car to a marsh at the end of their roadway to look at 15 brolga cranes feeding in the wet meadow. These are big cranes, gray with black on their heads that look much like our sandhill cranes. They flapped and danced as we watched. Back at the house we set out on a trip through Sav's new mangrove trail. He and his workers have built a wonderful forest trail that periodically drops into arms of the mangrove swamp and emerges along the shore. It runs for something more than a mile and goes through some of the most lovely forest I have seen. And different from any I have ever seen before too. The largest trees are paperbarks, but amongst them are a species of tree with lovely rusty red flaky bark (*Delinea*) on which orchids clustered. Stagorns made enormous clusters up the melaleucas, sometimes so heavy they fell off in bushel basket-sized chunks on the ground. There were many wattles too, acacias and some blue gums, and ones with green bark above and dark crenulated bark about to eye height. *Hoya* vines

were common as were many other kinds. There was a lovely broadleafed *Bignonia* too. So much, it was impossible to take it all in, or even begin to. The places where the trail reached mangroves were wonderful dark, almost ominous secret places. The trail followed a wooden walk set on cement pilings and one was led through a weird forest of prop-rooted mangroves, pneumatophores rising everywhere, pockmarked mud in between with many burrows occupied by a dark species of crab. The loud snaps were there too, though we never saw the animal responsible. There were more than a dozen species of mangroves too. Finally the trail led behind the beach by a berm amongst clusters of giant spider lilies, and there we saw a remarkable fern, the ribbon fern, epiphytic, and hanging like green wavy algal strips perhaps two ft. long, by the hundreds from a single clump.

We returned, said our goodbyes to this remarkable couple and their funny little house (I forgot to mention the Wren cottage, for visitors, a sort of house on the half shell with two open sides and a bedstead covered with mosquito netting, a dresser and other amenities, pictures on the wall).

Off we went to Townsville at dusk, with the Heinsohns driving the perilous road. A hundred miles later and we were at Townsville where we had a spaghetti dinner, a bottle of good Aussie Moselle and then found Ann's car locked with the key inside. They drove us to our apartment and then went back to get a spare key and deal with the stranded car. A fascinating trip with a lot of good people worked with or met along the way.

I get a feeling of some power in the conservation area from George. He is diffident and quiet, but he likes the local people and knows how to hunker on the porch, and he cares deeply enough to fight the good battle. Everyone likes him, and this takes the form of him being elected the president of the Wildlife Preservations Society of Queensland, and a member of the Australia-wide Conservation Foundation. He mentioned he felt uncomfortable with these titles because he was an American citizen, but he agreed with me it didn't make any difference where he came from, considering the good things for the natural environment he was trying to do.

July 28, 1982

Townsville, North Queensland, Australia

We have traveled down to the Townsville Airport to a flying service in order to take a flight along the coastline and around Magnetic Island, in search of dolphins and dugongs. We will fly at 700 ft. With George Heinsohn and myself is John Robertson, who will also be helping us with the boat, should we find animals. Our first traverse was up toward Magnetic Island, and then we will traverse across to Point Cleveland and down along some of Bowling Green Bay and back. The weather is clear and there is an increasing breeze from the south.

We fly over the town common which is an interesting habitat of marshland, grassland, eucalypt scrub, and pond habitat, much frequented by birds. It ends just against one end of the airport.

There is lots of good murky water nearshore, which is what I suspect these dolphins like—the tide is low, with much glistening mudflat exposed. We fly offshore about 5-6 hundred meters.

Dugong spotted off the mouth of the Boley River. It came up, by rising with the tip of its snout exposed unlike a dolphin. A lot of muddy water is issuing from the mouth

of the river. It sweeps out in long plumes below us. Some whitecaps begin to show, but for the most part the water is fairly calm.

Now along shores of Magnetic Island water is cleaner here as we leave the mud plume from the river. The dugong, by the way, was a pale tan. I have the outboard seat in the L rear. We fly 300-400 m offshore and I look out to sea on this traverse. We circle in a bay with many boats anchored. We saw what looked like a dugong. It rose as a brown blob and then sank directly downward. It did not come to the surface and arch as a dolphin would do.

July 30, 1982

Townsville, Queensland, Australia

George picked me up at 6:30 this morning, we loaded our recording gear in his car and headed for the Biology boat yard as the sun increasingly lit the surrounding hills with apricot light. We met John Robertson and a friend of his and headed for the main boat ramp at the harbor. We will launch our Stacer runabout (outboard powered) and head down off the flats south of the harbor and to the north coast of Cape Cleveland to see what animals we might have sighted from the air on the recent flight, and also to see if we can record a dugong.

George brought "tea" for us all, and I have tucked the Lockheed recorder and its batteries up under the bow deck, put the batteries in a rack there, and generally set things on diving suits to cut down shock and to protect from possible salt water running up the deck. That precaution proved a sensible one as when we went out into the harbor I noticed that there was water on the afterdeck and that it seemed to be rising. Indeed it was because we found the drain plug sitting in the motor well. John put it in and we were then able to pump the deck dry again. No harm done.

The day is calm and there are cloud primordia standing about, covering perhaps a third of the sky.

Off White Rock Bay, in quite shallow water we came upon a school of dolphins, perhaps 8-10 in all, which we later came to believe was a mixed school of *Sousa chinensis* and *Orcaella brevirostris*. The others at first felt the school was all *Orcaella*, and I felt it was all *Sousa*. I had seen a snout on one animal, and the others had seen the blunt head of another too. On closer inspection we could see that the fins of some, which seemed blunt-headed were quite falcate, while the putative sousas were more triangular, though even they show a slight degree of falcateness. I began to discriminate a constriction and folding on the necks of the orcaellas. We recorded two bands of this possible mixed school, with, I think, the hydrophone hitting and dragging along the bottom, which means we were in less than 10 ft. of murky water.

The pattern all along is for us to hear loud single bangs at the beginning of tape bands and for them to become less obvious as the band wears on as the animals swim farther from us. This makes me think that these single pops are animal sounds. I hear no click trains. To summarize, I believe we encountered both *Orcaella* and *Sousa* today, and that they swam very intimately together, but when harassed separated into two pure schools. From *Sousa* I continue not to have heard well-organized click trains but only scattered and sometimes loud clicks. *Sousa* has always been found in murky water, and in this case that's where *Orcaella* is too. *Sousa* seems to upend and muck in the bottom. It sometimes leaps and once we saw it clear of the water today. It seems without marked

pattern except for what look like worn places on its fins. It blows. It is slow moving generally and tends to raise its snout out of the water when chased. Even then it moves pretty slowly and never seems to leap away. Instead it tends to take evasive action underwater, coming up in unexpected sectors. Its groups are small and one can discern adult-young pairs and subgroups with only adults. Its school are often very disperse with animals 50-100 m apart frequently, though not apparently in flight. Its sounds are very hard to discriminate from the ubiquitous snapping shrimp except they seem louder close up. Is this an adaptive feature? Click trains would be discernible, isolated clicks are very difficult to tell from shrimp. Whether frequency analysis will allow this I don't know. If we saw *Orcaella* today the intimacy of its schooling with *Sousa* is impressive. *Sousa* follows shrimp trawlers just as bottlenose do, and swims along close to the trawl (to catch stressed fish?). I know no other odontocete that does that, except *Tursiops*. I wonder if the accumulation of *Sousa* near Double Island has anything to do with the use of that island for an anchorage for the boats. I wonder what *Sousa* is doing bringing up trails of mud when it is feeding. Does this have anything to do with the very stout jaws of the species, as compared to most other forms?

July 30, 1982

Townsville, Queensland, Australia

We had hoped today would be like yesterday but no luck. Last night about midnight it began to blow things off the clothes line. One towel left the deck, scaling two apartments down. It hadn't completely calmed by dawn when I arose, put myself together, and stumbled out in the hall to see if I could construct a cup of instant coffee. I made it by pouring hot water in the nearly empty bottle. They make hot water here with a crockery pot that has an element in it that is immersed in the water. The crockery is always green and gives the water a greenish cast, making me feel certain I'm swallowing Paris Green.

Anyway, stomach growling (no breakfast this time of day), I met George in his Alice Springs Falcon and off we went, meeting the St? at the harbor. Calm enough there but outside we could see white caps and sure enough, just past the jetty and we began to buck into it and continued to do so all the way to White Rock Beach [map]. It was a rough, banging wet trip. My glasses were constantly covered with salt—a major nuisance.

It just got worse, we finally ducked into White Rock Beach for tea and coffee. The south wind whipped over the 500 ft. mountains and down the canyons and out onto the sea.

Spotting was most difficult and recording wouldn't have been much better had we seen anything but sea eagles and silver gulls.

We fled for Townsville harbor and once there ended up cruising in calmer seas around the lee of Magnetic Island.

That island is covered with eucalypt scrub except in the canyon where some rainforest trees look dense, broad-leaved and green, where *Auracaria* trees grew from bouldery hills where brush fires couldn't touch them.

At the NE corner of the island I saw a dugong near two anchored trawlers. It's nose, head, and shoulders were above water. With a quick flip of water it dove and was gone. Though we waited we didn't see it again.

Back at campus I snoozed a bit after washing various bits of gear of salt rime. Tonight we take our scientific hosts out for dinner. We pack up for tomorrow's departure to Sydney.

April 5-9, 1983, Granite Mountains

April 5, 1983

Bunny Club, Granite Mts. San Bernardino County

We came in in the afternoon of Saturday, in a cold blustery day. The trip down was one of escape from the rainforest of Santa Cruz, out into the starry night at Paso Robles, over across the valley to the Kern River and up to Upper Rich Bar camp, which was closed.

We found a place to pull off, go down the hill to an old road where everyone could lay out their bags, some I'll admit on pretty wet ground. My bed was pretty much a mass of gopher holes and mounds, but somehow I slipped my corpus in between them and the rain never fell.

Up in the morning only five hours after we slipped in the bag. I forgot to mention the car that clattered up just as we were trying to go to sleep. It contained two drunks, one passed out utterly and the other driving. The awake one wanted conversation and some information about how far it was to Bakersfield. It seems he had no tire on one front wheel and was driving on a much battered rim, the remnants of the tire hanging on. We sent them on to the next camp.

Anyway, up over Walker Pass amidst heavy wind and some snow on the ground. I snoozed a bit, we gassed at Johannesburg and shopped at Barstow and headed for the mountain. Dinner, bed.

Today was spent taking two groups out to observe. We looked at pollination mechanisms on the desert almond and tent caterpillars. Richard found us a bee hive in a crevice down the wash below the main pond. One could see two new combs and hear a deep hum like a fan motor going, issuing from the crevices and there were some bees crawling around on the combs.

Dinner, singing with Olga and Richard and Pam and Gary. Only Gary can carry a tune. Then to bed. Steve's great and Larry does his usual wonderful organizational job. Two of our troops have a hacking cough and flu. Bob Vandergrift and Shawna Harvey. Poor folks. They try hard even so. Off to bed. The cacomistles (2) put in a brief appearance.

April 6, 1983

Granite Mts., Bunny Club

It's night (9 PM) and we are gathered in the cabin under the Colemans, 23 varied folk writing away under the lights about their day's experiences.

We saw old Dr. VanDenburgh on the way in, no beard, white hair, on a bicycle—we knew it wasn't going to be easy.

On the way in it began to snow just as we left the freeway. By the time we reached the cut off, veils of snow pattered wetly on the windshield. The bus turned into the dirt road and promptly became so stuck we could go not an inch in either direction. It took an

hour and a half to dig it out, after removing the spare tire which was jammed against the ground. The class dug with a will, my only worry that they would kill each other with their their vigor. How to keep the diggers in back from killing the folks under the bus was the problem—but we persisted, the snow stopped and we traveled uneventfully to the road above the cabin.

Next day I took two groups out in a fairly bleak day. We did well though, beginning to learn about how bees orient to their hives and how tent caterpillars make their nests. We came home singing across the bajada after the last session, the temperature dropping down below 50 deg. F.

A nice dinner, excellent talks from the physical factors group, notes and off to bed? We'll see.

April 7, 1983

Granite Mts., Bunny Club

It's the end of a long but good day. I've taken the day with two separate groups of six students and we wandered along the mountain base. On the first we wandered along the wash to the pond and spent our time trying to understand swallow flight. No simple task either, with things happening faster than the eyes could see. We watched them swoop and circle, flutter and dive.

But before we had spent half an hour at a kettlehole pondering surface tension and how animals deal with it. We tried to understand how they breathed—it seems they use a snorkel—really—a black tube from their upper tail. It ends in a hooked flanged affair that quickly pierces the surface film and suspends the larva head down. The larva is attacked by another insect larva—a segmented dragonfly larva-like animal that swims horizontally and when they are very close to a hanging larva they attack with a jaw snap. Most larvae escape but some don't. The head-down position, the lateral wriggle or snap, and long setae from each segment protect the larva—not unlike the head-down position of the fur seals, the better to see sharks and other predators from below.

The day was never very warm but at least the sun shone and in the wind-protected nooks we could warm up.

It's a grand, responsive, talented group. They emerge and all fit in and they begin to care for each other. All are eager and thoughtful and tend to helping us. Talents range in many directions. To watch them unfold, to return to childlike wonder is in itself wonderful.

April 8, 1983

Granite Mts., Bunny Club

Today was our touring day, so early we all finished breakfast and piled into the old blue bus. Matt Miller and Steve drove today, sharing chores. They, and Larry Ford, are licensed to drive the bus so I just stand up in the door well and watch the scenery go by.

We now have a powered "bullhorn" that lets us mention the interesting things as we go by. It really helps add information, and lets us guide things much better. It suffers, though, from the problem of overuse. I feel it is an intrusive act to break in, like a phone call, but judiciously used, it's a wonderful way to tie things together.

We headed for Kelso and gamboled on the green lawn while various phone calls were made. To our considerable delight Dr. VanDenburgh put in an appearance that bade well for our later adventures. He appeared in the form of section hand on the railroad in oversized dirty coveralls, a hard hat on his head and a seedy white beard jutting out. He lurked near a building corner and then retreated around it and disappeared. We looked and he was nowhere to be seen.

The day was sunny, for a change, and warm enough to expect a few lizards to emerge, and maybe a rattlesnake or two.

The ride up Cedar Canyon is one through a serial panorama of vegetation types. At the Cima Rd. we were in Creosote scrub. Before long it gave way to Joshua tree woodland and *Larrea* disappeared altogether. Then we entered a rich *Hilaria rigida* prairie apparently located on the deep alluvial soils that spread out over the fan from the mouth of Cedar Canyon. We turned toward Hole in the Wall and before reaching it entered juniper-Great Basin sage, thence into blackbrush and thence into a lovely high-desert bunchgrass prairie, where we turned off at the Rocking L ranch and made our way down to Gold Valley.

Jane Southcott was there, recovering from her hip operation, given company by her cats and deaf old snaggle-toothed dog. She welcomed me with open arms and invited us in. She also quickly had us tend to two crucial things she couldn't, on her cane, do—put gas in the truck and look in the tank to see how her water level was. She seems frail and full of concern about being by herself. She's built a little apartment for a caretaker and now has to find one. Two of our gals, Denise Polk and Lorna McNeil, plan to do the vegetation of her ranch and will help some, but not enough I fear. I'm not sure what she'll do.

She invited us to hike her mountain and showed us the way up a ridge behind the house. Then we attempted to record the dunes. Alexa Dvorsen had a cassette recorder and a mike. I had encased both in plastic bags so we stationed Alexa $\frac{3}{4}$ of the way down the slipslope and had fleets and echelons of naked sliders go by, making the mountain boom. I stationed a second time and again the fleets came. Tony Smith sailed by like a ship making a long boom as she went. Our playback was inadequate but we think we have a fairly decent tape.

The day had grown hot enough to heat our feet dangerously close to burning, especially over the windows of magnetite rains. But we all made it without mishap.

The vignette of the day was from below on the dune face of the class on hands and knees making their way back to the top for another slide, humanity reduced to its essentials struggling upward toward a distant crest.

The afternoon was a fairly lazy one, people getting caught up, taking baths in the trough, notes, just gabbing.

We had a good presentation about land use on the desert, excerpts from old newspapers about attitudes toward Mojave indians, a grand vignette of a family visiting the desert for the first time, a piece by Suse Shane on ORVs (very well done, and more). To bed.

April 10, 1983

Granite Mts., Bunny Club

Today is an open day. Steve and Larry led one group to Granite Peak. I puttered around the cabin and then in the afternoon Tony, Jeanine, and Mary Kazah went up the saddle trail toward Cottonwood Gap.

Robert Wiener and Jeanine Pollack came across what was probably a ground snake (*Sonora semiannulata*) about halfway up to the gap. It was described as olive above with orange spots a bit less than fingernail size (1/4 cm) apart. The spots were 1-1 1/4 cm in length across the midback and going down either side. It was stretched out on the soil of a rocky hillside amidst cholla, juniper, cat's claw, and more herbaceous plants such as *Sphaeralcea ambigua*. The day was cool, breezy, and partly sunny. The snake went down a rock crevice into rubble buried in the soil. We could not catch it. I did not see it, unfortunately, but I did see where it went.

Another find, Paul Edelman brought a *Sceloporus o. bisiriatu*s back from Granite Peak (male), where it was caught right on the USGS marker. So the species goes clear up, making it less likely we will ever find *S. graciosus*.

It was a slow day letting people gather their wits, get notes in order, and tomorrow we head for home around 7 AM.

June 2-6, 1983, Mono Lake, White Mountains

June 6, 1983

Thoughts on the Spring 1983 Field Quarter

Grandview Camp, White Mountains, Inyo County

Our intense days together draw to a close. Lately we have become more ready to laugh than study, more ready to stay up late gabbing in the glow of pinon coals than to sleep in preparation for tomorrow's work.

We huddle and hug. An arm trails over the neck of a newly dear friend.

High on the hunched shoulders of this massive mountain we know that tomorrow's twisting descent through pinon parklands and into the pre-Cambrian cleft of Westgard Pass is the end of a passage.

It is always so.

But the end of this particular passage has deep poignance because it has been so pure. In our circumscribed world of 26 we have built a subtle set of rules that have allowed each of us to question, to wonder, to touch the earth and each other without feeling foolish. It has been a place of laughter and a place where we could rest when we needed to. We came to know the essence of each other and from this came trust.

And we have had a magnificent quest. "Can we come to know the life pulse of a mountain, or a desert bajada, or a forest? And can we reflect such knowledge on the tangled human affairs outside the bus? In our beginnings, those long weeks ago, many of you were apprehensive. So used to striving toward some one else's measures that few really believed that one's personal passage was all that counted. Nor did many believe that we each (and I include Steve, Larry, and myself) would make the journey in his or her own very personal way.

But these things were there. No two windows-to-the-world would have admitted the same landscape.

How lucky Steve, Larry, and I are, really, to have shared this time with you all, every one. Because our understanding has also unfolded we are as fresh as any of you, and we too think about "Life After Babylon." When else will be able to compare seduction experiences with anybody? Waking without the clatter of pans, the click of knives dicing fruit, laughter mingling with the rush of nearby water and the morning chorus of birds will be bland.

Soon we will go to bed without looking first for stars, unscented by willow smoke and without a haunting indian chant and the clear lingering liquid notes of the flute.

But what of our quest? How far did we get? Are we any different for these weeks? Back home we speak piously of Ecology and to many it has become a banal buzzword of a generation. Can we see it, feel it, think in its terms?

In the desert we saw that plants ordered themselves in often subtle assemblages which only Steve could reveal to us. More evidently across some invisible line creosote gave way to bunchgrass or Great Basin Sage. We learned a little to see, to poke our noses close to tiny ponds to see how mosquito wrigglers breathed, and we wondered about complexity and adaptation as fearsomely predatory insect larvae swam toward our wrigglers with great cocked jaws, only to be deflected at the last moment by the wriggler's long setae. At once we understood those long hairs.

Once we saw the setae fail, the jaws clapped closed and predator and wriggler sank to the algal pond bottom of this microworld. It would never be the same.

We looked at a scarlet columbine nodding by the road's edge and speculated about the guardian form and color that excluded most pollinators apportioning sweet nectar to the few who could hover.

The Matolle River returns home to the sea, a quarter of a mile from our grassy riverbench camp. As Rachel put it, her spent waters pour from the veins of the mountain, only to be drawn up again into clouds that wreath and flow among the battered Douglas fir stands above us. We learn from feeling the power of the Matolle and from building tiny dams across her impatient rills that she, the clouds, the sea, the trees, and the land have one pulse, and are ineluctably one.

Even with this before us we struggle to see, and especially to think about the whole instead of its obvious parts. Linear minds from a linear society must build entirely foreign processes of thought to truly know in this domain.

Yet it is clear that this is our central struggle, one lodged deeply within our unprepared minds. On we go across northern California, the Sierras to the starved shores of Mono, the garden of Deep Springs Valley to our camp on this rim above Owens Valley.

We search for clues. Mostly we see that our precious view of a systemic world is not violated. No linear thing or process stands before us. And linked things are everywhere and what we cannot truly see speaks of great subtlety in such things.

Similar incomplete clues and similar lack of countervailing cases tell us that animal relations, the behavior of humans, and the construction of cities and farms are likewise systemic. Can we take our lessons from these mountains, islands, deserts, and

rivers back with us to shape human responses to present outmoded social constructs. That is the next, and ultimate challenge.

Maybe in some way, dimly perceived and not understood, our blue capsule and our odyssey themselves contain such answers.

KSN, Grandview, June 6, 1983

September 1-9, 1983—Tahiti, Moorea, Bora Bora

September 1, 1983

Los Angeles International Airport

Well, I learned long ago in field work that luck runs in streaks. If it's bad, it'll go away after a while.

The day before this trip to Papeete, Moorea, and Bora Bora with John Pearse and his wife Vicky, was awful. I couldn't seem to do anything right. My daughter wanted to borrow my pickup to drive to Idaho and I wouldn't let her go till I changed the oil and I left the plug out while adding the new oil. I burned a hose in half melting blocks of asphalt. I backed a tractor into my wife's pet dogwood tree and snapped it off, all this after getting a call from Joe Loug telling me he wanted to get the tickets, not me. Oh my!

Then off to the airport and down to LA where we expected to be met for a ticket exchange but weren't, and then onto a big Qantas 747. We took off OK at 9 PM, but no more than half an hour out the captain came on in his good Aussie accent with "This is your Captain. A minor part has failed, and Qantas, with its fine safety record blah, blah, blah"

So we turned back to LA, circled for an hour and then were hustled off while the plane went off for testing, came back and we went aboard again. The part was finally replaced but the mechanics went off shift before the engine could be assembled. Then Qantas announced we were being sent to hotels. At 5 AM we arrived at the Sheraton something-or-other, I was paired with a smiley black pentecostal minister from Melbourne and we went off for some sleep. Right now I'm in the lobby and we go back on board at 2 PM. Then because I saw a magnificent Dr. VanDeburgh before the trip, somewhere along the line the clouds will part, the mist will clear away, and we'll have a helluva trip.

For readers who don't know about Dr. VanDeburgh—he is the patron saint of field trips and he appears before us in various guises which we can learn to read for information about the trip ahead. He wears green or brown, usually, or blue, if you're facing lots of rain. And he has a white beard—the whiter the better.

The one I saw had a grand beard, rode a bicycle, and was all in green. Very auspicious, Dr. V. but when do you go to work, my good man?

Now why John, Vicky, and I should be off to exotic Tahiti—Mr. Joe had mentioned to me long ago that I might like to go to Bora Bora, where he has a hotel, to look for porpoises. Then things got so sticky in Hawaii that I terminated my spinner porpoise project there—the drug scene, violence, dirty water, and too many animals, which keeps us from following family lineages very well.

So I asked him if the offer still stood and he arranged it. Director Bill Doyle of the Center for Coastal Marine Studies asked if John Pearse might go to look into invertebrate

opportunities, and because Bill couldn't go, Vicky substituted. She will be invaluable because not only is she a fine invertebrate zoologist, but she speaks French which neither John nor I do.

We hope to look into opportunities of all sorts for the marine program. Can we establish a tropical arm for our students and researchers? We will visit Papeete, Moorea, and Bora Bora. Praises be, Mr. Joe has set up complimentary rooms for us at his hotel Taharaa at Papeete and his Hotel Bora Bora in Bora Bora. At Moorea we will stay at the Gump House adjacent to the fledgling marine station. Mr. Gump is helping to establish at the site below his house. I'll be looking for porpoise schools, clear water, cliffs, to set my surveying instrument up, a peaceful congenial place to work, and small dolphin schools.

So, let's see what this day brings. The dawn, I hope.

September 2, 1983

Well, after a good night's sleep, breakfast and a lot of standing around, we trooped back on board the same plane and at 4 PM began all over again—same cold towels, veal something or other, bar service, movie, squirming in the seats, and pacing up and down the aisle to shake out the kinks. About 9:30 PM we landed on the [?] runway, went quickly through customs. Our agent was a giant Polynesian without a smile whose hat perched incongruously on his huge head. He stamped things and we were off. A 14-km taxi ride took us to Mr. Joe's beautiful hotel Tahara'a at Matava Bay. It steps down the cliff as a series of terraces overlooking this arcing bay. The beaches are black sand and across the open water one can see Moorea, a dark greenish castle thrusting up from the ocean. Each of us has a terrace lined with flowers. The trip through Papeete was on rain-washed, almost vacant streets. In the dark it looked like the lush parts of Hawaii. Cascades of white plumerias, big mangoes, and beach almonds (karmani trees), octopus trees, and so forth. The air smelled heavily of perfume from these crowded trees.

A good, good sleep and next morning while eating breakfast on the porch, John and Vicky spotted a big dolphin school offshore in Mataai Bay. I guess 60-70 animals and I'm sure they are spinners. They were spread out over perhaps 300-400 m of water moving back and forth. There was some aerial behavior, but no spins, just head and back slaps. I'd guess the school was out 1/3-1/2 a mile. I could just make out fin shapes. Some seemed somewhat falcate and I thought I saw some canted forward.

The animals were moving fairly rapidly and going back and forth. I don't think they were in real resting formation, but perhaps descending to it. I could not be sure but it looked as if there might have been a reef beyond them (probably not) though not nearly so well marked as other reefs on both sides of the bay. Pt. Venus is perhaps 400 ft. high and would be an excellent theodolite location. Beyond the reef on this calm day there was a lee of calm water that didn't grade into wind chop for on the order of five miles offshore. So deep oceanic water is at least sometimes available for small boat work in the lee of Tahiti. The wind blows around the W. end of Moorea leaving a lee between the islands.

We were told that only yesterday the spouts of whales had been seen just outside the reef.

After much discussion we decided we had to head for Moorea today because the people there were waiting for us and because of our tight later schedule at Bora Bora. So, having missed the morning ferry we decided to fly over rather than wait till late

afternoon. Down to the little airport through the lush vegetation tiered up the steep hills. One could see that the tops of most of the trees had been blasted off by the hurricane of last season. They told me of 100 mph winds up at the hotel. Ed Fearon, a co-owner with Mr. Joe told me of partitions popping like corks on the verandahs, roofs sailing away and windows bending and exploding inward with the blast. The first such storm to hit since 1906, I believe he said.

Anyway, we flew in to Moorea and the ambiance was noticeably slower, even at the airport. The car ladies played scrabble and the taxi drivers smiled. The island, like Tahiti, is a high volcanic island. Moorea is a giant caldera of an old crater. Two of the bays that cut into the island enter this caldera. Left are ramparted cliffs, fins of lava, and vertical walled peaks that usually pierce into the misty clouds. A fringing reef defines the outer margin of a rather shallow reef flat, sandy nearshore, and increasingly crowded with coral heads toward the reef.

The water over the reef flats is startlingly clear in places though the deep bays are murkier (probably simply from depth).

We tried to find Luci Terhotua, the husband of Nui Terhotua, who is the local mayor. Both work for Mr. Gump, as does Luci's brother, Charles.

Finally we did and she lost no time in telling us that we couldn't use the Gump house because she and her four kids had moved in while her house, damaged by the hurricane, was being finished. She is a big, smiling, dominant Tahitian woman of 35 who, I believe, moved in after George Barlow had a falling out with Mr. Gump in mid August. We are "Barlow's boys," I think, and Luci, knowing where the power lays, made her move. In my view, if we were ever to use the station it was best just to swallow the situation, and take a nearby room. So we got her to set up a room at this nearby hotel for us at some reduction in price and then her brother Charles took us out in a fishing skiff. It's Friday, the fishermen all fish on Saturday. They go to church (Protestant) on Sunday—no boats—so today is it.

Sighing a bit, but recognizing that this sort of thing is standard grist for invading a new area, we signed in at the hotel—a collection of nice, thatched bungalows on the beach north of Cook Bay.

Charles, a beefy, pleasant French-speaking Polynesian (part), produced a fiberglass boat of about 15 ft., deep V bow with steering in a well very far forward, two Merc outboards, and a tiny string for an anchor line. Off we went, into the calm Cook bay toward the entrance. Vicky translated for us and we headed out to traverse up the coast outside the reef. Not long after leaving Vicky and then John sighted jumping dolphins in the choppy seas. Finally I saw them, dark shapes leaping and falling on their sides 1/3 mile out in the blue water from the reef. We closed on them, and formed several widespread subgroups over perhaps 1/4 mile of water. They, much to my surprise, proved to be stenos—rough-toothed dolphins, and perhaps 30-60 in all. It was very hard to say because of swells and chop.

I saw their large, sometimes ragged fins, their bodies splotched with scars, mostly from cookie-cutter sharks, but some much larger, grievous-looking wounds that must have come from large sharks.

We circled amongst them, watched them leap in their typical aerial behavior—an arcing leap, a turn onto the side, and a falling crash into the water again. Just like Hawaiian stenos.

We reentered the bay and cruised westward toward Oponohu Bay. We cruised into it clear to the back end. Its center is deep and dark—15 m or more, but the edges are dotted with scattered fishermen's and other houses, one a grand green tin-roofed place owned by an American. At the back of the Bay we could see the buildings of the French marine station, "Centre de l'Environnement" run by an ichthyologist—Rene Galzin, George says he's a pleasant guy who speaks a little English.

We cruised west of Oponohu Bay behind the reef. The boat channel, well marked by painted metal poles, let us follow a tortuous course among coral heads, some of which were nearly awash. It was a grand ride over clean coral bottom 6-7 ft. deep, amidst table corals, a blue coral, large brown *Porites* and scattered fish. A heron that looks much like a reddish egret stalked the shallows, brown boobies skimmed over us and a large tern croaked its rubberband sounds from perches on exposed coral fragments. We skimmed the glassy water, now calm and clear, that must have been a maelstrom during the storm as here and there we could see coral heads tipped up and out of water.

We went out to entrance of Oponohu Bay and not a quarter mile outside we came into a school of what I'm pretty sure was *Tursiops*, the bottlenose dolphin. It was small for the species, but the dark color, the well-developed beak and melon, the large falcate fins and its behavior all converge on that species. Several times I saw pairs, trios, or echelons of more animals riding inside wind waves. Some swerved near our bow. Most were probably at most eight-footers, and most were more like seven ft. None of the big brutes we are accustomed to in the Gulf of California, or off the California coast, were seen. I'd guess we could see groups that numbered 30 animals or so.

Vicki has been translating well for us though her gentility means we must pose most of the questions. Charles is a good respondent who does not tell you what he doesn't know—refreshing.

Then we stopped for a snorkeling excursion at the West entrance of Cook Bay. John is looking for groups of *Diadema* urchins, as possible subjects for a field class sometime. Though the reef proved interesting it had very few *Diadema*.

The shallow reef flat extends right up against the back of the fringing reef that extends up to tide line. The density of coral heads increases in that direction, too.

Charles anchored his boat on a coralhead using a bamboo pole with a big hook at the end and a single piece of twine to the towing eye. We dove in, leaving him floating on the glassy water. Then began a long snorkeling wander toward the fringing reef in 4-5 ft. of water. Mostly one steered carefully among the hard corals to avoid being scraped.

We saw almost no soft corals, so prevalent in the Barrier Reef, mostly table corals and a heavy brown *Porites*, a blue coral John couldn't identify. The stag horns were largely gone—I could see fragments on the clear sandy patches. In the *Porites* were two kinds of serpulid worms, their respiratory trees out. One was brilliant, brilliant blue, a red and orange and a striped one. They snapped in as we came by, or extended a finger forward. Small *Tridacna* clams (5-6 in. across) were as brilliant—iridescent greens and blues on their mantles. The swash of a swimmer would cause a slower closing, usually not complete.

Joh showed me the Cuvierian tubules of a giant sea cucumber *Actinopygea*. These two-ft. long brown or tan cucumbers had small light circles stamped on their backs. When one picked them up and stroked their venters, a mass of whitish tubules promptly extruded from the arms—like a mass of fine white spaghetti waving in the water. If one

touched it, it immediately adhered to the extended finger and one became enmeshed in a tangle of incredibly sticky threads (they rupture a membrane to extrude them). They do not, I recall, stick to each other. How does that work?

The fish fauna was rather modest, I thought, though one could fill in a long list after a time. Whitish lizard fish scooted on the white sand adjacent to coral heads. Lovely, iridescent, pale-blue *Chromis* schooled among coral branches and took refuge when I neared, flashes of blue deep down in the coral head.

A lovely, six-inch, big-eyed, bright-orange fish that I suspect of being a Pomacentrid, was common. I saw perhaps five kinds of butterflies, olive Acanthurids (surgeon fish), but very few wrasses, only one scarid and no parrot fish at all. All in all, invertebrates and fish, the reef is a specialized one, very unlike others any of us have seen. Urchins were few, John found only three *Diadema*, but many of a smaller Strongylocentrotus-like form (*Echinometra*). John says it's one of the most widespread of Indo-Pacific urchins.

I saw some *Fungia* (mushroom coral) and the reef was heavily populated by waving columns of a brown alga, *Turbinaria*. There was also a filagree-like brown[?] that gathered in great heaps among the coral heads (*Hydroclathrus*).

We swam back to the boat, came in, and jounced back to the hotel in the back of the truck (Luci says "Men in the back"). A good dinner, a free Mai Tai, which practically levelled Vicki, and off to bed which included a modest bout with mosquitos. Our Fale[?] is permeable indeed to the little critters, there being no screen on the louvre doors.

September 3, 1983

Moorea, Hotel Moorea Lagoon

Charles is scheduled to take us around the island today. John and I will look for a general ecological opportunity for our students, and for us, who might work out of the little marine station now in the works. It now consists of about one acre of fill at the edge of Cook Bay, below the Gump house. We launched there yesterday.

I called Phylly to have her call George Barlow so he could try to alert visitors subsequent to us that no house was available. All's well at home and our connection was immediate. Magic!

At 9:30 Charles picked us up in his Peugeot pick-up. We gassed up at Cook Bay and drove up a central loop road that goes back in the caldera and up against the face of the cliffed mountains. It's a spectacular drive. The road at first traveled through little patchy farms separated by trees. Often these were groves of a closed-cone pine, planted in rough rows, growing straight as a die uproad. I wonder if it is a tropical permutation of our Monterey Pine (*Pinus*) such as is widespread in the southern hemisphere.

The flora is much like that of inland Hawaii, poinciana trees, Java plums, mangoes, guava groves all tangled and nearly impenetrable, Han jungles, and even a slim, spindly relative of the ohia tree (*Metrosideros*). Many flowers graced the way and colorful foliage plants, mostly familiar—*Almandra* in lovely yellow-flowered banks, cohias, ti, hibiscus, ginger, and more. *Taconia stans* with lovely yellow trumpets was common like the *Plumeria*, an import from Mexico.

Near the top of the road we came to a pair of ancient marae, or stone temple platforms with scattered vertical stones, like headstones in a cemetery. In one there were also three box-like depressions about the dimensions of an apple crate, that we learned

from Charles were crypts of kings—small kings these, or good packaging, one or the other.

The marae stood in a forest of tropical “chestnuts” (*Inocarpus edulis*—Fabaceae); these with wonderful finned buttressed root systems and blotchy tropical tree bark. To one side a stream ran tinkling and gurgling over stones. In it we found a prawn-like *Macrobrachium* that pinched and probed at John’s fingers when he held it. I saw a little goby. On the banks a lovely, slim, blue-tailed skink scuttled amongst the leaves of the forest floor. There were several spiders and worms of interest—all in all a beautiful mid-Pacific forest environment.

Oh, I forgot the ferns and epiphytes which were prominent and varied. There were tree ferns deep in the shade and tangles of a sort of tropical bracken in the sun, single-bladed ones in clusters on tree trunks and compound pinnate ones on the forest floor.

We followed Charles through the shaded trail to another marae, this one a magnificent platform maybe 60 ft. long, backed at its upper end with a kind of tiered stone temple which faced across the alley at the magnificent fin of rock that was the major mountain (Mut Rotui) separating the two valleys, which coalesced under our feet. One tier of the marae was of rounded cobbles from the sea shore, the next slabs of flat mountain rock, overlain by another tier of cobbles etc.

There were, as I recall, five or six such tiers. [Drawing.]

Then a little spin took us up Belview lookout. We stood against the cliff of the west mountain which rose nearly sheer 2,000 ft. above us, its sharp peak mostly shrouded in fleeting clouds and vapor (Mt. Tohivea, 1212 m). Except where it was truly vertical a fuzz of vegetation clung giving the entire mountain a green cast.

Ahead of us we look down two valleys to the sea, down Cook and Opinohu. Dividing them is a giant cliffed spine of volcanic rock, rising at least 879 m between the valleys. Fins and dikes of rock were etched here and there into castles of stone, fingers and walls snaking up the green slopes and clothing all the gentler land hung in between is a leafy airy forest. It has been said somewhere that this is the most sublime vista in the Pacific. I know only a few and can’t judge but in my collection few match or approach it. Nature still reigns here—the green valley, the blue sea, paling to turquoise over the shallows, the white and grays of clouds, the ashy black of volcanic rock layered and piled by an ancient volcano whose heart once was searing with molten rock right where I stand.

I reacquainted myself with the candlenut tree, a lovely tree of pendant heart-shaped leaves whose gray cast makes them stand out from the darker forest when one looks at the sweep of a hillside. A dotting of them could be seen against the far northern arc of the valley, up against the place where rock rose vertically, leaving the tree cape below.

I traded with John, taking the bench set across the bed of the truck and rode the rest of the way there in the warming day. Only miraculous sunscreen kept me from a fine sunburn, but lily legs emerged mostly uncolored.

We headed west around the island on the circle road that travels on the nearly level apron of land at the mountain’s base. It is a rural band, but houses and people are in most scenes. It switches from sandy flats feathered with long, limber, well-spaced coconuts to denser forests of karmari[?] and hau[?],—and slopes dense and inhospitable with hale koa. Now and then we crossed the tiny estuary of a freshwater stream. Some smelled. Most had flowing schools of small silvery fish, probably mullet.

We stopped to push a bus at a park where a yearly taro contest was just finishing. Contestants brought in the roots they had raised and they were weighed. The heaviest was 64 kg., a giant brown root.

On we went. Now and then a pass through the reef appeared and I watched for fish, which I did not see. The two best passes were next to the channel between Tahiti and Moorea. These came in as broad bands of dark blue, into the deep channels inside the reef, with white breakers piling on the reef on each side. I think they bear watching as dolphin schools could enter. Because they are fairly close to the cliff, they would allow the use of a theodolite if animals were indeed there. Only study will tell.

As I write, two beautiful little finches have foraged up within a couple of meters of me. Olive-backed, gray-breasted, they have crimson eye masks and crimson tail coverts. They are half the size of some North American finches.

At the airport we dealt with some ticket problems and then came back to the hotel.

Resources for teaching and research are here in some abundance. The upland forest, its streams full of creatures that could somehow traverse thousands of miles of salt water, the trees, the fern flora which is another disperser carried by spores, some in the stratosphere. The dolphins need reconnaissance study. So far, I doubt that this is the place for a long-term study of their society, but the very species that live here and their characteristics remain unknown. Problems of tropical agriculture, mariculture, and society are here in abundance. Charles is one of 15 children of Protestant family—all live on Moorea and have 20 children themselves. It's filling up. Native culture contends with tourist culture. Population goes up hundreds each year.

The reef I'll leave to John and Vicki, but I can see it as a wonderful introduction to the tropical marine world for students. The fish, the coral, the indwelling worms and urchins, the in-fauna of the sand, the signalling systems of *Chromis* schools and *Dascyllus* schools, the sensing of goat fish, whose barbs are used to probe among the sand grains for food, sea cucumbers. There is a tropical marsh by the airport. There are mudflats alive with life.

We stopped in at the French station at the head of Opunohu Bay and will return tomorrow. They do various sorts of invertebrate work and there is an ichthyologist on the staff. There is a pond culture program raising *Macrobrachium* prawns next door.

We did a little snorkeling in the afternoon. All of us saw a good deal more than on the first dive. I checked families of fish and found snappers, goatfish, parrotfish, a goby, the parasite-picking wrasse, and other wrasses such as *Gomphosus*, a kihi kihi (Moorish idol), and Vicki and John saw boxfish. *Balistes rectangularis* is common but is the only triggerfish I saw.

The sea is clear and sparkling in most places. I fear, however, for the future of this place as population grows. How long can table coral persist?

I prodded a couple of big pillow stars (*Culcita*) over. They look like rocks, but once turned over they reveal their ambulacral grooves. John says a pearlfish sometimes lives in them.

In the evening Nui and Luci came in and told us about the marine station plans. They had trouble understanding why we didn't know about plans and we tried to tell them about giant universities and communication problems. Nui is a judicious man of evident probity and Luci I've talked about before.

They ended inviting us to a Tahitian meal. I asked about Mr. Gump. They had much affection for him and had named a son after him. He is 77 and has been on Moorea since about 1961.

They rather spilled all the problems between George and Mr. Gump. Poor George. I can imagine how he feels.

September 4, 1983

Hotel Moorea Lagoon, Moorea

John, Vicki, and I got up this morning, had breakfast, and walked westward to the French lab, Le Centre du Environment. It is located at the very back of Opunohu Bay and consists of a cluster of buildings including a couple of labs, a dorm and kitchen, and places to park cars and fill diving bottles, and the like. It's small and caters to individual scientists without families.

Visitors were there including a coral authority Michel Pichon from James Cook U, Queensland, and a younger man from N. Guam who worked on fishes. Their program is pretty much a survey of the biology of Moorea and mostly non-experimental except in the trophic sense. They gave us a bibliography of some 200 papers published since the station began in the 1970s. The main director is in Paris and only a caretaker is permanent. They were very friendly and most spoke excellent English.

As we walked back past the *Macrobrachium* ponds next to the lab, Luci and Nui picked us up to take us to a real Tahitian meal. We drove to a restaurant across the bay from the Gump place. It sits on stilts out on the bay, woven mats and thatch and a great, high, airy ceiling, and windows all around to take in the lovely bay, black cliffs, the green hills, and the sky decked in cumulus.

The meal was set out buffet style. One took a soup bowl for curded coconut milk and a plate for various goodies and then one ate with fingers—swashing each morsel in the milk. Nui had made for a crock set off by itself and said, "Not for you—raw fish." Since I like raw fish I made for it too. Wow. It was very fresh parrot fish slices anointed with a truly powerful rotted sauce made of fish bones and salt water marinated in the sun for four days. John and Vicki didn't try any but were downwind and that was just about enough.

The rest of the lunch was delicious—taro root, pumpkin and milk, sea food salads, a big mahi mahi, and more.

They dropped us off at our hotel and we snoozed for a couple of hours before an afternoon snorkel.

I saw a lot more this time around—a ghostly goby in coral sand burrows, paired with a shrimp. The sand was full of a tiny sea cucumber—raking the fingers produced dozens. John says there is a viviparous form and that one can see babies lined up inside the body wall.

I was challenged by a beautiful trigger fish (*B. rectangularis*). He had cleared a partial circle on the open, rocky bottom and he didn't want me anywhere near, even when I was two meters or a little more, away from his treasured circle.

He rushed at me and I shoved him away by waving my hands and he would rush again. Remembering their powerful teeth and jaws I left him alone.

As dusk fell the schools of tangs began to flicker over the open, sandy areas and squirrel fish inched their way into the open from below dish coral. I saw a nocturnal

cardinal fish poke its head out and I wondered about the crepuscularity of some reef sharks. They should be on the prowl too. Soon I headed for the beach in front of our little house, and walked amongst the thatched bungalows to ours (ole' 25) and headed in for a shower. John and Vicki came in later and we walked over to dinner (good sauteed shrimps).

September 5, 1983

Hotel Moorea Lagoon, Moorea

This is our last day on this island. Luci and Nui had suggested that we might take the boat out before our ferry.

I asked if we might go to Haapiti, a place Rene Galzi had said he always saw dolphins. His description made them sound like spinners, so needless to say, I was raring to go. John and Vicki will be glad too to see a different reef.

So, about 7 AM Charles appeared and helped us hand our baggage up to the Gump house while we took our boattrip. Somewhat to my surprise Charles launched at the Gump dock and said we would go by boat. Straight out Cook Bay he headed. The sea was rolling glassy smooth outside and we could see a long way. Not long after we left the pass Charles turned the boat east and soon he and John could see fins. Then I did too—a long way off. As we closed on them my puzzlement grew. They were bigger than most porpoises and there were four of them. They didn't roll like a dolphin but often their long back ahead of the fairly large, slightly falcate dorsal lay straght and black at just above water level. [Drawing with caption "very straight until the animal lifts his head"]

Then, the snout was sometimes raised so that one could see it was underslung. [Drawing with caption "undercut snout is very obvious"]

I never saw them blow. When they dove they dove for perhaps 30 seconds, maybe more. I never saw pale marks on the sides. They moved quite deliberately and allowed us within 20 m or so. We stayed with them for about 20 minutes and left.

From head on I could see the animal move its head up and down out of water while the back stayed in the same horizontal orientation to the water.

I'd guess the length at 10-12 ft. in the largest, the fin 2/3 of the way back to flukes and dorsal fins variable [?] large and in one case, with a bulbous tip that could have carried ectoparasites. I'm quite sure we were getting my first real look at *Kogia breviceps*, the pygmy sperm whale. Later Nui called them "otia" (this name was some allusion to a saddle or a horse because their backs bend like horses) and knew they were not dolphins. The fact that he knew them well makes it reasonable that they could be encountered with some frequency. Oh for a rewinding apparatus.

On we went around the west end. The sea grew choppier with a short and not very high wind chop. Charles navigated us nicely from his bow seat which I learn is a pulpit from which they can harpoon mahi mahi. Nui says they go far offshore, 15 miles or more, to find them and located mostly around mantas. The boat pulpit has a tight little seat and a joystick foreward and accelerator at hand. The joystick moves from side to side in a slot. [Drawing] From this seat the driver can maneuver up on fish and harpoon, singlehandedly. They use a stainless steel multipronged version of the Polynesian fish spear. The haft is about six ft. long.

We passed one nice open pass. We could look in the path of clean blue water between white breakers on the adjacent reefs into a clear turquoise lagoon, high volcanic

peaks behind, clothed in green. We passed by and rather soon came upon another clear pass and Haapiti Lagoon. The pass is deep blue water well inside. At the surface was a long trailing mass of *Cladophora*? (*Boodlea*?), a yellowish-green alga. John says it grows on the soft bottom . . . grows up and is shed into the water.

Behind this mat John spotted fins, and sure enough there was a school of 50-70 spinners. They promptly spun for us. I don't think Charles expected them to be there. But I'll bet it is an habitual bay for them,. Rene Galzin said he always saw them there, anyway.

The dolphins impressed me as smaller, a bit, than Hawaiian animals and much more dusky. The white on the belly was suffused with gray. In the water they looked chocolate brown.

Before midday the dolphins made their way out to sea. I was impressed that when we first sighted them they were zig-zag swimming. They were calm and secretive one moment, and moving more rapidly the next. There were clearly marked individuals, one with its fin essentially gone was there.

The water of the pass was dark from depth, where the dolphins gathered, but there was probably 75-100 ft. of lateral visibility. Charles said the clarity depended on currents and that it was often clearer. My poking around about winds[?] suggests that this is usually the lee area, and that like other haunts of spinners it utilizes calmer waters.

The hills behind were close enough and steep enough to place a theidolite station there. All in all it looks like an excellent place for a longitudinal study. The animals are not hunted or bothered according to Charles and others. Whether the school mixes with others is, of course, unknown, but there may be others at other passes toward the airport and Nui says they sometimes come in to Opunohu and Cook Bays.

Thus, whether the population is smaller than the Hawaiian one cannot be foretold, but one thing one can say is that all could be worked by small boat, including that at Papeete, in good weather. The channel between Moorea and Tahiti is only a dozen miles wide and should be easily traversed. By the way, as I write this next morning we are on our way to Bora Bora and as we flew out over this channel, I looked down and could see 15 whales that were probably sperms (they could have been *Mesoplodon*) in a straggly school, only perhaps five miles out from Papeete.

Back to Haapiti. After observing the dolphins for a while Charles put us on the reef right alongside the pass, for a snorkeling excursion. It's a real pleasure to swim with two folks who know so much about the reef as John and Vicki do. We poked in coral caves, flipped rocks on the bottom, to see who lived underneath, and generally snooped over that reef, spouting latin names and telling me bits of natural history.

The reef rises from scattered coral heads back toward the lagoon to become denser and denser as one approaches the sea and finally to coalesce into a solid reef at the sea edge, on which one can stand and walk. There is a change in species, too. It becomes richer and richer as the sea is approached. I was delighted to see large, sprawling anemones, each with a contingent of brilliant black and iridescent blue *Dascyllus*, little relations of the sergeant major. The little fish bathed in the tentacles and had their little tiffs with each other just as the more usual anemone fish do (*Amphiprion*). I saw only one of these, and it didn't seem to have an anemone.

Fire coral was common (*Millepora*) (it's not a coral, but a hydroid, really)—a brown coral changing to lemon yellow on its tips. It is to be avoided as it can give you a

real sting. There were other noxious critters too—the crown-of-thorns was there—I saw perhaps eight or ten. One finds them crouched over coral heads, which they eat. One can usually predict them in advance by the presence of patches of bleached and dead coral. But they weren't destroying this reef, but instead in balance. Only occasional corals had been killed, amidst a sea of live ones.

The fish were a different assemblage in part from those on the other side. Sailfin tangs, brilliant little wrasses, ghastly goatfish, and a bright-yellow-lined rudder fish were everywhere. Crevices everywhere held a brilliant iridescent blue and yellow pomacentrid.

As we swam back toward the boat we looked up and saw it going away at full speed back into Haapiti Bay. So we paddled around for another 20 minutes until it returned. They had gone to pick up coconuts off the beach for us. Two with new sprouts were sliced longitudinally, and the "coconut bread" exposed, the way the growing plant mobilized the food value in the solidified milk. It was rich and tasty.

All three of us were sunburned, not so much because we were left on the reef but because we didn't take enough precautions in the boat. It'll take a couple of days to subside but we aren't really burned.

We took the inside passage back, following a marked channel that zig-zags through coral heads and into channels. It's faster, I think, than going outside, and very beautiful as one skims over the greenish flats suspended by crystal water.

Well, what, in summary do I think about the Moorea Lab and what we might do there? The environment is lush and rich with opportunity for good students. I could do much there with my animals, from the first studies ever on pygmy sperm whales, to, probably, a longitudinal study of spinner dolphins. The reef has almost endless possibility and would allow our students to broaden their horizons a great deal. This place is in the mother fauna of the tropical world, and it needs to be experienced in fine detail to be appreciated.

But there are problems. First, it is fairly far away. But costs of transportation are only modestly more than say, working on an outer Hawaiian island. Second, it is French and largely French-speaking. It would be good for students to face that. Third, it is in "paradise" and we will be told over and over we are on vacation, when, actually we are at work. I recommend ignoring this largely, but attempting to show the intent to do serious work in various ways, such as production of science.

Fourth, the station plans are embryonic and the situation at Berkeley is stand-offish at best. George Barlow has soiled his nest with Mr. Gump and is no longer effective as interface. Whether there is a replacement I don't know.

Fifth, in talking to Luci and Nui I find a rather dim view of what they face in operating such a station. No one seems to know how maintenance costs, or operational costs are to be handled, who pays and how much. They seem to think a Tahitian gift of support will run things. These items must be clarified or no campus of UC can afford to get too involved.

Sixth, the role of Mr. Gump needs to be clear. If he is in charge he needs to define this charge and to tell the University what its degrees of freedom are, and what its responsibilities are.

It could be good, it could be a can of worms. If good, we could benefit, if not, we shouldn't touch it. For us to take part, I think something like the Panley Fund should be

set up. This fund, though small, provides on a competitive basis, modest support for UC students wanting to work in Hawaii.

An ability to use this area, whether Tahiti, Moorea, or Bora Bora, will be modest though it could be sustained. I'd guess if we could field 4-6 student projects, two longer [?] staff projects, in a year we would be close to our normal potential at present. We shouldn't subvert most work at home for work here. If transportation and some subsistence for such a level could be placed in a competitive fund and operated by an academic committee a total amount of about \$15,000 per year would suffice. Larger group projects might utilize University Expeditions as a source, or regular grants.

To make this a real and continuing CCMS I see this support as a necessity.

Our trip across on the ferry was uneventful and dolphin-free, though I kept a good watch. I'd guess two hours in my recording vessel would make the trip.

We cabbied it up to the hotel where, as before, we were greeted most graciously and treated like visiting royalty. Scientists are scarcely used to such treatment and it could go to our heads.

Ed Fearon and Mike Wilson greeted us and saw to it that we had front row at the show. Tahitian hulas are pretty honest fare, I've always thought, though I guess the old, totally uncovered version was even more honest than our present one. Done by truly beautiful women and who can say nay.

September 6, 1983

Hotel Bora Bora, Bora Bora

We packed and were on Air Polynesia at 10 AM and off across the open sea to these tiny bits of land, as noted before, only a few minutes out of Papeete I looked down upon a school of sperm whales straggling along a drift line. Now that would be something—a place to work with sperm whales.

We flew over flat Huahine and then later Raiatea, and shortly Bora Bora, to land on a motu at the edge of the broad lagoon.

We piled in a launch, crossed the lagoon and were picked up by two "Le Trucks," who ferried us to Hotel Bora Bora. Now I know what Mr. Joe meant. The hotel is a cluster of individual thatched houses around a central diving and check-in area and office building and is wonderfully tastefully done. The houses are trim, wood, windows, screens, and thatch. A tray of fruit and two bottles of wine greeted us. Out front palms arched over the immaculate strand and beyond to flickering turquoise and deep blue. Frigate birds hovered overhead and a sea breeze fluttered the leaves. Further beyond white waves leaped along the fringing reef and cumulus drifted like white ships.

If ever there was a recreation of the dream of tropical paradise, this was it. The staff mirrored it all, friendly and graceful and capable, too.

We were greeted by Monty Brown, the manager, and he is arranging a boat for us tomorrow to look at reefs and the passes. Monty is an affable Kaamaina boy from Kona.

John and Vicki and I felt our circumnavigation of Moorea had been such a successful way of getting our bearings that we decided to do it again. We rented one of those pressed metal Citroens, powered by a lawn-mower motor, or near equivalent, and started off, first mastering the mysterious shifting mechanism—a lever on the dash. Bora Bora is much lower and drier than Moorea, but some monolithic peaks rise in vertical cliffs to produce spectacular scenery. The lagoon is broader than that at Moorea, has a

single very large and very deep pass leading into a giant deep water lagoon, which as some one said, and they were wrong, “could anchor all the Navies of the Pacific.”

There are a few mountainous islands (motus) out in the lagoon, but mostly a very long motu of sand clothed densely with coconut palms, borders the outer lagoon—or sometimes just a reef at sea level.

Vast areas of the lagoon are shallow too, with white coral sand just a few feet down, making the water white as milk apparently. [Note on side of page—“Trash, not just from storms, but old rusting ?? and just plain junk, and it is being hacked at by development in various places. It is, I think, seriously threatened as a “tropical paradise” by these things.”]

Bora Bora seems more remote, more oceanic too, than Tahitia or Moorea—brown man of war birds hover and dip, brown boobies and noddy terns swoop and call over the palms at night and shearwaters call their plaintive cries.

Our trip took us on the only road, about an hour’s trip to go around. Most is on the flat just above sea level and most is a coconut grove with wet land pockmarked with land crab burrows. We watched one retrieve a big leaf from the center of the road, haul it to his burrow only to have a furtive claw rise up out of a neighboring burrow to clip away at it.

Up towards the airport our car simply quit. Two gals stopped to see how we were doing and so we pushed it to the side of the road and hitched a ride. Finally we found a phone, after two failures and were soon picked up by Fernando?/Antonio? who entertained us with stories about Vaitapu and a local Tahitian who wanted to build a ship restaurant but who instead sank the ship spectacularly in the bay and then got another, also in the bay.

A fine dinner and to bed. Tomorrow Richard takes us out to the pass in the morning to look for dolphins and to dive. I forgot to mention we saw a *Manta* and some *Mobulus* leaping and cartwheeling out by the airport.

September 7, 1983

Hotel Bora Bora, Bora Bora

After a fine sleep with the wind fluttering the thatch and whistling about the eaves—our houses are right on the beach, facing windward—and the little surf spilling against the beach, we arose at 7 AM.

Monty had told us something of the dolphins here and he seems to know them. He said there were none that habitually used the pass and that he had rather seldom seen them outside. He mentioned seeing *Tursiops*, *Steno*, and pilot whales (he used latin names), and told us of once seeing two whales encrusted with barnacles lying on their sides outside the pass. These must have been humpbacks.

Frank, an affable and competent Algerian Frenchman took us out in a Boston whaler. We cruised out the deep channel and turned south to a point where the wind began to pick up a considerable chop. We could see the atoll of Tubai on the horizon and Mapiti, rising high to the northwest. Frank and Monty both reported that dolphins frequented the passes on Raiatea and agreed that they were not here. They weren’t this time. But I’ve learned I must check. I once had a hotel operator tell me there were no dolphins in his lagoon and in fact they went by his place nearly every day. But these guys knew better and were right.

Lubai, Frank told us, is owned by a French lawyer and operated for copra and that many Bora Borans go there to fish, especially for turtles, which are becoming rarer at Bora Bora. He says the locals have no idea of conservation and don't understand saving young fish or protecting certain areas. They have partly resisted the idea of protecting the reefs in front of the hotel. We will inspect these thoroughly tomorrow.

Frank took us back inside the reef and around a high motu and right back of the barrier reef. There we threw the anchor out onto a coral head and stepped ashore onto the tiered reef platform itself. It is a nearly level coral platform about 50 m wide with oceanic combers crashing on the outer side and a flood of water usually flowing inward. Sometimes it subsides and everything is exposed and sometimes it's waist deep with white foaming seawater. The rising waves are blue and translucent before they crash all at once in foam. One has to brace oneself strongly to keep from being tumbled by them. Vicki fell once but was not badly scratched.

The platform varies and new organisms seem to come in near the wave break and one can see fissures running deep into the sea from the outer platform margins.

The platform is pockmarked with crevices and holes and little depressions. In these one can see organisms such as sea cucumbers lying. John was surprised at the dearth of urchins in these places. We jumped with shoulder-deep water back of the platform. Oceanic, clear and refreshed by the constant inward flow, this is what refreshes the lagoon and comes to flow out the pass. In view of the influx we encountered, exchange of the entire lagoon should be calculable, and my very offhand guess is that it might be frequent.

Our first dip in and we were surrounded by butterfly fish—a lovely one with a yellow back and tail, a black tail spot and two vertical dusky bars. It's not Hawaiian, so I don't know it. Other fish swirled about—brilliant parrot fish, tangs, wrasses, the black triggerfish was common, the *B. rectangularis* less so. Cleaner wrasses stood on station near boulders waiting for clientele to come in to have their parasites picked.

I looked up and noticed a black-tipped shark and then another, each a bit over six ft. and very well-fed looking. Their pattern except for the black fin tips looks not unlike a spinner dolphin.

They circled us, never coming closer than about 10 ft. and never seemed to be more than curious. It turned out they are fed here by the staff of another hotel whose divers do it underwater. They are indeed well fed, and apparently pretty tame and not at all feared, though I admit to being uncomfortable that they might be behind me. Frank says as many as 20 may come in. That, he says, is also why we were constantly surrounded by clouds of curious butterflies and tangs.

The corals here are as colorful and diverse as any I have seen. A blue encrusting form (*Montipora*) sets the dominant theme, followed by mawls, patches of red encrusting organisms, somber browns and lighter yellow. So near the flooding platform, sand is sparse and only in pockets but dead coral is littered about, doubtless being ground to sand and washed inward. A brilliant plush green alga was common. The most striking inhabitant, other than the very diverse and colorful fish, are *Tridacna* clams. Their zig-zag mantles were exposed everywhere, often several on a small coral head, or even bored into the rocky pavement of the reef. Only the mantle and shell tips showing. Most are eight in. wide or less. They are jewels. The only similitude that strikes me is fire opal—

bands of most brilliant iridescent blue or blue green, or tan, shining on the coral heads or reef bottom.

The water was clear as glass. At its surface was usually a contingent of ghostly half beaks or needlefish. They swam at the silvery interface and I watched as they moved up into wavelets and down into valleys between them. I'd love to experiment with the signal systems that let them school.

The Pearses uncovered all sorts of invertebrates, various urchins, cucumbers under overturned coral boulders, and a number of molluscs. *Trochus* shell was very common. It was introduced here in the 1950s. Considering that the animal is good to eat and the shell valuable (it's made into jewelry, buttons, or simply polished whole), the reef is not that overfished yet. *Tridacnas* good to eat too, and I saw hundreds.

Back at the Hotel I talked to Monty about his needs for a reserve, about the opinions of the local people. He told me of a great die-off on the outer reef some years ago in which sea level seemed to have lowered enough to leave much platform exposed. He said the stench was awful and the kill spread inland as water washed rotted material into inner waters.

It's hard to see how such a sea level change could happen and then reverse itself, but I guess it did.

Late in the afternoon I walked down the beach, thinking out this and that. Schools of mullet flickered in the shallows and I tried to see how they signalled each other. I think they must always have another in lateral view or they must play catch up. If only fins and tails are in view they race after their schoolmates. Size is not important, nor is position in the school (ahead, behind). I saw Radakov waves when they were disturbed—a wave of influence moving at something less than the speed of sound swept through the schools when I tossed pebbles into the water.

On Moorea there is a blue-tailed skink. Here it is copper or brown. I think this is the skink that is all over Polynesia. It seems to frequent coconut debris and to creep into wooden boats. These scuttled among downed coconut fronds, or sunned on coral rocks.

I've seen only one gecko here. A sleepy eyed Frenchman, far gone from martinis, had him on the bar and called him Charles. Charles was a little sharp-snouted, black-eyed lizard with darts of black along his sides. He seemed not at all agitated to be held and the girls at the desk said more lived up behind the signs above the bar. I have no idea what form it was except it looked like my memory of a hermaphroditic species.

John returned from swimming the reef in front of the hotel and says it's in bad shape—much dead coral, but many fish.

Tomorrow, we dive it again and look at it with the glass-bottom boat.

This is a languid place for the visitor. The days flow by, taken up by little things. For the staff it's probably much different. Monty has a severe water shortage on his hands. His reverse osmosis freshwater unit needs cleaning but he needs two days with no visitors to do it. We're probably 60-70% full now (visitors) and it has been over 95%. I'm told no one can rely on Vaitape to develop a decent water system. It's got to come. A solar-powered one would be a natural for this place, if economics warrant, or even just an adequate catchment system such as they use in Bermuda.

Vicki had gone out on the "sunset cruise" and she didn't return and didn't return. Then, in the dusk I saw her walking quickly up the walk to her bungalow. Even in the dark I could sense her anxiousness. I walked over and she had been in a ship wreck of the

catamaran. Someone had changed the buoys and the skipper had a new crew and they hit a coral head. Most people were sitting down but standing ones included Vicki were tossed onto the deck. She was OK but was red with scratches on her hands, arms, and fingers. Her glasses were broken but had not gone overboard. She's OK, though, just bruised and sore.

Dinner, papers, and then to sleep. The wind whistles outside and the noddly terns still creak overhead.

September 8, 1983

Hotel Bora Bora, Bora Bora

This morning we took the glassbottom boat out to get some idea of the distribution of the disrupted coral reef, and we swam some of it later with snorkel and face plate. In the boat we could see that on the Raiatea-side of the hotel (SW) there was much dead coral inshore especially. It was represented by piles of white and gray staghorn and broke piles of dish corals. In amongst these slag heaps of pieces, some new corals were establishing but were small and mostly older *Porites* or new blue coral and carpets of algae, much of it *Turkmania* near shore and a lower form out deeper.

Around the corner in front of the hotel where the water deepens there is less destruction and around in the lee, by the dock, not only do species change but there is rather little evidence of damage.

Offshore, even in shallow water, destruction is not nearly so noticeable, most is alive and diversity is great. Two outfalls go into the area of destruction and one is on the property line in the lee, in an area of low biotic diversity.

The effect we see could thus be old and not yet regenerated. It could be caused or enhanced or unaffected at all by the outfalls. It is quite local. Swimmers from the hotel can reach nice reefs by the dock off the west end, or out 100 m from the SW beach. And by glassbottom boat fine reefs are easily accessible.

As for the reserve idea, as a need specifically of the hotel, it would be nice to protect the reef nearest the hotel, but it will be hard to sell the idea that special things are there to protect in the biota. Most is better represented out a little. Therefore I think it's likely to be a rough row to hoe with officials, even if we develop a well-documented faunal and floral list. A direct appeal on behalf of this and other hotels might have more chance of surviving inspection.

I do think poisoning regimes ashore, and outfall policy and content should be looked at carefully to make sure they are not causal. John says dead coral and live coral can be aged by rings. That might pinpoint when the kill took place. And I think current regimes around the hotel should be known. There was a strong set from SW to North as we swam this afternoon. I could not, ultimately, buck it and had to come in. The trades are up and whistling.

We're beginning to get a feel for the Hotel's problem. The reef is largely dead near offshore of SW the hotel. It is covered with a mat of algae mostly, but fish are very abundant. It hasn't recovered in six years of time since the die-off. There is talk of a channel being dug for the movie "Hurricane" that is said to have changed current

patterns. Sand is said to be excavated from the beaches around the hotel and to be replaced artificially.

We noted three outfall pipes from the hotel. One from the kitchen, goes out not far from our cottages. Another returns concentrate from the desalinization plant, at about 50 ppt of salts we figure as opposed to 31-33 for normal seawater. The other pipes go out on the other side of the Hotel. On our side there is no ready access to deep channels and the kitchen pipe must end in 10-15 ft. or so, maybe a bit more.

What is being added by these sources and by the poisoning they do for crabs and rats?

Kitchen cleaners, food wastes, pesticides, fertilizers that might cause overgrowth of plankton or just feed fish, or are coral polyps simply clogged somehow?

The waste from desalinization is not now very large. 44,000 liters of water are produced a day. For three produced, seven are returned in concentrated fashion.

The reef should have recovered more than it has in the time since the kill, it seems. The heavy fish population suggests feeding is going on, probably from the kitchen outfall. Fish are notably more tolerant of pollution than invertebrates and these corals probably require the purest of water. Even parts per billion of some chemicals can kill them while fish can tolerate many changes in the parts per thousand range.

The notion that the channel has cut off flow is opposed by the removal of sand by the current [?] ... need to replace the beaches, which suggests fairly strong flow. That one is, as yet, imponderable.

They need to know about current regimes around the hotel area.

We need to understand the other outfalls and the relation of outfalls to dead coral and algal mats. Maybe our glassbottom boat trip at 10:30 will help.

We begin to see the fragility of Bora Bora. There is a quiet lilt and grace to the people. They are "laid back" as the Santa Cruzans would say but that makes them vulnerable. The major vulnerability I see is social. Water can be solved, pollution can be controlled, but social destruction can be a permanent blot that could embitter these childlike folks. The plans, underway, I understand, for a Hyatt Hotel of 250 rooms violate all this and those who control Bora Bora are not strong enough, or do not care enough to protect her.

Surely such a hotel will have to import work force, instead of, as here, using local families and giving them good lifetime jobs. Surely the rift between native and visitor will grow as it has grown on Hawaii until it simmers, ugly and threatening, just below the surface, ruining the very thing visitors seek.

It can trivialize lives and tear up values and probably erode the tourist business too. One hopes for better.

Surely the new hotel will compete with this one and some graciousness will suffer at each.

September 9, 1983

Bora Bora, French Polynesia

During the night I could feel unwonted things going on in my stomach and other lower parts. Soon enough it hit in full force and cleaned me out. With medication, which I carry on these trips, I stabilized things and wanted nothing more than sleep. I cancelled out on the day's snorkel with Frank, sending John and Vicki out to explore the lee reefs

of the island. Poor Vicki, aside from several abrasions and cuts, is stiff in the arms and has trouble using the fingers of one hand to pull on fins, tie laces, and the like, but she bravely went off anyway.

I just slept, read a little, and slept some more. By lunch time I could join John and Vicki and hear their stories of the dive (lovely staghorn corals). Then toward 16:00 our bags were taken up to "Le Truck" and we sauntered up. Monty came out and we discussed the coral problem. Mr. Joe had apparently called down to the Tahara'a saying if we wanted to visit authorities it could be arranged. Neither John nor I can stay over as suggested. School presses, students need our cosmic advice, classes have to be organized, and so forth, and we are scheduled already for the day after we return.

Monty had looked into the matter of chemicals used in the kitchen drain. There is something they use now and then that dissolves all organic matter. But the more I think about that, the more I doubt such a problem. The current set seems always toward the deep entrance channel and much of the kill of coral is upstream from the drain. I rather think sand dredging, either by the Hotel or from construction upstream is a possible cause and/or wave action from storms. The coral behind the fringing platform on the outer reef is not badly damaged but that on a windward beach along the hotel is. This could be due to the fetch from reef to shore, in which big waves could build up. Big waves reach deep and could tear off the dish or platform corals and snap the delicate staghorns, which make up most of the dead coral. The heavy *Porites* obviously weathered the storm. Now it would have been killed by siltation too—so storm damage seems most likely.

In the lee of the hotel the coral, while different, is pretty well intact. But was, what is now a lee, a lee in the storms? The dead coral looks years old. When did they have storms here? The hurricane (or cyclone as they call it here) was only last year, and then not before back to 1906.

Corals are reestablishing. The *Montipora* (the blue encrusting coral) is well represented. The plumose alga, *Turbinaria*, is, it seems to me a successional plant and it is in a fringe along the shallow water.

The water dynamics of atolls come clear to me now. The fringing reef acts as a bathtub. Over its rim waves crash sending sheet after sheet of water into the lagoon. The sea level inside rises a matter of inches higher than outside. Water then escapes through the passes and circulation patterns inside are determined by how the water flows for escape.

In Bora Bora, only a single pass exists and all flow patterns therefore relate to it. The Hotel Bora Bora sits at the head of the deep water channel to the pass and water sluices into it from far up lagoon. Monty says only when it is very calm does the current nearly stop but that in his experience, it doesn't reverse. It shouldn't.

Well, today we talk to Mike the hotel manager, about Mr. Joe's wishes and then will take a jaunt out to the Arboretum and the Gauguin Museum. These are at the neck of the island, which is made of two main volcanic centers, each thrusting up a mountain, with an isthmus in between. [Drawing]

Well Mike told me Mr. Joe had indeed called through and we arranged for a dinner tonight with Ed Fearon. We'll discuss the reef problem at Bora Bora then.

Vicki, John, and I rented a Peugeot lawn-mower motor-driven car and sped off eastward toward the isthmus of the island. It was some drive. The nearer the isthmus we got the more blasted the landscape became. It looked like the full brunt of the April

hurricane hit there. Houses were blown apart, especially roofs were removed, and near the water everything sometimes went. Windrows of palms were down, many now cut into lengths. Tangled piles of trees lay on the beach, or in the mouths of streams. Some lay where they fell. Many exposed trees such as huge old kamanis were tattered where limbs had been twisted and wrenched off.

Incongruously, windows in some newer buildings were intact, and even a little way off the beach things weren't so bad. At the isthmus we stopped for lunch in a half-boarded-up restaurant. The food was good and it seemed "business as usual".

Once over the isthmus the evidence of hurricane was almost absent. The flora became verdant and varied. Not far down this road we came to the Paul Gauguin Museum. It is a very well-done chronicle of this strange life displayed as a series of open pavilions. It traced him from his childhood in France through an early successful business and marriage through his renouncement and wanderings through Polynesia. I like his art, its bright blocky colors, its capturing of Polynesia, but this mysticism is his own.

Next door we visited the Arboretum before going on down the windward coast. Aside from some beautiful flowers, two things struck me—one a giant Indian banyan tree with aerial roots as large as most trees and the second, a wonderful grove of tropical chestnut trees that have the most remarkable buttressed roots. Many of these are vertical fins of wood radiating sinuously from the main trunk, and most only an inch or two thick in most places.

The windward coast is verdant and riven with clear flowing mountain streams that pour from the highlands. Misty green valleys with fluted lava walls that seldom could be seen entire because of a cloak of clouds. Around the whole coastal shelf of Tahiti are houses and little plots of tropical fruits and ornamentals. Most people were Tahitians, outside Papeete.

Papeete itself is a prosperous tropical place—no third-world poverty was very evident though many live in thin-walled houses of no great extent. One feels they like it that way. There are no really tall buildings, a small but nice harbor along a rather steep coast, and there without a fringing reef.

Back at the hotel we had dinner with Ed Fearon. He's a nice, open guy of about my own vintage. I thought he seemed a bit beaten down by some of his problems and the difficulty of getting past a demonstration to do needed things. He felt the Mayor system slowed progress because unskilled people were trying to do things like keep water systems going. He felt as we did that it was probably best for us to live[?] up the support of Dr. Bernard Salvat, Director of the Moorea Station, before making an official presentation to the Authorities. John and I are still trying to digest our findings and trying to prepare a set of recommendations. Salvat has headed major worldwide efforts at Coral Reef conservation, and since he is French, and important locally, we feel if we, as Americans, can bring him in, we might actually inject some ideas into matters such as the degradation of Bora Bora.

The Protection of Coral Reefs From Human Damage

Coral atolls and reefs are amongst the most beautiful and interesting marine habitats in the world, and their attraction has begun to lure more and more tourists to them. They are also incalculably diverse and scientifically interesting systems.

Together these things have caused protective measures to be proposed and in some cases implemented for some reefs. Two sorts of protection plans have been suggested: 1) for large samples of reef unoccupied by humans, and 2) for reefs already used by native peoples and tourists.

Our comments concern the latter and result from a modest survey of only two such reef systems. One at Moorea and the other at Bora Bora, French Polynesia. Our work was a first reconnaissance done at the request of the operators of two hotels in the area.

We present these ideas as grist for discussion in the hope that they might contribute to the long-term conservation of these systems and the people they support, both indigenous, and the operators of tourist installations and the tourists themselves. Our ideas are probably not new, but they do represent the considered views of three marine scientists, two invertebrate zoologists, and one marine mammalogist-ichthyologist.

The coral reef systems of a well-developed atoll system cannot survive in dirty water, so maintenance of water quality is the important . . .

There are two parts to this: 1) First, most reef corals require sunlight because much or even most of their nutrition may come from indwelling plants called zooxanthellae. The microscopic plants produce food by photosynthesis which both organisms use. This means that most reef corals grow only in shallow clear waters that allow penetration of the very specific colors of light used in photosynthesis and 2) many reef invertebrates, including corals, are very sensitive to being clogged and killed by siltation. Thus sediment size, load, and kind may be critical to reef health.

While reef fish are much less affected in the short term by all of these things, they depend ultimately on reef productivity and will fade as the reef fades. So the crucial items for planning for the health of atoll organisms are 1) to know the water budget of the lagoon through time—how fast is the lagoon refreshed, and how does this refreshment vary; 2) to know the depth patterns (bathymetry) throughout the atoll; and 3) to know in some detail the current regimes of the major parts of the atoll lagoon; 4) to know the general distribution of the organisms which are major components of the reef system; 5) oxygen tensions at selected points during these tides; and 6) water clarity profiles.

Much of this information is not especially difficult to obtain. It requires an opportunity to sample some features at varying times throughout the year and it requires straightforward surveys of others. Considerable existing data probably already exists.

Once such a baseline is in place, much less complete measurements will allow measurement and assessment of annual changes.

The following scheduled monitoring will allow good correlation with baseline data.

- 1) wind direction and speed (daily record)
- 2) wave height outside lagoon
- 3) current velocity at passes (24-hr. record each two weeks)
- 4) water clarity
- 5) tide height

To do part of the monitoring standard weather sheeters including recording thermometer (sea, air), anemometer and rain gauge should be established at appropriate points on windward and leeward shores. Other measurements can be taken by a

technician at regular times. These baselines themselves will allow local planners to assess many potential impacts on the reef. For instance, by knowing current velocities at a given location, and knowing expected seasonal fluctuation, a planner could easily pick out the time of least impact, and could assess downstream effects on other installations. (High currents will insure rapid flushing of any sediments and thus a quick return to good water quality. Low water temperatures are also likely to be safer than high temperature periods when animals may be close to physiological limits.) For example a new dredging project could be assessed in terms of its effect on existing facilities.

The monitoring will allow correlation with the effects measured in baseline tests. If, for example, wind velocity is low at a given time, a planner might know that lagoon refreshment rate would also be low and thus an especially dangerous time for dredging.

Physical Damage to Reef Organisms

While natural processes do damage reefs, these are usually in balance over time. But, when human impacts are added, a reef may degrade rapidly. Such impacts we are familiar with are 1) construction damage, 2) anchoring of ships, which tends to uproot or crush delicate corals, 3) swimmer impact, which can break dish corals or staghorn corals especially, 4) coral collection, both commercial and amateur collectors, 5) fishing, especially for embedded organisms such as *Tridacna* clams. Effects are yet to be severe immediately adjacent to tourist facilities, where swimmers are common, boats frequently anchor, and where pollution from other activities by the facility may disrupt the biota.

It is suggested that, in view of the special and growing importance of tourism in French Polynesia, a special effort be made to assure pristine reef conditions near shoreline hotels, where the reef is a major attraction. This might take the form of establishing a protection zone to 200 m offshore of all such facilities and 100 m along the shore on either side of their boundaries. Rules for such zones might include 1) control of all outfalls so that no poisonous chemicals, or tertiary tainted wastes, be allowed to enter the zone, 2) a particulate matter standard be met, by any activity within the zone and that for particulate matter oxygenation outside the zone special precautions be insisted upon to assure that this standard be met in all indicated protection zones, 3) that no fishing (either with hooks and lines or spears), shell, or coral collecting be allowed in these zones, and 4) that all boat docking or beaching be done only at designated sites except for craft of such shallow-draft (canoes) as to be unlikely to cause damage to reef organisms.

The Sociology of Change and Reef Degradation

No matter how careful people may be, heavy use can degrade a reef system. At Bora Bora we saw much change only a few months ahead as two major new hotels are planned. At present most of the work force is composed of Bora Borans, who have some degree of pride for their island home. This crucial element will be less with an imported work force.

Atolls are very finite things in terms of space and the impact they can stand. The practice of importing labor and of building new housing to support them can be expected to impact the atoll, to reduce the quality of fishing and of such things as shell collection.

Construction in the Lagoon

Any work that changes flow patterns of water drainage can be expected to cause ecological disruption both up, and especially downstream. Any such work that increases turbidity, such as sand mining, could be serious. Any fill of terrestrial soil, or runoff of construction on shore may be serious indeed. Pristine water is the life of the lagoon, and the flow patterns it has established over time are a crucial part of its balance.

Outfalls

Standards should be established and monitored for the following items in effluents.

- 1) No non-degradable organochlorine pesticides or biocides.
- 2) [end]

March 17, 1984

Baja California Norte, Bahia Los Angeles

George Heinsohn and I made our way down to San Diego and thence to a charter flight to L.A. Bay via Tijuana where we passed customs perched in our airplane seats. Then off and along the west face of the Sierra Juarez and down near El Alamo and over the very spine of the Sierra San Pedro Martir. Right under the plane passed La Providencia, a rugged peak of granite fins sparsely clothed in trees. Behind we could see the lagunas of the main masif—La Grulla[?], etc. and off to the SW the dark canyon of Santo Domingo.

The Gulf was calm; the pathways of slicks wandering off from below us.

At L.A. Bay the runway is now paved and we were escorted to a motel (new), fed, and then wandered out to the bay and distant sand spit to watch the birds dive—brown boobies and terns and pelicans and gulls. A tight feeding flock of eared grebes dove in the shallows. I could see them drive fish, which dimpled the water ahead of them.

After dinner we wandered off to bed.

March 18, 1984

Puerto Don Juan, just outside Los Angeles Bay

The morning was spent up in the cirio forest above L.A. Bay. It was magnificent and in bloom. I found a zygophyll that looked for all the world like jojoba, but was in a wholly different family—that of *Larrea*. I scratched a *Bursera microphylla*—torchwood which bled sap like turpentine and much more.

Finally in the afternoon we boarded and made our way out to a nearby anchorage.

Bottlenose and common dolphin were seen near the bay entrance in separate schools.

March 19, 1984

Isla Partida Norte

The wind ruffles Canal Ballenas but nonetheless we spotted a whale—a Bryde's, I think—small, less than 40-45 ft. I'd guess, nondescript gray, modest fin, evasive. Just south of Isla Smith.

The channel was flecked with white caps and little short rollers, but we soon put her on the fantail as we went south along the buff and pink cliffs and battlements of Angel de la Guarda Island. We rounded the tip and as we doubled back up the east side we encountered a big bird flock and a common dolphin school in a feeding frenzy.

It was a melee, with boobies rocketing like arrows into the water in bunches. At the same time big pelicans heeled over and dove, only to bob up quickly. Light little Heermann's gulls fluttered down, picking at invisible motes in the water.

The dolphins nearly always circled the area where the plunge-feeding birds worked. Once the boat took us very close so that I could look down. I could see the greenish-white flashes of dolphin bellies down maybe 15 ft., darting about but roughly in a circle. Often the surfacing dolphins traveled in an arc around the falling, diving flock of birds. The dolphins obviously stayed deep enough to avoid the plunging boobies.

What seemed obvious was that the dolphins had forced up a school of fish and that birds were taking advantage of it. Once I saw fish no more than 3-5 in. long, and dark and scattered in the water, not in a tight school. The fish did not seem to dart and swim in unison as a tight fish school. Others reported fish [?] but I did not see them. I wonder if they could have been whole fish. I saw a dolphin chasing fish on a fairly swift, erratic course. The frenzy went on without abatement while we were there—maybe ½ an hour.

I felt that it was possible that the fish were disoriented. Their school seemed very diffuse and uncoordinated. The dolphins did circle below and may have corralled and maneuvered it. We could not tell. The dolphins did circle and there were deep animals and surface animals. The target school often moved with considerable speed.

Onshore at Isla Estanque on the east shore of Angel de la Guarda we were immediately greeted by two distraught peregrine falcons circling and screaming above a steep volcanic hill. Later their nest and two eggs was found up near the top of the hill. The eggs lay in a scrape without nest material. In spite of disturbance the birds returned to the nest as we left in the Humber rubber boats.

Dennis Conejo caught a giant female *Sauromalus hispidus*, which I talked about.

Then back to the ship, around Raza Island where it proved too windy to land and thence up to anchorage at Isla Partida. I could look up at those lava scree slides that formed the type locality of the fish bat *Pizonyx*[?]. Later we saw some. I gave an impromptu lecture on spinners, which was well received.

The visitors are an interesting group; several are functionaries of the International Nature Conservancy or World Wildlife Fund. I've appended a list. Others come from all over the country from Hawaii to North Carolina and Long Island.

The food is excellent, the staff professional and friendly, and the captain a real pro (Captain Hempstead). Sven Olof Limblad, the owner's son is aboard—a bright, affable, professional guy to whom I took an instant liking. And especially, great and good friend Bernardo Villa is with us. He gave a nice talk on Isla Raza, helpfully translated by Ernesto Barillo, the International Nature Conservancy director from Colombia.

To bed, sunburned and tired.

March 20, 1984

Isla San Pedro Martir

By the time I'd rolled out, the dining room was full. For some reason no clacking of coffee cups penetrated our door and I slept on. But I made it for french toast and sausage.

We cruised on calm seas down the east side of Las Animas and then San Lorenzo Island. This long, narrow island is lined with the sharply faceted spurs of a fault-bounded block. It looks hard to land on and climb, very barren.

The hanging valleys above those 75-100-ft. facets would be hard to reach. At the south end, out in the channel, we encountered a lone blue whale. Our skipper expertly put us on top of it and several times we had views of its spatulate snout, nostrils, broad, mottled back, and knockled[?] vertebral column, and occasionally its tiny fin, and once its flukes, which just skimmed beneath the surface on a dive. The group was delighted. Gary James, an Orange Coast naturalist, and I gave commentary. He is a fine lecturer—clear, accurate, and knowledgeable.

Later, out in the tide-rip-marked channel (Hempstead says up to 4 kts), we encountered two fin whales who put on a good show for us, as did some common dolphins. We headed south for San Pedro Martir Island, a smoky ship in the distance—the island farthest out in the Gulf and one with the highest plant endemism. It's a precipitous, cliffed, volcanic island a couple of miles long and more than 10 ft. high.

As we approached, swirling birds came into view. Brown and blue boobies, red-billed tropic birds, and flocks of gulls and pelicans swirled around the guano-splotched cliffs. The island had been a guano station and all over her cliffs were walls, platforms, and trails. I suspect much had to do with a place to store the collected guano. Where can one put a sack on a precipitous island like this?

At the island, after lunch, we entered the Humber inflatables for a snorkel in a sea lion cove. It was cold—60-61 degrees or so, but my two layers of shirts helped. The bottom was rich with algae, and fish swirled in and out among the fronds. I saw wrasses, angel fish, sergeant majors, rudderfish, and triggerfish. The sea lions, including an old male, kept their distance.

I dried off and soon was back on the inflatable for a tour of sea lion colonies and bird rookeries and then a hike ashore.

We landed on a rocky promontory and clambered up the blocky volcanic slope to a guano-collectors trail that lead over to a little flat where the walls of old collectors' shacks still stood. Fragments of tile showed that these had been houses, now only partial walls.

I searched for *Uta palmeri*, an endemic. It is a big, drab uta—grayish brown with a lighter gray belly. Its blue spots were evident but scattered equidistantly over its entire back. Its blotch was all but gone.

I couldn't noose one. They ignored me and focused attention wholly on the noose, which they resolutely refused over their heads. I could walk within a foot or so of them, but I could not noose them. Dennis caught two with his monofilament noose.

The people on this trip are a very diverse, talented, and interesting crew. The inventor of Rada (Daly[?] Vollum), a crew of interesting Conservancy and World Wildlife people and more. There is a grand lady named Isabelle who is 87 and who has brought her daughter and granddaughter along. She's great. Tomorrow. Isla San Marcos and Caleta Santa Maria near Tres Virgines.

Oh yes, a juvenile gray whale and maybe two patrolled this coast. The waters are dense with plankton because of the fertilizing effect of the bird rookeries above. The whale was about 25 ft. long and very white. I think it had plenty to eat because the waters

were dense with mysids. I suspect this may be a waystation, just as the Farallons, Vancouver, and the Queen Charlottes are.

March 21, 1984

At Sea South of San Marcos Island

We traveled south last night to the vicinity of Santa Rosalia and then went ashore at Caleta Santa Maria for a hike up a deep winding wash that ran toward the coves of Tres Virgines NW of Santa Rosalia.

Before we went ashore we maneuvered among some whales that I thought were blue whales. But our views were of silhouettes in the distance. So we abandoned them and made our landfall over a cobbly beach against volcanic hills.

I walked with Fritz and Jean Deinhardt and had a wonderful time talking to them. Fritz is head of the Epidemiology Dept. at the University of Munich and his wife a Ph.D. in a similar area at University College, Univ. of London. Both are urbane, witty, deeply knowledgeable, and broad in approach.

I asked about their work, which is now developing an infectious hepatitis vaccine. Fritz said it is the world's leading infectious disease and the cause of much liver cancer. His approach was at the level of gene splicing and switching and directed at third-world problems to make vaccines cheaply enough to reach such people.

As we walked we looked at the variegated cliffs, the immaculate palo blancos, the gray-green ironwoods, and the torchwood trees that sometimes choked the wash floor. I looked for *Peterosaurus* in the cliffs but saw only *Sceloporus magista*, *Uta*, *Callisaurus*, and *Urosaurus*. A cucurbit blocked the rocky hillsides with spreading mats of vines which bore little pitcher-shaped cucumbers and jojoba plants were common (*Simmondsia*).

A few birds flitted by and we watched the ardilla scamper up the hillside. One group found a considerable flock of bighorn sheep up the hillside but we saw none.

We wandered back down for lunch aboard and then steamed off toward San Marcos Island.

We were detoured by a considerable encounter with about four blue whales, including one large one, off Santa Rosalia. Our skipper very skillfully put us onto them, including one encounter about 30 m off the port beam. The intake of breaths could be heard, mingling with the blow of the whale.

On we went and made a 4 PM landfall at the NE corner of San Marcos Island where we landed for another walk in another even more densely vegetated canyon.

George is all over the landscape photographing and biologizing. I think he's having a stellar time.

Tomorrow we reach Danzante Island and have a barbecue ashore at Santa Catalina Island.

The weather was essentially flat calm today and the sky china blue without clouds.

I decorated one of the passengers (Elaine Simpson) into my "Environmental Revolution" with *Mentzelia* leaves stuck to her shoulders. She promptly fired me and ordered silk sheets for her cot on the *Sierra Maestra*. Such gratitude. I hope the revolution can succeed without me.

March 22, 1984

Santa Catalina Island

The night was spent steaming down to the Santa Catalina area. We slipped past Danzante—cliffed and castellated and thence onto Santa Catalina offshore. The *Pacific Northwest Explorer* put us into a cove at the south end where the boats went ashore with snorkelers, and we went ashore to hike the hills.

I went off with Bernardo and George, up the granite cobble beach, and up a spur of the island. The cardons are, it seems to me, remarkably green and almost obese here, and the barrel cactus are truly giants, many taller than a man and weighing tons.

I found one flipped over and rotting and was able to dip my hand into the pulp at its base and come up with a handful of watery pulp from which I could wring a brownish, smelly fluid in some amount. It wouldn't have been hard to obtain a quart or so, if you could stand to drink it. I was interested to see that various island life and found this source. Some black beetles, like coryxids, swam in the pulp, and the island land snail was found alive under such a fallen barrel cactus.

The uta—*Uta squamata*—an endemic, is beautiful. It has a brilliant greenish blue tail and after body and is spotted with blue. I was not able to catch one with my noose. Once again they were terribly noose-shy.

They were found mostly down in the arroyos up under the sprawling limbs of big-leaf elephant tree (*Bursera hindsiana*) or copal tree. These arroyos were floored with wandering washes of fine granite gravel and bordered with copal, cordon, and a large-podded legume (*Pithecellobium confine*)? (palo tierra), barrel cactus, palo verde, often intertwined with vines of a cucurbit that looks like a dwarf-leaved *Marah*.

One frequently finds the swollen roots of this vine partly above ground with vines coming out the top like a corona [drawing].

We had a nice barbecue on the beach—steaks, chicken, sangria, and fine guitar and singing from Tracy of the crew. She has a rich contralto and plays well.

After dinner a number of us hiked out with lanterns looking for the elusive rattleless rattlesnake. One had been seen on a day walk, a *C. ruber* relative.

Anyway, we scrambled up the wash. A couple of geckos came out (*Phyllodactylus bugastrolepis*—an endemic). At a glance they look just like other *Phyllodactylus* except maybe plumper. Then we peered at two scorpions and finally a nice specimen of *Hypsiglena torquata catalinae*. Then we scrambled back over the cobbles helping to clean up camp and thence made our way back to the ship. I was walking with Peggy Parr (nee Sullivan) who turns out to have been at UCLA when I was there and knows all my botanical pals (Carl Epling, Mildred Mathias) and Ray Cowles. We had a grand time. She is now married to a guy who doesn't much care about nature, so she goes off on trips while he stays in Colorado, or something like that.

Bernardo saw some bats and in general, at the age of 72, scrambled over the hills like a mountain goat. He's amazing.

During the night we traveled down the coast and made a landfall off La Paz very early. Well before noon we were tied up at the main pier and were off to La Estrella for a great feed of mariscos, fish, beans, shrimps, and much more, plus abundant beer or margaritas. Afterward we visited the very nice three-year-old Anthropological Museum where I tried to identify some of Ed Jauss's pictures that Sven had given to the museum.

Then George, Bernardo, and I walked back, shopping (unsuccessfully) for hats for George. His head's too big and he has too much hair to fit a Mexican hat.

On board we ate again (help!) and generally socialized and as dusk hit cast off for San Jose Island.

March 24, 1984

Enroute, Cabo San Lucas

At dawn we woke at anchor in Bahia Amortejada, Isla San Jose, and at 6:30 were out for the dawn patrol of the nearby mangrove swamp. I went with Sven Linblad as his resident naturalist. We entered on the outgoing tide over a rather shallow bar, and once inside, the channel deepened to 6-10 ft. or so in places and just about everywhere navigable in our rubber boats. (Humbers—a British make). There were at least three species of mangroves—red (predominant near the water), black, and white. There was a reasonably good display of birds—a pair of oyster catchers unconcernedly wandering a sandbar, willets, snowy egrets, a couple of black-crowned night herons, flocks of darting doves including white wints, a reddish egret, pelicans, and more.

Sven, who never seems to miss a bet for gentle adventure, took us quietly up a side channel. I was surprised with abundant fish life—cornetfish were common as were gerrids and snappers, mullets and rays. We even saw trigger fish amongst the prop roots and some larger fish that darted away.

I took two trips in, the last a bit wet as the breeze freshened and the tide dropped. But nobody got very wet. I was able to tell a few stories, mostly about mangroves, to the folks. I'm earning my keep since I had to give a lecture in the morning after breakfast. I just told them stories of natural history, adventures in Baja, and my discovery of *Phocoena sinus*, the Arva—[?] at the cape, and about catching gray whales. They seemed to like it.

Then in the afternoon we put ashore at a long white beach on Isla Espirito Santo. Bernardo and I spent a couple of hours looking for the black jackrabbit. Their sign was everywhere—pellets, forms[?], and gnawings at the ends of pitahaya branches.

And finally we saw one—a big, dark, blackish-brown fellow with rather short ears and not notably fleet of foot. He disappeared off in the copal scrub. We hiked up toward the interior mountains, first on sandy flats covered with shells, attesting to the force of storms that must occasionally force water ½ mile inland. As we climbed it grew rougher, rocks and gullies, and desert pavement. The rocks were a mix of volcanics, chalcedony, and maybe some limestone, granites, and metamorphics.

Cardons, palo fierro, and others were common. Down near the water was a mangle dulce—with little juicy red fruit.

Soon after coming aboard we hoisted anchor and headed for the Cerraloo Channel and darkness.

Learning to See in Nature

The main thing one must do to see is to trust nature to know the answers and not to take your own second guesses as fact.

Another way of saying it is: "nature is the authority" . . . She knows what's going on; you don't. So, it's as simple as that; ask her and trust her.

She'll not tell you all at once so you must ask over and over, usually in little bits, hemming in the point you are really after with little salients; paint a picture with questions, each more refined than the last, and between each, mull her answer and refine your next question.

One way is to ask a broad question at first and then dissect it finer and finer. Your eyes will open as these questions paint new aspects on the canvas. As a matter of fact, you almost can't help asking that broad question at first. You simply don't know enough at first to be specific.

Example: Frinigillid flight

You will correct your questions as nature lets out little aspects of her secrets to you, and your eyes and mind will open more and more.

Thus one iterates back and forth between one's ignorance and nature who knows it all.

A fatal error is to settle on a conception of yours as fact. That stops the process of seeing cold in its tracks and you see no more.

Nature is so intricate that this unfolding process can go on and on just as long as you want it to, and always before you is a vista of the unknown.

This is because nature is built by adaptive compromise between other organisms and the physical world, and every feature of the organism you are studying. Creatures are not built by engineering specifications to fit this or that design criterion. They are infinitely complex adaptive norms.

Example:

One stops when one is satisfied with one's level of understanding, not when nature has given her entire design to you.

We are preeminently creatures of words. We classify, divide things into boxes, put words on whole sweeps of phenomena, and then go off sure we understand. But nature is made both of continua going in all directions and into everything, mostly seamless and without end. And little units such as individuals are dealt with by nature as digital bits but in a statistical manner. Ten thousand individuals draw a curve.

The electronics engineer would say we are primarily digital and individuals, and nature is primarily analogic. It depends on how fine you slice it.

We, in one sense are digital from the myotomes of our muscles to the coded messages in our nerves, to the vertebrae in our backbones, to our words. We must divide the world into packets to understand it, and we build everything we know as if we used bricks. Yet, this process is only an approximation of reality.

It is an approximation between our need to classify and the flow of nature that we attempt to deal with when we try to see. So, we chop our questions ever finer, like a chef slicing garlic, and piece by piece we build up a simulacrum of reality.

Does this digitization even extend to our genes? There in the double helix lie specific commands to do specific things.

But, however hard we try, never, I think, should we sit back smug and satisfied and say that we know.

But, recognizing who we are, one of our most important means of understanding is words. Use them with as much care as you can muster, use them with all the precision you can, and know that each little packet of phenomena they embrace is just that—a class more or less true.

So we use journal pages and pens to see.

You will find, I think, that writing words on a page unfolds understanding in a way so deep within us we hardly know what has transpired.

And those questions, tests, will come so fast sometimes that you will hardly know what has happened either. One proposes, and checks with nature sometimes all in a single glance, and sometimes one waits for weeks for an answer. Often you must dig, contrive, and struggle to get an answer.

Much in nature is in proportions, in equilibria (especially), in speeds, in temperatures, in weights, in angles. One can often see better by putting numbers on things. And one can cast reality in words better with dimensions on what has been seen.

We can learn to make measures; even approximate ones when we are in the field. How long is your finger? your fist? your pace? Can you count seconds, and can you estimate 100 meters?

But much you cannot see, limited as you are by being a human. We live at human height, speed, time and our ability to understand fades as we deal with living things much bigger or smaller than we, or faster or slower than we.

I think of the ponderous avoidance reactions of mother-young pairs of whales; just at the edge of our comprehension, or the social behavior of starfishes—utterly opaque to us until speeded up by time-lapse photography, when starfish can be seen meeting each other, whirling, touching, and reacting to each other.

And I think of mouse courtship; happening so fast it blurs. Only slowed film can make it comprehensible.

I find I have developed an almost subliminal mistrust of machines that come between me and my animals. The unvarnished view, incomprehensible though it may be, of a real animal behaving free from bias induced by my presence, is what satisfies best.

Homogenates, preparations, telemetered or filtered data, thermometers, even, make me shift in my chair. I'm not sure I'm going to like it. But those gadgets can do so much that seduction is the only word for their allure.

Yet, when I've truly seen something a wild organism has done, even though I don't necessarily understand it, there, there I have my "Hook In Nature" . . . A trail has been opened that one may follow secure that some way, some time, nature will explain herself.

Having faith in nature I'm seldom let down. There I was, after all, one on one, me and nature, and she said it to me loud and clear.

there are lots of reasons for breaking contact with nature. Some are easy to deal with and some much harder to sidestep.

Our buns resting on angular granite crystals may destroy our will to look. Or we may simply become bored. That gap between what's interesting to a human and a lizard may be hardly bridgeable. After a few hours of watching lizard naps in the sun, watching a few desultory push-ups and occasional flicks of the tongue, we may rise, stretch, scratch, belch, and break off our conversation with nature.

So it is important to do what one can to forestall such ruptures. Be comfortable, sit in the shade, ward off the bugs, and stay dry.

And when you write choose your words well. Remember that nature has subjects and predicates and that language is most perfect when it does too. The shorthand of telegraphic sentences is clear evidence that the observer has not yet slowed down to "mountain time."

Achieving mountain time, slowing down from paces set by cities is a crucial step to take. We bring the imperatives of city lives to nature and are blinded until we shuck them off. You will find yourself fighting, getting bored, and then, at some miraculous point, you will go over the threshold of boredom and find yourself on mountain time, and happy to spend your day with a star flower or a cactus wren, on its own schedule and pace, you having come closer to fitting into the silent ticking of the mountain and all its life.

Granite Mountains

Learning to See: Subsequent Reflections

Arrogance builds blinders. It is, after all, an inward-looking attitude. It is almost by definition, an attitude that ignores other attitudes or states of being. There is scant meeting ground between an arrogant person and the doings of nature, especially when to gain understanding one must have much capability at discarding bad ideas, especially one's own. They are the questions that failed, and unless one lets go of them the unrolling story stops.

The pet idea held too long, in opposition to all tests, is dogma not science. And good natural history is preeminently science. In fact it is at the center of science.

But all this relates to how we come to know. The unravelling of nature's threads requires imaginative ideas, little tests, and much discarding of failed ideas or more often, their continued reshaping.

But beyond this are those troublesome "why" questions. Why does the bee dance, or the globe spin? The answers we construct to these sorts of questions spring from our evolving world views.

Such answers have changed throughout our human history, always shaped in the dimensions of the world at that specific time and place in our history.

A Pueblo tribe, living in apparently timeless patterns unchanged from generation to generation, and knowing only a world of sky, corn, and maize, the surrounding tribes, inner dreams, forests, and animals built a view of these things that gave rules, and spun out reasons for being and ways of behaving.

Implicit truths sprang from being essentially part of the process. Indian society ticked onward like the voice of a silent clock, just as the mountain does.

But in time it seemed to prove inadequate. It was inadequate when asked to deal with the jarring arrival of Europeans, but were they any better equipped except by numbers and the rapacity of their view?

Both antagonists had explained their world whether they could or not, and both encased their pronouncements in dogmas so rigid that to violate them was to risk excommunication from each society. In neither case did their throwing-away muscles include ideas in their world view.

I see people building their lives around such world views block-by-block, cant-by-cant, and soon even the discarding of patent misfits amongst the blocks is so destructive that they live with the world-view rather than changing it.

Some structure is better than no structure, when trying to decide how to live.

If such a world view supports our need for opportunities, sociality, provides tests and opportunities that show we are alike enough to trust, contain our sexuality, and lets us surrender our destiny to its interpreters, it is likely to succeed. If it entertains us, so much the better. But it does not have to be right in any larger sense.

It need include no more than was needed by the Israelites or the Pueblo dwellers, even now. It need not deal with "why" questions in any real way to work. It must, instead, work socially, and its constancy, predictability if you will, is a positive thing for its practitioners.

Not so natural history. It works by revolutions of various sizes from the discarding of a tiny little salient of a question to greater jolts that shake whole viewpoints. No wonder the leaders of this or that sect who have arrogantly assumed responsibility for the direction of their followers whose central tenet is to be believed, recognize it as the enemy.

Darwin, we recall, regarded himself as a natural historian. This gentle man seemed never to understand the calumny heaped on him as he so honestly sought true things.

We have scientific traditions now that make it easier, but in many places the battle lines remain drawn and tense, and those who work by dogma fight for it with ferocity born of having their very reasons for being threatened, threatened by simple iterations of tiny questions about nature and tiny tests to see where her vote falls. Silent, she watches this strange metaevolutionary human battle, one side concerned with the here and now business of living, and the other the larger understandings that begin to tell us what we must do to function as a part of nature. Closer and closer we come to understanding natural process and our place in it. At the same time, the dogmatists fight and there is no other word for it, fearing but not comprehending fully the rearguard action.

Will these two ways of understanding and dealing with the world come together in a coherent view? There is no room for dogma while we learn, I fear, and that will surely upset those who live by it.

Subtleties are missed by the dogmatists of religion. They fear materialism and godlessness, seeming to need the haven of leaders who tell the way, uninformed or not.

How can this be? I don't fear those things. I'm at peace with a godless world. I'm at peace not being led. I'm at peace knowing my rules are ecological. The religious dogmatists fear that theirs and my ethics should fragment into ruleless anarchy, if my

view wins. Far from it. My rules, I think, are better than theirs because they spring from a glimmering comprehension of how the world actually works. My little tentative questions, and those of my colleagues, have led us to paint in the broad outlines of the ticking of the mountainside, and everything it implies.

We needn't worry at all. How can we convince them? It's a first step, that's all. Beyond lies what we propose with our knowledge and whether we can propose anything useful that can square these two courses of human experience.

We grapple with our humanness—all the list of things that are partly supplied by past incomplete world views. Natural history speaks about all those things too. But when can we listen and ask more questions of nature and learn who our real preacher is, and under whose wing we should crawl?

Our ethics spring not from god but from our sociality and our ecology.

French Camp

Slowing Down to Mountain Time

Why should we care about the land? I think we are evolving into the view that “to know the land is to love the land.”

In this class we look at the wellsprings of our own caring for the natural world.

Knowing the land can take, and should take several forms, encapsulated under:

- the aesthetic immersion—the sounds, the wind, the . . .
- the unraveling analysis of learning to see her processes.

The mountain lies there, and yet already we know that on its slopes and in its canyons are intricate stories, each complex and unending.

What Are We Doing On This Mountain?

Taking the next *personal* step in seeing how nature works. It's not that you don't already know, but books and the hillside are vastly different. We're awaking the little kids in us. That sense of wonder is the basis of good science.

We took and tested the proposition that nature holds the answers, not us, and that if we can contrive in various ways to keep ourselves out of the equation as we ask her, we can see.

And by asking ever more refined questions, whole skeins of her doings can become apparent to us.

I mentioned pace to you. How perceiving whale avoidance or starfish sociality was too slow for humans to see easily.

Here on this mountain meadow we'll try the next step, having to do with our own pace.

The faster we move, it seems to me, the more we internalize our thoughts, and hence, since we come to deal with ourselves instead of nature, the less we see of the surrounding world.

- * Fast cars to Las Vegas (capsules)
- * A runner stressed to the limits is concerned with breathing, muscle fatigue.
- * “A fast talker knows no belly plants.”

So, today we do a niche hunt and test two new dimensions of seeing. First it will test our abilities to slow down *to mountain time*. We will have to cross *the threshold of boredom*. You'll spend all day with a single organism. For some of you, that may at first be difficult. All day with a grasshopper you say? Who is talking is your city self and city pace, which has scant time for the minute doings of grasshoppers. You'll have to get over that, let yourself slow down, lay down on the grass and get eyeball to eyeball with grasshoppers. Walk the hills finding where, precisely, they occur. Let you guess why.

As you slow, reflect that the hillside, each square meter in fact, has hundreds of stories, interlocking, different, full of things we do not now understand. You'll be threading your way through one such skein, while all around the mountain goes about its business, with only the wind and the rustle of leaves to remind you that anything at all is going on.

It's that almost silent intricacy that's so remarkable about these wild places.

Now, what you should do.

Two or three of you work together and pick a common organism: a flower, a tree, a beetle, a spider, a lizard, a fungus, and describe its ways of living, its niche. Use every means at your command to discover things about it. If it's a plant, get a common mature form with flowers and fruiting bodies. Key it out, starting with the family key. Use the key to learn its parts, its morphology. Where does it occur? What pollinates it and how? What are the physical conditions of its life? Only on North-facing, dry, rocky slopes? In deep shade? How do its flowers work? Leaves? Plant shape? Seeds? What relations with other plants? What is it like through time? What are its roots like? How does it deal with insects? Sun? Rain?

For animals: Harder because only some stages are apt to be around. How does it feed? Meet mates? Deal with energy needs? Communicate? Deal with predators? Where do you find it? Take a beetle and ask such things.

In the grassy meadow at Gamboa Homestead.

Grassblades lighted green by the mid-afternoon sun. The airy note of bee violins comes from all directions. The grassy swale dips down amid oaks, big-leaf maples, madrones, and a scattering of yellow pines at its edge.

This field once bent to the service of the homesteaders is now a home of bees, floating monarchs tipping this way and that, spilling the gentle air from their wings. Reddish-orange ladybirds fly purposefully a foot or two above the nodding grass tops. Lupine pagodas with green bud roofs and purple floors below thrust up amongst the grass. They draw most of the attention of the bees. Between two trees an unseen air column rushes, its path across the grass marked by waves of nodding green heads. They flash light and rise again as the wind passes.

The deep duff of pine needles laid criss-cross over old greyed cones and dehiscent branchlets, [?] and gray like old platy snakes. Too [?], I must sit on its springy surface and lean back against the rugose tree.

It's warm but I must trudge up through the field and the road above and thence back to the old cabin. My swinging feet leave a wake of footprints in the calf-high grass.

A bark of jigsaw puzzle pieces tan and gray, the bark of a grizzled old sycamore.

April 14, 1984

San Bernardino Co., Granite Mts.

The Granites have woven their spell again. Our fine group has responded to the giant fawn monoliths by feeling properly awed and small, and warm and safe clustered here in the cabin against their bases. The open vistas stretching across distant sloping land and jagged ridges have created freedom and aloneness the way a forest never can. We sweated in the warm days and were parched an hour before reaching precious water at Bruce's cabin, pointing clearly enough for us to our personal fragility, as well as that of the flies, butterflies, and birds that flew there too to drink. As the streams dry with the approach of summer, they leave a wake of dessicated algal matting on the gravel and fringed with tinder-dry *Mimulus*, whose roots lost touch with the cool underground flow. Probably they were not simply the ones who lost the statistical game of life—and slipped into death, but had completed their part in the cycle. Who knows. It pays for *Mimulus* to bet some of its substance on temporary places where survival is chancy.

Up in the cabin we 28 have somehow circumnavigated each other to eat, sing, write notes, tell stores, dance even, and to sleep with skunks and cacomistles pattering across the floor or slipping quicksilver-like over the rocks and bunks. There has been much joy and personal adventure in little things for everyone, and we teachers have ladeled out fare so rich no one could gather in more than a fraction of it. Or, I should say, the desert has done this.

I led little groups down to the washes and we hunkered down under junipers or up against sugar-crystally boulders to talk of seeing, and nature, and how one can only see by believing her. And then we looked—at bee hives, tent caterpillar nests, at water striders, and mosquito larvae.

Steve led similar groups through the vegetation, noting where the invisible pediment below the alluvium dropped away, leaving many plants unable to reach water and the flora suddenly simplifying. He told them of strategies for dealing with heat, conserving water, and for photosynthesizing halfway, to complete the process at night.

And then we encouraged our students to search for themselves and they've gone off in all directions to see the eagles or watch the spiders eat, or to pounce on a sunning gopher snake.

Peg Mathewson is a born naturalist who knows a great deal already and who is filled with verve and curiosity. Michael Levy says he's been involved with "interior living" all these years and is now ready to look outside. And Ed Smyth, a man of elegant language, taking it easy now after a trek nearly to Granite Peak with Steve—a long hot, hard hike, but rewarded with reaching Granite Mt. Plateau, where they found a pinon-juniper forest and two small springs running in winding little creeks amid grassy banks. Steve says either could support a spring box and my live-riders[?] cabin.

Caitlin Bean, Jenny Griffin, and Mary Cunningham, George Banuelos, Alan Harris, Michele Murillo are now my blood brothers. We were sauntering up the wash near White Fang when Mary glanced down and saw a perfect bird point on the alluvium. Everyone took it as a portent. I found some less perfect pieces, flaked from rhyolite. Mary's was jasper. Then Alan found a limpid greenish chert spear point so we had to scratch off scabs, dip fingers in each others blood and kiss the earth. I actually scratched

my arm with Mary's point much to the horror of some. And then George showed us a partially hidden rock back close to the cliff base all patterned with petroglyphs. Down in a cool crevice we looked up to see pictographs on the sloping roof above—patterns in hematite. Was it painted on? Perhaps mixed with cactus juice? Certainly it is not powdery, but well adhered to the rock. There is no hematite here. Where did it come from and in whose pouch? What could a chemihueve trade for it, do you suppose? Such a price would seem to make it more than a casual act to paint these simple little pictures.

We crawled up in a cool crevice wholly inside one boulder—cool rock-temperature air, and crystalline granite gravel under one's boots. Caitlin, irrepressible Caitlin, heard me say I'd seen a rock that looked like a snail—"Dr. Doolittle's snail." She shouted and nothing would do, but that we should ride him for pictures, so up Jenny, Caitlin, and I went pulling at invisible reins and giving switches with the riding crop.

Steve had started the day off at dawn by going to Cottonwood Spring to watch the flowers of *Opuntia basilaris* open. His stories had been so intricate and wonderful that a repeat visit was set for this morning. We were up at first apricot light on the Van Winkels, and off over the bajada. By 7 we had located our plant, a group of seven or eight nearly spineless pads margined with flowers, undeveloped ones, four ready to open today and several that had gone by. The flowers last only a day, but it is enough. It is, in fact, a bee festival, with bees circling impatiently for the flowers to open and sleepy ones poking their heads out of yesterday's flowers, where they had spent the night.

There was much discussion of what sort of bedroom that must have been, the moonlight streaming in through interleaved magenta sheets, down among the china-red stamens and then when the sun came it must have become a warm, humid cocoon, getting ever hotter, driving the bee out like a camper from a sunstruck down bag.

The four buds about to open at first hardly looked the part. Their greenish sepals clasped the petals so tightly, little of their magenta could be seen. Gradually, gradually the sepals folded back, releasing the petals bit by bit. Still they could hardly be seen, but at the flower apex they revolved and unfolded until a crest of magenta could be seen—30 minutes since the sun first struck the flowers. Not long after, impatient bees began to circle—tiny trigonids, occasional solitary bees, a bigger grayish native bee, and Italian honey bees, the biggest of all. By 45 minutes the flower throat was all but open and bees probed at it. Our sleeping bees pushed up out of yesterday's flowers and zoomed away. Antennae first, then a head, and as the old withered petals wriggled they popped free, seeming to hurry inordinately to leave as if exit was somehow dangerous.

By then the rest of cream-colored anthers on vermillion filaments could be seen and a big, cream-colored capitate stigma and style.

Bees entered. Trigonids were everywhere, seeming to annoy the larger bees if they tried to share a flower, and one kind of big bee was all a flower seemed to hold.

The dusky native bees dove in, stopped for 4-5 seconds clasping the stigma, as if in some propitiation of the flower, and dove head first amidst the stamens to suck nectar from the flower base, their abdomens pulsating with the act. They emerged covered with luscious cream-colored pollen from head to tail, and flew away.

The Italian bees landed on the petals and walked in, avoiding the stigma and never feeding on nectar so far as I saw. Instead in a frenzy of plucking they gathered pollen, passed it to the middle legs where it was plastered to the abdomen and, as the bee left the flower, it hovered a few seconds, passing pollen to its hind legs where it was

plastered in a roundish lump on the midleg. It took only minutes before the bee was so laden it seemed to need to circle to gain altitude before streaking away. Very different these bees. Only the native bees seem to contact the stigma—coevolution, it seems, etched clearly in the behavior of the bees.

OK, I did want to mention the dune singing. Two days ago we piled in the bus for our annual visit to the Kelso Dunes. The morning was warm and still, and I worried for fear we would suffer from heat, and I worried about burning our feet should folks hike the mountain barefoot. It was calm and cooler than I expected at the dunes but my worries were still in order. People carried socks and it saved us as especially the magnetite covered sand became searing.

The dunes sang, people capered and flung off their clothes and slid and dove down the slopes in cascades of sand.

I listened at the top (though I slid, too), pressing my ear into the sand. Even though people slid 300 ft. away, the deep hum was very loud at the crest. It had traveled in the layers of the slip face, I think, piped upward to my ear. The sound came from the heart of the mountain loud, as if the entire mass was vibrating. Does the arrangement of layers contribute to the production of sound? Is its subtly layered form a part? Do platy minerals like magnetite, for example, line up and define the margins of these layers? If so, does that contribute? I dunno. Dunes with magnetite sing and beaches bark.

May 21, 1984

Matolle River Mouth, Humboldt County

Rules for Rivers and Watersheds

1. Water will move everything it can. The weight of each rock is a calibration of the strength of the river that bore it.
2. The river will spend its energy every minute, every second of its descent to the sea; it cannot store it once it is in the river's flow.
3. If it can't move it, it will go over or around it.
4. The mountain raised by the enormous forces of continental collision and the slowly churning interior of the earth provides the teeth of the river and adds this energy to it in the form of rocks whose weight gnaw at its own slopes all the way to the sea.
5. The elegant balance of the river's system, including the tiniest rills high against the crests, is only to be seen over time because rains come and go, and the hillside will store water energy in its duff and soil and in the plants that clothe it. In the end, though, it balances out, every part, perfectly.
6. Each rock or grain of sand has a number that describes precisely what force it takes to move it downstream, and when its number is reached, off it goes. The number is more than just its mass, or its density; it is also its shape, and the way the rock fell in relation to

the current and other rocks. If close to equilibrium it will flip and fall and fall again until it lodges and assumes a no[?] larger than the river can then move [??].

7. Narrow a river, or steepen her fall and she speeds; widen her or level her and she slows. Speeded she scours in a swift and powerful flow, roaring over boulders and scouring out pools, or she becomes quiet and peaceful and wide. So it is with the air as well.

8. Only a matter of scale separates things blown by the wind and those carried by water. Barchan dunes belong on sea bottoms and deserts.

9. A stream close to equilibrium, at peace with itself, will have its tributaries entering each other "at grade". A measure of responsiveness of each part of the watershed to the others. If they don't, some disruption has intervened. A forest removed, a part of the soil bared, a dam. But in time, the river will win and will return to inner peace.

10. In a river a simple geometry speaks of equilibrium, a complex one of various processes in effect approaching that same equilibrium.

11. Slow rivers wind and fast rivers straighten.

12. Banks and berms and flood plains are energy absorbers. Once the channel is full, the water flows over and out of the river and into still ponds, by the imponderable billions of pounds, each pound that much less to drive the river or claw at its banks and stream channels.

13. River engines murmur or rock, just as do gas engines. Volume not pitch calibrates power.

14. The corrosive grains and cobbles carried by a river heat as they clash, as do the currents as they themselves rub against one another, and 90% of what the river does is to warm itself from the icy cold of rain at the mountain rim to warmth before plunging again into the sea.

15. Life, land, and river are truly locked together as one.

June 6-8, 1984

Grandview Campground, White Mts.

The wind spirits of the White Mountains blast at my tent. Its thin nylon fabric slats against the metal poles, and on one side bends in, pressed by the gusty wind.

I arise, climb awkwardly out the door into the morning. I shake the folds out of my coat, which has been a folded pillow during the night. I walk eastward down a rocky defile to chase away sleep before breakfast.

Suddenly, over my shoulder, I sense a raven flying 30 ft. over the pinyon tops. I turn and watch it as it changes its undulating, loose-winged raven flight into an urgent circling drop onto a rocky outcrop below.

Its legs outstretched, talons spread, it wheels down in a magnificent coordinated arc. Its wings are cupped in tense downward curves, primaries spread and separate, fingers reaching out to grasp the air that slips between them. The raven's head thrusts downward toward the rocks, beak ever so slightly ajar.

In a glance I see the object of this maneuver—a black scaly lizard splayed on a sunlit rock shelf, half out of a crevice.

A flash of black, the lizard is gone, and then the raven stalks a few steps across the shingle, lifts into the wind, and slices away across the gray-green trees.

In some exquisite balance between the reaction times of a warming brain and the distance to safety, the lizard had gauged how far it could afford to emerge and it had, this time at least, won.

Who cares? Why should we have taken this long journey together through wild California to seek such vignettes. What might our time on the mountain have meant?

Well, for me, the things I have sought have been wonderfully realized. Again this spring interlude has been my springtime rejuvenation. It has been the tenth chapter of the most precious single thing in my professional teacher's life. I have learned and I have changed, along with you. Let me describe what I hoped for:

First, I wanted to unlock again our chance to wonder. It's so pure a thing in children and so tattered in us, or structured, altered, or even absent after passage through our educational system. Why is it that this passage so often wrings out and discards the very wellspring from which real seeing arises? Well, the needs of mass education are the culprit, leading to universities structured by committees and run by administrators who may seldom deal with the student capital they ostensibly serve. Education, while assignable to neat boxes, budgets, and flow charts becomes the giving and reception of predigested segments of human knowledge. There is scant space left for the individual spirit to meet with and ponder the world.

We are, whether we like it or not, an elite, the quite special intellects, chosen among many others from a University that is itself composed of an upper stratum of human endeavor. We should, if anyone can, see with clear eyes.

But as Steve and I know from past experience, when back in the Pleistocene we ventured on our first trip to the Granites, many of you would and did struggle to unlock your ability to wonder. What, you asked, would we do with a free day? Weren't you going to correct the English in the journals? And for heaven's sakes, how would you be tested, and judged?

Well, no, actually, we weren't intent on doing any of those things. We knew it was useless to set rules for wonder or to try to guess where it would lead.

Wonder, I knew, comes in parts. First there is the wordless absorption of a world; our sliding, circling, sluicing journey on the Matolle, for instance, was one example. No one will ever fool any of us now about many river things, even though we splashed and sunk each other and held fashion shows on the gravel bar.

Second, wonder can lead us into that analytical question and answer game with nature that we have learned to play. We pose the question, look, and nature affirms, denies, or more often waffles in incomplete acceptance. We dig deeper, focusing all the

past learning we can muster like a flashlight beam, on some tiny event like a cactus flower opening just after dawn, or my raven and its lost lizard.

Play, I think, and words, are handmaidens of wonder. Wonder flickers out like a fragile flame in the face of a structured professor-student hierarchy, or in the face of pride, or the internal troubles of tangled lives, or sickness.

Wonder is fostered, on the other hand, if we let ourselves shuck our pride of position, or age and all its trappings, and crawl on our hands and knees among the mosquito wrigglers. Play is an oblique reaffirmation that it's OK in this company to shuck clothes, or not, and crawl among those wrigglers.

And don't think that Steve and I alone have those trappings of age and position. You, too, are well on your way to crusting over with such veneers. They settle in like boiler scale, with nary a sound.

The second thing that I sought was the chance as an educator to step aside from my usual role as a purveyor of predigested facts and concepts to become, with Steve and Don, orchestrators of events. I wanted each diverse member of our group to feel the time was their own for personal discovery and reflection.

After all, what counts is your flash of insight, for a possible example—that the living and physical worlds are a single unit, we might call it “life-land”, or that flowers and bees are designed together. Jenny's personal discovery that *Mimulus* stigmas closed down on adhering pollen grains, or Monica's that the stigma of the same plant may [?] down to the retrorse hairs in the corolla tube to pick them up, can be an anchor for understanding, not only of that plant, but of the wider world, including human cities and societies, which after all, run by the same rules.

The rich trove of discovery that you, in aggregate, have uncovered is nothing short of remarkable. The personal electricity generated in the process flows through us all, and as we talk and question and fit the pieces together, we come closer and closer to being seers.

And third, I wanted very much to let the full play of our individual diversity hold sway in our adventure. Steve and Don and I could not, not ever, hope to provide what we could collectively give to each other. Besides that, such an attempt would be an enormous lot of work, and of course we would fail. Our “windows to the world” are too limited and we must see and be together.

So, for example, we wanted Roy to be the marvelous compassionate Roy, full of music and clear views about human aspiration that he is, or to have Gail and Peg share their wonderful insights into aboriginal life, or George his way with birds, or even the frisbee.

So many vignettes emerged—Sally's elegy to the blue bus, Diane's mordant description of Jeff covered with trappings, pockets bulging with stuff, advancing with wild originality, eyes seemingly on independent courses, or Jenny, the first to reach the salt, turning graceful silhouetted cartwheels as Ellen W. and I plodded painfully across the pointed sedges, or Ellen Van G quietly gulping the miles of this or that mountain, or Ed sharing his crystalline poems evoking the flash and flap of those steelhead at Big Creek, and then veering 180 degrees to give insightful and lucid reconstructions of the Geology of the White Mountains.

And finally, I hoped we would all ponder and seek linkages between the rules and events of pinyon jay and cushion plant lives and our own, and especially how we might understand and foster our love of the land and its life.

I think it is clear to most of you that seeing as we have performed it is no captive of science but a first step to things as diverse as philosophy, human relations, literature, and science. Each such intellectual direction, to be real and true, requires that we look and see clearly and speak true things. Science, I think, is only a curiously encoded version of this—a set of social rules that allow us to test incremental steps toward a larger but always incomplete truth. Science is a human process like those others are, and no more than they, relies on seeing as we have tried to do it.

Well, I'm at an end now, my hopes fulfilled. But beyond these things, for me as for many of you, this adventure has made me care deeply about you, my wonderful and diverse new friends. I want it to continue. I hope some of you will help me, for instance, build my tree house, which will become field quarter hotel so I can slide soups and salads down to you on a cable. This will allow you to avoid the starched flower-embroidered guest towels of my house, and will let you feel free to restore osmotic equilibrium over rails 80 ft. up. It will let you mark my house in Santa Cruz on the intersecting trails of future wanderings as a place where you are likely to meet old friends.

—KSN

April 6, 1985

Kern River Gorge below Lake Isabella

The Eleventh Field Quarter takes off. It's a fine group of talented folks representing many different viewpoints and experiences. There seems to be no difficult personalities among them.

We took the route south on 101, across at Paso Robles to Bakersfield and up the Kern River Canyon. The camps were full, it being Easter weekend and so we cut into our nook behind a little hill up a steep slope from the Kern. Our crew spread around, finding places in the grassy swales. Steve and I stayed up by the parked bus and not many yards from the highway. Cars ground, raced, grumbled and roared in both directions most of the warm, clear night. In spite of it all, I slept pretty well once I'd decided not to sleep in inside the bag, but to use it as a blanket.

About midnight two cars roared up, turned in behind the bus, and out poured about seven young folks replete with tackle boxes and collapsible rods. I got up to make sure they didn't block the bus. They trooped over our crew, loud voices ringing in the night. One was lame and being helped by the others down the steep hill.

I listened intently to make sure all was well. They came up at dawn—poachers from South Dakota—whether they caught anything I don't know, but blissfully off they went, vrooming down the hill before our breakfast.

April 7, 1985

Bunny Club

One of our stops today was my first look at the TNC S. Kern Riparian Corridor Reserve. We drove in, unbidden, and Rick Hewitt graciously gave us a rundown. He is

the Davis-trained Reserve Manager. The reserve headquarters is set in a group of old gingerbread farmhouses set on a nice grassy plot set with trees of various kinds.

The reserve is 1,000 acres or so of dense riparian corridor of Fremont cottonwoods and willows. We walked to the brawling, swollen, brown river and thence back to the bus, and off over Walker Pass.

By dusk we were poised to take the bus across the edge of Kelbaker Rd. which had been bladed again. The giant trench would surely have trapped us had we not shovelled for 30 minutes to build a causeway. Even then the rear bumper dipped within inches of the dirt—but we made it unscathed.

It's warm here and I'll bet the days are going to be up there if clouds don't roll in.

Dinner, good music, and then off to the sack. I, for one, slept like a log, the cool desert air wafting in the open window and the red-spotted toads calling down in the wash.

April 8, 1985

Granite Mts.

It's a good group, by golly. Lots of good, pizzazy folks with all sorts of skills.

Today was the first of two days taking groups out.

First we wandered down toward the old pond and out to the beehive. Dawn Breese was along and boy can she spot birds. A sharp-shinned hawk, just a dot in the sky, goldfinches, swifts, warblers, and so on.

The stream had left some pools and seeps so we could look at surface films, wrigglers, and the like—and then we wandered down to the wash and then up to the bee hive, which was in full operation, with maybe two bees a minute entering. None seemed to be coming out. The heavy hum pulsated on twice while we were there—I suppose ventilating the hive.

We tried to psych out how they could find the hive crevice by doing some simple experiments—putting packs near the hole. Putting a piece of flowering Haplopappus at the main entrance caused mayhem for some bees only. These would go in and out several times and then maybe walk in. Others just went in, maybe deviating from course a few degrees upward to the top of the entrance hole.

My crew did well, pinpointing the variability of reaction which is the exciting thing. If it had been a taxis[?] I would expect uniformity. Far from it. Perhaps a cast reacted this way, and perhaps it was the variability of learned behavior in bees. I suspect the latter but can't really separate things out.

Then out into the heat of the afternoon—up around 87 degrees or so, and off to the north to Cottonwood. Everybody seemed a little logy and I was having a bit of a belly ache and then finally a pretty fine muscle spasm that made it hard for me to carry even my daypack. We hunkered in the wash and looked at water striders.

Steve stayed out until dusk watching the unfolding of an *Oenothera* flower and waiting for the pollinator. He suspects a hawk moth, but didn't see it.

Lots of music, good dinner (stuffed baked potatoes), reports (geology, weather), and then people dispersed quickly enough.

The BC porch is getting wobbly. It will be great when it's replaced.

Two cacomistles showed up. One right in a roomfull of people during reports and the other out on the porch—a big adult—ran off with something it rifled from somebody's pack—I suspect toothpaste.

Jenny Griffin and Bruce Bannerman showed up last night. She's out here helping him do this or that kind of work—cleaning Dorner Cabin, filling chuck holes in the road. Nice of her, by golly.

April 9, 1985

Granite Mountains

Steve and quite a retinue including Chris Moscone and Holly Green are off to Granite Plateau to scope out the location of springs and a potential source for the high-altitude cabin that I want to lift up there by helicopter.

The day is clear and bids fair to be hot, so I decided to stay behind in view of my brush with salt deficit (cramps in my back that all but immobilized me). I hope Steve takes care of his associates.

Ann Zwinger is due in today so I will hang around to greet her and to talk to her. She'll be here just one day, and then on south, I think. She's gathering material for a new book, I think,

A couple of groups wanted to hike around looking for lizards, so I ended up going on a long walk down towards Van Winkel. We strolled along, looking at all sorts of things—birds of several species, hand-worked stones, insects and flowers, and then as the day heated up we took refuge under an arroyo wall in an arc of shade. I propped my head on a mud ball, swept away the fallen soil from the cliff, revealing white sand beneath, and then hunkered down for a doze amidst desultory conversation.

Soon we walked back across the swelling land of the pediment. What was unusual—a *Xantusia* scuttling away as a foot rolled a *Yucca shidigera* log, a flock of black-chinned sparrows, a Bendine's[?] thrasher silhouetted.

Herman is an affable, bright hail-fellow-well-met retired air-force Colonel who instantly fit in. I led Ann around trying to catch a *Xantusia*, which she had never seen.

We finally found one, broke its tail, and returned to camp both feeling I'd disturbed too much terrain in the process.

Dinner came and so did darkness, and two of our crew, Aaron Rosenberg and Daria Walsh were missing. The flight log showed them to be attempting to go over the Dike of Jewels from the west side. Since they'd started at 2:30 PM they were predestined to end up in the dark halfway up the hill on a boulder-choked canyon. That indeed is what happened. Steve and I sent out a party to provide a beacon light and see if they could be heard.

They came in voluntarily an hour later, Daria especially revealing her fright at the descent. But they were safe and we retrieved our light crew.

Dinner, conversation with Ann about being a writer, and then to bed.

She impressed me as unidimensional, and not deeply philosophical about her work, though her instincts often expressed are for conversation and protection of the natural world. Her art, which she calls "illustrating" is crisp and nice. Herman is the photographer and well equipped with Rolloflexes and Nikons.

Off to bed.

April 10, 1985

Granite Mountains

I'd thought about going to the dunes but had suggested leaving by 7 AM and that, I realized, was too late. It would get us up on the dune when it was too hot, so swinging with it, we moved our schedule and headed out for Hole-in-the-Wall. Dunes tomorrow. The days have been hot and clear with almost no trace of clouds. Things warm up fast, several of us are supplementing with salts. I, for one, came close with my cramps to being immobilized by it; so these changes in schedule are crucial.

Bruce brought in a packet material that various people are using called "Emergen-C". It's a mixture of tartaric, aspartate, dextrin, whey, potassium phosphate, and other stuff. Section hands have been adding salt to it.

Anyway, we pattered along looking at tortoises up along Granite Pass road, prickly poppies by Kelso, the old Government Road, and then up in Cedar Canyon, not far below the Hole-in-the-Wall cutoff, we saw a green patch up in a fold in the hills on the right going up, which we went up to see. It looked like a patch of wild roses over a spring, but there was no spring and it tumbled over a granite outwash on a fairly steep hill. The patch of very visible light green was maybe 100 m long and half that wide. No rose, but maybe in the family. The plant was in full flower and it was dioecious with numerous yellow stamens on the staminate flowers and divided ovules on stalks (gynophores?) each topped by a stigma. Steve keys it as perhaps oso berry or *Osmaronia*. It looks good except it is far away from its coastal range. (It is *Forestiera*, desert olive or adelia, a member of the Oleaceae). There are other plants in these mountains like this—the *Arctostaphylos* up on Granite Peak, the fir, the serviceberry, the *Garrya*, the goldencup oak, the maidenhair fern—who knows how much more?

Anyway—on over to Hole-in-the-Wall for a good hike down around and over the pyroclastic walls and minarets. The swifts performed on schedule, drawing gasps and enthusiasm.

The owl pellets strewn along the base of the cliffs where the trail canyon widens were great fun to sample. True to form Dawn Breese was right in there and found a bat skull in one, which she later keyed out to *Ladarida*, the Mexican freetailed bat.

I was interested to see the prevalence of kangaroo rats—perhaps a third of the bones. Woodrats and mice were the most abundant forms.

I puzzled over the huge inflated bullae of the k-rats. It is a curious arrangement. The meatus goes right through the bulla and the oricles seem inside it. I didn't find them. I wonder if it is an arms race between rats and owls—the soft flight against hints of detection that let the rat jump and escape. The owl must have few second chances though barn owls do run after prey on the ground.

Then we headed over to the petroglyph cliff at the south end of Woods Mts. We had one student—Cynthia Horowitz—who actually had helped build a gallinaceous guzzler, so stopping at that architectural object was no mystery. Then, later, when the class was up on the cliff, I lay down by the bust and felt the cool breezes sweep over me.

On our way out we hit a section of the Mitchell Cavern road that had been newly oiled. We caught a beautiful red racer, which bit me, and horned lizards skittered across and then a nice big gopher snake down past Essex. Just up the road from Essex was a fine display of desert sand lily (*Lilium mojavensis*).

Gas at Cadiz where the old guy who runs the store seemed on the edge of departing this world—bags under the eyes, the shakes, nearly white, unkempt hair—I think he drinks off hours.

We were back at the cabin before dusk.

We had a grand presentation on the local aborigines in which each person was decorated with a face mask of the Mohaves.

It led to a thoughtful and concerned discussion of how free we should feel to read the Chemehueve myths out of season when the Indians themselves read them only in winter—to do so in another season was to invite snake bite.

There was an aura of magical belief and unwillingness to violate a taboo that might hurt one of our members. I counseled not violating anybody's feelings—if anyone didn't want to read the myths, I thought we shouldn't. There were several who were nervous so we didn't. But I had expressed my feeling that such taboos had a time and place and were from a different culture. They were, [?] social rules that held a society together.

In the back of my mind I didn't want to risk a circumstance where we had an event that was construed as due to the taboo. The power of the taboo hung heavy and its effects at social control were clear and sharp even though the Indians were long gone and we of a different and supposedly more objective culture.

After it was over and we hadn't read it I pointed out that the Reporting Group had "read the myths" out of season anyway. That seemed to be OK, though, but the absurdity crept through a little for some people, I thought.

Then, as we crowded in the dinner line for our falafels, Doug G. shouted "Scorpion! There's a scorpion on her," pointing to Deborah. Sure enough I saw a tan form scoot around her hips and up over a pocket. We searched her and couldn't find anything. Then a few minutes later I heard a cry down the cabin trail. Deb had hunkered down to pee and when she put her pants back on, the scorpion stung her. One of the girls with her stepped on it.

I walked down and retrieved the scorpion for identification and to see how she was. She said it was like a mild bee sting and didn't hurt. I identified it as *Vejevus*, a mild form.

Later Susannah Freeman came to me and told me to think over that event in light of the reading. She had been the most concerned one of the presentation group. I already had, wondering what other people felt. Her concerns and those of several others were a strong feeling of the power of such taboos. Doug Grabill said he hadn't made up his mind about gods and mechanistic ideas, so he didn't want to take part.

Heartfelt and deep, I thought, and a remarkably powerful force for social conformity.

I thought but didn't say, "Well, yes, she was stung, but we hadn't violated the taboo by a public reading. It was a scorpion, and didn't such stings occur commonly enough?"

But Susannah said, "Things like that happen too often not to have meaning."

I thought, "You have a will to believe. You jump to a conclusion about cause that won't stand scrutiny. How human, and how powerful."

Where does the tendency come from? Our human need to generalize from the data of our world drives such explanations. The need to understand, and perhaps the simple comfort of surrendering explanation to a simple clear cause instead of hewing to the skepticism needed to derive classical proof.

Anyway, off to bed after the cabin cleared out.

April 11, 1985

Granite Mountains

Dune day. Up at dawn and out of the cabin by six. The clear heat of the sun through pure blue sky made it clear it wouldn't be long before the dune would be scorching. I told everyone to carry their socks up the dune so when we started back they could put them on and prevent a set of burned feet.

I was surprised to find the dunes nearly barren of flowers and even the burrow bush match dry. I suppose the viscissitudes of rainstorm tracks passed them over other slopes.

Anyway we started across the sand apron looking at tracks. There was a whole convention of sidewinders in one blow-out area, but we came no closer than to follow one into a burrow.

Umas were out in force, though, and we found one dead, apparently bit by some animal, judging from the bite marks—perhaps a sidewinder.

We ascended from the east after stashing our packs under the highest desert willow. I delegated the job of carrying Randy Wells's tape recorder and hydrophone up. Ah, the pleasures of professorhood.

We reached the top at 0930. The air was still cool but I could feel the bite of heat coming up on the sand. I gathered all the folks around, most naked by this time, and told them about dune origins and sand dynamics.

Then we set up the hydrophone and recorder for our great Dune Song epic.

Jim Thorne was our engineer. Frank Murphy was producer—wearing the earphones. Ern Englund was the Maestro, using a collapsible lizard stick to direct the musicians (everyone else). They swam, tumbled, zoomed, and boomed past me. I was Sol Hurok, the Impresario.

I was able to adjust the frequency of the sound by shoveling in the sand near the hydrophone—that produced squeaks or barks, maybe as high as 1000 Hz. When someone jumped hard it made a deeper note, and when the whole slope face began to move a deeper note emanated. I could feel it on my feet—and it seemed about as fast as I could sense—maybe about 30/sec. (30 Hz).

When the whole hillside went, the sound reached down into regions where it may have gone below my hearing and certainly below the level of our little speaker to respond.

Our grand finale was everyone going by on the wide-open slip face. The result was a note that lasted well after (several seconds) everyone had slid to a halt. Also accompanying the actual motion of the dune is a very characteristic white-noise hiss. This stopped abruptly when the sand stopped sliding.

So there is a resonance—and it is very loud within the dune—we had to cut the record level down to keep it from going offscale. I think Jim kept the level constant too, by turning up the volume as the sound went down. Oh hell, that probably did in our diminuendo.

If we assume that sound travels 2X as fast in sand as in air, a wavelength of 30 Hz sound ought to be about 5 ft. Now if there was a reflective layer down in the sand, say at that depth sound could resonate back and forth between the surface and the moist layer.

There could be traveling waves laterally too a la the sound channel in the sea in which lateral reinforcement occurs.

The moving mass of sand should be lozenge-shaped, that is tapering in all directions.

I suspect that the resonators may be tabular magnetite grains that rub over one another [drawing].

So, within the mass there are millions of little resonators, below and above a reflective surface, and laterally the sound could travel in the dry sand. Certainly the sound is much much louder in the sand than out. There. I've said it.

Anyway, we headed back to the cabin, dessicated and ready for lunch and a nap.

We had a nice session around a campfire over by the water. Adam Rose especially, produced some grand music. He has real facility with the guitar and a very graceful voice. Neat guy, too.

As a matter of fact the group is a splendid one all around. Everyone is convivial, there are many points of view, intelligence is everywhere, good spirits abound. A group of beautiful caring people with whom one can share the wild world, and with whom one can learn too. That's the magic of this—the opening of this diversity and the sharing of streams of life, of the vibrant aspirations of these young people—the best there are.

Erin, Blythe, whistling toad calls on the deck. Marshall doing her stretches before going off for a run. Jim Burkey changing his shirt after a long hike up behind Quimby's nose. Tamara puzzling over a list[?] of squaw bush with galls at the leaf edges. Ania perched crosslegged out on the deck scratching notes in her everpresent journal (courtesy of Prisma products).

Steve is up on the wood bridge in his favorite spot sipping a beer. He's so much more in command of himself this year, so sure, so mellow, such a terrific complement to everything I do.

June 6, 1985

Dechambeau Creek above Mono Lake, Mono Co.

People are scurrying through the aspens bringing in their gear. Steve and Marshall and some others are down spading Jan S.'s garden as a kind of pay for using our lovely campsite.

It's a china blue day with the disc of the lake shining below.

Last night we built a nice fire down among the willows in a fire circle of some other party. Our group gave a nice summary of the local geology—Long Caldera, the Sierra, ancient life.

After that Cynthia H. and I gave a nature note about how we drank [from?] a certain creek and fell asleep only to awaken very small, struggle our way through the giant willows, lean against the paved side of a sleeping rattlesnake, climb laboriously up to the fountain of youth, descending in a Perrier bottle ballasted with rocks to tip over and ride up on the top of wavering, spinning gas bubbles rising from the spring bottom 50 ft. below.

Before that we all took a long hike down to the lake shore up to the Fountain of Youth and some up Wilson Creek to look at the vertical canyon walls and others up to Black Point. I was adjusting to the altitude a bit so took the short route.

My major adventure was trying to cross one of the creeks entering the lake and having the bottom swink away below my feet. As I went deeper and deeper in, my zoom lens, hanging down from the camera around my neck, dipped in.

It imbibed water in the end, and a little puddle can be seen through the end lens. But miracle of miracles, I'd gone far enough upstream so that there was a halocline—the corrosive lake water below and clear stream water sliding above. Only the clean water appears to have entered.

The usual man-eating noseeums are out, nipping at collar and hat line. They're vicious little bastards. Mosquitos, though, aren't very evident.

Well, I'll sign off for now—the engine is warming up, the bus is loaded, and we wait for the garden crew to return and then we are off.

Seeing In Nature

History—What does one do? I found that at first, it is often very hard to see very much at all.

As an outside boundary there's fear—and that shuts the eyes almost completely, especially in any place we don't know.

But even without fear there are things in the way, and like dispelling fear they are mostly internal things to the observer, that must be swept away so the view is brought into sharp focus.

But not all that the observer brings is troublesome. There is also the essential imagination, the essential experience that lets one ask penetrating questions of nature, and there is the wordless emotional perception of the outside world. This world of the senses and emotions requires no more than an alert presence.

This is, I think, the world of most other higher animals on the planet. The emotional, wordless world is a magnificent, vibrant one, full of beauty, love of the land, the fears, the smells, and the glancing light of the artist, the harmony of shape and color, of birdsong, of the relations between animals and the silent harmony of the system, the place. It is to this world that we appeal as we assemble a "sense of place," or as the ecologists' more stilted language would have it—"habitat selection."

One can gain "wisdom," I think, in the unspoken world, but one does not unravel the discrete stories, the individual pieces of the puzzle in anything like the same way. One deals in metaphor rather than words.

Parenthetically, isn't that what animals are likely to do, and isn't our tendency to dream in metaphors an indication that this most puzzling of human doings is very ancient in source and in our history?

As always the emotional half of our being to some extent wars with our rational half. The two are not perfectly mated even though their aims are, in the last analysis, the same. That is to say, both together let us be human and function successfully in human terms.

I like to let one have its say and then the other, so that the powers of each may fully as I can make them be parts of my seeing.

It takes some doing since the doings of right and left brain are so inextricably mixed in our perceptual affairs, and yet require such different supporting behavior from us.

Let's say we want to watch a swift drink at a pond. First, I say, sit quietly and take it all in. Pass no judgments and ask no questions. Let the natural frame around the event soak in. Watch the flickering, volplaning birds arc down a canyon of air on to the shining pond. Watch them dip, leaving a spreading, pencil-trace of ruffled water and then arc up and away, wings flickering so fast eyes cannot truly follow. Sit for an hour watching the echelons of swifts come in and then leave to become gliding specks in the distant china-blue sky. You've learned something of the larger frame of "swift life."

Stand up, shake the loose granite crystals from your pants and prepare for the hardest part. You now have the beginnings of a complete frame of birds and world, of rocks and pond, of life and land, within which analysis can occur. To build a true larger frame for some events may require months or years. Some relationships are of course elusive and setting the experiential frame is a matter of truly living with the circumstance. . . . You have a guide that nearly always will provide a measure against which . . .

The next step as I do it is to continue circumstances that let me push back my part of those emotional connections to the world as best I can, and to watch events with as little intrusion of my . . .

July 9, 1985

Wrangell Mtst. National Park, McCarthy, Alaska

Phylly and I sit 200 ft. away from the face of Kennecott Glacier. They say this toe of the glacier pulses. Right now it is "deflating" and retreating, but sometime ahead it will send a surge down its ice river and push out again toward McCarthy, a mile down the canyon.

When it surges, it is supposed to swell higher as the viscous ice surges down canyon. All fluids—air, water, ice—are alike I guess and this huge, dirty plastic river is no different. This is the so-called Kinematic Wave.

I'd guess its wall at about 100 ft. high here—a 45-degree slope at the top extending downward a half or less of the slope and then a vertical drop or even overhanging cliff to the water. A wedge of air indents the cliff bottom above the milky glacial melt pool. This undercut wedge goes under the ice cliff 10 ft. or more. It is a wedge, sloping to within inches of water level as far back as I can see and widening to a couple of feet at the outer margin.

The face is constantly pelting down rocks of all sizes, some landing in the extensive pond at the glacier edge, sending up towers of brown and white water. Others crash into boulder or ice piles with sharp, clattering reports or deep, booming crashes.

The glacier freights an enormous load of till and cracked rocks of all sizes, from gravel that sizzles as it streams over the precipice to house-sized blocks of porphyry that must send up enormous towers of water and sound as they arc into space and then land. We can see that many have fragmented as they landed and projectiles should sometimes reach even where we sit.

Our seat watching this spectacle is precarious enough—atop the till over a calved slab that melts and slides behind us into a subsidiary pool. It's unnerving to hear sliding and crashing on both sides of one's vantage point.

The glacier face runs with rivulets of water coming from the melting face. The layer of till slides as it is undercut, plastering the 45-degree slope brown with mud. The vertical face calves off great vertical sheets that tip backward and fall at the glacier base as they are undercut and as they erode inside, probably along cracks. We can periodically hear rumblings from inside the face and once watched a four-ft. boulder fall inward to boom inside the glacier.

As the big rocks fall and hit the pond they send shock and displacement waves under the ice with a staccato collapse of the roof of the undercut following, and sometimes clearly enough, arcing blocks of blue ice from above fall and undercut the glacier.

One can see that big boulders from the till burden sometimes sink into the ice. One sees them set like raisins in the face, all the way from the surface down 30 ft. or so into the glacial mass. Below that it is blue, without soil or rocks, showing that the burden a glacier carves and carries is primarily borne atop it and doubtless carved at its edges and added to by alluvium from above the ice; lateral moraines that coalesce.

The glacier face is streaked with curving lines that intersect like crossbedded sandstone and are probably formed the same way. Or are they marks somehow, of the plastic deformities in the ice as it bends and pulses?

We waited, watching the rivulets and the shower of boulders, and even uprooted plants, for one of the giants to fall but but none did while we watched, though several were so precariously balanced and being undercut that their fall seemed momentary.

In the gathering dusk we turned our backs and headed for McCarthy. "Don't turn your back on a glacier," they say, and as we walked away a shuddering boom came—one of those precariously perched rocks finally lost the bit of gravel that held it, and arced out away from the ice face onto the debris below.

The till burden carried by the top of the glacier accumulates here at the toe over the whole surface of the glacier by ablation, or melting from the top down. Farther up the glacier only the merging morainial lines mark the white ice with curving longitudinal lines of dark soil and stones.

The ablation surface may appear to be wholly a field of till, but a closer look shows it to have exposed ice faces in many places riven with vertical water runoff lines. The ablation topography is hummocky in the extreme and here and there sharp triangular mitred peaks stand up. A further look shows that in the deepest places ice water streams run and finally pour either off the ice edge or into its mass through swallow holes. The till is thinner than it appears at first glance. Most of the topography is ice, coated with inches or a foot or two of till. Thus the shape of the ablation terrain is largely the shape of the melted ice. Those mitred peaks are faceted points of ice formed as the sun heats the surface till and its interstitial air. The piled till probably does not slide because of material below it but merely lets the ice melt in place, its meltwater running down the topography and its process moving up-slope in a headward fashion just as ice cutting does to the rock beneath, resulting in a steep-faced mitre as headward processes meet. The angle of the slopes must stand at "maximum angle of repose." [Drawing]

Does slope angle vary with angle toward the sun? Is the face away from the sun different than that toward it? I didn't learn. Water in ice meanders very nicely, even on fairly steep slopes. It cuts in so effectively that I suppose a meander form can occur when on soil it might not persist as the soil was washed away.

July 20, 1985

Kennecott Glacier, Wrangell Mts. National Park, Alaska

The whole group of us walked up to Kennecott and thence out onto the Root Glacier with Ed La Chapelle, in preparation for the class glacier hike later next week. It was an interesting time.

Root Glacier comes down off Mt. Regal, tumbling in a gigantic ice fall—stairstep blocks of ice on a 45-degree angle slope for 2,000 ft. and then regroups into a white river of ice, which was the way I found it a mile above Kennecott. Glaciers seem to heal themselves from such splits. I'm told my intersecting curved lines at the glacier face are just that—places where a shear plane developed in the ice horizontally, when, perhaps, the sole of the glacier caught on irregular topography and the flowing ice above split—only to reheal and perhaps split again leaving intersecting marks on the glacier face.

I walked out onto the ice. At its edge it is steep and muddy. Higher on the ice it levels and undulates. There are, to be sure, erosional valleys in the ice, rivers on the ice, falls, and the like that are steeper. But one can walk easily without crampons in most places by watching one's step.

The sun was out so the ice was melting and rough. I stood easily on fairly steep slopes. But let it cloud over and freeze and I'm told it can turn to glue[?] and one cannot stand without crampons.

The till of the glacier accumulated as the ice melted. Here and there handfulls of dark pebbles accumulated and they became heated by the sun and then sank in little pools of ice water atop the glacier.

These merged into streamlets. One could see how ablation could, in time, accumulate till atop the glacier.

In places fissures split across the ice. The ones I saw were narrow, an inch to half a foot in width, but blue—turquoise as far down into them as I could see. Sometimes, streams ran down holes into the ice, probably piercing the glacier to the roaring stream below that had coalesced from many such sources. Some of these are dangerous pits piercing a 1,000 feet of ice, tumbling near vertical and surrounded with slick, sloping ice—traps for the unwary.

Yaakov had his ice axe slip nearly into one capable of swallowing a person and he had to be belayed out onto the ice to retrieve his vital axe. An unwary person could easily have slipped, slid, and been swallowed up in a plummet inside the glacier. There are, to be sure, traps out there.

I walked back from the group, who were going to test crampons, ropes, and the like (I had none) to join Phylly up on the trail. We walked back the long trek to McCarthy down the old Kennecott Mine Roadbed.

The minebuildings are mostly falling into decay now, but much is left—the giant boilers, the stamp mill (the stamps were removed)—but bunkhouses, offices, gymnasium, residences, and more remain of a once-thriving town at the glacier edge. We met people who had lived and worked there—come with wistful faces full of the past to look at the silent, peeling, decaying hulks.

[this is the order in the journal]

July 8, 1985

Wrangell Mts. National Park, McCarthy, Alaska

Today is a long-postponed day. We hike to above timberline into the Alaskan arctic-alpine, which we can see on the mountains all around the valley. I'd guess in most places its about 2,000 ft. above the valley floor.

One of the local residents, Jim, met us at 9:30 with his hay wagon and very spastic Jeep pickup vintage at 1947 and pulled us up the five-mile dirt road to Kennecott. This was the mine headquarters where the crusher and the business end of this giant copper mine is located. Now it is a series of decaying red wooden structures, some like the one processor, huge, tottering edifices of shrinking boards, rusting machinery, and peeling paint.

Above, far up the mountain were three mines, one said to be the richest copper mine in the world. It was in these precarious remote mines, shops[?], and bunkhouses that the miners stayed. The staid, family-oriented community of headquarters was not for the miners, and they passed right through to the pleasures and booze of McCarthy down the road.

At the headquarters the gymnasium was identified as was a school and various other buildings, all served by a regular-gauge railroad that stretched all the way to Cordova when the mine was active. It closed in ____.

Our hike up, participated in by the whole class of 15, was to look at tree line and the arctic alpine. I expected Krumholtz and old trees, but that was not at all what I found.

We started up through dense alder and willow thickets on a relentlessly uphill gravel road that wound past the upper works of the town and then into untenanted, vegetated slopes, with dense undergrowth of several flowering plants in addition to the two predominant species. White spruce was common and of close-needed spires usually 30-40 ft. high or so.

Chiming bells (*Mertensia*), a lovely borage with pendant blue flowers was everywhere as was a rather large-petalled, pink wild rose. It was a steep but not unpleasant climb on the cool, partly overcast day. Gradually the vegetation became more open, the willows lower, and the alders all but dropped out. Bunchgrass became common as did a low alpine birch. We left the birch trees behind. Flowers became more numerous. *Trientalis*, a low-growing white dogwood, Nagoon[??] berries, a *Ranunculus*, a lovely white anemone, a low-growing, white-flowered *Dryas*. A juniper appeared—a low-growing mat plant here. This began to thin and become lower. Finally at a lunch stop a cushioned *Phlox* appeared.

At lunch class members produced stoves and made hot tea as clouds swirled not far above us.

Across the valley we could see a rock glacier descending a steep, U-shaped cleft from the main peak above.

Its lobed surface of rocks was grown with arctic lichens—yellowish curves defining the topography. One could almost see the viscous flow, ice below amid the rocks.

Phylly turned down to wander at Kennecott and I went on up to a tram station set high on the steepening slopes, almost amid the clouds and up amongst the snow patches not yet melted.

Ben Shaine cut a poplar to see how old it was—at 2-3 in. it was only 10-14 years or so old. Later, near the tram station, he cut another, a spindly willow an inch or so through and it read 35 years. Heather came in as did shooting stars and some other low-growing alpine mat plants. No Krumholtz at all. No old plants so far as we could tell. Nancy Summermann says it's still in disequilibrium—the march to treeline continues she says.

But there is a transition, even if the players are not all here. I suspect it's regulated by growing season. High as we were it was only 4,000 ft., so UV and other truly high effects are not involved. June-September/October at best and much of that cloud-shrouded up there. Many plants were just reaching blooming condition, though. Chiming bells seemed farther along high up than below. Their flowers were becoming pink while below pure blue prevailed.

July 25, 1985

Thoughts Upon Re-reading *A Sand County Almanac*

Leopold's clarity of vision is almost as pure today as when he wrote it. The major change is that the ecological ethic is taking hold, though it seems malformed frequently enough with the various viruses Leopold saw.

To me his ethic does not go as far as it needs to go. Not only do we need to understand and live the fact that we are just part of the world, but we need to extend ecological consciousness into what might be called "evolutionary consciousness." We need to seek out and understand ourselves in the evolutionary sense. In such a search lies answers to the inequities in our society and relations to other societies as well as to the ecological world at large. "The naturalistic ethic."

Putting a monetary value on temples is an attempt to quantify and evaluate the spirit. So it is when we seek to put the value of wilderness in dollar terms.

Why do humans gather in cities?

How deep and pervasive is appreciation or need for "the wild" in each of us? To love the land we must somehow know it. Can a person in the city slum have such love, or does fear so predominate that appreciation is lost?

Am I wrong to feel that "land love" is somewhere, somehow in all of us?

Leopold rightly calls for a land ethic, saying our tendency to give the job of conservation to the government tends to absolve us from doing it.

We must join ethic with government. Much the individual cannot do alone, or even collectively. It's a matter of scale. Some needs are simply too great, and our understanding too incomplete.

A fossil unearthed he says, comes from a place where there is no time. But there is, its march the slow end of the cycling-recycling world. the carbon in the trilobite had been locked in place for 500 million years, but now it is again ecological currency. Between that fossil and the daily mobilization of O₂ from a plant are all other speeds of recycling into the life process . . . some nearly as slow as the whole span of life on earth and some immediate, and everything in between.

Our view is so short, so limited, that we perceive and understand mostly the immediate. This masks the fact that the whole world is inextricably limited to the history

and processes of life and truly the world evolves as a whole—its life, its continents, its seas, and its gasses.

Leopold talks of the A-B cleavage and land health. A's put prices on things. B's are ecologists regarding the land as biota and man as part.

The first type are creatures of the industrial revolution: "If I do this, I get that." "Get" is the point. B's get everything including themselves.

Science is accused of being an "A" activity (linear, reductionist), but its methods are as applicable to systems as to linear events.

Science works by examples and this tends to atomise processes and relations but it also seeks to synthesize between examples—to develop general rules within which examples can fit. Systems and different levels of integration are best understood through the scientific method.

I suspect science rose out of reaction against the dogma of the church—covert, at first, railings against the pronouncements of the clergy—logical refutations of doctrine. That the reasoning process itself was pitted against the "revealed word of god's servants—and the battle was on. A key feature must have been to reject dogma that did not stand this or that logical test.

June 9, 1985

Grandview Campground, White Mts., Inyo Co.

Yesterday up in Wyman Canyon, I stood to my calves in swirling, glinting water, naked except for the camera hanging from my neck. Down the narrow canyon, cries issued from four sleekly tanned people partially obscured under the falling glassy sheet of a 9-ft. waterfall. The water pummeled them, seeming to force out these cries of wordless pleasure—Holly, Adam, Deborah, Tamara.

Ten ft. above the water a lithe, dark-haired figure crouched in the sun atop a polished slab of fluted granite, in a hunkered aboriginal pose of knees against chin, with brown toes slanting down, feeling the inequalities of the steeply sloping rock—Kelly.

I turned to face upstream where the creek's flow split into two little stepped cascades running between lush, perfect fields of green horsetail rushes. Above that a willow arched over the water, casting it in dark-green shadow.

At my feet the water flowed like uneven glass, focusing and unfocusing the half-inch cobbles of the streambottom—brown, gold, pale tan, and amber. Below me the water crowded into a smooth, granitic sluice. The sheet V'd and slid in a downward arc over the boulder face. It merged into a roostertail ridge from whose crest silver globules of water were hurled into the air over pure white foam.

Did my friends and I belong in this perfect stream? Was our tread among the horsetails an affront, or was it part of the life of that cleft canyon?

I wondered about the sense of perfection indistinguishable from love that swept over me as I watched the glowing colors of the pebble bottom, and when I thought about the free cries of my friends, free of the pretense of masking garments . . .

Early in the quarter I suggested that an important thing we would be doing would be examining "the wellspring of caring about the natural land and its life."

Why, after all should we give a damn if the human race changed the world, and if the new one didn't have pinyons and free-running streams?

What tells Daria that she should enlist to save Mono Lake and thereby to enter a wrenching struggle over power and vast sums of money when the aim is to save that disc of blue, its black mountains and islands, its dabbling flocks of gulls, grebes, and phalaropes as a symbol of much larger inequities in our society?

What does Jim seek when he wanders the world, guitar on back, to write songs of the beautiful bells in Swiss alpine valleys or to learn stories of djinns and magical [?]?

Or why doesn't Susannah avoid the surely coruscating human drama of modern-day Kenya? What about Kirsten in Alaska, Beth in Boulder, Howard in his beloved alpine lake, with his dreams of the Sierra ridgeline? Or Holly, Adam, Chris, and Steve, soon to be on that barren granite ship-island in the desert? Or the rest of you in your personal journeys of care and exploration?

The broadest commonality that I can see is that present-day science alone, is not enough. A larger view stirs each of you now that combines the simple-seeming emotional love of the land, with what we can dispassionately learn about it. Even though two of us are card-carrying scientists, we are that way too. So the question shifts a little and becomes two. First, what's wrong with present-day science as a base for natural philosophy; and second, if we can pin down where our elusive love of the land comes from, is it the missing piece? Very nearly, I think. Together they form what I, at least, mean by natural history, as well as I can perceive its shadowy boundaries right now.

What about my first question? A whole generation now skirts science, touching it gingerly as if doing it can somehow degrade our experience and our perceptions.

This perception is, I think, correct. We need a more generous, more encompassing science. But I also feel we must not retreat and think we now know everything we need to know. Although in the last three centuries or so, science has wrought a major revolution in world history, and we now know most of the outlines of how things work, our needs for knowledge are far from over. In ecology for example, we have only defined part of the problem, not its solution.

Having said that, what's wrong with present-day science. I see two major areas of contention. First science seems to wring out all emotion, most beauty, and most grace from the world it builds. There is left scant space for the "rightness" of our afternoon in Wyman Creek, yet we viscerally know better. Any adequate natural philosophy must allow scope for the emotional wordless world to enter. We know "the wellsprings of our care for nature" include these things quite centrally.

Second, science seems to dump its information mindlessly on a world scarcely able to assimilate or deal with it. There, for me, the choice is direct—either attempt to restrict our minds and opt for a world in which truth is selectively available to build our philosophy or press ahead with the unfolding story.

For me this choice is clear. I want my philosophy based, as closely as I can make it, on true things. I don't want to retreat to a world of dogma and magic, of explanations made whether or not we had the supporting facts.

Our human history, you know, has been to explain the world whether we could or not, because having rules for living was expedient and gave control over those who wish to follow, even though the rules might be imagined.

The power of science lies in its rejection of this method of social control. It first tells us how we must proceed if we are not to lie to each other, and second it tells us how to shed dogma as a regular course of events without social revolution.

None of this speaks about technology, which is the social application of natural law, and I won't say more about that difficult debate of our times here.

So, I want a science that includes us, our unspoken world, the animals and theirs, the plants, and the ecology.

It has to include us lest we never reach mountain time. No system that separates us as we really are from our world can be real, or adequately explanatory.

No explanation that omits our care, our camaraderie, or our deep affection for each other will do, for it is the glue that joins us in our quest, and that makes it worth doing.

No explanation that excludes jokes and laughter will do. They are the rapiers that tear away pretense and unmask false explanation.

No explanation that omits music and the exercise of our physical beings will do, for they define our fitness and even the very ways we organize our thoughts, our explanations, and our language.

What then are the sources of our love for the land? I suspect they lie very deep in our preverbal emotional beings, and I expect them to be widely shared by other animals.

The calculation that we and the chimpanzees share 99% of our genes doesn't surprise me. After all, by the time our natural ancestors were around, most of the evolutionary work needed to form us both had been done. The intricacies of our muscles, bones, hormonal systems, DNA, circulatory systems, and yes, even behavior, were there. Even the beginnings of language were there.

Surely also our wordless emotional attachment to the wild world around us is also largely shared. Surely our love of the land springs from ancient roots in us. After all, even in our two million year history, only 1/20 has been spent in civilization.

This emotional attachment speaks clearly enough of ecological balance, of the silent ticking of the mountain, of the things our science has only defined, not solved. When we slow to mountain time, we come closest to the inner peace of our ancient balance; we reach best for bridges between our modern world and all that built us. Those, I suspect, are the wellsprings of our care.

They are also why this odyssey of ours, which refused to deny our emotional love for the land, its waters, and its amber stream-bottomed stones has unlocked such marvelous diversity from each of us, far transcending what any one of us could bring alone. Our experience has been a collective one, based on a marvelous diversity of viewpoints and experiences.

This environment of equal "air time" for each of us has achieved what I wanted most—that each of us follow our own unfolding path of exploration supported by the shared perceptions of the others.

The bonds that have been built between us, will often persist a lifetime. I embrace you, each one, in deep fondness and as a treasured traveling companion on the journey just begun.

October 25, 1985

Rio Vista, Solano Co.

Well, four of us are perched atop a bridge over Shag Slough—Randy Wells, Sue Kruse, Ken Marten, and myself. We are watching an operation to chase "Humphrey the

Humpback” out of the river and into San Pablo Bay. It’s been in the papers all week and they finally tried an idea of mine, the use of Oi Komi driving, using metal poles. It worked for a mile or so yesterday, but the whale refused to go through the rickety old bridge on which I sit. Humphrey is getting tattered, perhaps from sun and perhaps from osmotic stress of the fresh water on his skin. The day is sunny with a light breeze. They will try again today after having removed some old pilings from between those that hold up the bridge.

Diana Rees called me yesterday and reported the whale clicking as it “inspected” the pilings, just as if it echolocated. Maybe it does. If it does it should express bubble streams from its nasal valves, and if so this could have relation to the evolution of echolocation. So we are here to observe and record.

We drove up and entered the zoo at 9:00 AM, a field headquarters had been set up in a construction co. headquarters N. of Rio Vista. The press was everywhere, Fish and Game was everywhere, whale types were everywhere, Senator Garamendi and his staff were there, and Rep. Leon Panetta called in. I was whisked off for conferences and lost my team briefly, but finally was reunited and we made our way up by Fish and Game vessel. Possum cops were everywhere being official. An entire troop of California Conservation Corps. lined the bridge to dump a plastic barrier behind the whale should it go through the bridge. I hope it doesn’t turn and become entangled. The plastic should be acoustically transparent.

So we went while the boats are upstream banging on their pipes and working their way toward us.

The boats took up station across the channel with maybe 75 ft. between them. Seven of them turned the whale toward us and crept along as it zigged and zagged across the slough, ever closer to us.

It came within 40-50 ft. of the bank and turned again, usually 100 ft. ahead of the boats, blowing only occasionally. It’s only 300 yards up slough now, coming closer.

It is 200 ft. across and seemed to sense the bridge and to turn away in a circle. The pipes can be heard and chinking intermittently. It took a wide circle nearly across the 100-yard-wide channel.

Here it comes, again.

Circling and blowing 50 m away in the brown, nearly opaque water. Its 80 ft. N. of bridge, circling as boats approach. The pipes were about 10 ft. sections of 2-in. pipe, capped on both ends and filled with water. They were lashed over the side of the boats and when whacked on, the upper end made a very loud, metallic crack. I was quite surprised what a din they made and it must have been much greater underwater. Even from 200 ft. away the whale reacted strongly and could be easily turned. In more open water a semicircle of boats would have been required because the whale tended to zigzag back and forth in front of the boats moving slowly downstream.

When they get in open water they will need a good semicircle of boats to guide the whale because of its tendency to move at nearly right angles to the advancing boats.

The boat operators were frightened of the whale. Once when it slapped its pectorals in frustration while near the bridge, the boats instantly all backed up another 200 ft. even though they then were 300 ft. from the whale. I hadn’t realized how goosy everyone was. Later I told them what a marvelous example of Skinnerian one-trial

learning it had been. The whale, I said, had trained them to back off with a single wave of its pectoral. Sheepish looks.

The people at the bridge were all tired, frustrated, ready to give up, and Debbie, Diana, and Mark were remarkably unwilling to do anything that would agitate or disturb the whale, even though to so hang back meant the death of the animal. I found that mindset hard to take and pressed hard for driving the animal until it went through, which it finally did. I wanted it done subtly, but with quiet force—keep the pressure on when driving, said I.

Its skin is speckled and brownish and though the dorsal is white on its margin, I see no sloughing skin. It seems to move pretty normally to me.

It circled within about 30 ft. Boats all but stationary 200 ft. back. That time it circled within 30 ft. no bubble trails evident.

The big white pectorals sometimes slide[?] [over?] the surface on these circles. The pectoral came up like an oar sculling.

Its pectoral circled within 10 ft. just below me. Closer, closer. All covered with barnacles and white. I'm in the blows every time he circles now—drifting, odorless spray, very fine, showing rainbows.

He turned on his side, sank, and sulked, perhaps 30 ft. N of bridge, staying down 5-7 minutes and then began a tight circle again, 30 ft. N of pier—no bubble trails at all.

Hanging facing bridge 20 ft. ahead of him, right below me.

I see streams of bubbles from corner of blowhole as it faces bridge. Following that it wallowed into a tight turn, flippers and flukes showing and bubble bursts boiling to the surface.

Somehow it senses the bridge in the water that has 8 in. visibility at most.

There were probably 40 reporters all in a gaggle off to one side of the bridge and the CCC off the other side giggling in the bushes in their helmets.

As for the whale, it finally made its way into the bridge shadow, a thing that had dissuaded it earlier, and then bolted through. But by that time I was in a conference with Sen. Garamendi and the leadership of the Naval Weapons Station at Concord (where the nukes are kept). The whale hit obstructions under the pier and seemed to have trouble with its long pectorals, but made it through and bolted to freedom down the long empty channel.

Garamendi planned all the details—press, planes. Bruce Mati will fly in with a radio tag. I dissuaded them from trying to dry dock the whale (40 tons of whale can kill you). He is a handsome, articulate guy of 40—a liberal conservationist—a real comer—a Harvard MBA, Ethiopia in the Peace Corps.

At first I couldn't find my compadres but finally they appeared and we drove home, having dinner at the Terminal Restaurant—it was better than it sounded.

Does the whale echolocate? I'd guess it may in a simple way. Many of the clicks seemed to come from outdrives, not the whale, but quite a lot of grunts, chirps, and grates[?] did come from it as it maneuvered in the channel.

The whale clearly did avoid obstacles. It circled and avoided the banks, and especially it stayed some distance away from the bridge. It paused and circled from my estimated 200 ft. N of the bridge and refused at first to approach closer than 30 ft. or so repeatedly. It stopped, head pointed directly at the bridge, twice, for many seconds. Phonations accompanied these bits of behavior.

What could have mediated these things? Well, it could have touched bottom (about 20 ft.) with one of its long pectorals. But the circling in advance of the bridge or the stationing closer could not have been done with a pectoral.

Could the bridge shadow, which was cast in the water have been involved? This shadow hit the water about 10 ft. from the north side of the bridge and the whale came close to it but almost never entered it. The whale's eyes were located about 8 ft. from its jaw tip and would have been more like 12 ft. from the shadow when stationing. It's hard to see how the whale could have detected it from so far away given the 8 in. light penetration in the water. But, perhaps . . .

When a "cracker rifle shell" a concussion device, was later fired by CF&G personnel at the whale, the whale promptly ran on a sandbar and finally floundered its way back into the water, as if its navigation had been disrupted temporarily.

The streams of tiny bubbles are suggestive, too. They came from a lateral corner of the blowhole (right in one observation) and lasted two or three seconds at most. The streams of bubbles I saw were a foot or two long and contained a dozen or two dozen bubbles.

When we look at the tapes we will see if there are sounds with this many pops.

April 7, 1986

Granite Mountains

It's morning, and the food group has provided me with a splendid cup of coffee, so I've repaired to my bunk for a few notes.

We left Santa Cruz under threatening clouds and headed down to Paso Robles and thence over to Wasco. Frank Murphy and Steve Gliessman are driving—two steady, cool heads at the wheel. The class is a talented one—the 12th Field Quarter.

We slipped off to the Kern River Gorge under our big digger pine and it was still deciding about rain. Joe Jordan said a big low-pressure system was off southern California, so we were likely not to escape it, even out on the desert.

So we bedded down hoping to make it through. We didn't. Steve and I ended up under the bus inches away from a sharp metal projection that inhibited my movements. At least I found it before hitting it with my head.

The flowers are out in some force so we keyed a bit and listened to Steve tell about Mediterranean grasses and then headed over the Walker Pass, down into Inyokern, and thence out to the Garlock Fault valley. There we looked at pressure ridges and fault traces and talked about rotating blocks. Sarah Finnemore, a transfer student from Williams and I had a good time arguing about structures.

I slept to Barstow, and then enlightened one and all with tales of Pisgah, Hectorite, playas, and the like, until we cut off Kelbaker and wound up the desert road to the BC—all clean and secure. Many exclamations from first-timers as we stashed food and other stuff in the upper cave and prepared food. I got a nice fire going and soon we were cozy and warm.

Dinner out of the way, we settled in. I, for one, was a bit spacy and travel weary.

April 8, 1986

Granite Mountains

Steve and I started our guided tours, his a plant-community one and me, my observation stuff. I have a couple of new ideas that I talk about—one is the Gestalt—the soaking up of a scene to give you a frame within which to ask questions and the other the right brain/left brain affair. We really do impose pattern on our observation and it stifles seeing new patterns. But having got around the inner template in various ways, one needs access to the left brain for concept formation. Here's where the iteration with a notebook comes in. One thinks while writing and ideas come out of the pen tip. One deals, I think, in relationship at this level. The analogic mind is accessed for pattern and then the relational mind takes over. The playing out of language is an exercise in complex relationships . . . the ultimate symbolic representation. But seeing it isn't, except inside the mind. Math, since it sometimes has no access to outside real-world patterns and forms, is the ultimate relational activity—the play that explores the limits of such a mind. But it is militantly symbolic and hence digital and is only related with difficulty to the analogic outer world of graded systems and emotions and metaphors. Yet the evolved patterns of the wild are of these things—a world of ultimate interaction in many ways.

Yet life is also digitized at a very basic level. Vertebrae are divided into myotomes and articulated vertebrae, ribs and the like. Ganglia, lymph glands, rods and cones, nerve impulses, synapses, compartmentalize the analogic reality stream into manageable generalizable segments.

The class is a lively and talented one, and a diverse one. Some are very experienced. River runners, biologists, geologists, ethicists, artists, and more. We have our truck drivers, train riders, musicians, dancers, bird people, developmental psych, and outdoor ed people.

April 12, 1986
Granite Mountains

Well, much has gone on in the intervening days. It's a wonderful, diverse, lively class, and it's together too. Today I drove over to Granite Cove where Phylly was staying with Dick and Teresa and we headed up the new trail (the Monolith trail) to the Plateau.

Dick and Frank Murphy and I pulaskied and shoveled, and in the end produced about half a mile of a very nice trail up from the cove. We nearly reached a little plateau with a remarkable vista of the cove, Bristol and Danby Dry Lakes, and over to Van Winkel Mt.

It was a great pleasure to see a real trail emerge with nicely thought-out switchbacks and a nice granite gravel tread. Up above we have much work to do.

Joe Jordan was with us—he's been a wonderful resource person. He's a marvelous teacher and a warm, committed person and has given a good lot to us.

About halfway up I rolled a rock slab and there was a *Tantilla utahensis*, the black-headed male. Its head was gray all right, but not black; its body honey colored and its venter pale vermillion. I'd guess it was 12 in. long. Dick put it in a water bottle and we kept climbing.

It was a warm but not hot day, but the work warmed and drained us. I was pooped by the time we reached the little plateau and welcomed lunch sitting on a rock overlooking the sweep of the desert. Then, on and up across to Juniper Spring and over two bowls to the "Chateau Plateau." Dick and I relaxed, drank a bit of lemonade left by Adam and Holly for us. What a nice gift!

Later they came in, two warm and wonderful young friends having a special time with the singing pines and the scudding clouds. They seemed so happy. The cabin was full of evidences—notes on the wall: “Holly made 12 great discoveries today 4/9/86,” “Adam did amazing carpentry today 4/11/86,” for example. Such a simplifying experience! The mountain, no road or visitor most of the time, only the sun, the slow stream, the 12 wandering cattle, including a bull and two calves. The spring is ahead of the cattle—right now. The squaw waterweed is bursting with leaves. On the soil the *Eriophyllum* dots the landscape with butter yellow throats.

I showed them how to place the well point—they have it in the creek where the cattle walk. But there is a good place up under the boulders where clean water seeps out. I think there’s a good place to obtain clean, uncontaminated water. Maybe they’ll do it. Until then I hope these new chlorine kits will suffice. They put a few granules of sodium hypochlorite in and then purge it with H2O2. Makes nice water.

Well, we turned and hiked back down, Dick and I talking about the upcoming five-year review of the reserve. Then, after letting the *Tantilla* go, we spent some time at Staples Ranch psyching out how to rebuild it.

Now I’m back in the BC after dinner and ready to go to bed. We shove off at 8:00 or so. I’ll pick up Phylly and will be off to home.

Steve Gliessman’s Journal

June 6, 1986

Grandview Campground, White Mountains, Inyo Co.

This morning as we all sat around talking about our unusual and off-the-wall “exploits,” I began to feel a certain unexplainable discomfort. It hung around into the morning as I was reading journals written on that jewel of an island we were a part of for a week. And then, as I read into one journal, something happened. One of you was having difficulty being with yourself, of being with the island, and took off into a several-day verbal dialogue with yourself, of why you are here and where you are going. This is something I’m sure all of you are asking yourselves as this Field Quarter experience reaches maturity. And as for many of you, your University experience begins to prepare its seeds for dispersal out into a very complicated and troubled world on one hand, and a very powerful and beautiful world on the other. This past 10 weeks, we’ve all been able to share and learn from this second side of our world.

We began with the wonderful calming nature of the Granite Mountains and the patient yet tenacious desert. We began to see the pattern and process in nature, shedding the weight we each had been carrying at home as we run our seemingly endless but necessary circles with ourselves. We began to feel each other, feel the sun and the wind, the plants and the animals, and especially the sand . . . I had to go under for 24 hours myself to shed some of that weight—weight that as a result, I got to see had really gotten to be too much. I realized change had to come, and soon.

Then you were off to Big Creek. I missed you all a lot that week, felt pulled away from the connection that had started to form, yet was able to deal with an altered perspective with all of those things I do in Santa Cruz. That process is really rolling for

me now, and I'm excited by what lies ahead. Yet, I needed yet another reminder of how my energy flows, and you experienced it very directly (my throat) on Santa Cruz Island.

Oh yes, the island . . . It was wonderful to share it with you. Did you feel that something special about it—that islandness? Weird, different, special—all sorts of different senses were awakened in all of you. Blue sky and blue ocean all around us. We were alone. Discomforting in some ways—very comforting that we can be alone in others! The plants (and animals) reached out and greeted us—showed us their uniqueness in many different ways. Each of us found ourselves in different ways too—under the green water of the pool, in the 30-ft. jump into it, on the beach that its water eventually flowed to, in the amazing wetness that the island seemed to have to generate that pool, or under the kelp forest surrounding us. I got to learn some new ways to “tell” you about it without so many words. Thanks for listening. A special, special place.

Then north we went, to the wonderful Smith River, on our way touched by the Douglas fir and greenness of the Nature Conservancy Reserve near Branscomb. Something I think touched us all as we explored with both Conservancy caretaker and part of the local heritage[?], what it means to preserve wild lands. That entire trip, apart from the beauty of the water, mountains, plants, and animals have awakened, strengthened, and intensified both our rage with what we see happening to our natural environment, and our determination to really have an impact on what happens from now on. Our manifesto expresses this so lucidly.

As you headed east on that trip, I headed even further east—to Detroit, carrying with me all of you and where we had been. A different forest—inner-city Detroit and the Kellogg Company, but similar processes—an urban environment crying out for help and seeing different ways people have decided that they will make a difference. Real compassion exists in our world, and I see it in all of you.

Together again, we traveled over the immense Sierra Nevada, so impressive that they seem surely capable of withstanding human onslaught and disregard—but we've learned otherwise, and look forward to changing that. Mono Lake was our resting spot for a few days—as it has been for centuries for all the migrating birds that count on her for refueling, nesting, or sustenance on their life journeys. And we learned how disregard for the rights of one part of our world for other values has placed an entire ecosystem on the brink of death. As we've learned this quarter, due to the interconnectedness of all things, eventually it will catch up. And we can no longer think that it will catch up so far into the future that it doesn't matter—we've had some important reminders during our 10 weeks—Libya, Chernobyl, Hardscrabble Creek, brine shrimp, a timber lease, a night call of the sawwhet owl, or snow melting on the mountains above our camp. And, it was especially meaningful for me to share Robbie with you all. She saw me with you, and she experienced all of you. And you will all be getting the official invitation to our September 7th celebration of life and loving in a few weeks. We hope some of you can be there, and I know all of you will be, no matter where you are.

Now we are here at our last stop on this special journey within the journey we are all on. Green against blue, merging through gray (or is that *Chrysothamnus* green?). The seed planted 10 weeks ago has sprouted, grown, flowered, gone to fruit, and produced yet more vigorous seed. The never-ending evolutionary process awaits you all, and the sweepstakes raft is ready to cast off!

So where did that discomfort I felt this morning (it's gone now) come from? I guess it was some inner realization that during those times we were talking about, that I had a lot of disregard for others around me. I was not aware of the impact I have on others, no matter what I do or how I act. I also know I needed to go through that time in order to learn—to learn to regard, to revere, to understand, to love. I also learned that I can (and have the responsibility to) have impact on what, and who is around me. It's like at this moment, by knowing this, I can complete with you all, and share with you the shift that happens as we go from disregard to full interconnection. And I learned a lot from each of you:

Michelle—sensitivity
Lisa C.—joyfulness
Diane—strength
Kim—delight
Joel—reaching out
Wyndham—lightness
Sara—commitment
Tom—eagerness
Eric—simplicity
Bethany—thoughtfulness
Hank—determination
Lisa K—growth
Chris—acceptance
Maria—delight
Susan—playfulness
Frances—expressiveness
Ann-Marie—openness
Peter—risk
Bill—dedication
Rebecca S.—warmth
Heidi—happiness
Rebecca W.—centeredness
Stuart—yearning

And Frank: another year to share this odyssey and give it away. You've done an amazing job, again.

And Ken: good friend, colleague, and teacher. You've done it again—been totally yourself and shown each one of us how to do the same.

I guess I feel a little like a plant does (!) when it lets its seeds go. Yet I feel mostly a surge of hope.

You'll do it—whatever you choose, and in this context of responsibility and commitment we've developed for each other and our wild lands.

You can do it
You really can
Let yourself do it.

A couple of favorite sayings:
It's not where you are going, it's why you are going there.

And remember:
the process of getting there is the quality of being there.

Thank you all, and carry a blessing from the god/goddess/all that is, we've been able to experience together.

June 6, 1986
Grandview Campground

Thoughts At the End of Field Quarter 1986

I've taken my chair up away from camp a couple of hundred yards where the voices of classmates have begun to lose their words. The babble now carries only the happy emotions of camp life, like squirrels chattering softly to each other as they bask in the sun at a burrow entrance.

My back is to the high mountain sun. There is a clarity and sharpness to its light as it warms my shoulders deliciously while my arms are still cool.

Down across the open slope, shingled with dull, brick-red Polita shale fragments, I can see the Sierra between gray-green pinons. The short section of ridge I can see is the Palisades Rim, where a tiny glacial fragment still hunkers in an north-facing cirque, now under a blanket of snow. Above, the ridge juts into the china-blue sky in jagged slabs and fins of pale purple.

As I settle to write, I hear a tapping behind me. I turn, and 50 ft. upslope I see a hairy woodpecker busily inspecting the bark of an old patriarchal pinon. The bird bobs this way and that, peering under slabs of bark, and now and then it probes with an authoritative rap. I'm surprised at how much force is involved. Fragments of bark fly and fall into the cuff. I thought I saw the bird catch some bark insect, and then pause, its long bill slanted up. What caught my attention most, though, is that the woodpecker backs down in a spiral around the tree as it searches, more than it moves upward. I see it use its stiff-pointed tail feathers as props in this curious locomotion. Then the bird hustles off, swooping with spaced wingbeats, to another tree upslope.

Light makes beauty here. The pinons are gray-green puffs of smoke against the blue sky. The buckwheat mats are handkerchiefs of palest greenish white scattered broadcast across the open spaces. Deep in the Great Basin sage clumps, the sun lights silvery bark and little tracts of tan soil while the deep recesses are black by contrast. Not so under the pinons where needle duff and fallen cones tinge the shade a rich brown.

I settle in my chair and begin to think about our times together. Our journey, I told you, would be a quest for the "wellsprings of caring about the land and its life." All of us would seek to know why these natural things were so obviously precious that many of us should seek to devote our lives to them in some fashion.

Why after all, should Susan and Peter choose to inject new levels of indignation into the rules I wrote about land stewardship? They too, I thought, must feel to the depths of their being care for this land.

I think there has been an unfolding of each of us going on during our journeys and it has centrally to do with this question.

We have searched in several distinct ways, I think. In one path we divided and classified and analyzed. This is a very human approach, I think, since we people divide and classify everything.

Here we've looked with the analytical tools of science, seeking pieces to our puzzle that one day we may reassemble to find understanding.

On a more visceral plane, we've shared the magic of water together, watching it run turquoise and amber in the still free eddies of the Smith, and felt it bubble and cascade, cool, across our fanning bodies in Wyman's Cleft.

We've looked with lilt and humor knowing that eyes are open when full of laughter. He or she who jokes, I feel, is not so filled with certitude as to be blinded, but instead is free to recognize the absurdities and inequities of our human world.

We've practiced looking with a child's eyes. The child has no pretense and we've sought to look without that particular scourge of adulthood. I think that he or she who can look with the wide eyes of a child also escapes the reductionist trap that leads down and down into less expansive realities until all chance of understanding the broader pulse of the world gutters out and disappears.

Those same wide child eyes lead us to love. We can now speak of the growing affection we feel for each other as each of us lets the others in.

Make no mistake about me, when I pat you on the shoulder or tell you how much I treasure your presence, or give you an embrace—it's no teacher's stratagem. It is because you are no longer mere members of the passing student parade, or mere names on forms. Each of you has emerged in vastly richer terms. Each of you has unfolded an utterly individual persona of worth and commitment, and each of you has somehow touched outstretched fingers with me.

This emergence has been of two sorts. One salutes your wonderful diversity and the other our commonality. The commonality is an almost wordless love of the world and its life.

We now search together, where at the beginning we did so alone. Just as we perceive our commonality of purpose we grow more accepting of each other's diversity. The poet, the artist, the teacher, the artist, and the scientist become equal partners in our seeking. Even our tools merge. The artist casts aside the mind's stereotypes in order to see and hence to draw, and so must, we find, the naturalist. The words of the poet must be selected with greatest care in order to capture the essence of things, and so must those of the aspiring botanist who would conquer Munz.

Even the music that has floated upward amid the smoke of our campfires carries with it emotional freight and access to wordless communication. We communicate on many levels at once and it speaks, most basically, I think, of bonding and reaffirmation.

Speaking of bonding, I must confess that in spite of your valiant efforts, I remain unbonded to lentils, those scurvy, sawdusty, flavorless little flying saucers from another lesser planet, and only lightly to tofu and yogurt; but then you can't win 'em all.

On everyone's tongues at many places in our wanderings has been that curious thing we call beauty. But maybe it would be better to call it a deep sense of rightness, of a world working by time-honored rules.

The silvered and decaying branch of a pinon is beautiful but it is also . . . [cut off]

Beauty—the mountain clasps me, as it does you, in its peace, touches me with its whispering wind freighted with desert incense, and in every fallen silvered stick, every cone, every shadow and every swooping bird, every musical stone clinking under my feet. I love this land and every other place we've been, to the deepest recesses of all that I am.

Science has revealed many of the beautiful things I know about it, the tiny worlds within worlds, plants and insects tied in evolutionary bonds, the magical senses of migrating steelhead, the subtleties of dolphin minds, the linkage of light, physics, and a lizard warming on a rock, the miraculous unfolding of a primrose, timed to meet its special moth.

Yet the power of these things stems from a broader view that encompasses them all, not their reductionist elegance.

It's when they become parts of a grander scheme that lets us listen with understanding to the silent ticking of the mountain that we find that our human cadences are inescapably linked.

That turf, we find, can hardly be seen through a single window. It is equally the property of the naturalist, the poet, the musician, and the teacher.

There is in short, not only a place for the diversity in each of us but a necessity that we pool our views to understand "the wellsprings of caring."

I love you all,

Ken

Joel Dunlap's Journal
June 6, 1986

Last Day

A bittersweet day. Like the lives of the plants and animals we've been watching. This quarter, this sharing, this love is ephemeral in its immediate expression but immortal in its memory, future, and new paths. This is the 44th day of our time together, and I know it's going to be missed, but I think we've all been touched in ways that won't fade so easily. I know I have, but if I had to tell you just how that feeling of being touched happened, I couldn't really put a finger on it. Part of it was learning. The plants and animals I've seen and come to know to some extent have taught me about life strategies, processes, and forms—some simpler than others, but all amazing in how truly complex they really are, with morphologies, physical laws, environmental pressures, biochemical processes, and whatever else entered into their creation and sustenance. It is also the sharing. Ken and Steve gave their life's passions to the telling of all these stories around us. Cosmo Joe and all the people of the group gave their particular inputs. But it was certainly no sacrifice for any of us. Whatever was given came back 25-fold. And most of that was in fun and really a genuine love that's developed. Time passed together with

both nature and people is also a large part of what this experience has been, too. There's a sort of knowing and feeling of closeness to another that only comes with time, and only comes with a sort of unthinking mind. Time passed is an accommodation too to comfort in and patience with what's around you. Time-spent knowledge co-evolves with facts and interactional knowledge that one gets from talking to a person or watching a plant. Fun has been a huge part of it. We seem to be naturally for having fun. Those that live with a sense of fun as a driving, sustaining force have a strong capacity for living and learning.

And so it ends soon with Bluebird of happiness flight back across Tioga Pass. But it won't pass badly. For gaining a piece of what makes life wonderful and full is never lost, and is exquisitely felt. The singing goes on even though the music may stop. And the world we entered for a quarter will be there, in the trees, water, and hearts, longer than most any of us know.

And so we all say farewell to a quarter that's been nothing but swell. Though the lizards will rest easy even though their stomachs are queasy now that we've stopped giving them hell.

April 13, 1987

Granite Mts., San Bernardino Co.

It's about bedtime on the first day at Granite Mts. for Field Quarter No. 13. The dinner is being cleared away. Guitar music floats in from the porch, where the clear cool light of the full moon lights the rocks and desert. Even so, lights twinkle from the 40-mile stretch of highway over by Goff.

We've had some nice soup and garlic bread and a good salad with wonderful dressing.

The fire burns down to embers and the three Coleman lamps wheeze and grow a bit dim.

The people emerge. Vibrant, tentative, wonderful, various. There are strong personalities, some of great simplicity and warmth, a struggling, preemptory one, and on and on. It unfolds and will take as long as we are together.

We saw Dr. Vandenberg today, and it was one of the best visions ever of the great Dr. V. We approached a roadblock manned by Caltrans people. One with his back to us held up his "stop" sign and as we slowed, he turned toward us—a fine white beard and mustache graced the face beneath the white plastic helmet. He waved and smiled and turned his sign to "slow" as we passed. He had hidden from us in his orange jumpsuit till the last moment and then turned. A hot tip, a good one, a few tricks, we decided.

I'm pooped and ready for bed. The flowers are scattered and patchy and not much is out at the BC.

Tomorrow we do "observation sessions" and a Frank Murphy trip to handle the plant communities.

Off to bed.

Observing

Not so easy as it seems to do it well.

1) The Gestalt—the baloney filter. Soak up the behavior wordlessly to form an idea of what really happens, against which to later test your questions. You'll come to know what questions make sense.

2) Right-brain Activity—Getting rid of or getting around templates. Going back to childhood before the templates formed.

3) Removing Yourself from the Equation—So many things that shut your eyes.

Physical discomfort (phenocrysts in gluteus)

Internal stress, mental unease.

Not being on mountain time—questions of pace. The pace of bugs, lizards, mice, whales, starfish.

Macho—turning inward. Nature is the authority.

4) Asking Questions—Spinning the Wheel

Experience, knowing what living things do.

Your experience.

5) Throwing-away Muscles

Must be as strong as those devoted to acquisition.

6) The Journal

Thinking out of the end of your pen.

Precise words.

Measuring words directly against reality—and memory.

Quantifying as a way of seeing.

Complete sentences. An indication that one is reading mountain time. Events in nature are complete, with subjects and predicates. When one uses telegraphic language one leaves out vital elements.

Proof: The step beyond seeing usually consists of proving it to others. Biology, being stochastic, requires numbers to describe it. The interrelation of everything.

April 14, 1987

Granite Mountains

Today I took out two observation groups; one to the S. and one to the N. The first wandered down the wash toward Floyd Dominy Dam. The day was moderately warm and rather few flowers were out, though we are told there is a good show over by Budweiser Wash. There is evidence of a considerable downpour here in bent-over willows down by Willow Spring, and by erosion of the river bed below the house. I suspect this was too recent to affect flowering here.

My first group looked at *Daphnia*, which we found in squirming aggregations at some places on the little stream issuing from Floyd Dominy Dam. It leaks underneath,

and I will have to go down with a shovel to see if I can find the exact source. My guess is it's leaking under the south limit. It should be rather easy to fix. We'll see. It is a splendid structure nonetheless.

Our *Daphnia* are amazing little critters—little valved animals with legs and antennae that can protrude. They can open or close the valves and protrude some sort of mouth parts to scour the surface of tiny sand grains that I suppose have accumulated algal films. Even though they suffered considerable predation from the larvae of _____ that was fairly common in the water, they seemed to show no evasive maneuvers at all. They seem to rely on the disparity of numbers, which was great. I wonder how long their life cycle is.

The other hike concerned aggregations of little dipterids over water at Cottonwood or Cove Spring. I found essentially random, evasive maneuvers. There too, with the lateral or horizontal dimension exaggerated. That is to say that the movement of individual flies wins. [??] dominant horizontal, but still possessed of random features.

We hiked back in the gathering dusk with a great smoky moon lined with blackish cloud strips.

I'm in front of a nice fire and will soon go to bed.

April 16, 1987

Granite Mountains

It's afternoon. the sun increasingly slips behind the ridge and the shadows of rocks and the cabin lengthen to the east. The heat dissipates as little cool breezes come from between the rocks. It's still parched and baking out on the bajada. Here on my bunk my only annoyance are swarms of gnats that seek out noses and eyes and exposed skin. A hat discourages most of them. Voices of students keying plants and discussing toads amplexing down by the dam drift in the window.

I'd been down there all morning tracing a leak in the new dam. Hot work, and I did find a place where water simply went under the dam. The old dam had not gone down to bedrock as advertised, but simply deep into the gravel in some places where the clay layers had been broken, and water just went down and under. I dug out quite a bit of the face and then ran the water away from the dam and down into the arroyo below.

I think a good trench, some more cement, and a little bentonite may make it all work.

Where the muddy water swirled slowly below the dam, I noticed little arcs of clear water and then could see a *Daphnia* at the head of the track. Close inspection on hands and knees in the muddy creek edge showed them to move through the opaque water, leaving behind a little clear wake. I presume the animal was filtering as it moved along. I watched to see if there was a cleaning maneuver for the filtration apparatus, but I never saw a clear example. Some of the traces were about 1-2 in. long before the little critter dipped out of sight into the murk.

Mosquito larvae left wonderful eddy swirls, alternating from side to side. The larvae popped to surface now and then, hooked to the surface and breathed, only to switch away in a swirl trace.

The class straggles in from various observation ventures and everyone chatters, photographs each other, shows bones collected from beneath an owl's roost, discusses

keying plants, stumbling over family names. Denise works happily in the midst on her presentation of mines of the area.

April 17, 1987

Granite Mountains

We're back from the dunes, and most of us are taking it easy in the afternoon heat. It's bright and still and hot, but up here in the cabin it's shady and breezes cool us, though gnats insist on landing if noses and eyes are left unguarded.

My skin feels nice from a dunk in the water trough that almost everybody shared. We had sand everywhere, and it grated in a sort of cosmic, full-body discomfort. To remove 95% of it in a single dip was bliss and then to stand on the granite apron near the pond and dry in the sun was to have been transported. That was followed by a nap and now people straggle upright and take up notes or other activities.

We left at dawn. Frank had quite miraculously mobilized us as the skin faded from pink to blue. We chattered over the washboard to the parking lot S. of the dunes and got out while the sand was still cool with night. The dune primrose (*Oenothera deltoides*) was scattered sparsely about, almost ethereal in its whiteness. I knelt to photograph one and then a dune *Astragalus* in bloom.

No umas were about at first. We did find a couple of sidewinder tracks, but they ended at burrows, and we did not see a snake.

It had been a still night. Marks were everywhere. Beetle tank tracks, compass marks of rice grass leaves on the sand, the humped lines of *Arenavaga*, and a track of a road-runner—big, sprawling feet, all claws and joints.

On we went up to the bivouac under the desert willow trees at the base of the main dune. There in the sparse shade we shed shoes and much other gear for the climb up the smooth arcing surfaces of immaculate sand above. I cautioned everyone to carry a pair of socks if they took off their shoes, knowing how fast the dark magnetite can heat to searing temperatures.

It was my 14th climb, and I was very unsure that I could make it because of my knees, but the pain and swelling had faded, and gave me no special trouble really. Just slog, slog, a step at a time. I counted 20 paces on the steep slopes and closed my mind in on them until I paused for breath. I've had harder assents for some reason and reached the crest pretty easily. I gathered the people around to listen to me talk about dunes, even though they were anxious to test the "booming."

I told them of the Tule Arroyo Dune, its wake, its way of moving and pointed out the venturi that I think exists at Kelso Dunes, aiding in forming them. Then everyone, or nearly everyone, stripped down and stood holding hands on the brink and jumped. They went sliding and rolling clear to the bottom and the mountain thrummed in its loud, deep voice. An ear put beneath the sand gave connection to the mountain itself that hummed so loudly it penetrated one's very soul it seemed. I could feel my head vibrate in the intensity of it.

I didn't slide for, being content to watch the others gambol and slide and cartwheel down, and then to struggle on hands and knees back up the 37 degree slope.

It has its magic, this dune and this rite of leveling together naked in the sun. There is trust and sheer animal pleasure, usually masked. There is the connection of brown bodies against the precise slope of the tan sand. The immaculate slope, the curves against

the flawless blue sky. It's a giant sandbox, too, to play in. It's open and it's safe. I made it clear that everyone could be his or herself and we had plenty of room, for no one to feel social pressure—and some just removed tops and one stayed behind, which we all respected without comment.

An almost visible tightening of the group resulted as it always seems to do; people were freer, they lounged more, with legs propped against the seats of the bus; they took their naps less self consciously and rapidly moved toward a cohesion and ease that begins to make this spring experience an odyssey from which all can look out, content that the group is there in support, in a land of gentility and support.

I always find this process a bit miraculous; especially the watching of personalities, hopes, fears, unfold.

Frank's off around the base of the mountain to tell Philippe that we want to go road riding tonight instead of sticking around for dinner.

Gerry Hillies and three congressional aides in the Land and Energy Committee of the Senate were here last night. This coincided with a fine presentation by our people on history and land use issues. The people liked it, I think. They were under some bombardment by Gerry about the upcoming Cranston Desert Parks Bill. One aide, named Tony, was a real kick—an older, pot-bellied guy with a sharp wit. He navigated his belly between the class members, saying, "Stand aside, woman and child." He announced that all congressional staffs were run by girls named Cathy or Pat and said the bill probably wouldn't make it this year because Pete Wilson hadn't co-endorsed it.

The discussion on the deck was good, solid stuff with enough of the tough issues emerging to make people think. I snuck a carne asada from Bob, the district manager's grill and later as the Colemans dwindled to one over diehard notetakers heads in the cabin, drifted off in the warm night [??].

April 19, 1987

Granite Mountains

Well, we made the loop to Hole-in-the-Wall and back uneventfully—nice weather, with the usual main events. It was hot down at Essex and at Cadiz, but even so, we found a fine old lady tortoise out on Kelbaker and all went well.

Then today I worked on Floyd Dominy Dam while Frank led another bunch up Cottonwood Gap to Granite Peak.

I had dug down along the dam pretty sure that we had a leak somewhere. The little stream below seemed to be fed from the dam somehow and by rights all water should have been pooled above the dam. Sure enough, I found a place where the old dam had not reached bedrock. I could almost stick my shovel under it right where water boiled through. So a crew and I trenched all along the inner face, finding only the one leak.

Philippe Cohen and Cindy Stead had brought the cement mixer and our five bags of cement. So we hauled all this down and Jim Keller, Tim Rush, Christine Fritz, Shannon Scott, and Andrea Nelson, and I started to dig and pour cement. Chris and Shannon became "mud maidens," preparing a slurry of clay to block pores in the gravel while the rest of us dug and cemented. The mud maidens decided to paint faces and legs with mud—bunnies in honor of Easter. I saw a picture in the making and ran back to get my camera. By the time I had returned another group had arrived, stripped, and were totally plastered with mud. I received an annointment—a Lincoln beard. I promptly put

them to work shoveling sand over the dam. They dug a respectable pit in a half hour or so. The patch may hold—time will tell.

That evening, the groups straggled in and finally only Joe Jordan and Mary Moreno were missing. It grew dark and still they didn't come. I walked the road calling to the cliffs with only echoes for an answer. Finally I decided at 10PM that Frank and I would head for Philippe's and contact the Sheriff's rescue team. Finally that time came. People had more and more realized the tenseness of the situation. Fortunately it was a fairly calm and not very cold night. Both Joe and Mary had worn only light clothes and had just a few things in a backpack. They had lagged behind Frank, who, though he had waited, never saw them.

Philippe called the Sheriff and after some waiting we got through and their emergency team was soon signed on to arrive at 3:00 AM, about a dozen of them. Frank and I drove back to find many of our crew up and waiting for news. I put them to work assembling a list of supplies for two of our teams. Frank would lead one, including Jim Keller, Rob F., and Karen Goodell. The other would be led by Tim Rush and would include Cindy Stedd (who knows the trails), Ingrid Booth, and Mack Travis. Two runners, Martin Skeper and Jim Scholland, would provide communication between camps. Gwen took charge of food and Tim Burnette assembled supplies. It was all done fast and with enormous goodwill and concern, as everyone thought of the two out there in the cold night, and perhaps hurt.

Fitfully we slept. About 3:00, on time, arrived a great crew of old boys with a full rig. They camped out in front of the B.C., a winking long line of lights in the yucca scrub.

I drifted off and somewhere near dawn, Joe appeared by my bunk and in a tentative voice told me Mary was in the bus, where they had laid out bags to beat the wind. I put my hand on his arm and could feel his tense muscled arm quake in the night chill. He was in a thin flannel shirt, an undershirt, and his shorts.

Joe and Mary had misjudged time and arrived off the plateau S. of the Monolith at dusk. They had tried to clamber down one of the boulder-choked feeder canyons and their flashlight gave out. Joe did it a step at a time, helping Mary down the big jumps by catching a dim glow as the flashlight charged. Mary had been tangled in catsclaw and had banged her head. Joe held her and rubbed her to bring warmth and she fell asleep for an hour and then they began again, finally emerging and hoofing it around the base of the mountain. Joe met the rescue team. They were elated not to have to call in the helicopter or to go up the mountains themselves. I roused myself to thank them, but by the time I made it down the hill many had left. I did express this to a couple of them and will write. It was a very comforting feeling having them there with their obvious professionalism and excellent equipment. They were specialists in mine rescues, having tripod gear to hoist people from vertical shafts. As Philippe put it one of them had a tonto complex, looking for footprints in all the washes, even though 29 students had tromped it all, and our people were almost certainly up the mountain.

About 5:00 AM, after I had drifted off again, Philippe burst in the Bunny Club door saying, "Ken, Ken, you want to see my injured owl?"

I was dazed with sleep and replied something like, "For Chrissakes Philippe, an injured owl at this hour?"

I stumbled out to see a barn owl wrapped in a blanket with a broken wing from gunshot. I could make it out in the dim light but soon enough went back to sleep. At last report it is hopping around Philippe and Cindy's living room and may make it.

Later in the morning I visited Joe and Mary in the bus. I gave them a hug and told them we were all elated by their safety and to stop worrying about feelings of guilt. They were cheered as they came up on deck and not a trace of recrimination had been heard. The group tightens.

April 20, 1987

Granite Mountains

We empty the outhouse today—another plastic experience. We also ran the great experiment with Karo syrup to see if waves go up a syrup stream to make it wiggle, or does the wiggle start at the top.

We set up a ladder and poured from roof height onto a great pancake cooked (and flipped) by Rob. We tried to see if putting a knife edge in a flowing syrup stream would propagate a wave back up the falling stream and we tried flowing syrup over a knife edge. Kate and [?] did this, and I thought it wiggled lots more, but the test was not definitive. The notion is that a waterfall flows over a knife edge and that it acts like a flute that induces a vibration in the column of water (or air).

I'm told that sometimes this can cause whipping of a waterfall and noise that can be quite overpowering.

The other relation is a Fronde number in which a ratio of rate of flow of the fluid (the syrup) is less than the wave propagation velocity in the fluid. A wave will travel up the fluid from below producing a series of nodes. The knife edge test also shows this. I must say my test was less than conclusive though it did offer a priceless photo opportunity and I thought Kate's knife edge had probably worked. The column did wave fairly widely. [Drawing]

A final note. We found that the Sheriff's Rescue Group thought our request might have been an Easter prank. They put together the following elements: Easter, Joseph and Mary lost, Mary's last name was Moreno, which means sheep, Joe's—which is Jordan. Well, I think they were relieved to find it was on the up and up, since some had driven all the way from Apple Valley 100 miles or more away.

June 2, 1987

Aquatic Res. Lab, Sierra Nevada, Mono County

We've invaded SNARL's new dorm, which is a grand stash for about 25 students. The food group is thrashing around trying to bake two potatoes for each of us (56 in all), mashing avocados, mixing salad, and making garlic bread. A royal feast, I say.

It's been a long, sometimes draggy day for me but I'm ending it on a high note just watching all the activity and camaraderie as this event unfolds.

Andrea is out tromping over the meadow outside the windows chanting a Beatles song. Marion is eviscerating avocados into guacamole. Several others construct salad and others of us write notes, play flutes, sip beers, sit crosslegged under the big windows, jagged Convict Peak jutting skyward. A gigantic moraine all but blocks the view.

This bunkhouse is a wonderful, functional stash. Dan Dawson has been a great guide. He took us up to Valentine Reserve nearby and lead a nice walk through its diversity. It is a small (150 acres more or less) place with a wonderful untouched meadow, a chaparral-covered hill, a lovely waterfall on Mammoth Creek, and a nice forest area of lodgepole pines, Jeffreys, and white and red fir. Down amongst the trees are cabins, nice log affairs with good stoves, bedrooms, etc. I think I'll contrive to have Phylly and me up here for a couple of weeks next summer to look at lupine sapphires.

June 6, 1987

Grandview Camp, White Mountains, Inyo Co.

Thoughts At the End of Field Quarter 1987

The mixed rain and hail sheets down outside the bus. Our windows are steamed opaque by our warmth. We sit lined up in our seats strumming guitars, writing, filling time. My fingers rub on the glass and clear a window to the outside. I see silver drops grow and fall from pinon needles onto the springy duff that grows ever darker with water.

We near the end of our long wander; most of the rest is going home, back over the Sawtooth "Range of Light," down across the ancient island arc basins and onto our wandering continental fragment that happened to dock at Monterey Bay.

Each of us has emerged in these last weeks, like a slide coming into focus. We were all cut-outs at the beginning, just names, positions, appearances—nothing more. The textures of warmth, wit, and care only unfolded with time. Now we can play in the mud together, or pass a laugh across a vacant desert road by jiggling each other's tummies with our heads. This is a wondrous thing, really. Twenty-eight remarkably diverse people finding that they can laugh, care, play like children, and see together. Down in their deep recesses people everywhere must be like that. In that possibility, which we made into a local capsule of reality, lies the hope of our world, both it seems for us and for the wild things of our world.

Yet in another sense we began different and we end different. For some, because of the clear space they now occupy, opening their eyes to the mountains, the clouds, and the bird song has been simple.

For others such "seeing" has been a more fitful thing. Their eyes and minds have sometimes been restrained by other imperatives. "Seeing," we find, is not so simple as I portrayed it at the Granites. There are more than phenocrysts where one decides to sit that can obscure vision. The buffeting of our lives, too, shapes the clear places through which we can see. Windows are fogged by more than the demand of our "creature selves."

The chatter and subtler concourse of our sociality demands so much of our attention that we come to treasure times of solitude, demand it even, to clear away the clutter of relationships, let our vision clear, let ourselves hear our own heartbeat and reach a simpler state.

But once alone it seems only inches away from those comforting, consuming words and laughter to the all-embracing impersonality of the mountains or the river, the vastness and austerity of the desert or out into the imponderable abyss of space.

In such a jaunt as ours, we have looped away from civilization and back again. We find ourselves pulled back as if on strings. We look for the assurance that our pack contains its flask of water, and a sandwich before going farther. Why should we bother to dare such times alone? Why not just surround ourselves wholly with the artifacts of our own making and with the members of our own kind. In other words, why try to be a “naturalist” at all?

Well, first there is beauty unlike in its perfection to anything contained in a city. It never fails to appear, on any mountain, in any wash, especially when one is alone and can see.

The fluted wood of a sleet-etched bristlecone trunk or the welling crystal water of Wyman Creek as it slides over a perfect pavement of amber, black, and tan pebbles has its counterparts in every naturescape.

Those things can reach deep into our emotional center, somehow in an ecstatic embrace together—we and the mountain. In the last analysis we then find that we are truly home.

Steve and Frank and I have made this curious assumption that atomistic analysis of the pieces of our world is not enough and that by looking together and at everything we could come to know the most important thing. In our long wander we have attempted to take in the natural world whole and examine it with group vision and collective intelligence.

In that attempt we say, are to be understood the connections that knit the world together, with us as a part. In it is the route to balance about how we deal with the world and with each other.

In fact, it is an article of faith with me that our only real chance of caring for both humankind and the world is to know both as well as we can possibly contrive. The world is simpler to see clearly than ourselves, I think.

“Know oneself, Know one’s world,” and then design accordingly. So armed with the best approximation to truth that one can devise, the path becomes possible, the naturalistic ethic will be shaped and we will perceive paths to guide us. Unarmed in this way, wrong turns prove to be ubiquitous and no sign corrects our mistakes.

So, my dear voyagers, our various journeys of seeing and understanding have just begun. I embrace you each, as precious new-won friends and fervently wish for each of you, in your own time and space, the continued pursuit of the vision, and of the gift of clear eyes and mind, with the clarity and simplicity of children, whose windows carry no film of vapor to obscure seeing the drops of rain falling from the gray-green needles.

With deep fondness and respect,
Ken Norris (sometime spam fairy)

April 11, 1988
Democrat Springs, Kern Co.

Field Quarter 14 landed here on the tanks of the Kern at about 5 PM, the day warm and still. Now dusk comes on and the sky light dims. I have my sleeping bag on the bank and am sitting in the quiet, listening to the murmur of voices. Everyone jumped in

immediately to cool off when we arrived. I'd guess it to be about 80 degrees F, still, and really quite lovely and calm. The gray-green river flows by in a very wide pool; above I can hear the riffle over on the opposite bank. People come together but still have much distance between them, especially the shy ones who still wander alone by five yards, or sit still on the sand, 15 ft. from the nearest busmate.

But the barriers fade fast.

We catch an ant lion larvae and watch it burrow seemingly faster than we can dig. I like the group; everybody seems centered and direct. I don't see the removed ones who can go either way—learn and experience more than everyone else, or disrupt.

The light fades, the creek shimmers dark and rippled, bright with sky light. I have my folding chair and sit on a sand bank at the river's edge. Not long ago I took a quick dip and emerged feeling clean, my skin smooth.

The ice is breaking; we come together and tomorrow we go off up the canyon, into the ecotone, the joshuas, the *Cercis*, and flannelbush, and then over Walker Pass and down onto the upper Mojave.

The year is inordinately dry. The winter rains quit very early and now brown swales show between the oaks and the spring flowers are fading fast. Pink clarkias poke from the hill slopes as we drive by and *Encelia farinosa* is in full yellow bloom. But most has gone by as summer comes early. What will its depths, in September, be like?

April 12, 1988

Granite Mountains

We drove down 395 through rather arid desert—desert gold gone by flooded between the bushes north of the Barstow road.

We got last food and stuff at Barstow, viewed three Vandenberg, and then headed out.

Dr. V. had a black streak in his beard, but one in front of Safeway had a pot belly, mumbled to himself, and stuck his cigarette in his ear—all good signs.

We arrived before dusk and got in and set up. Philippe and Cindy came in and then Roger Samuelson who had been fooled by a trick lock and had to walk in.

Everybody is wearing in nicely. Roger gave us a long technical/legal description of what it was like to put a reserve system together. I think it was generally well received.

April 15, 1988

Granite Mountains

Yesterday was raw and cold and from time to time it rained, sometimes pretty hard. The creek came up rapidly, at first muddy and then running clear.

A fine group went with me morning and afternoon, one looking at *Populus* leaves and one a *Penstemon*-like flower—*Keckiella*, which we described in detail in order to key it out. The last session grew rawer and rawer and when we quit I was close to chattering teeth.

At dusk we hit the cabin, dinner, and presentations.

I wrote a long, imaginative journey with Virginia Parrish. We became very small, walked among the crystals, rode in bubbles on the water, encountered yellowjackets and more. Great fun.

Then we snoozed off. This morning we took the circuit. The dunes were dark with rain and the clouds low over the land. After a nice hike in Hole-in-the-Wall we headed up the road just to the south and up toward the crest. We found a mountain capped with lava over whitish ash beds. We hiked up a brush-choked wash, the white float of opal (amorphous quartz) scattered in the wash. It began to rain and we were soaked before we got back. Low clouds scudded by as we clambered aboard the bus and headed to Essex, Cadiz, and home to the cabin before dusk. We had an electric discussion of land issues and how to protect the desert. A few songs and to bed.

April 16, 1988

Granite Mountains

Finally the rain broke through. When dawn came the sky was streaked with jet stream clouds in bands over the Providence Mts., and a veil of fog obscured the ridge. About noon the blue broke through and by afternoon it was clear and mostly warm.

Today was "Hike Granite Peak Day" for those who wanted an adventure. A fair number stuck around the cabin catching up on notes and sunning in the newfound sun.

Patty Lieberg, John Godino, and I decided to do some trail work on the plateau trail. We headed off on foot to Philippe and Cindy's place to get tools. This was a shovel, a mattock, and a pulaski. We walked the valley floor putting ties on bushes next to the trail and thence up the canyon in which the trail runs.

At first we just spruced up the trail here and there by rearranging rocks or brush but soon we reached the place where the trail crossed the creek again and started up the bouldery spine that leads up to the Oak Spring trail.

There we rearranged the trail in earnest, totally bypassing one especially bad spot and chopping our way through a big, scrambling catclaw bush. We cleared one long gentle bypass that is now a fine trail.

Patty whacked away at the offending bushes with a will and once I heard her say "Avast, you lily livered slime" and take a huge swing at a bush. Other emanations of this sort introduced me to a new side of this slim, quiet little gal. John chipped in with sterling banter and we had a generally good time, though as usual I pushed myself pretty hard and was thoroughly popped on the trail down.

Philippe offered me a thing I couldn't refuse—a shot of Grand Marnier and a hot bath complete with Rogers and Gallett soap. Boy it felt good. Back at camp I had a nice snooze and then Sandra McDouglas gave a very polished presentation on Australian environmental issues. She is very sharp, with a kind of cool judgment that made for a good presentation even though everybody was tired—off to bed.

Vaya Maria Padaskeva and My Big Adventure

Virginia Parrish nee Vaya Maria Padaskeva and I were walking down in a crystal valley. The way was hard. The right-angle, zig-zagging trail made us clamber over sharp, shiny shelves and to shinny down the opposite side, holding with the tips of our boots into the vitreous layers of pellucid glass.

High above us rose uncertain mirrors of stone as if we walked deep between towering skyscrapers on Fifth Avenue, New York.

Up there somewhere we could see patches of sky and scudding, swirling clouds. I poked my walking stick in the crevices to help me down, and Virginia, an agile sprite, skipped ahead and gave me a welcome hand when the drops became dangerous to jump.

We felt our way around a crystal angle and there ahead of us, curving across the sky, was an alabaster bridge of cleanest ivory, a vaulting arch that seemed to span the whole sky, just china blue and palest buff shadowed in long curves beneath.

We looked up in awe as we walked beneath the now-shadowed arch wondering when it began and where it ended. At one point, what looked like the fluted console of an ivory organ hung down from the arch. The floor on which we walked was now purest glass.

Curious spheres rose as high as Virginia's head on either side, as we carefully negotiated the slippery floor, the kaleidoscope of angles and drifting surfaces that surrounded us becoming curved forms in those spheres.

On we went, the floor now a rocky pavement stretching away as far as the eye could see.

"Virginia" I called querulously, because she was nearly out of sight ahead of me down the smooth slope. "Stop! The fog makes me lose my way."

She stopped and turned, waiting till I caught up.

Just then, coming from far off behind the crystal palisades, we heard an angry whine approaching rapidly, rising to a premonitory shriek of sound. Just in time she jerked my hand and pulled me under the canopy of great veined leaves beside the trail. We were no more than under it when the angry snarl materialized into an aerial craft that zigged and zagged this way and that, right over the trail on which we had just stood.

We lifted the leaf and looked warily out, hoping we would not be seen, but too curious even if it meant risking our lives to hide wholly out of sight.

What we saw gave us not a moment's peace. We quaked in fear and pulled back shuttering the leaf down over our heads just in time as the craft whined near, hovering just yards away in the air. We found a hole in the leaf and was able to watch, as though a porthole, at the awesome machine—a glittering, pentagonal, arching windscreen swung around, sending glancing showers of hexagonal light across the surrounding bushes and right over where we lay, momentarily blinding us in the flash. We thought we could see faces inside the windscreen and the yellow and black-patterned fusilage. And then, too fast to follow, it was gone.

At first we were too drained and frightened to move, but soon we realized the soil on which we had crouched was soaking with cold water that soon crept in and chilled us. Hearing no approaching whine, we began our journey again, listening fearfully for any returning hint of the craft's return.

Ahead now we saw a shining disc of still water, as shiny as glass. It stretched away and disappeared in the unsubstantial distance, merging into whispering, swirling fog that hinted of eerie shapes and forms behind.

Virginia skipped along at the water's edge, now blithe and unafraid, too intent on what lay ahead to remember our fear at the craft that had so shaken us moments before. I had to hurry to follow as she passed a rocky promontory to a place when the water was no longer calm but rippled with long, crystal waves that raced, curling and breaking on the shore. They were clear as glass and one could look through their curving, moving faces to see the varicolored rocks and little darting fish.

A great slabbed rocky headland loomed and when we first rounded it I saw Virginia stop abruptly, sheltering her gaze with her hands. Her head swept up in obvious awe, and then I saw them too.

Perfect curves of brilliant light arched toward the zenith, and as we moved, motes of rainbow light raced up the curves and out into space until we could see ourselves, little as ants walking toward ourselves. In moments we found ourselves against an insubstantial, wavering, dancing crystal wall that curved out of sight far above us, and into the distance on each side. A weaving flow poured down the curved glass and wove away beyond our sight, with tiny bubbles that were rafted and bobbing along, trapped in its swirls.

It seemed we could go no farther. "What do we do now, Ken?" Virginia asked, seeing our way blocked.

"I was just going to ask you," I replied.

Virginia poked her fist at the wall and it went right through, and so, miraculously, did Virginia, pulling her other arm in behind her. She stood on a glistening trampoline, a yard away.

Tentatively I made a fist and poked at the membrane and I too was enveloped for an instant and then inside.

We found ourselves in a focus of bright warm sunlight, the air utterly still around us. It felt wonderful to linger for a moment, but Virginia was soon off sliding on the slick floor, racing along feet first toward a distant glass wall. The floor began to slope up but she was moving too fast to stop and went right into it feet first. Just as she touched it, I heard an audible bang. The wall disappeared and far above us the dome quivered and shook in shimmering rainbow light.

Off to the side I saw a smaller dome only 10x as tall as our heads. We poked at the wall, and though it was tougher, we were soon inside and soon it began to spin while we propped ourselves against a wall, feet pointed toward the spinning center.

Our craft cut loose in the current and we found ourselves in a pliant crystal raft spinning and sluicing as swift as an arrow down a granite sluice, rocking and bobbing so steeply we nearly tunneled to the center.

In a moment we were aground, Virginia and I again in the open air walking up the gravel slope.

Only behind us was light, the sky ahead occluded by a black dome striped by an interdigitating double row of huge gold teeth. A dark mouth where the teeth were parted beckoned, and Virginia, fearless as ever, lept through into the darkness. The opposite wall was blue, radiating warmth and heaving slightly. From it came sonorous repetitive sounds like those of peaceful breathing.

I touched Virginia with my walking stick and we found ourselves in Laurie's tent pressed against the walls, the first tap tap of the afternoon's rain on the nylon.

Niche Hunts

Purpose: To perceive as well as one can in a day or two, one piece of the incredibly complex interacting system that is defined by the living things on any mountainside. It is a lesson in the use of the observation skills that you are honing.

Every plant and animal has its own special story of life; how it finds its nutrition, how it deals with the physical environment of light, heat, water, chemicals, how it deals with or uses other living neighbors.

Our job is, so to speak, to lift the tent flap a little and see how much we can perceive of one story in the limited time available to us.

From this we can hope to perceive something of the whole. We can imagine the complexities, the strategies, the intersections, in what I call not very precisely, *the silent ticking of the mountain*, or the collective ecological-physical-behavioral processes of the life and land together.

So what we are up to is the attempt to see into nature's processes both immediate and over evolutionary time.

How can we do it? Especially how can we do it in the short time available?

1. Be satisfied with little windows in the world of the organism and then predict or imagine the rest.
2. Find organisms that can be watched:
 Numerous or stand still. Don't pick fleeting rarities.
3. Plants are easiest for these reasons.
4. Animals are tougher because of fleetness, hiding, rarity. They tend to use much more space.
5. Find an abundant, easy to observe organism.

 Find out where it lives. This will tell you much about its tolerances, conditions of life, water, shelter, associates, etc.

 Walk around first and describe where you find it.

 What does the range mean? What is physical? What is social?

 How does it transport itself? Why?

6. Look at its form. (Munz as a way of seeing a plant)

 What does its form mean? Can you guess (hypothesis formation) why pubescence?

 Why funnel-shaped flowers?

 Why long flower stalks?

 Why are leaves shaped the way they are?

 Why is color used?

7. Dig it up—half or more of the plant is below the ground.

 Look at roots, tubers, interconnections.

8. Use your Observation Series as a way of seeing out of the end of your pen.

May 10, 1988

Upper Boronda Camp, Big Creek Reserve, Monterey Co.

I haven't written yet on this trip of Field Quarter '88, but the sun is dipping over the ridge and I'm almost alone in camp (David is here). The troops are scattered from one end of the north reserve to the other. With luck they will miraculously appear as dusk falls, and I can relax and listen to the music and general hubbub of 23 bubbling souls, all exchanging the many joys and experiences of the day.

It is cloudless and calm. The recent rains have the meadow green turning brown and the soil where my feet scuff at the edge of the camp table is moist.

The ambiance of the group is together on the things Don Usner and I set before them. This time the second niche hunt.

The first dawn at Redwood Camp went well though everyone is low key. The Santa Cruz Island trip was hectic and rushed—6 days and all feel it to a degree. It saps people's chance here a little. Even so some wonderful little vignettes accumulate.

An ouzel's nest down below the confluence drew a lot of attention. It was placed about 12 ft. above the swirling stream up a vertical face with few places a predator could climb.

The next, incongruously, was in the sun on a tiny ledge—a dome of moss, redwood twigs and other vegetation, with a funnel mouth pointed 30 deg. downward. Mother and father had to feed their three young on the wing.

Others looked at morning glories and though most energy was spent on the flowers, the revelations were in the stems. They had ribs that spiraled and hastate leaves that were on long pedicels that place each far out from the vine. The effect is that the vines can twist on themselves and on each other and can thereby become very strong, just as a rope does when its fibers are twisted.

Don tells me that his Datsun pickup stalled when a tangle of morning glory (*Calystegia*) became tangled with his drive shaft. He had to cut them loose before the car would start.

Just as we came into camp someone caught a beautiful mountain king snake. Soon Patty Lieberg had it in her hair and so did Carleton Eyester. Pictures, pictures—I hope they come out.

I spent the day trying to locate students to discuss their organisms. Jack Nelson goes his own independent way keying out and studying lupines. I found him wandering the open hills and then found Carleton and Erin out on the bluff tracking hummingbirds and Michael, David, and Cristi down in the creek trying to psych out miner's lettuce.

We stumbled through the key together but were unable to see anything very small for lack of a decent hand lens. My Swiss Army knife lens failed to reveal the ovarian details, I fear.

They straggle in, racing the dark. I'd guess half are here and we have half an hour of light, I'd guess. Worry. And it gets worse each year.

Don is concocting spaghetti. Evan Goldblatt just hiked in. The decibels go up. Fourteen here, and another nine to go.

Tomorrow we hike out, stop for nature notes and then hit the bus and home.

June 2, 1988
Grandview Campground, White Mts., Inyo Co.

Thoughts At the End of Field Quarter 1988

I sit upslope from camp, among the pinyons. My feet are dug into the warm, dark, pine needle duff. Out in the sun, beyond my circle of shade, the hill drops gently, a sensuous undulating slope covered by a mosaic of red tiles—fragments of the Polita shale.

These rocks reached the mountain surface in our tick of time, 580 million years after sand and silt first sifted over and buried them. Once below the surface they left living time and entered the almost timeless pavan of the earth itself. The mountain came to be under them and cradled their buried layers, and now holds them aloft for the winds and waters of the surface world to erode, split, fragment, powder and reencorporate as a future bookmark in the passage of earth time.

We are of that surface of course, and of its particular buffeting stream of time. Ours is in Gaia, the living terracious biosphere, where as one friend puts it, hyperstabilized DNA, the thing we call life, perpetuates itself, arranged in an endless stream of little statistical living packets encased in this or that body shell, moving, touching, shedding, engulfing, influencing in a probably fractile mosaic.

Sun streaming down warms and lulls me to a delicious lizard warmth. I curl on my gortex jacket, which I have cast on the needles. The win soughs over me, going uphill, the collective music of a million caresses upon needles and branches.

I place my cap and my face to shade out the sun and look upward to a thousand glittering drops of rainbow light striped black with Newton's Rings, wherever sunlight penetrates the weave. I move slightly this way and that, better to see the play of colors. Before I drift off I muse that life, I suspect, is no step at all away from the things and processes we call non-living. Our native Americans were deeply right when they propitiated the land and their prey before going hunting.

What, then, is this dance of ours? This pain, this love between us, these hopes of ours, why do we clasp and cherish each other so? And why, out here, is the mountain slope a palpable part of these events, as though the essence of life itself might slip out of our grasp if we turned away from it?

Why do we need to laugh and dance together here, man and woman filled with precious love and care, when these things seem so hard to achieve in our cities?

Because, I think, this mountain is true, as true as the tiles of rock spread before me that span all the years of metazoan life and now reenter its processes after that unimaginably long absence. and while we are on its slopes together, so in large measure have we become true as well.

That is the power of the mountain. Some part of sham and false paths have somehow been left behind for a time. This pervasive trueness touches everything we are and everything we do. While we are here, and we sense that we can learn the ways in time.

For instance, it seems utterly natural to run along a trail naked, or to play the glistening water of Wyman Creek through our dusty hair. We have somehow escaped into a new and infinitely precious space.

Escaped from what? Well, as a man three times the age of many of you, I am almost poignantly joyful to be playing amongst you, to share your vibrancy and new visions, and to feel the powerful sense of rightness you all, every one, share.

My years have filled me more with a sense of process than a certitude about the rightness of my perceptions. Too many times have I been painfully taught new truths by you for that. It is also fair to say that slowly, almost glacially, some patterns that connect have emerged, been tested, and still stand, as I, like you, have struggled for understanding.

These I lay amongst the Polita tiles as bookmarks to understanding that have helped me form my view of the world and how it works. Let me share some of these with you.

I have come to believe that the truth of the mountain is profound beyond any of our momentary understandings of "rightness." It, I perceive, plays out in the music of its wind, streambeds, and gray pinyons, a song that can tell us what to do if we listen, can tell us why we must love, and why we must walk lightly with the rivers, the streamside plants, and the mice that scurry down sagebrush tunnels.

It says, simply: Live by the rules of the land. You are no different or more special than any other part.

It says, Know that you are both men and women and that neither of you can understand all the rules of life alone. Only your collective perceptions encompass the world. Therefore, share and treasure each other for these two partly different ways of seeing, for there is no other route to the mountain's soul and the mountain's instructions. The keepers of the life force and of connection to the mountains (patterns through time) are different levels of the same rules, and they are not equally distributed amongst us.

It says, the mosaic of life is an endless turning and what matters to the earth is the process, the flow, just as it cares for rivers. Every part interlocks with every other part. The world, in fact, evolves as a whole, not as a group of disparate parts.

This says eschew those times and places where human arrogance would place the guidance of the earth in human hands. All who would tell you this, I think, are false prophets.

Instead, it says the guidance is collective and transcends any such arrogant pretense. The earth and its life is a watershed writ global.

It says, to a remarkable degree, the living earth is self-corrective, and such arrogance will be righted with utter surety. Somehow, the self-correction of the river and the earth have been captured in the processes of life itself and are found in every cell.

It says that the collective wisdom is as much held by the lupine on the hillside as by any one of us.

It says, most of all, seek to know yourself as a part of the larger world, in the deepest earth sense, for in no other way can you find the wisdom to act your proper role.

It says unless you come to know yourself you will always misstep and the earth will always correct you.

It says that death is part of life and that life is often profligate in anticipation of death. Only in the largest sense of Gaia, does life seem sacred to me, in the same sense that a watershed is.

It says the inner ring of life that stands bravely up to the impartial face of the mountain is what you can give to eachother in laughter, love, solace, and strength. No personal goal you can reach is as important as this.

It does not protect any of us from pain because pain is a part of life, and because we are ecological actors only in a collective ecological sense. Focused inward we typically fail to understand this. And though we may rant at the moon, it will not avail us.

So, I offer to you this. Always find a mountain and learn her rules, clasp her to you until you are one, savor the majesty and infinite economy of her process and pace. Love eachother and seek together because there is, indeed, no other way, so far as this old seeker can see.

I love you all,
Ken

July 11-12, 1989
Tanzania, Tarangire National Park, Arusha

We arrived in Nairobi three days ago very late, and because Alan's main suitcase didn't show up, we waited and waited, amidst that sinking feeling that it was lost with all the clothes except those he was wearing.

It was a long, long flight. Carrie was a bit under the weather. She slept almost all the way from Frankfurt where Alan's luggage presumably was lost.

There was a tense time aboard at Frankfurt when a woman accompanying two black folks didn't show, leaving her luggage on board (they thought), and we waited while they emptied the luggage bays.

Finally we were off to Nairobi and then to the gracious, elegant Hilton and finally to bed.

Next day was spent shopping, Alan making many arrangements, buying clothes, etc.

Nairobi is spanking clean with towers and banks and hotels. The city lies on a rolling plain dotted with trees and grassy fields.

It was refreshing to see equality in the eyes, posture, etc. of the blacks. They can be so elegant—much more beautiful than most whites, in my view. Here a whole middle class is arising. Many shopkeepers are, as always in this part of the world, East Indian.

We took an ancient taxi to dinner at the old Hotel Norwich a bit out from the city center and had a grand meal with a [?] of tables on a veranda. Most of the clientele was well-rigged out blacks; I'd guess we were in the 20% minority and yet it was wonderful and gracious. Why can't others, such as South Africans, understand how easy it would be for them to be the leaders instead of the pariah?

Off to bed. We took our first anti-malarial pills that we bought here—for chloroquin-resistant strains—a new drug called Paludrin. They are supposed to upset your stomach sometimes, and my notably tender gut responded by giving me a bit of a bad time all day today, but I'm hanging in there. It's supposed to get better in a couple of days.

Anyway, we drove south, out of Nairobi across undulating grassy plains studded here and there with flat-topped acacias.

The road is paved but has a great many sinkholes in it, and every village has murderous speedbumps to slow you down.

It was with great excitement that we began to sight large animals. Nubian asses were common and a few antelope. Then we came upon about six giraffes not far off the road. They are incredible beasts whose heads rear up into the canopy of the local trees. This is the Kenyan race and quite distinct we are told. Our driver was a knowledgeable young man who pointed out several mammals and birds and even knew most of the plants.

Soon the huge bulk of Kilimanjaro loomed through the clouds, streaked with snow.

Arusha, at the foot of a precipitous volcano, Mt. Mero, is an attractive, bustling town of more than 100,000, vegetated with large, tropical trees, silk oaks, tulip trees, big figs, and others, and a tumbling stream comes off the mountain slopes and through town.

We are at about 5,000 ft. and four degrees south of the Equator. It was a mellow 75-80 degrees F. I would guess. Clouds hung over the mountaintop.

We crossed the border at Namanza, traded vans. We drive in very nice upholstered vans and are whisked through most obstacles quickly. Namanza is a bit scruffy; one instantly sees the effects of prosperous Kenya and impoverished Tanzania.

The border was a "mass of Masai" women and men in traditional garb clustered around pushing this or that trinket on us. We weren't buying.

The Masai herdsmen, women, and children are everywhere along the road and out into the bush—each with a herd of cattle or goats, driving them slowly along with a long, knobbed stick (a fimbo). The men wear red plaid (mostly) or red-striped clothes over the shoulder wrapped around the neck, legs bare, with sandals or not, out there in the bush with the predators. The women wear many colors and mostly shawls are worn over their heads.

The knobbed sticks, I find, are symbols of respect for old men, and the long, unknobbed sticks sometimes spear-tipped carried by everyone are seen.

I wonder what it is like to herd cattle in lion country—which all of this seems to be—or goats? They seem so helpless, both stock and people, but they coexist in the same bush with the lions. But one wonders how many lions are left outside of the parks. That I don't know. A way south we turned east through polycultured corn and bush legume fields toward Tarangire Park.

On down the fairly good paved road we went until we came to the road into Tarangire Park. The park entrance is a nice kiosk staffed by smiling Tanzanians, and beyond the Baobab (bah oh bab) forest started. These colossal, obese trees dot the rolling plains and ravines. Great column-like trunks support a spreading corona of branches, some bedecked with pendant fruits. The trunks, many of them, must be 30-40 ft. in circumference. On most the outer bark has been stripped away by elephants in search of moisture. Some are burrowed clear through as elephants worried their way into the central, pith-like interior, often said to be full of water.

We made our way to the Tarangire Park Inn, which is quite spectacular. The buildings and tents are arranged on a bluff overlooking the sandy, winding Tarangire River. There is a gracious wood-trimmed bar and dining room, a pool and a couple of dozen big, two-cot tents with a porch, a bathroom, and shower. We occupied the first one next to the pool. Phyl and I lit up a mosquito coil to beat back the one or two who were in the tent, had a gracious drink with Alan and Carrie, then dinner and bed. That night the lion grunted, roared, and coughed in the night within a few yards of our tent. I heard him about 2 AM and think the assessment might have been correct.

Before all this happened we took a drive on the dirt roads of the park and were graced with many animals—10 to 15 or more times what one could expect on a similar American scene. Herds of lovely impalas, Grant's gazelles, and zebras were everywhere. Wildebeasts were also common—usually traveling with zebras. There was a kind of alley on each side of the road which was relatively animal-free and then lots and lots of them. I'd guess this animal-poor space at 15-20 yards in width or just enough to avoid intimate photos with my 210 mm. zoom. But a few wandered closer, and I clicked away happily.

Phyl and I enjoyed the ostrich, which were common, and we hadn't expected them at all. They are huge birds, weighing perhaps 200 lbs. The black and white males,

sporting pink legs and necks were courting the grey females with a kind of Australian crawl motion of their white plumed wings.

But I was a baobab man for sure. These curious trees silhouetted against the sunset were strange and beautiful. Film disappeared down the baobab hole.

We saw too many mammals and birds to discuss here. I'll just list them and talk about a few special events.

One bird of importance was, we learned from our driver Musa, the "physical shrike"—actually it's called a "fiscal." They are black and white, mockingbird-sized birds with very long tails that they fence back and forth with one another. It looked distinctly "physical" to us.

Then in the afternoon we watched from the veranda a quite wondrous scene. Down below us (we were high on a bluff) lay the winding sandy river. Its banks were grassy and sloped and dotted with acacias and other trees. Zebras flooded down over the bluff to a rolling place—hundreds of them. This rolling place is an open earth pan in which many zebras rolled. They spread out and one arm of the herd waded into the stream to drink. Soon we heard short barking, like a yappy dog. The barks came in pairs and I could make out different pitches in some. At the same time the zebras that were barking left the stream and began to flow back upslope in the grass. Soon enough we made out a lion drinking right where the zebras had been. Sectors of the herd yapped away in staccato fashion and one could see the zebras were alert—heads up and flowing away through the grass. Others farther away from the lion grazed unconcernedly. The constant attention of these predators doubtless begins to define the "circle of concern" and it ends quite close to the predator—it has to. The energy of flight can only be expended now and then. The same must be true of fear. It's very useful if it's always present.

At night one could hear the barking going on in various sectors. I suspect the pitch and cadence of the paired barks may carry information about the imminence of attack and its location. Perhaps even individual zebras are identified in these calls, so like spinner dolphin whistle choruses.

Musa, a fine driver, generally seems to have only modest sense about where a 2-wheel drive van should go. We came to a broad, sandy wash with steep banks on both sides. Obviously no place for us. "Shall we try it?" Musa asks. "No," says I—"it's an obvious trap." In we went and bogged down right in the middle. Much wood gathering, jacking, wheel spinning, and pushing later (after about two hours), and finally we emerged. We were, we found, about 1,000 yards from some park building, but we didn't know, and as Phyl and Carrie wandered up and down the wash, I had justifiable visions of lions, cheetahs, or what-have-you bursting out of the bush, not to mention upon us who were ministering to the car.

Then we came to a washout which we had to back around and were stuck again, this time with vultures in adjacent trees.

Tsetse flies are everywhere and bite like leopards. They easily penetrate most shirts, can fly 20 mph (so as to keep up with our open-topped van), and DEET sort of discourages them, but they search around until they find a clear spot and nail you.

We traveled with a huge Grant's zebra and wildebeast herd for a while, files of them rocketing across the road ahead of us.

In the afternoon light we came upon three elephants ambling along amid a few baobabs and in extensive grass savannah. The marks of their destruction are everywhere—branches ripped from trees, ones that had been tipped over, and of course the bark ripped from most baobabs and great holes excavated in them in the dry season. Right now the grass is deep here—often waist high, but we are told it is grazed nearly flat before the rains come again.

We sit in three tiers of seats in these safari vans—the tops push up and you can stand, elbows on the rim, and look out at animals within a few feet of your car.

Tarangire is a beautiful place and relatively little visited.

Another gracious meal, a time spent watching sunset come over the scene below us, to our tent, and then the sounds of night—hyenas and lions. Tomorrow we are up and off at eight to Lake Manyara and thence to the Serengeti, and then back to Ngorongoro, and then to Nairobi.

July 13, 1989

Tanzania, Lake Manyara Lodge

The road to Manyara is along the dusty slopes above saline Lake Manyara, which rests against the scarp of the Rift Valley. It goes through fields of corn and an unidentified legume, through dusty whitish lake-bottom soil and thence across the north end of the lake to a park on the west side of the lake right against the 1,000-ft. scarp of the Rift Valley.

Just before the park the dry, almost desert, land sharply gives away to gallery forest. At its edge is a nice village, whose Swahili name refers to mosquitos. I can believe it. Muddy ruts are roads. We turned off into the forest and soon came to the park entrance kiosk and museum. We all bought pins for our hats, the proceeds of which will go to conservation.

The road leads through the forest—all sorts of unidentified trees, vines, and such. Black-bottomed streams coursed through the dark forest and an occasional blue monkey was seen, an arboreal species with an inordinately long tail—1.5-2x as long as their bodies.

We soon came to a series of rookery trees, white with guano, housing cormorants, yellow-billed storks, and white pelicans. A [?] monitor bathed in a sunny patch alongside a stream, and I thought of Ray Cowles (my old professor who did his Ph.D. on this lizard species).

The dirt roads took us out into open scrubland dominated by acacias, palms, and broadleaf trees I couldn't identify. The place was tromped flat by the feet of animals—zebras, giraffes, warthogs, impalas, and troops of baboons between the clumps of vegetation. Alan spotted a dikdik (a tiny deer) and though we watched every tree limb for a sleeping leopard none came into view.

Reticulated giraffe were common, [?] down leaves in the brush, their knobbed heads often poking up over the general vegetation. We maneuvered to avoid falling in aardvark holes. There were a lot of elephant signs but no elephants, until the last when one refused to turn around for us.

The park is remarkably full of large animals, so full it's hard to see how they all subsist. The trees have their troubles too but they fight back with spines and inedible sap.

Musa, our driver, took us down the windy dirt paths to the hippopotamus pool at the lake edge. Almost all—about 30 or so, were piled on an island just across a narrow lagoon—an incredible heap of protoplasm. Giant, 4,000-lb. (I guess) animals leaned on or rolled against one another in the warm sun. Their skin is pinkish brown and one could see considerable scarring from their sharp front teeth. They are supposed to be very dangerous in the water but not on land. They are reported to be able to slice an attacking predator in two—so says Musa.

They do flap their ears and spin their tails and they do sweat pink sweat, as I had been led to believe before we arrived.

We had lunch under a thorn tree looking out over the flat, and then to the lake—a lone wildebeast stood head-down and forlorn at the lake edge.

Alan and Carrie are good traveling companions in every way. They know about personal space, and are full of interest in everything they see. Alan has interesting things to say about economics, foreign exchange problems, and the like.

Then in the late afternoon we retraced our track and out of the park, up the precipitous scarp to the Manyara Hotel (name is not exact)—a gracious place set right on the lip of the scarp. It ran out of water, with most rooms filled, but carried on bravely and we had it the next day.

From our window, we could see the length of Lake Manyara, and we could look down over the hippo pools we had visited earlier. About 20 hippos were piled on the far mud bank like so many elephant seals, mostly sleeping. Now and then one would amble over and lie down—plunk. Many were scarred, presumably from their razor-sharp incisors, which Musa says can slice an attacker in two. One or two swam, flicking ears. I saw some twirling their tails and even saw what I think was pink sweat.

July 14, 1989

Tanzania, Jeronera, Serengeti National Park

After breakfast in the extravagant dining room overlooking the pool and out over the rift valley and Lake Manyara, we drove off west toward Serengeti. The road goes over a highland bench dissected by shallow streamcourses and covered with maize fields, some of family size and some 1,000 acres in extent. At one point we came upon a troop of baboons ripping ripe corn ears off, munching as they ran along. Musa shouted at them, to no avail of course, as we drove by.

The road gradually wound up into the true highlands of Ngorongoro Crater, into cloud forest bedecked with Spanish moss and perhaps ferns and wreathed in fog. The road grew red and rutted from spring mud and finally we found ourselves on the crater rim looking down under the loud deck to the salty lake and the valley floor to the far rim perhaps five miles away . . . a helluva crater and a complete one.

How do you suppose *Hippopotamus* managed to get to the valley floor? (Later—my reading tells me that some hippos wander long distances over dry land—something like 1,000 km—so reaching new waterholes is part of the scheme.)

As we drove along the mountain we encountered many Masai, with their cloth raiment, their fimbo sticks, and sandals. Many were elegant, slim blacks with glossy skin and elegant features.

Musa spotted a group of four young men with walking sticks so I could bargain for one. I'm no bargainer and settled for 1,000 schillings (\$7), which was way overpriced

but worth it for the radiant smile that spread over owner Nilalai's face. He couldn't believe his luck. What I paid is some significant piece of his annual income. He'll be waving sticks at tourists for weeks. The stick is of hardwood of some kind, knobbed at one end and great for walking.

By the way, we'd tested a bottle of "dry red" Zimbabwean wine last night. It was hardly dry but fruity and fine if you called it something else.

At the Crater Lodge we passed the Grzmek monument—the two biologists instrumental in saving it through the Frankfurt Zoological Society. Michael, the younger, was killed in an air crash near here at a fairly young age.

The hills became drier and as we dropped to the plain, the terrain became parched and grazed within an inch of the surface, we are told by the passage of 100,000 wildebeasts on migration.

On the hill down we passed Masai moving camp—all strapped to burros, and all in traditional raiment, many with long lion spears. Down below in the grassy valley we could see their temporary camp of brush and brush huts where they bring their cattle in at night.

The acacias began to dominate—beautiful spreading umbrella acacias and little whistling thorn acacias with what look like 2-in. galls all over—each the home of a colony of guardian ants. The wind plays whistling notes with the ant holes, like blowing on an ocarina.

Finally we were into the foothills and to parched Olduvai Gorge so famous for human history. There is a nice little museum there with the story of 2.5 million years of human history back to *Australopithecus bosii* and *Zinganthropus* through *Homo habilis* and *H. erectus* through modern man.

One looks down from a lunch shelter to the gorge and its five beds. An intent black named Lucas, who shushed the neighbors who were intruding on his spiel, told us, very accurately I thought, the history of discovery from its beginnings with a German butterfly collector to the Leakys. He had taken part in recent digs. The name he said, came from Oldupai, the Masai name for a yucca-like plant—that was corrupted to Olduvai.

After lunch, on down the road we went and finally the grass began to deepen and the Thompson's and Grant's gazelles became more frequent. Finally, ahead of us a rocky hill loomed from the plain and well before it we came to the barren-looking gate to the park, like the entrance to a Texas Ranch, and then to the hill, named Naabi, where we checked in, went to the john, and picked up a young girl ranger, Tabitha, with a radiant, wall-to-wall smile. She said she could ride to Seronera with us (where we will stay). She knew a lot and told us about the cheetahs and lions at Naabi and other things.

The grass grew deeper and the antelopes even more abundant until they were to be seen in all directions in clusters, resting, grazing, walking slowly.

Surprising to me, we saw a good many antelopes, zebras, and wildebeasts, and others alone, often a long distance (maybe as much as 1,000 yards) from any group of animals, even close to dusk. This is surprising to me. I've never seen a dolphin that far from its school. I wonder if the extra dimension at sea accounts for this.

We reached the Seronera Wildlife Lodge. it was built around a kopji with many of the smooth granite boulders dramatically in the dining room and bar, with lovely views all around and varnished wood everywhere. Our rooms were nice with a good big

bathtub, and a view out onto the veldt. Giraffes and warthogs walked by and hyraxes were all over the rocks and almost in the dining room. They had flocks of cute little babies.

Our meals were wonderful, decadent affairs by huge picture windows as the sun set red over the flat-topped acacias. I was struggling with a stomach et al. irritated by the malaria pills we are taking (and probably our evening scotch), but managed to take in some sights [?] which Musa took us to see—a remarkable array of marvels—before we returned for dinner. The most exciting was the leopard. We drove down along a slow-moving stream lined with lovely flat-topped yellow fever trees, thence off on a barely visible trail through the knee-high grass toward an isolated sausage tree—nothing but trampled grass—then to another of the species. There, lying in the grass was a lovely and somewhat nervous leopard. We drove right up within four or five yards and were able to stand up and watch and photograph from this incredibly close distance. The shutter and our voices caused the cat to stir and I mused as I'm sure others did, that there was but a single bound between us.

What a sight, this great lithe cat, so beautiful, so powerful, so much on a hair trigger about how it should react to these infernal tourists, that cluster around; we so intrusive, blatant, and protected by the insubstantial oddity of our vehicle; so incomprehending really about this supple, powerful cat that could fell any one of us with a blow. But I clicked away, as fascinated as any at being able to invade its space. It was wild and we had somehow found a way to nullify its power, confuse it, challenge it into ineffectiveness, and then we nearly forget what it really was—we had almost, but not quite, trivialized it. But when we left, its patterns went on as they always had; this new element that had no place was forgotten, as the cat stalked and caught its prey as it always had.

As we clicked it pressed its head down, never leaving us out of its gaze, reacting slightly to the sounds we had made. I was glad when we left and glad we'd been there.

Dinner in the gracious dining room and then to a bath and bed. The water comes to the lodge from a borehole nine miles away. One houseboy told me the nearby water (1/3 mile) isn't fit to use even it from a well.

I went to bed with an uncertain stomach and planned to sleep in if a night's sleep didn't stabilize things.

July 15, 1989

Tanzania, Seronera Wildlife Lodge

It didn't really, so I opted to stay at the lodge while the others went off on a drive. I had a delicious sleep, photographed the lodge, the hyraxes, read *Sex as a Sublimation of Tennis*, wrote notes, and had half of a lomatil pill, which worked wonders. It stabilized the irritation I was experiencing from the malaria pill, scotch, or whatever, and soon I was back on track.

In the afternoon we went out about 3:30. Phyl reported all sorts of adventures with lions and other critters. Under the conditions, *Sex and Tennis* was what I needed.

In the afternoon I went with Musa to the hippo pool nearby. They are huge critters but stayed far away. Musa says they are amongst the most formidable of African beasts. They can, he says, slice an attacker in two with their blade-like incisors.

A few words about Musa. He is a rather slight East Indian, very dark, probably 40. He knows an amazing lot about the animals and nearly everything else here. Driving with him is like going on a whaling ship at sea. He knows many other drivers of tour vans. He stops and exchanges news with them. I sensed a quiet command from him. He seems sharper and quicker on the uptake than most. He steered us through every hitch easily (though he did get stuck from headlong driving, I thought). We learned later that he has not been to India, probably having spent his life in Africa. He has a wife and two kids eight and ten, and has been a tour guide for four years. He may be a "stringer," which is an independent operator who takes overflow from our tour company, Wildersun of Nairobi and Arusha.

After my brief and rather unsuccessful hippo foray, we picked up the others and took a long drive down along the watercourses lined with the lovely, open, yellow fever trees, where a variety of animal marvels awaited. Jaunty warhogs, the old male's faces featuring long "warts" and tusks. They ran off, tails up with a puff of black hair at the tip, like the [?] that dune buggy people use to avoid crashes as each comes up the opposite side of a dune. In this case I'll bet the hogs keep track of each other in deep grass as they avoid attack.

We saw our first topi, a big roan and bluish black antelope, and later found a pride of lazy lions in the grass alongside the stream. One female disdainfully refused to turn around even though we drove up 20 ft. in back of her. No amount of imprecation or animal sounds stirred her in the least.

Back at the hotel we had a leisurely dinner—the soup, a sort of dense miso, seems the same every day so far. Then tomatoes, coleslaw with carrots, sometimes plantains which are like very flavorful mashed potatoes, and a meat dish, and a light desert, three big Safari beers (a wonderful rich brown beer that we all loved), maybe a little fruit and then afterward we walk up between the boulders to the coffee, after-dinner drink room for coffee and look out over the darkening veldt where we could usually find antelopes or warhogs or a giraffe ambling along, and Marabon storks in the trees, then the dark and its sounds, a light here and there but mostly just bush and dark. In the morning the red sun came up through the trees just as we woke up and readied for the day's trip to Ngorongoro.

July 16, 1989

Ngorongoro Crater

Musa loaded us in his Nissan van—which has nice wide windows and a pop-up top which had been installed in Nairobi. We all could stand up and see out, photograph, and simply experience being within feet of a lion with nothing but air intervening.

Musa located an old male, regal in his mane, lying behind a low bush. He sank into the ground in utter relaxation as we stared at him. Vans began to gather and soon he was completely ringed with cars. Tourists pointed at him from every direction and he just slept. Musa, chuckling over it all, had us off to the side where I was able to photograph the tourist circle. We drove off, wondering what lion's life was like on the Serengeti. I guess off the tourist track it may be peaceful. After all, we tourists can only cover a tiny bit of the Serengeti.

Oh, I forgot to mention the promenade up to the restaurant that included an incline of smooth and varnished wood, I think polished everyday. You could walk up it

easily but you had to be careful not to slip. The little kids (and Alan) discovered instantly and we frequently found them running and sliding down amidst peals of laughter.

As we rode along the trees were left behind and the sea of grass began. A rather remarkable diversity of animals were there nonetheless. Herds of Thompson's and Grant's gazelles were passed and some larger antelopes. Furtive jackals and embarrassed hyenas were seen, the latter have little short tails, sloping backs and look back at you over their shoulders as they trot head down.

Soon we reached Naabi Hill and the gate and were out on short-grass veldt and thence past Olduvai and up the haunches of a great volcanic mountain to where the Masai people herded their zebu cattle. You saw them, often little boys, fimbo in hand, walking alongside 30 or 40 cows—to take them to the kraal of brush at night next to their temporary villages, which we could see on the canyon slopes beyond our rough dirt road. Musa negotiated between the largest checkholes but merely accelerated when the rocks were baseball sized.

It was on this hill that we met three secretary birds fairly close to the van and I was able to photograph them reasonably well. These long-legged hook-beaked birds must stand close to three feet high. They eat small things—lizards, snakes, cicadas, and the like, and pace through the grass with long liquid strides, darting their heads down now and then to catch a bit of food. Ours were disturbed by our proximity and partly flew, partly ran to alight light-footed as the gossamer condor, and then to glide away on broad, boldly patterned black-and-white wings. Their hawk-like heads sport a dozen long plumes that bounce along behind their heads like so many pencils over their ears. Maybe that's why they are called secretary birds.

Masai boys rigged out for the tourists burst from the bush, black faces painted with white maze patterns, and waving two long supply plumes from their heads. I'm sure they lure many a tourist to stop for "play for pay" photos. The other Masai men are almost all in red cloths slung over shoulders, long brown legs ending in sandals and clutching a fimbo—often crosswise across the shoulders or large end down as a walking stick or a cattle prod.

We were able to look over the hotel porch right down on our future tent camp, very much the dispelling the air of "outback adventure" of our future camp-out.

Not long after we entered the cloud forest and were soon at the Ngorongoro Wildlife Lodge, where we parked for lunch, served in the hotel which was set right on the precipitous rim of the five-mile crater.

We met our new driver, A. J. Olote, a smiling man from the Kilimanjaro area of Tanzania. He ensconced us in an almost new Land Rover and soon we were headed for the "down road."

Olote, as we called him, was a patient, careful driver and negotiated the rocky, awful road with aplomb. It took us down the dry western side of the crater past an open woodland of candelabra euphorbia trees and thence out on the crater floor. As soon as we reached the flats we passed through clusters of animals, streams of wildebeasts, graceful flowing herds of gazelles, clusters of ponderous, huge African buffalo, and herd after herd of Burchell's zebras.

The black and white "test patterns" of these zebras fascinate me. They should mask motion sense in an attacking predator—through something like flicker fusion. But I also wonder if they are especially useful at night when rod vision is in force and where

the black would be the absence of light and come to mask the contours of the animal. As the animal turned end-on, the black stripes might be especially useful in masking shape.

We rocked and bounced our way up into the yellow fever trees where an ancient old male elephant stumped ponderously around and then onto the slope before the crater wall where our camp was set, out there back of the stone ranger's house. We found our cook tent, a canvas shower, a canvas bathroom, a dining tent, and two big Coleman dome tents big enough to stand up in easily.

And up above 1,500 ft. was the façade of the cliff rim hotel, lights winking on.

Two camp helpers greeted us: Cristophoro the cook and Emmanuel, who served and generally took care of us. He was a deferent, gentle young man with only a modest collection of English words at his command.

Later . . . Such delicious decadence. Leapfrog scotch and wine at twilight, the moon sinking over the acacias and the waters of Lake Magabe behind when we finally came to dinner time.

[continued from above] As we reached the crater bottom, Olote took us on a long tour to the south limit of the crater. We saw so many mammals and birds it is hard to discuss them all, and I won't try. I'll just list them and discuss a few. We wended our way through the great herds of wildebeasts and zebras and came out on the grassy flat that edges into Lake Magabe—a soda lake that the Masai used to “salt” their cattle. They drive, [?] their cattle over the rim and down repeatedly during the year to provide salt this way. We could see their trails crisscrossing down the crater wall in many places.

Olote knew his animals and a great deal about the crater, but he had never heard of a whale, nor had Musa. Think of that!

After a short while on the road, we came upon 12 lions, females and cubs, lounging in the deep grass near a sluggish series of pools. The lions were every which way—upside-down tummies bare and paws folded, stretched out on their sides and only now and then did one sit up, or much less rise and walk a few steps to collapse like a sack of beans back into the grass again. They paid not the slightest heed to us but snoozed on. Olote said they had fed heavily and might lounge around up to five or six days if the meal had been big enough before going out after another.

Later when I made an estimate of a quarter of a million ungulates in the crater (or so); the nine or ten prides of lions in the crater could never dent the food supply.

Rather near the lions we came rather close to a lovely trio of crowned cranes—two adults and a young with just a few spokes on the crown. When they fly one can see the bright red through the black-and-white back and the graceful, light-winged flight as they stroke away across the sky.

Olote took us down to the water's edge of Lake Magabe where thousands of flamingos of two species stood in the shallow water, or swung their heads back and forth over the bottom, straining the algal film. To do this they hold their heads upside down like a reversed golf club. Out beyond they cluster in huge aggregations making clots of pink on the blue water.

We drove to near the water's edge and watched them a long time. A long file straggled by in front of us, the species mixed. On one side they hunkered down in the water splashing water over their backs and many took flight as they came closest to us. The greater African flamingo is a beautiful, but grotesquely slim bird standing perhaps five ft. tall, with big broad wings splotched with black and crimson. When it flies, its slim

and vine-like neck and heavy head are thrust forward in a sinuous curve and the long, long feet trail behind. The greater flamingo appears palest pink on its body until it flies when the deep colors are revealed. The lesser has beautiful pink body plumage and seems the more abundant and doubtless makes up most of those clots of pink we saw from a distance.

I'll leave rhinoceroses until tomorrow though we did see some this day out east of camp.

Even though my air mattress leaked and the tents were set on such a slope that we all threatened to slide out the tent door, the camp had an air of decadence about it. Drinks in the dusk, a bird calling insistently, and later the cough of a lion that paced near camp with nothing but the insubstantial presence of a ripstop nylon tent between us. Phylly, fearless as ever, made her way up to the canvas john when the call came before dawn, while I timorously did my thing in the grass alongside the tent, soiling the environment. As Ernest Thompson Seton said "Don't throw garbage near your camp. It draws bottle flies."

I suppose we had as much to fear from a badly navigated elephant as a lion, but what do I know?

July 17, 1989

Ngorongoro Crater Floor

We circumnavigated the lake today—a nice long, jouncy ride, but Olote was an excellent driver who never once threatened to rush into a swamp or a sand trap. At one time we followed a pride of lions through the grass. First we came upon the old boy, his great mane flowing. He was very visible above the grass and had almost no charge of real stealth in the daytime. Up perhaps 200 yards ahead of him we came upon the girls, down as low as the grass, flowing forward at a rather rapid pace. They stopped now and then and turned their heads quizzically our way and eyes turned toward us, and then went back to their movement. No prey was in sight and Olote said they were just traveling.

On we went, up over the "bottlecap" hill that was supposed to be the last of the eruption that formed the crater 2 million years ago, according to Olote. Over the grassy summit we bounded, in and out of 4-wheel and down the back side, where we encountered eight ostrich children, some of whom were from time to time doing the most exotic dance. Perhaps two separate groups danced around each other in the most light-footed, swirling, circling dance. Others were doing some of the rowing motion of the wings. All this followed a race down the hill by these jolly juveniles. I thought I could tell who would mature into a male and who a female but none were mature.

Down the bottlecap we went and out onto the grassy plain, where we encountered a bat-eared fox, sticking its head out of the communal burrow. To the north was the crater wall, its canyons choked with trees. On the east, water seems to be plentiful as long marshy areas, choked with sedges, finger out toward the lake and cause wide decorations of the road. One took us clear down to the lake shore. It must be all but impassable in the rainy season.

In one of these bogs. Olote called out "rhinoceros!" and there it was, a great, granite-gray lump all but buried in the sedges. It didn't do anything either. Olote told us about attempts to protect them from poachers and how a full time patrol is now involved, but still the numbers are now very low. Of course it is the aphrodisiac horn trade that

does it. There are only 15 rhinos left in the park, as a result, and few anywhere. Kriss[?] handles are another reason for the kill.

As we came toward camp we saw more—eight in all. One old boy was out in the open, his two sharp horns all in the clear. We circled him, obtaining a hatfull of slides. Then we saw seven more in deep grass, including a juvenile, praises be. One had the most enormous horns, long needle-like protuberances. Even though we could see ribs under their skin, they are essentially armor plated by thick skin and Olote said the lions can't touch them. The ones in the marsh were white with mud, but they are technically black rhinos, with an over-hanging upper lip and an expression like Randolph Churchill.

Another posh dinner in our tent, the bird still at it, the moon sinking over the acacia, the soft air, the crackle of charcoal under the toast, warm water in the little plastic basin to wash the face, and giant instars of some giant grasshopper in Carrie's pants, and off to bed, with lions chuffing about, and who knows what giant beast about to plant a foot on our tent, but we slept well. Fatalism sustained us through the night.

July 18, 1989

Kenya, Nairobi, Jacaranda Hotel

After breakfast in the crater, we loaded up our bags, leaving the boys to tend to camp (such decadence!), and off we went up the opposite road, right in back of camp. It was rough, but not especially steep and quickly took us up into trees, much more like cloud forest than the other road. It did climb a mighty steep scarp though, before it came out in the forest not far from the lodge where Musa waited for us. We transferred gear and off we went backtracking to the border where all went quickly enough except that one glassy eyed, big, sullen, customs man challenged Phylly's currency declaration and made her cough up all her U.S. cash. This required her to unbutton her blouse and open her money pouch and then to count out the bills (she came up short), and the customs agent impassively changed the total and off we went. Phylly handled it all with incredible aplomb and even thanked the custom's agent. What a woman!

We shifted vehicles to a posh Wildersun van and finally hit Nairobi gridlock, but our driver zinged through it as if he had done it ten times before, ending up at the Jacaranda Hotel, about 2/3 the price of the Hilton and very nice—nice restaurant, an attractive sit-down patio under the trees.

Off to bed to recover a little before heading for the airport tomorrow.

July 19, 1989

Capital Hotel, Lilongue, Malawi

We tumbled into an inadequate taxi and headed for Jonu Kenyatta Airport, bought food and booze, and then took off on Kenya Airlines. We didn't see much, a glimpse of Lake Victoria, and then clouds, and finally to a bumpy landing at Lilongue, Malawi.

We tried to arrange to pick up a car we had ordered (Alan had), and it didn't come and didn't come and finally we settled for a sedan and made our way toward town. The airport is architecturally modern and seemed efficient, which is more than I can say for the car rental agency.

We drove down a newly paved road and every half mile or so through an allee of tall flag poles (of wood) set on each side of the road, each bearing the Malawian flags fluttering in the breeze. There was a broad and neatly trimmed mall on either side of the

road planted with various tropical trees, some in flower. It went for miles. Ah, the values of authoritarian rule. Many things can be done that are difficult to do in other democratic cultures.

Rather soon we turned off to the Capital Hotel, which were our digs for the night while we tried to get our car rental straightened out. The hotel is posh—all wood, brick, rich plantings, each of us with a window garden, two restaurants, shops, etc. Our rooms were splendid, too.

We had a gracious dinner in the restaurant that didn't require a tie. I had cichlid from Lake Malawi—very nice fish—foot long fellows I'd say. Thence off to bed. We made it so far. It's cool and delicious here—70 degrees or so.

July 20, 1989

Malawi, Mizuzu, Rest House

Alan and I rounded up a 4x vehicle this morning after a relative minimum of fooling around. We drove to the agency headquarters and Alan dickered with the East Indian office man. We had two choices—a land rover with the top lifting off and a Nissan Patrol, with cracks in the rear windshield, 100,000 miles, and a spastic battery, and a headlight that winks on and off. But, it looked better than the Land Rover. We drove back, me in the sedan following, Alan ahead leading. It's all left side of the road stuff with roundabouts, and I was nervous but made it OK. Soon enough with Alan at the wheel we were off to the north.

We took the inland road that skirts the highlands since the land road is supposed to be awful. Our M1 was paved (mostly) and new and good and we zipped along through acacia scrublands and saw little villages with thatched roofs and schoolkids in blue. Many waved, especially the younger ones. The teenaged boys seldom did.

We stopped for lunch at Kasinga Rest House (More cichlids and chips for me), thence up the road to a detour into a little town where they pumped petrol in with a hand pump and the john was a concrete shelter with a hole in the center of the floor, thatched roof, etc. Alan is a sure, swift driver who has things under control. I was having the willies about driving on the wrong side of the road, mostly because I don't trust my reactions in a situation where I'm asked to react, instead of think.

The road took us through the forest on a dirt track in the red earth that was often rutted and difficult but toward dusk it took us to Mizuzu. As we climbed the plateau we entered huge gloomy plantations of a slim-needed pine and blue gum eucalyptus set so close together the trees excluded nearly all light at their bases. One looked down the close-set rows into a black box. These forests are huge, sprawling over hills and valleys as far as one can see. They were planted there about 30 years ago by the British for pulp wood and are now mature but have never been used except sporadically for timber and firewood.

After dusk we saw the winking lights of Mizura and soon entered town—I'm told of 25-30,000 people. We sought out the rest house (the sign was printed on one side and we came in on the blank side at first)—and finally up the rutty driveway to the place. We had signed up for two rooms and they were waiting—about 20 bucks apiece as calculated in kurachas, the local currency. Simple rooms with the facilities in adjacent rooms. We went off to the local hotel for dinner. I tried my first cassava bread—doughy, of good flavor, and more fish (I like fish). Then back to bed in the blowy, rainswept night.

July 21, 1989

Chelinda, Nyika National Park

We followed a good, paved road through scattered thatched-roofed villages to Rumpbi, a little town set in a foothill valley where we stopped at a gloriously clean gas station, where I had quite a conversation with a business-suit-clad gentleman—everyone speaks English—and then we were off, waving to smiling schoolkids in their blue clothes. Literacy is said to be high here. Gradually the road took us up into a short-tree forest and thence into deeper scrub. Phylly spotted two species at least of *Protea* in bloom—one a lovely pink one that lighted up the forest in many places. It seemed odd tromping off in the bush without being restrained (we hardly were allowed out of the car in Tanzania) to inspect this or that plant. No spitting cobra, however, got us.

Finally we arrived at Thazima Gate of the Nyika National Park, and were greeted by a gracious ranger who waved us in. We had to enter before 4:00 or the gates close, but we arrived about 2:00 PM.

We took the 4-wheel route up through the forest and saw remarkably few birds, one troop of baboons, and a reed buck. It was, in fact, impoverished.

About halfway along this track, which got very steep and rocky at times, we met a 2-wheel sedan out of commission, its front wheel suspension broken, a young man named Marsh and three dark women standing disconsolately by. They had dispatched the other car in their party for help, but we promised to take word to Chelinda for them, which we did, but I have scant confidence anybody did anything about it.

The forest was full of proteas so Phyl had a field day crawling around in the forest to see if there were new ones to be had. We saw some nice big purplish-blue melastomas in full bloom.

Not long afterward the terrain opened into rolling hills, entirely open and grassy. Much of the terrain had been burned to promote new growth. It looked like the Eastern Washington prairies, and we could see miles away into distant Zambia.

We saw our first roan antelopes—grotesque horsy antelopes, very large with long, pendant tails, heavy shoulders and heads and ridiculous ears that jut out like semaphore signals and seem to go all which way. The grassland was sprinkled with reed bucks, and we saw several. They are very like our deer except their horns curve forward. They frequent the open slopes, and we often saw them on the skyline. The animals are warier here than in Tanzania, probably from the ministrations of poachers whom we are told concentrate on the antelope and water buffalos for meat.

Finally our dirt road curved down off the rolling hills, past a dammed pond toward big groves of pulp wood pines into Chelinda. We drove up to the Park headquarters in a log cabin next to a “pickled-snake-in-a-bottle-museum.” After some cogitation we were checked into Chalet #4, and then we drove over to our new digs. It is a little four-room house set in the forest—a nice kitchen with a woodstove, two refrigerators, utensils, glassware, sinks, etc., a living room with a big fireplace, dining table, sofa, and chairs. I rushed in to start a fire because it is cold. To do this you have to unload the wood which fills the whole fireplace to the top. I made shavings and got it started, and then our houseboy, Peter Mtumbuka, came in and started all over, putting the wood back in and lit it. The wood is wet enough that it didn’t simply go up in a flash, but burned hot enough to heat the house all night. Live and learn.

Peter is a gentle, deferent man of Bantu extraction, reportedly a good cook.

Out back is a huge A-frame woodshed for logs from the local forest farm—pulp pine, mostly, and a water heater—a big, galvanized tank with piping set atop a wood furnace that belched flames and smoke when in full operation. It delivered steaming hot water to our bath and the kitchen.

Such grace in the wilderness—a good drink of scotch, wine from South Africa (a good white and nice cabernet) and then dinner cooked and served by Peter. The women, especially, loved it though I soaked it up too.

We checked out the village—a gas pump and general store, a school, dispensary, churches, and more. More than 100 park employees plus children lived there amid the pines, most in little, boxy, cube-like houses with almost no windows. It's chilly up here on the high plateau so wood fires are ubiquitous.

Back at our chateau we read till lights went out at 9 PM and headed for our nice beds, but not before gathering around the fireplace to warm backsides and listen to the night noises. A bush buck barked outside.

Carrie had heard about the possibility of going for a night drive for leopards, so it was arranged. At dusk we met a deep-voiced park employee, who it turned out was one of their poacher patrols, to take us out in our car on the roads around Chelinda. he told us about his job. He went to all parts of the park and sometimes into neighboring Zambia and was not allowed, outright, to shoot poachers unless they started a fracas, but to capture them and bring them back in cuffs and chains, whereupon they were fined and released. I don't know more, or how effective it all was. The poachers sought meat (buffalo and roan antelope especially) but also elephant tusks. He stayed out for 6-8 days and was a tracker.

Our drive turned up two leopards skulking along through the brush alongside the road. One was large and the other small. I saw the eyeshine and the forms. He said they were not dangerous to man but caught deer and smaller animals, as well as local chickens.

Back at the Chateau we wrote notes by the fire, had a little wine and scotch, and went off to baths and bed, with piping hot water in a great old bath tub in a cavernous bathroom. It's briskly cool.

July 22, 1989

Malawi, Chelinda, Chateau #4

Today we drove to the northernmost point reachable by road from Chelinda in the park—Jalawa Rock and overlook. We drove all day on the dirt roads of the park and never saw another car. The road, sometimes a challenge of rocks and gullies and sometimes smooth and easy, led us over the rolling open grassy hills, about half-blackened by recent fires. The newly burnt grass was just black but that burned earlier sprouted with new green growth and was frequented by many roan antelope and many more reed bucks. These latter have forward curving horns and are gray with white bellies and look very much like a deer. They were rather skittish and usually fled if we came within easy camera range.

The weather is worthy of note—here it is mid winter and days are crisp and sometimes the wind drops temperature to chilly levels—upper 40s, I'd guess. The sky is

dotted with cloud and often enough these drop low onto the rolling hills and we drive through mist. Now and then pairs or small groups of zebras were seen—a brownish cast differentiated them from those at Ngorongoro.

Our road led us north to a promontory of land where finally I pulled the car up off the black into the grass and we got out to hike toward an unseen distant point overlooking the northern lowlands of the park, where, we are told, one sometimes sees dozens of elephants and buffalos in the remotest part of the park.

As we walked the rutted road became a single trail and then the land became a rounded ridge and then a fin-like promontory and finally a sheer-walled pinnacle with sides dropping 1,000 ft. to the rampart-like hills and thence into a valley dotted with distant trees and laced with green watercourses.

The trail led us through grassy fields with scattered protea bushes and occasional copses of trees that I could not identify (except that many had the growth form of oaks and were either acacia-like or of families I couldn't recognize). The herbiage also had the growth form of grasslands in woodlands everywhere, but the players were mostly African natives: lion's tail (*Leonotis*), *Tradescantia*, *Tacoma*, and others I couldn't name. The fin narrowed and we walked its crest, the hill dropping off to a sheer cliff on each side. Finally we hiked up a steep shoulder to narrow ridge and thence to a ladder that took us up onto the ultimate point. We picked our way down between gneissic boulders to the point itself.

At first we could not see the valley below for the swirling clouds but finally they parted and we could see far down into the valley below—a thousand feet down and far away to where the acacias were dots on the brown-green landscape. Beside us on either side we looked apprehensively over the sheer cliffs and then nestled amongst the boulders, out of the wind, for our sandwiches and good Malawian Carlsberg beer. The clouds swirled in and around us blotting out the scene as we left, retracing our steps to the waiting car.

I piloted back up the dirt road to Domwe overlook; once again atop a steep scarp where we could look out into Zambia below—a river wound past little villages and we could even hear the waterfalls from our distant perch. Domwe was marked by a water-heater-shaped concrete monument and by very cold wind. We thought it was in the upper 40s or low 50s, so it was pleasant to ride off inside the car in the waning afternoon towards Chelinda, and to arrive at dusk at Chalet #4, where Peter had a fire going, our clothes cleaned and drying on a rack by the fire.

We all settled in for a little wine and scotch in a round of toasts to us and our adventure. Then followed conversations about this and that and off to bed to listen to the night sounds—the barking of the bush buck, black and white ravens, and owls. And, oh yes, as we came in, an African porcupine hurried ahead of us on the road, all his very long quills deployed toward us. Such magnificent rear guard protection.

We had driven in down between plantations of *Pinus patula* forests—a tall pine with almost silky pendant needles, four to a bundle. They had, we found, been planted 30 years ago by the colonial government for pulp wood and were now maturing. They are reportedly not very good for construction wood, though we saw many groves of Monterey pines as well, all planted in close rows so they they grow straight.

Animals we saw today included little groups of warthogs that run with their tails crooked (unlike those of Serengeti, who stick theirs straight up), a family of bush pigs—with smaller, shorter legs, and that flow close to the ground and disappear as if by magic.

I asked Peter about his religion—he sports a silver and ebony cross on his chest—and he said it was Roman Catholic and that there were two other sects at Chelinda—I didn't catch what they were. We saw the side-striped jackal a couple of times today, out in the rolling grasslands. They are handsome, very coyote-like dogs, with a darkish lateral strip on their otherwise tan-gray bodies. They are reportedly inoffensive and shy.

July 23, 1989

Chelinda

Today we decided to visit the “Junipers,” way off on the east side of the park where we could hope to look out off our high plain toward Livingstonia Falls and down toward Lake Malawi and then to Tanzania beyond. It was an overcast day, the cloud deck nestling on the high ridges as we drove off from Chelinda. The road took us first over long stretches of open rolling highland plateau and thence up on curving traverses into the fog.

Now and then, roan antelopes or reed bucks would materialize and bolt away into the mist. After a long time, but over better roads than most, Alan piloted us down out of the clouds to open valleys where we could see patches of what look like rain forest tucked in the folds of the streamcourses. We wondered if some of the taller trees we saw were junipers, but couldn't tell. Most trees were decked with beards of Spanish moss and prominent was a pinnate-leaved very green tree with reddish stringy bark. The basement granodiorite began to poke up through the meadows and finally we descended into a tree-choked valley and we could make sure of our first junipers—young, conical trees, like Christmas trees, at the edges of a tall gallery forest patch in which we could see ragged trees maybe 100 ft. tall that turned out to be old-growth juniper.

We parked at a little turn-around and soon a black man, shoeless with tattered clothes appeared and welcomed us. He led us over a little bridge and a swift brook, around a dense copse of trees to his cabin, where he and his companion lived, five or six days away from Chelinda, acting as interpreters and guides in the juniper forest. We didn't think we needed a guide, but he insisted we see the guest cabin and directed us down a forest trail. We emerged after 200-300 yards at a spare cabin set above the streamcourse. I unlocked the cabin so we could look in—two bunk beds, a stove, lanterns, Banda's picture; and then we settled in at an outdoor picnic table for a beer and then off to take the main trail to the forest. The brush was full of a plant that looked much like poison oak and since I had touched it I took pains to wash off in the creek.

We walked uphill and plunged at once into the gallery forest—only 200-300 hectares of it, but immediately a different world. The light filtered and dimmed and at once we begin to see the buttressed trunks of old tall junipers, lianas hanging down. *Dracaenas* and other deep forest understory plants filled areas where the canopy let in light. Soon we heard the chorusing of blue monkeys calling back and forth high in the trees.

We found a place at the base of a lightning-struck and burned juniper to sit and eat our sandwiches. Lianas as thick as my arm swayed slowly like bell ropes and up in the trees we could see clumps of orchids (Malawi is very rich in orchids). Our trail led us

first up the steep slope and then down in a circle. We passed many junipers 4-5 ft. through, with lovely cinnamon bark and trunks that shafted upward clean of branches for many feet. We passed many other trees we couldn't identify. We emerged into the surrounding grassy hillside, received a letter from the guard to his son at Chelinda and began the long drive back.

Not long after leaving the junipers we spotted a pair of elands, young and adult on the open hill. They are big antelopes with neck wattles and black spots on the backs of their front legs. We are told that in some places they mingle with cattle, which are near their size. Wary animals here as poachers seek them out.

Alan cut off on a side road to Kasarawba overlook. On the way we passed our biggest group of roan antelopes yet—perhaps 15-20. These almost comical animals are hunted here and wary. They pounded over the ridge and away across the grassy hills.

The trip back was long; reed bucks on the horizon, a family of bush pigs that simply disappeared, down to the forests of Chelinda, over the dammed ponds where, we are told, the planted rainbow trout lurks, and up to our wonderful, comfortable chalet where Peter had our laundry ready and dinner soon after. More good conversation and then to bed with the wind howling at times.

July 24, 1989

Malawi, Kasunga Guest House

I was at the wheel again as we left Peter, Chalet #4 with its leopards on the front picnic table (so we were told), and thence out onto the road that borders the Zambia side of the Park—through the Cholo—Forest, or so the map said—mostly *Brachystegia* sp.—a spreading, broadleaf tree that spreads like an acacia, with bark like a western oak. The road was one long red dust bath almost from end to end. We emerged with everything dusted—our hair, baggage, and car caked red. At the park border I turned the wheel over to Alan and we picked up a passenger, a young black gal who wanted off at Rumfi where the pavement begins and we were very glad to get off the washboard. Rumfi is set in a broad farming valley and a large turbid stream rushes through it. The surrounding hills are of granite domes (or inselbergs as the guidebooks tell us), baobabs and acacias, thatched farm houses, goats, and cattle with little boys behind driving them with a switch, broad schoolyards with floods of little kids and teenagers decked out in blue jackets but usually with short pants and sandals or no shoes at all. Gaggles of young women, many with babies on a sling over their back, trudged along as we dusted them in passing. This produced no noticeable change in either where they walked, or their temper. Everywhere we have gone we have been greeted with broad smiles if we smiled or waved, dances even; the little kids waved first much of the time. The men were usually more taciturn though it took little to get a rise out of them too. Very few man-woman couples were seen.

We stopped by the river for lunch and were treated to a vervet troop moving through the streamside tangle, eating selected branch-tip leaves, and to women in their usually colorful wraparound skirts, many with Banda's picture emblazoned across their anatomy.

The houses are small and round of mud and wattle or some of brick with grass thatched roofs that come to a peak. Granaries for cows are frequent and sometimes we

saw the village pump, women washing alongside greenish streams, usually several together discussing animatedly.

I drove after lunch, taking us through the road construction and the pulp wood forests to Mizuzu where we gassed up and Alan took over. We asked the Mizuzu Guest House people to call ahead for us but I doubt that they did. Even so if need had been we could have pounded the desk at Kasunga and demanded a room—but the inn was far from full as it turned out.

We sprayed our rooms with an aerosol pesticide called “Doom,” which listed a frightening agenda of chlorinated biphenyls and other goodies and listed dire warnings—but it slayed fleets of mosquitos and assured a comfortable night. Dinner was spare—chambo, fried potatoes, salad, and fruit cocktail out of a can. To bed with dogs in chorus in the spare forest.

July 25, 1989

Kudya Discovery Lodge, Liwonde

It will be good to change cars at Liwonde where we pick up a Peugeot station wagon. Our Nissan Patrol 4-wheel has seen better days; its battery threatens to quit at any moment, loses charge over night, I suppose from having the battery jounced over all these rough roads, and the windows leak exhaust—the back is of plastic, cracked, flexible, and threatens to depart momentarily, scaling off across the brush. But, to be fair, the motor is pretty good.

We retraced our steps to the capital at Lilongue and took in a little of the town including the government buildings—all the ministries—neat almost Indian-looking buildings on a well-manicured hill of many trees and flowering plants that looked generally clean and attractive. We gassed up, bought a few lunch goodies, and were off on the road south to Dedza and Liwonde. The population density grows to the south. We passed large villages of thatched houses—so soil-colored one had to look sharp to see them at first, into the Monadnock country near Dedza, advertised as the most beautiful in southern Africa—I thought that was overblown quite a bit—but interesting nonetheless. And thence near Dedza on the high plateau above the lower rift valley.

Little boys held out something for us to buy that we could not identify—it looked like half a dozen smoked rats between a forked stick, but just when we decided to stop for the next one, they gave out. I suspect they were smoked fish.

I was interested in the granite domes because here one cannot invoke glaciation to explain their shape. They look much like granite domes in the Sierra in shape though exfoliation sheet jointing is nearly absent. One does see an occasional spalled-off sheet but mostly they are smooth. So is such jointing caused by ice burden and relief when the ice leaves? Could it be differential cooling from the ice seeping in causing differential expansion and contraction? I wonder.

We stopped for lunch in a planted Monterey pine grove and as we sat there eating our peanut butter and Robertson’s marmalade sandwiches, sardines, and bread, a little gaggle of ragged children began to watch us. One little boy carried an even younger child. Momma picked dried ears of corn in a nearby field. I took some bread and the old peanut butter jar to offer the little boy. My attention frightened him and he turned to run away, but as I proffered the bread he turned back warily toward me, finally kneeling in

front of me, hands outstretched toward me. I gave him the treasures and he scuttled off to his father who had been working in the corn patch.

The road wound in the hills and began to descend toward the south end of the lake by the time we reached Ncheu, where people and stock and little schoolkids were all over the highway (they are in every town.) I turned the driving over to Alan at this point, and he took over in his usual competent way while I took a breather in the back seat with Phylly. Alan is much better than I at mastering the left side of the road stuff, especially in big towns, so I have tried to drive in the parks or in open country. Mozambique was on our right now with border points every now and then though the military presence and that of police is scarcely evident in Malawi.

Not long after we reached the lake level plain we came to Liwonde on the Shire River (Shir-e). We watched for signs and soon saw one advertising the Kudya Discovery Lodge and a short distance down a bumpy dirt road we turned into its gate—a scalloped, white-painted cement wall circled it and a big parking lot by the long, long string of rooms. Phyl and I and Alan and Carrie were on one end and to the right was the lodge—tiled entry area, dining room, a couple of bar-eating spaces with tiled floors and thatched roofs right at the edge of the river, clipped gardens, a swimming pool, boat launch area, and extensive lawn, which we learned the hippopotami kept closely clipped—amazingly close, in fact. I had no idea they could graze so well. There was a sign that said “Beware of Hippopotamus”—one, we found, was not supposed to wander around on these lawns because the hippos came out every night.

Phyl and I piled into our room. I “doomed” it to kill the abundant mosquitos and we went off for a pre-dinner nip of scotch and South African wine on the Strout’s front porch. We watched as the afternoon light faded over the Shire. It is a big, broad river (200 yards), lined with pampas grass and papyrus reeds and flowing smoothly but at a good clip.

Soon we noted people gathered next to the river and heard the pulsed snort of a hippo cruising 25 yards away in the river. They congregated each evening, we found, near the boat slip and then came out on the lawn. While we sipped excellent cold South African white wine we watched the hippos congregate, one pair mouthed each other noisily and another heard their snort and came in from 200 yards away, eyes above the surface all the way, swimming along like an express train. Apparently some social imperative was involved as the social equation became notably more complicated with his (we think it was a he—they can be larger) arrival.

I crept down with my flash camera and snuck along the cement wall until I was 25 ft. from them where I took several pictures that may or may not turn out as I left it on automatic instead of 1/60 second as I was supposed to do.

David Toft, our tour guide and arranger, showed up and we had a beer with him. Reminds me of an Aussie, though he is from Rhodesia—short sleeves, sandals, tan, outdoor type, 35, competent. He laid out our plans. He’s been a tobacco farmer and now a guide. He knows a lot about birds and game animals, understands business and how to deal with Malawi officials. He comes from Kenya where he lived on a farm.

That night I woke to hear clipping, like someone working a lawn edge with very sharp shears. I pulled the curtain carefully aside and there on our little patch of lawn (like Bermuda grass) was a hippo dipping along, not 20 feet from our door. They are low, stout

animals and this one reached $\frac{3}{4}$ way up the scalloped cement wall—three ft. or a bit more at the shoulder, I'd guess. I scrambled for my flash unit and grumbled trying to put it on in the dark. Phylly turned on the light to help and the hippo was gone in a flash—not an easy thing for such a bulky animal to do—but they can move. right through what I had been calling a hippo-proof gate.

July 26, 1989

Malawi, Liwonde National Park, Shire River, Mvuu Rondevaals

Kim and Dave were with us at breakfast. Kim, a pleasant, open-faced girl of about 30 took most of our luggage to our camp by 35 miles of jouncy dirt road, while Dave led us through the river by boat. Kim has done much of the logistics for us and is efficient, helpful, and very pleasant. I thought she might also be pregnant.

A barrage at Liwonde has backed the river up into a broad slow-moving stream, bordered by the grassy park lands of the forest and into some of the small tributary streams. The barrage is a series of adjustable gates that span the river and which can regulate flow according to the [?]¹—off in the river. Here it has created wonderful hippo habitat.

Dave took us down to his 18-ft. outboard (Merc)-powered speedboat, loaded us aboard, and barefoot, pushed us out into the river. He does not fear billharzia because it is slow moving and easy to treat and he gets tested once a year.

Right in front of the hotel the river is probably 300 yards wide and upstream toward Lake Magoda it divides now and then into various channels and marshlands.

Dave estimated there were 1,500 hippos in this piece of the river. Certainly one was seldom out of sight of them. The more I ask about them and see the more plausible an ancestral relative they make; on the vegetarian side of the equation to be sure. They show the following convergences:

- 1) Subdermal fatty layer
- 2) Scarrable skin
- 3) They blow on exhalation just like a whale. The spouts are explosive exhalations on surfacing from both nostrils that merge into a single, rather diffuse, upward jet of vapor in which it is hard to distinguish separate contributions of the nostrils.
- 4) When they swim fast they show vertical propulsive undulations of the trunk, and according to Dave, they are dangerous at this time.
- 5) Their calls, which Dave says they make through the open nostrils, sound like pulsed resonant grunts in which one can heard a slurred, clicked structure. These calls are given in air after the ears are flicked back and forth as if to empty them of water. Then they call. They call back and forth and respond with the ears in air. I have no evidence for underwater sound propagation, but I expect there is some component and it ought to propagate well. Can the hippos hear it?

Hippos are reported to graze with their horny lips, not their teeth. The teeth or tusks are reportedly very sharp slicing weapons of awesome capability. Dave thought the hippos tucked the hindlegs forward when swimming fast, but he wasn't sure. They swim rapidly underwater leaving a bow wave over their heads.

As we went up river in the open boat, we met many interesting birds. The white-breasted cormorants roost in riverside trees in great numbers, painting the leaves white until growth is stunted and the trees die. Several dozen trees near the river were so affected and housed hundreds of garrulous cormorants who streamed in from Lake Magabe near dusk.

Dave drove us up a little, slow-moving stream that enters the Shire. Malachite kingfishers are little, extravagant, metallic-green birds, red and speckled—very small. We saw the big brown Hammarkopfs, who nest for a very long time and keep building a messy pile of sticks up in their tree.

Dave brought along some cichlids and stopped to pick up a floating plant which he divided and stuffed in the gills of each fish so they would float.

Soon we came upon two regal-looking fish eagles perched atop dead palms or branched trees at the water's edge. They are elegant, black-and-white-headed birds with a rusty cast to their backs, probably about the same size as our bald eagle. Maybe the two are variants through this one is the more beautiful.

Dave gave a great whistle and tossed a fish 40 ft. out from the boat. The eagle swooped from its perch, and faster than I could track through the viewfinder of my camera, plucked the fish from the water and was wheeling back to his perch to pick it apart.

Only when I looked over the top of the camera did I come close to catching the moment when the eagle plucked the fish from the water. We'll see.

After that we passed a point where cormorants nested and Dave said we would see crocodiles. Sure enough, big (perhaps 8-10 ft.) crocodiles were there sunning. When they saw us 50 yards away they walked and slithered into the vegetation-choked water and disappeared. I guess there were 4-5.

Then we passed close to a cut bank where Dave pointed out the little circular bore holes—maybe 2 in. or a little more in diameter, which were the homes of pretty black and white pied kingfishers.

We cruised on over glassy water, stopping to look at some elegant water lilies; then because the sun had grown a little warm, up went the [?] top and out came a cooler of cold beer and soft drinks as we drifted the lovely papyrus-lined river. Such a scene, such big gulps of life! Just like we owned the place.

The Shire is not very clear, but greenish and roily, which fits the scene. We poked our bow into the reeds where Dave had seen some water bucks. They are gray and have a perfect white circle, perhaps a bit longer in radius than their tails, which swings in the middle like the hand on a clock; and boy, do they swing their tails. I'm sure it's some sort of signaling pattern but need to see them in flight to see what they do with their tails. I suspect they may be staggered in flight or follow in file.

We saw several lily trotters or jacamas, my first view of these incredibly long-toed birds. They literally trot on lilies, white and brown, and a bit flighty.

The grassy fields often to the water's edge were punctuated by tall *Borassus* fan palms—tall trunks and a puff of fronds. Some had a swelling $\frac{3}{4}$ of the way up the trunk, and we were told this developed just before the tree began to flower at about 40 years of age. It looks for all the world like the swelling on our *Eriogonum inflatum* stalks—and may serve the same function—dissuading unwanted visitors to the flowers or seeds—rats in the case of the palm probably, and beetles for the buckwheat.

Dave said the water that had been backed up by the barrage and was killing those whose roots were constantly in water. But the broad river formed a very important, protected spawning ground for the chambo who migrated up into it.

We soon pulled up to Mvuu forest camp in the National Park, which is a series of four or five brick rondaveals—circular, thatched buildings maybe 20 ft. in diameter. The four of us occupied the two rooms and two johns of each. We had two mosquito-netted bunks on each side [drawing of building].

Lunch was served in a nice, open lunch verandah next to the river. Kim produced a fine lunch, and then we were off in the boat again, this time out of the Shire and into the lower end of Lake Mulombe. The afternoon wore on, the light turned pink over the distant mountains and colored the trees and rushes.

As we left I could hear antiphonal music, a counterpoint of voices and rhythms from the camp on shore and soon we saw a great bonfire flicker and flare.

Dave had a secret place to show us and landed on a reedy bank, jumped ashore, and bade us do the same. We carried our drinks ashore and there ahead of us was the most amazing baobab, almost entirely clasped by the roots of a strangler and a sycamore fig tree. He led the way to a little door that let the slimmer ones squeeze inside (Phyl and I merely looked inside).

The sun set now, casting rose over the Shire, and silhouetted the reeds against the water. A lovely scene. Soon came a clinking chorus of little frogs—like tapping a spoon against crystal. Dave showed us the Moma tree which provides a cheap drink to elephants when they eat the seeds.

Back on the water we skimmed in the almost black back to Mvuu, its snorting hippos and a nice dinner that Kim was preparing. She barbecued chicken on an outdoor charcoal grill set midway between the cormorant roost and the place where the hippopotamus roared.

The Strouts and Norrises had their ceremonial scotch and wine and a beer with the Tofts around dinner. They were a little defferent and had to be invited to share with us.

Talk wandered to Dave and Kim's lives. She was raised on a farm in Zimbabwe and allowed that things stabilized after the blacks took over. He was from Kenya where Dave's father ran an outback ranch where they cooked with hippo oil—the best he said. He'd emigrated to Zimbabwe and had served four years in their army and tracked across the border into surrounding countries. You can understand why he is so at ease in the bush.

Phyl and I retreated not long after to our Rondevaal., its mosquito bars and dark cold-water john, where we listened to night noises. But first we trotted off with the rest to seek a hippo who had decided to wander through camp in search of grass. Risky, I thought, but no one else seemed worried as we stumped around in the dark with inadequate flashlight beams playing on rows of impala eyes, and the squat shape of the hippos sliding through the bush.

July 27, 1989

Malawi, Liwonde, Discovery Lodge

This morning we went for a 3-4 km walk in the bush near camp. We were accompanied by a handsome, lithe guide, Benson Gondwe, who walked with the grace of an antelope, his ancient Senfield 3006 crooked on his arm. Dave most often flanked us,

out alone in the scrub, both of them spotted animals well before we saw them. The dust of the trails was covered with tracks, the knuckles-down tracks of baboons, serval cats, impala prints, and once the trail of a lion.

We were in Mapone woodland with baobabs, palms, acacia-like trees, and the remarkable python vine—like a giant wisteria—great, hauser-like vines, twisted around each other like snakes and around and up into large trees.

The impala lily (*Adenium obesum*) was in bloom, lovely rich pink and white trumpets springing from fat leafless branches near the soil.

I took a couple of pictures for Phyl who was quite entranced with them.

We came upon three or four shallow brown waterholes, some choked with water plants and others of open water. We sat down under a tree alongside one and waited while birds flew in, and come in they did. Flocks of fast-flying peach-faced love birds settled along the water's edge and skittishly took to the air at our slightest movement. The gray-hooded kingfisher darted in and off in a nearby bush. We saw the crested form and long tail of the "gray go-away bird," a name supposedly related to its call. We were all sorry it wasn't the "bare-faced go-away bird" but it lives to the north in Tanzania and Kenya.

Dancing herds of lovely impalas started at our coming. We saw groups of half a dozen horned males down the forest lanes, bolting and stopping stock still while they tried to make us out, and later we came upon a flowing herd of maybe 30 or more females accompanied by two males flowing through an open meadow.

A little later we crossed two hippo highways, trenched footpaths that these huge animals use at night when they come to graze. We sighted greater kudus off in the bush—amongst the biggest of the antelopes—three does and a buck—and then they were gone.

The trail reached the road that led to the camp and we began to trek across wide, grassy fields with the sun beating down by then. It became a hot hike by the time we ducked into the shade and reached a cold beer at the tables overlooking the green Shire.

The gun had been to dissuade irritable elephants from taking umbrage at our invasion and possible lions, but our guides were taking it all calmly enough. I have observed "escape distance" behaviors in Dave though. He gives hippos considerable berth and even more to crocodiles, I thought.

After a nice lunch we said goodbye to Kim who goes by road again with our luggage, and we returned to the river in a vain attempt to sight a fishing owl in its daytime tree. Then we took off down the river toward the Discovery Inn. Dave took me past two dozen hippos while I tried to photograph a blow, and then he spotted a considerable herd of elephants, including two engaged in a ponderous shoving match—a slow-motion affair in which one frequently pranged its tusks in the rear end of the other.

Dave beached the boat in a little narrow channel and even went a short distance on shore towards a mother-calf pair grazing 75 yards away. I must say this made me a little nervous as there was no way we could have moved very fast out of the tight winding channel, but I guess Dave knew what he was doing.

Soon enough we were at the lodge again and stashed in rooms, this time widely spread. We paid Dave, and took his and Kim's address. A good show and very nice people and wonderful to be out of a car on our own.

July 28, 1989

Malawi, Livingstonia Beach Hotel

We traded in the Nissan gratefully for a Peugeot station wagon. The Nissan's battery died outright, I believe, and we were relieved to have a tighter car that didn't admit as much dust. Soon enough we found the back doors both lock when you are inside and these passengers had to be "released" from outside at every stop. And, Alan pointed out that the key was almost broken through. It also had 210,000 miles on it and some very slim tread indeed. But, it was a lot more comfortable and piped in no exhaust.

We headed south toward the old Colonial capital of Zomba, at the base of the Zomba plateau, maybe 35-40,000 people. We immediately loved the place—it is set in hilly, tree-shaded country, high enough to be cool. The people were very friendly and even the street vendors remarkably non-pushy. We bought wine, some more malaria pills (so we will have enough to taper off when we get home), bread and cheese, and Phyl went to the bank for a few Kuacha.

Soon we spotted the village outdoor market. It occupied a whole shaded block and was a remarkably colorful, interesting, and clean place. The women dressed in bright-colored clothes and the fruits and tomatoes made long swatches of red and yellow between their colorful promenades. There were tin-smiths banging away, basket-makers, pottery, long tables of dried and smoked fish, and much more. Alan had to pull us away. I took a lot of wide-angle, surreptitious photos. I could just set the focus and adjust the shutter speed once and then snap away without disturbing anyone. Only one woman seemed to notice what I was doing. Such faces, such clothes, the little children, the color, the sculptured and stooped old men, the bustle, the chiseled bodies of the workers excavating a new wall, the women's faces as they fondled their children.

Off we went up a long, narrow, winding road toward the highland-forested (farms of trees) Zomba plateau. Soon we could look down on the town through tall eucalyptus trunks, *Dracaena*, acacias, and many broadleaf trees I couldn't identify. I didn't know it but the road was half of a one-way loop. I kept thanking my stars that we didn't meet anyone.

At a promontory close to the top we came upon a delightful inn with a verandah terrace below the hotel that hung on the mountain and looked out through the twisted arms of *Brachystegia* trees to the valley and Zomba, hazy and smoky far below. We stopped for coffee and were served great steaming pots—twice more than we needed, before driving down the "out" road. Once in the valley again, we headed for Lake Malawi shore.

Soon we were among the thatched roof villages again, hard-packed dirt, granaries of wicker often set up above the ground (and presumably above the rats). Baobabs returned, fallow cotton fields, cassava and many, many people, on the roads, working slowly, or just lolling around talking. School was out and we encountered a flood of children in blue.

We stopped for lunch at Nkopolo Lodge and the nearby Leisure Center (where we actually ate). The lodge was posh, gardens, a truly lovely lakefront dining room of wood tables and elegant pale blue and white linen.

But we had our own bread and cheese so off we went to the leisure center where by dint of buying a beer all around we commanded a table by the beach under a thatched parasol. Pretty posh. I had a Carlsberg stout—grand stuff if you like it.

Along toward late afternoon we signed in at the Livingstonia Grand Hotel—equally elegant and with an old colonial history. Pictures of Livingston, his wife and topi-shielded men in puttees lounging on the porch being served drinks.

The place is a garden now with gracious, airy rooms, great bathtubs and floods of hot water to wash off the Malawi dust, and a fine dining room upstairs for a look across the lake over dinner. We four had our evening libation—South African red wine or scotch and thence off to dinner. At night the wind blew enough to kick up waves and their crash lulled us at night on fine beds, fans overhead (too cool to use) and off to sleep. I had a raft of laundry done so as to arrive home with mostly clean clothes.

July 29, 1989

Malawi, Livingstonia Beach Hotel

After breakfast I talked one and all into visiting a local aquarium—which turned out to be a place that raises and ships the colorful cichlids to various places for the aquarium trade. I've never been too excited by cichlids—and after a polite visit returned to the hotel for lunch and a good long afternoon nap.

Carrie somehow found out that there was a fishing village next door. Soon we had three guides: Lawrence, Charlie, and Thomson. They took us through the wire gate at the back of the hotel into another world. It was a fishing village but also had a kerosene-lamp-lit restaurant of one room and a dirt floor, a brickyard, a place to smoke fish, and many little thatched houses. A thousand people lived there.

First we looked at net—nylon, $\frac{3}{4}$ in. mesh or so, plaited sennet lines (very strong), plastic bottle floats. Then we passed trays and tables of little cichlids drying—some only an inch long, their bellies not even slit. Next came a brazier on which slightly larger fish were being toasted, also not gutted. Then we went to the smoker where trays of cut catfish parts in screen bottom trays stacked over a smoky fire cooked for a day.

Then out back was the brickyard, which they said the chief had chosen when he decided where to place the village. They had one brick form they dug, mixed in water, and put mud in a single brick form by hand, patting it down, and then turning it upside down to dry. A 1½"-long indentation put a dent in the brick which I suppose helped to key them together. The brick maker was incredulous when I told him I made adobe bricks. We compared recipes and decided sandy soil was best because it didn't crack upon drying.

Then the tiny little kids began to gather. I had three by the hands squealing and trotting along at one time.

We left through our fence and paid our guides a few Kuatcha—they wanted 20, and went off to bed. Our guides kept asking for clothes and shoes. They were ragged, but as they said, they had enough to eat. I want to send them some of my excess clothes.

Tomorrow we drive to Lilongue and board a plane and head for home.

July 30, 1989

In the air enroute to Nairobi

We had a nice drive up to the plateau with only minor adventures. We had lunch adjacent to a strychnose tree—in SE Asia it supplies strychnine—here it may not be poisonous.

Then we had a hassle turning in our car—the agent never showed and we left papers and data with the American Express agent—only the speedometer didn't work so it's anybody's guess. Then through customs, a body search, on Air Malawi to Nairobi. We now wait for Pan Am to get its act together. It's 12 midnight.

July 31, 1989

West Germany, Frankfurt

Well, what was it like? First, the company was the best. We each saw different things and traveled easily with safety and mutual enjoyment. We emerged wanting to go on (why leave the Livingstonia Hotel now?) We experienced an amazing lot—the animals, the continent, the scenery, the people, some of their problems and prospects. We didn't see the worst of Africa, but instead places on the way up, scratching and clawing their way up toward a future age when blacks have their own skilled classes.

We saw and sensed the remarkable friendliness and openness of the people, especially away from the cities. It always seemed possible to light up the kids with a smile. The reticence may stem from our tendency to travel poker faced and their deference to us as exotic, unknown curiosities. We were surely creatures from another world and another life in many ways. It's hard for us to realize how unimaginably wealthy we are compared to Benson who earned 1.80 kuatcha a day (a kuatcha was 2.74 dollars).

The wild animals are confined to parks for the most part and pursued and threatened elsewhere. We saw very little life, even birds, between park boundaries.

Health is an enormous problem. There is no way most people can avoid malaria and other parasites, considering how they live (no screening, no way to avoid parasite vectors).

The difference between rich and poor, even in their own cultures, is great, and probably growing greater. The struggle with education is being waged. Many obstacles intervene—culture, money, tools, a history of [?], etc. But I think, at least where we traveled, it is cherished and even a lightly trained person by our standards can mean a lot, and can become important.

The most progress has been made when there has been peace and relative stability and especially a willingness to use professional whites as part of culture. That was the case in Malawi, but rather rare elsewhere.

The spectre of AIDS hung, for me, everywhere. I wondered about its impact. Uganda, that we edged upon, reportedly has an infection rate of 40%. How will that play out? It may also have been very high in Kenya, Malawi, and Tanzania.

Population growth is an enormous countervailing problem in these countries and drags heavily, I hardly doubt, on everything they attempt.

For us, our trip was an idyll. We traveled as four warm comrades, had wonderful experiences by the dozens, and shared a sense of the preciousness of our trip in the group sense. We shared a lot. We are indeed, the fearless four.

The continent is largely undeveloped where we went. The people raise their own food mostly without benefit of irrigation or powered pumps; they wash in the green rivers, they do not have toilets or bathtubs, they cook on local wood (now in increasingly

short supply in many places), and their villages are apt to be clusters of thatched rondavaals. Only now and then does one find towns or cities.

Men mostly walk with other men, and women cluster, carrying food or clothing on their heads. Couples are rare.

One senses balance in their lives—time for songs and time for play. The kids seem loved and they carry even littler kids. Moms sling their little ones on behind in big swatches of cloth, often with the beloved leader Banda's picture on it, and always a splash of color and somehow clean.

One sees rather few old people—those with gray hair for example, but swarms and gaggles of teens and twenties. Life expectancy in Malawi is a bit over 40.

My impression is that “undeveloped” is a curious word. The land is developed and it holds about what it can in terms of people and their present methods, unless the artificialities of hi-tech civilization allow a denser society. The limits now are disease, mostly, but certainly locally, food, and sometimes warfare. I suspect there is now a cap growing on a population that will be increasingly effective if development doesn't intervene.

Africa is beautiful. It is also mostly old, old terrain. Only the Rift Valley with its scarps and its associated volcanos and deep lakes is young and abrupt. I was swept away by the miles and miles without any improved road at all, just away from the tourist track, but with people on foot driving flocks or herds of cattle just about everywhere.

In Ngorongoro we were shown Masai trails all along the rim where cattle were driven over to reach salt licks, and the majority came from places where there were no roads. Where it was only “untouched” skyline and forest and grassland, it would have had 40 hamlets, gas stations, motels, etc. in our country.

It made me realize how thoroughly enveloped the U.S. is and how the parks and reserves we have saved are now precious relics of a past time far more distant than in Africa—even though their game animals have been decimated. Much could recover in Africa where it could not in the U.S.

Well, that's what occurs to me at the moment. Now we dive back into American reality.

Grandview Campground, White Mountains, Inyo Co.

Thoughts at the End of Field Quarter, 1989

I've taken my chair upslope of camp among the now-silent pinyons. Cone shards carpet the shale beneath their gray-green branches. Warm morning sun glows off the smooth curves of the shaly slope, brick-red fragments of the Polita define the hill. I muse about this final uncovering of layers of sea bottom, which were sifted down before the first fish swam. The rock's moment of exposure is also its last. This sea bottom, so recently an intact moment in time, is already fragmented into tiny tiles only an inch or so across. Soon enough they will be dust and the Polita chapter will close.

Lizard-like I soak up the warm sun. It feels so good penetrating into my body, "healing," after a ravaged spring that I sometimes barely found my way through. Without my friends in the field quarter camps there might have been no spring.

I hear the wind come, off to the right over the ridge where the Sierra scarp comes into view. The sound is soft at first and then louder, air's breath on the trees. It sweeps over and around me, never changing pitch, only becoming louder and more directional. It sways branches overhead first—not down as deep as I am in the forest.

This wind must have come from some massive wave pattern in the unseen atmosphere that lies over the hogback ridge of the Whites. The lower side of this heaving blanket of air must have sent fingers and rivers of air down to play amongst the pinyon needles and, now and then, down against the shale where I sit. It is the voice of this powerful spot so much a touching of sky and mountain, a place for birds of the air such as swallows, swifts, and falcons to volplane in and swoop by before they rocket out over the thousands-of-feet-deep canyons of air in which they live and which define this ridge of rock on both sides. I'm as near to heaven as I'll ever get, I think, given my rationalist's view of things. Never mind, no moment could be more perfect. In fact, maybe that's what people meant when they talked of such things.

My boot rests against a windrow of cones banked behind a low bush, testimony to the fierce fire of life in these pines. The molecular will to live spews forth these cones, broadcast against the possibility that a tree will fall and there will be a vacancy in the subsoil battleground that determines which seed sets and which falls unable to penetrate, and is eaten. That's tree time. Only a century may matter much. Only the statistics of a million seeds may count. Certainly nothing I see in my day here matters at all to them.

All our passions, fears, hopes, loves, and touchings-of-spirits, are concentrated in the very now of a tree's life, or of a shale layer, or a mountain. Yet we live that moment with a singular intensity and a singular consciousness of what we might think of as our own "purpose." We live our moment as well in a city or a University as on a mountain like this, and yet there are differences that matter. That is why I think Field Quarter and ventures like it may have a valid role to play in affairs between we humans and our larger world.

Field Quarter is a curious hybrid venture, a mixture between a melding of 26 intelligent, caring, balanced people who are as diverse in outlook and experience as I could contrive from the list of those who applied. The diversity I sought assumes stresses, simply because it demands equally that members be tolerant of each other at the same time as it mixes them into an intimate brew. Only our obvious and happily universal care has carried us through. But most of us have felt those contrived stresses, too.

But, I for one, would have it no other way because a canalized view of the world from this or that special viewpoint is, perforce, so sterile an experience. We need to know that Yonat's intense social equation with the many people and people-problems she cares about so deeply may consume her seeing, so that contemplating a *Ceanothus* may not be all that interesting or exciting, and only after a time could she see why it was important.

We need to know that Libby's love for her city, its matrix of caring people, and their interwoven patterns of life is deep, and that only in our ignorant arrogance do we put our viewpoint over the place where she grew and still stands.

We need to know how Micah views history and nature and how he sees science as neither good nor bad, but instead outside the ethical pale.

We need to hear John's clear vision about knowledge and how it can point the way to a gentler interaction between humans and their world.

We need to hear the near-universal discomfort with science. How dare it dump its products upon our world unsorted, unjudged, and unassimilated?

We need to ponder the uncomfortable mixes of a worldview based on phenomenology and one based on faith.

Will it do to have a world in which we rely, as all of our ancestors did, on world explanations that we made up? Is it okay to explain your world even if you can't and then to live by the product?

Or is it more sensible to seek the boundaries of truth and to shape our affairs around the result?

Will knowledge of the world and how it works really provide us with the tools for living, or will such facing of reality present us with a world so harsh or difficult as to be unacceptable?

The diversity of social viewpoints we represent has also been set to the task of understanding the ecological rules of the wild world and of seeking to understand what they mean to us, how they might fit among our more obvious social constructs.

I've moved now, up higher on the fin of the hogback. The Polita shingles are larger and ring like bells as my boots hit against them. Gnarled and beautiful limbs too far away to be carried to a campfire are under every tree. The rock outcrops in sharp plates, and the mound cactus nestles against them—giant pincushions splotched with vermillion blooms. Lichens splatter the rocks with chrome-yellow, orange-red, and palest lemon.

My view opens across the Owens Valley, now takes in the Long Valley caldera and the entire Sierran crest to well south of the cirques of the Palisades.

Fields of dusty blue cloud shadow alternate on the Sierra with the blinding light reflected from snow-covered slopes cupped in jagged rock. It is still silent calm.

I've heard surprise that after all these years of leading Field Quarter students to these places, I could retain my spontaneity or care about each of you. Let me say simply that aside from my family, these annual ventures are the most important events in my life. You are my companions in that life, my source of understanding about how the world changes and how I must change, too. You are the rejuvenators of simple love, joy, and human care that make life an unfolding adventure of understanding instead of the repetitive playing over of a long-learned theme. Life for me would be very much less rich without you. I love you all in so many ways and I feel graced to be amongst you on this mountain. I hope you will be with me always for just a meal or when you might need me, or just want to check in.

I've moved again, picking my way to a rocky ridge overlooking Black Canyon. I can almost see Shulman Grove now. My chair spans a breadth of pinyon felled by lightning, I believe. It is an utterly lovely thing, lying outstretched and twisted on the shingle now, rich buff and pale lemon yellow wood, with whorls of black, which I presume are plant fibres that stain its wood. The roots are burned but I can see where the sap has sunk to permeate the wood until it cuts like wax and will catch a spark and light—the flame wood of the Indians.

What might we have learned? I hope people perceived the life on mountains and deserts as intricate and interwoven—the 10,000 stories on a mountainside. I hope you

perceived this life as running with the greatest economy with wastes, or life itself fed back into the cycles of life to take part again and again. I hope you can perceive that this world in balance is the only one that can last and that our human constructs have swung very far away from such a norm. To me there is no question that compensation will come. It's only a question of how ordered or disordered it might be and if we can hope to influence this process.

I'm also sure that our own lives are best lived if each of us finds a way to be on the positive side of the equation, and if we cluster together in nuclei of care and of love and support for one another.

I love you all, every one.

Ken Norris

July 2, 1991

Bahamas, Grand Bahama, Freeport, Lucaya Beach Hotel and Casino

Yesterday was spent in the long trip from San Francisco/Santa Cruz to Grand Bahama Island. But here I am, the next day, in the Lucaya Beach Hotel and Casino. The tables are still, down the hall; it is too early, but the fauna is gathered in the almost stifling heat of the beach at my back. Flip has not yet arrived.

No major hitches yet. I climbed the mountains above San Francisco Bay in a lovely clear dawn turning orange as I descended the hill to long-term parking and thence to the gate . . . looked at Nevada, the northern Great Basin, and thence into broken clouds over the plains and into the hill country; Nashville, and thence to Miami and a switch to a puddle jumper to Grand Bahama and the Xanadu Beach Hotel—grand but decaying. Nothing much worked but the people were pleasant, slow, and if you slowed a little, doing their job according to the local rubric. Nonetheless, [?] don't work, the toilet bubbles and steams, why I do not know. Flip called it "the pits" and moved to a more live[?] casino-hotel down the beach.

The place is flat coral, casuarina, a clean under[?] shore ("Where is the snorkeling?" I hear one disgruntled woman cry.)

Now I make sure I have everything—towel, dark glasses (a must in this bright light).

I don't know when Flip will arrive, but I'm stashed in some expensive room and nearly ready to go. I'm apprehensive about how I will handle the heat and the light, but we'll see.

Flip showed about 6:00 PM. We went to dinner and got caught up. Off to bed watching Wimbledon on the TV.

July 3, 1991

West End, Grand Bahama Island

Flip and I had breakfast, paid our bill, and were met about 7:00 AM and driven down the island to West End Village—very dilapidated and seedy. An old hotel rotting in the casuarina jungle, and then we came to a nook of a harbor replete with big yachts, tour boats, nipping flies, and 98% humidity, and then, half an hour after we sat on the dock, in came the *Wren of Aln*, our catamaran home for the next five days. She's sliding in now, looking trim and tended. Denise Herzny standing on the bow. She's bright red to the water line (the boat, not Denise). Here's the crew of the *Wren*:

Lynn Thomas—Cook

Lynda Green—Activist, interesting

Dan Sammis—Skipper

Denise Herzny—Research Director

Bill Carr—First Mate

Dave Schrenk—Technical Assistant

Chris Travbhber—Director, L.A. Harbor Presidential Board

National Geographic Photographer—Flip Nicklin

Janice Hawkridge

Joetta Roddick-Shea

After a perfunctory customs check, we headed out onto calm seas, in the blue deep water, up along the inner margin of the bank that defines Grand Bahamas Island. Soon the low fringe of trees that brushed the horizon at first disappeared and we were wholly at sea. The sun beat down quite unmercifully for a poor, pale, coastal Californian. I shed down to a shirt and shorts and doused myself with sun cream, which seems to have cooked.

We cruised along, now over the bank, now in blue water, till we reached the sunken hull of a wrecked steel sailing ship, perhaps 250 ft. long, called the *Sugar Wreck*, down 18 ft. (1908). We anchored and everyone tried all their gear by stepping overboard and swimming around. The bottom was dotted with waving clusters of soft coral, patches of sea grass, *Fungia* corals, and quite a fauna of lovely fish down in the bits and pieces of the wreck. I saw Pomacentrids, a hawkfish, some little striped schooling forms and others. I was mostly busy trying out my new diving gear—a suffocating sexy electric blue and black dive skin that bid fair to give me some real sun protection, a skull cap courtesy of Lynn (essential for my exposed and vacant head skin), a pair of electric lime green flippers, and an old mask that works pretty well. The water is like gin. All around the horizon stand afternoon cumulus and even a hammer-head cloud or two. The swells are low, maybe a foot, and the air very warm.

I've begun to know our fellow passengers. We'll see how it comes out at the end. There is a pair of women who met in a sauna—both have been around a lot to various countries—Joetta and Janice, the former much to the Near East and the latter Europe, I believe. Both hold views about the future shape of the world. Linda, outspoken activist, mystic, seeking and finding connections of intelligence, love, peace, family, contact between persons and animals. The responsive chord that dispels the long loneliness.

The crew is attentive. We have an elegant meal just as the sun sinks, blood red beneath a cloud deck.

We talk of the blind fish of Iran, of Japan, and Japanese and much more.

A video in the cabin (Audubon, about dolphins). Off to a sleep on the gently heaving deck in the variable breeze that crosses and recrosses the deck.

Scorpio hangs like a great jeweled hook, from the jib top, the mast light swings in a crazy little circle. Winds come in gusts from dead ahead and the pencil flashes of fish darting scribe the swells. It is damned hot and dripping with humidity. As the air cools the sticky air glues me to my plastic pad.

Conversation with Linda Green—

Connections make a difference to them. Intelligence. Do we understand it? Maybe not. They're peaceful, take care of each other. Family structures seem strong. Loyalty to each other. Do they love us? Why? I think so! In view of the terrible things we've done to them. Telepathic connection.

Are all these things we miss in our relations with ourselves? How much is made up? How much do we really know? Does it matter in the face of the problems we face? Is this an emotional cry about the way we deal with our world? Powerlessness and faith.

Bahamas, Over White Sand Ridge

The heavy wind buffets as I try to cover myself with a thin, knitted coverlet—too hot! I move aft to get out of the blast a little and find a place on the fantail with just a little breeze and by sleeping on top of the coverlet, the sticky plastic is avoided.

A shot from Cape Canaveral arcs up and across 2/3 of the northern sky. We see the orange ball of the launch, watch it arc up, watch separation No. 1, then see that fall in a glowing arc, see the second fall, and then the clear bright line of the rocket bend over and finally disappear outside the atmosphere.

July 4, 1991

I finally drifted off astern on a too-short pad, but generally comfortable. Finally, I watched the glorious dawn come, billowed clouds stacked high over us in decks, the upper billows turned elegant pale-pink-orange against the gray-white clouds in the foreground. Down below the floor of the cloud castle a fringe of gray pokes down. The primordeum of a water spout. It swirls into a long finger, but never reaches halfway to the sea.

Dolphins are sighted, a couple of bottlenose and then later 2-3 spotted dolphins laze by. Flip, Lynda, and Denise are rapidly in the water swimming, hopefully outward. The dolphins flirt and are gone. Denise knows many of them now and knows generally where they go and what they do. We talk of how they fish. They will dive down and come up with flounders.

Dan the skipper says he's watched the *Bothus* events and thinks it's different when he chases one and when the dolphins do. He says when he scared a bothid up it fled purposefully away. When the dolphin caught one, it often fluttered around the dolphin, this way and that, to be snapped up. I saw the latter clearly in one video.

Another video showed the black eyes of the fish above the sand and the fish's outline was evident.

There is much echolocation going on during these feeding sequences and much scanning.

We saw one sequence with a bonito following a dolphin in the kleptoparasitic position.

We cruised along the margin between indigo blue and turquoise and past two other boats waiting for dolphins and at last to anchor on the fine coral sand in 20 ft. of water.

We set a watch for dolphins and three times saw them, only once close enough for divers to insinuate themselves.

I dove on two and not on the last when three young spotted dolphins came in as we cruised over a sand bottom 20 ft. down. Half a dozen divers entered the gin-clear 81-degree water over immaculate sand and were soon with the three who stayed with them, tumbling and diving in the water often close enough to touch, though we had been instructed to refrain from reaching out. No one did. The dolphins dove and gyrated around the humans. Half an hour later the divers return. I hear cries of pleasure, wordless often enough.

Lynda's quotes: "I tried to sing to one." "I heard them whistling. They'll both be on tape." "I swam around them and they me with just inches between us. I don't want to anthropomorphise, but I felt so connected."

The dolphins seemed never to speed up but to accommodate to the slow humans and then after half an hour they quietly speeded a little and left.

There was no denying that they "dropped by" with the awkward human swimmers or that there was a kind of comradeship there. They lollygagged with the swimmers, circling and twisting, arcing off for shallow dives. Or that there was trust. There was no pulling away, not a hint of aggression or fear. They knew what to expect of humans and it did not send their pulses racing. A gentle welcome, a connectedness flowed back and forth and then they moved on, not with a burst of speed, but just "moving on." Perhaps the dolphin telegraph told of events ahead and they said, "Well, I gotta go now. Thanks for the little swim."

Then another group was sighted—five or six fins against the luminous turquoise of the shallow bank. I went below and pulled my dive skin on, grabbed my fins and mask, and tumbled off the rear step into the warm sea. I cut across the catamaran's retreating stern toward my comrades already in the water. Below me, lazily over the immaculate rippled sand, glided a yearling spotted dolphin, going about as fast as I could glide with fins alone. We cruised along silently, me above, he below, tail outstretched and gliding. He rose slowly, turned at face level, curved half a dozen feet in front of me. I could see that the immaculate baby's breast was giving way to a juvenile's speckled belly. He curved away as I stopped to watch, soon becoming a gray form among other gray forms of his brethren against the dark blue of the distance.

I was awkward in the water from a long time away from fins and face plate, but I persisted through water seeping in over my moustache and worry over getting cramps from using fins for the first time in a long time.

My but it's hot out here. The sun blazes down, the sea glitters and reflects. It's in the 90s with 98-99% humidity. One doesn't move fast, except in the water (81-84 degrees F). In fact, it's not far from physiological limits, seems to me. The sky steams with cloud billows; only the sea ameliorates, and it's there that the dolphins cruise.

I must say these new "Dive Skins" are marvelous—a full body suit that stretches to fit and protects just about everything from sun and modestly cold water.

We had a great 4th of July party at dusk even though I failed to get people to give political speeches. We had bunting, a fine steak dinner (on the barbecue), drinks (margaritas), and then fireworks made by Captain Dan. He'd made these from kit rockets and firecrackers. They whooshed and banged, a couple even arcing over perilously close to the mast.

Then we talked. We have three women aboard as visitors (Jan, Lynda, and Joetta), who were great fun to quiz about why they wanted "to experience dolphins." All had had personal experiences, near-death transports, clairvoyance, etc. that made them impatient with the stiff "rationality" of most scientists. There was, I thought, a need to believe, a great openness to connections with the animals, a need for unspoken trust and what better wild animal than the dolphin, who actually came to us, in evident acceptance and interest.

There is, it seems to me, deep femininity in all this, deep concern for the state of the world, much concern for what humans have wrought, and not a little feminism that says: "We women must find a way to make our values work in the world, as opposed to exploitation and destruction." This connection comes to mean much, the cooperative way, the nurturing way.

July 5, 1991

Bahamas, White Sand Ridge

I don't think I know all the dimensions of this, though I try to extend myself. We saw a few dolphins today, all spotted as far as I know, and they lazed on past us without giving us much chance to join them. Apparently, this is increasingly common. I don't wonder. For these tactile animals there's little in it for them, seems to me, and contact is frowned upon, at least on this boat.

I'm getting a little more used to the heat. It doesn't seem so oppressive though I don't think it's cooled down any in actuality.

"Over the whirs of the margarita blender, the call rose: 'Dolphins!' from Captain Dan." (Quote from Flip). I raced below into the sleeping compartment to change into my suffocating, sexy dive skins, stripped down, and caught both feet in the fabric. A silent tussle ensued as I bent over, oblivious of what might approach from behind, and freed each leg in turn. I hurried up the gangway, stripes slightly misaligning, grabbed my mask and leaped in, swimming after the others already in the water. The two juvenile dolphins, Barb and Mask, swirled in front of me. Barb pooped out a long, lumpy, olive stream. I clasped my hands over my mask straps so the larger particles would go past unimpeded. Is this a statement of the relation between the species, I mused . . . (This I read to the assembled divers after we returned.)

I paddled toward the dolphins who swirled in arabesque with the divers. Chris, the doc on board and the president of the board for Denise and a powerful swimmer swirled down with the two animals towards the bluish white sand carpet, 25 ft. below.

He was photographing as he and the dolphin twisted in a tight spiral toward the bottom.

The two came over to me as I paddled toward them. One arced over and around me, turning its speckled belly toward me in what I knew was a signal of affirmation. The other arced and rolled behind and around me. I rolled and dove down toward the bottom as Barb swirled past again turned her belly in affirmation. I reached out a hand and trailed my fingers gently on her dark flank and onto her tail. She stopped her tail beat and my fingers trailed across the top of her gliding flukes. She turned again toward me and arced effortlessly away, my fumbling swimming a gross charade of her effortless locomotion. Beyond the pair I could see my companions in the water: Chris, Janice, Joetta, Flip, and I could see the gray shapes glide toward them, waiting in the water. They gamboled this way for half an hour, moving among the enthralled swimmers.

Not a hint of distrust or fear or aggressive intent passed between us. A remarkable encounter with wild beings.

Dan says it began when treasure salvors worked on the *Maravilla* wreck near here and dolphins came in around the divers, curious, attentive.

When Dan first came in 1985, they merely anchored the vessel and the dolphins of all age classes would begin to cluster around the boat waiting for divers to enter the water. They would play for as long as two hours. Now with more boats in the area, it is heavily the juveniles, such as Barb and Mask, who play for long.

I had clicked to them and could see their brown eyes goggle at me, but not turn away or toward me resulted. I suppose they've heard it all.

Dan said the pressure on the dolphins was rising. More boats that wanted to remain unregulated came to visit and the dolphin's interest is waning.

Dan is afraid for the future and his attempts at getting the Bahamian government to permit visitors failed as other boats resisted the attempt at control.

My impression was that to adults we clumsy humans were no longer the stuff of curiosity, except to the curious young. I know I've felt that way too. My fires for contact are not nearly so strong as those of those of us who made their contact with dolphins for the first time.

Joetta talked to me about her experience, mostly in Saudi Arabia and Iran, out with the camel people. Interesting and easy to talk to, I thought. She seems able to go anywhere and deal with anything. Very centered, seems to me.

Her meeting with the dolphins was a strong experience. They stitched her with echolocation clicks, which she said she felt strongest on her sternum. She had circled down and around with them, halfway to the bottom, for the better part of half an hour.

July 6-7, 1991

A good dinner, talk, videos of the day's events, and out onto the fantail on a pad with my light blanket over it to keep from sticking to the plastic. The lightning flashed and then the thunder boomed closer and closer. Finally, I moved under shelter, but the rain bypassed us. Finally, tired of teetering on the inadequate bench, I moved back on the fantail pad. The blanket was damp now, almost sticky and finally I got up, rummaging around for a towel, found an inadequate one, and went back to sleep. Now breakfast is past, the day grows hot and muggy, and I got out on watch for a couple of hours. It's typified by light puffs of wind and low chop and a cloudless sky with the hot sun searing down, and the turquoise sea all around us, a band of ultramarine at the horizon where the deep water is, and cumulus castles growing in the distance.

It grows hotter and Lynn, Dan, and I slip into the water over the wreck of an old metal tower. Gray grunts were there in dense schools, clustering over the angular metal, so close they must have touched fins. Out in more open water were special schools of yellow-lined grunts. I saw one follow a barracuda from a distance of three ft. A cluster of half a dozen three-ft. barracuda lay quietly in open water, 20 ft. from the metal while nearer in, two or three trigger fish sculled along.

I doused myself for a while and climbed clumsily over the stern and washed off.

Not long after lunch, a group of five dolphins cruised lazily up to our inflatable and our team poured into the water, Denise leading with her big underwater video pod with which she has been getting absolutely crystal clear tapes from right among the animals. You can count every sp. if you want to.

[Map of area]

We're headed back down along the bank toward the west end now, seeing if we can find dolphins along the edges. Denise says bottlenose may be found throughout the shallows, but spotted are more toward the bank margins.

Back into the water again. My mask leaks over my moustache as I expected it to and is a damned nuisance. I haven't taken time to get my act together as regards skindiving. It's been a long time and the motivation is low. I'm afraid of sunburn, especially on my scalp where I have already had keratosis removed. But, in spite of this, it's been a pleasure to skim over the rippled coral sand 25 ft. below and look for fish, conches, and the like.

I've had a couple of good conversations, one with Lynda and one with Denise, about the lure of swimming with the dolphins. Here's what I perceive:

There is a widespread feeling of powerlessness in the face of contemporary problems by many people, especially women, who are still oppressed in many subtle and not-so-subtle ways. There is fear that we are destroying our earth, and men are heavily implicated. There is fear and revulsion against the growing violence in human society.

There is fear about where science and technology are leading us and the strong perception (and actuality) that this is significantly male-dominated activity. The tendency toward analysis of everything feels like a root cause, leading to unleashing untold forces upon humankind that we are seldom ready for.

Consequences are the increasingly obvious degradation of the environment and the human and natural condition of the earth. What remains unspoken is the reproductive force that [?] that problem. The dolphin is known to be "intelligent"—what shapes this take is mysterious. It lives in the 70% of the earth that we don't inhabit. It has a remarkable, innocent acceptance of us.

With all our guilt about the state of the world, here is an animal that will, if we let it, allow us to just be in a momentary, almost cosmic meeting of two species. Can they, somehow, be teachers? They appear to know about the good in us and accept us into their midst for this good.

From their standpoint it is a totally non-judgmental meeting, and from ours it is pervaded by their "good." They seem to perceive this connection in ways we do not easily understand when we try to analyze it, but when we are "just being," there it is. They appear subtly and almost unknowably sensitive in their acceptance of us.

I once thought sexual overtone was deeply involved—the powerful racehorse of the ocean, sleek, powerful—Poseidon—but I no longer think this is central, though it may be there at times.

Denise's project goes on for six months to a year. She charts this vessel for \$120-140,000 a year. She has elegant video capability and data logging and handling capability. Her foci have been identification, following life histories, some emphasis, but modest, on daily movement and habitat use. She is narrowing down to more and more important questions. She sees interesting vistas ahead and is reaching toward them. My impression is that her program would benefit from further structural consideration and attempt to:

- 1) Define where the animals go.

- 2) Sharper questions.
- 3) Pinpoint what they do at night and by season.

This afternoon as the sun slanted across the water, leaving the depths darkening toward lapis, we came across a group of perhaps 12 spotted dolphins, including old friend Romeo, an old fuzzy spotted male. The sea was flat, with wandering corridors of glassy water amidst large tracts of inch-high ripples.

The dolphins approached the *Wren*, lazing along in a loose group spread over 200 m of water. Some were down and others up. Their formation was so loose. There were old fuzzed males with white beaks, speckled juveniles, and small two-tone young, as clean as little tunas.

We are divided into two diving watches so that we will be easy to keep track of, and my time was up. I went below and through my gyrations to get into the lycra dive skin, which for all the trouble has kept me completely free of sunburn on most of my body and comfortable in the water, too.

Into the water I tumbled, a hand on my mask to keep it from being ripped away by the rush of water. I ducked, blew the water free from my snorkel, and looked around the underwater perimeter to see my shipboard friends swimming ahead 50 m. away amidst a cluster of dolphins. I stroked closer and soon was with three of the animals myself. They dove effortlessly toward the immaculate rippled sand 20 ft. below. The lead dolphin twitched its snout almost imperceptibly from side to side, snout angled toward the sand, two ft. below. It and its companions twisted their heads down, searching and then rammed their snouts in the powdery sand, up to their melons. One snapped and emerged with a fish in its mouth.

Later, a two-tone juvenile did the same, obviously echolocating the bottom, detected something out of sight below the sand, and dug its snout in and came up with a 8-in. sea cucumber, which it carried up a ways, shook and dropped, drifting end over end. I did not doubt that the dolphin had detected a shape through an inch or two of sand, or that it would rather it hadn't been a cucumber.

One lizard fish was caught in this way and the dolphin carried its prey right in front of Flip.

Dan Sammis, the captain, is a gazelle in the water and I swam above him, looking down as he swam in tight twisting loops with two juveniles.

The dolphins twisted and turned right with him, and shot ahead with occasional fluke strokes that told what they do alone.

I tried it—with an old mottled mom and her daughter. They stayed right with me, they on the outside and me in the center. The game was synchrony, the arabesque, and I was not good at it while they were consummate dancers, but not, remarkably, impatient ones. They obviously slowed to our pace much of the time, and when they wished to, rocketed away at a pace no one could follow, off into the blue veil where some imperative called.

The old mom, Hedley, and her baby, Havana, a sleek two-toned child who carried a remora, came by so close I could look the remora in the eye as it hung on Havana's belly, up between her pectorals. Its light-gray, pudgy body swashed limply in the current as it held on tight by its head sucker disc.

Down deep below I could see Flip, weighted and able to cruise right with the dolphins down among the channels and ridges of the coral sand. He moves as easily as a big sleek fish, dark-skinned now and powerful. I watched as he spun around amid a spiral of dolphins, his camera face glinting up toward me, finding and choosing what to see later.

PRI, a ferzed[?] adult female, came by with her speckled teenaged (four-year-old) daughter Poindexter. She let me swim close with them. I pulled up alongside—inches away—the old female, so close I could see every spot and tooth rake, and watch her shift her brown eye back to watch me. Poindexter slid up between us. I was in a dolphin school, so close I could see only part of each dolphin. A pectoral reached out toward me as we circled together, the sleek body of the juvenile slid up between us until her and her momma's dark flukes cut up past my tentative hand, held in close so as not to push them, and arced away, out of touching distance and away toward the others who gambled with other swimmers.

Obviously we were in a game. They were willing to play with us, though they continued to feed as we watched and later . . .

After my *tete a tete*, I paddled after the others, now off in the blue haze at the edge of visibility. I could see the dolphins arcing and circling among the swimmers, graceful, swift as arrows, compared even to Dan and Flip, and at a distance I could see that it was the dolphins who waited, patient with the humans. But when Dan, a fish in the water at 20 ft. down, began to swoop up and over in outside loops in 10-ft. vertical swoops, I could see the excitement run through the attendant dolphins. "Here was one of these aliens," who swam well enough to be fun. The juveniles bolted into a pantomime of his arcs, up and twisting and over, with no obvious thought of a breath. Dan broke away and glided, head up toward the distant mirror of the surface. The dolphins turned away. But impatience with us is not a mark of these dolphins. Quite the contrary. They were remarkably patient and gracious with us, not show-offs of what they could do so infinitely better than we.

That patience and acceptance of theirs was striking to me.

Yet their life patterns continued. In the afternoon a group of adults had a jaw-snapping spat with each other, intense enough that our divers moved out of the way, afraid of becoming objects of attack. The dolphins also continued to feed when the opportunity arose and mothers sent subtle signals to their children to stay at her side or face the discipline of a slap of her broad dark flukes.

Even after we left the water as dusk began to fall over the sea, they stayed with us. A pink-bellied baby bounded across our bows in a series of joyful leaps, short-faced and innocent of [?] as any baby.

As night fell, the boat drifted out 575-800 ft. of water. Dan put a light over the stern and the life began to gather. At first the game was to catch the darting schools of squid that flashed in and out of the light circle, but then I began to notice a wonderful array of smaller life and we dipped it up in buckets, the net mesh being too large.

Little grass-thin, brownish pipefish drifted by, hooked like a sea-grass blade. Only their tiny eyes and snouts gave them away as we dipped them up.

One magical little larval fish drifted by and was scooped up in a bucket. Looked at sideways through a mayonnaise jar by flashlight, it was a beautiful mote of life. A

pudgy, rose-red body, shining silver, visceral cavity, rose silver gill covers and almost invisible crystalline fins, shimmering with passing parades of sine waves holding it, fluttering, in place against the glass barrier. We slipped it back in the sea.

A flying [?] came up, whitish wings outstretched. A yellow-bronze file fish drifted by, mimicking sea grass, and then a larger one. Then up came the most lovely animal of the night; a flattened squid, a bit like a cuttlefish, but without the pneumatic shield. It had apple-green-jade eye capsules and patches of color pulsed across its body—garnet red, golds, blacks, dustings of charcoal. It had rather pudgy arms and a dorso-ventrally flattened body. It held its arms together in pairs, bent upward when it went forward and streamings behind, I recall, when jetting backward. I would guess it at 5 in. long. It had been drifting when we caught it mimicking flotsam. We let it go.

A chain of salps revealed itself by the dots of dark in crystalline bodies, so transparent that only their faint scintillation revealed their presence and then the ciliary waves that propelled little red worms into their “mouths.”

We quit and headed for the deck above. I had a bit of fear about stray electricity from the light’s junction box sitting on the wet deck just above when we dip-netted.

July 8, 1991

Now we cruise along on the flat disc of the rippling blue sea. The water is clear turquoise here, lighted from below by bright sunlight reflecting from the brilliant white coral flats below. A band of dark blue off toward the horizon shows where the deep water is. I am urged to go swimming with a school of about a dozen *Tursiops*. They are battered in various ways—a fin tip tattered, a fin missing, a forehead white from some old altercation.

Flip, Bill, Denise, Janice, Joetta, and Dave are in before me and off in the direction of the school. I with my dive skin take longer to assemble. I feel better every day in the water—my arms loosen, my kick strengthens. I come to terms with my moustache and mask. Feels good, I must say. Another week or so and I might approach a fish as well as I ever did.

This boat works well. Dan is laid back, Lynne the cook is the soul of friendliness and cooperation. Denise focuses the program and looks at dolphin videos far into the night. Big Bill, the first mate, is strong, competent, and quiet. Not many rules here. Cameras and dark glasses, hats, radios, sun-tan lotion are piled in a jumble, on the instrument shelf of the bridge. But things . . . [?] . . . and Dave can fix anything.

I asked Denise to give me her study aims as a way of helping, if I can, as an Advisory Board Member.

- 1) Following individuals through life history as a way of understanding communication. Building a life table.
- 2) How do roles change over time?
- 3) Tactile, sound, posture, chemical, vision.
- 4) Need to develop rapport. Have them know us. Investment in relationship is Denise’s. Letting them let you in. Need a comfort zone.

She is working on a Ph.D. out of ? University in Ohio. (Joe Meeker teaches there.)

In the afternoon we crossed down the reef edge to a place where Dan anchored over a coral flat heavily populated with fire crab, violet and ochre sea fans, scattered brain coral, and little, winding, sand-floored reentrant valleys, 6-8 in. deep. The *Wren* was anchored in 12 ft. of water (she draws about 3 ft.).

We were taken by rubber boat 300 yards ahead of the vessel because of the current and let to drift back. It was a wonderful drift over the plant-animal-populated landscape. Many reef fish nearly familiar to me cruised the channels and flitted among the rocks; demoiselles, *Chromis*, iridescent blue with forked tails, green-turquoise parrot fish sculling jerkily with pectorals and tail dragging behind, wrasses, and the ubiquitous black trigger, identical for all appearances with the Hawaiian Humu humu ele ele.

A yard-long barracuda cruised along just ahead, expending little energy in his slow course. Pomacentrids were about—blue and yellow ones and a drabber brown one.

At the boat I hung on the safety line for a while, looking into the water and then went aboard, washed down, put my shorts on, and headed for shade from the still-potent sun.

About that time, a call went up: "Wreck, Wreck!" from some divers up over the reef a ways. So, reluctantly, back on went the lycra, fins, and mask, and back into the turquoise water to sea. The rubber boat dumped us in 10 ft. of water and there she lay—anchor chain stretched out, links 6-8 in. long in a long tangle to a metal stock anchor.

What we think was a metal mast step, encrusted with corals and sea fans, lay below me, perhaps 14-18 in. in inside diameter, and if this indicated the mast, she was in the 60-80 ft. range. Bent metal straps, 14 ft. long and ending in a big metal eye lay across the reef. I could see metal pins in some. My conclusion was that they were metal binders for the hull—the proper word is unknown to me, that defined the half arc of the hull.

Lynda and I most ungracefully got back in the rubber boat and headed for the *Wren*. Captain Spastic and Little Eva, we concluded. Another shower, strawberry daquiris on the afterdeck.

I must gather all my gear together and figure out when my flight is and head for Washington D.C.

We had a grand last-night party as we cruised back over absolutely flat water—strawberry daquiris—an execrable invention but effective, dinner, wine, much singing and guitar playing, and then creeping off to bed at some awful hour (about 2-3 AM).

July 9, 1991

Up blearily, packing, going by taxi to the airport, customs, a little American Eagle plane and off to Miami, thence Washington D.C.

September 4, 1991

Tahiti, French Polynesia

Fred drove Phyl and I over to San Jose and we began our long trip by loading our luggage onto a flight to Los Angeles and then to a Qantas flight to Tahiti. I had a business-class ticket courtesy of *National Geographic* and Phyl an economy ticket courtesy of us. I mentioned this separation to a gal at the ticket desk, and she gave me the sourest expression—a salute to my extreme sexism, or so it seemed. I, the oblivious male with the obedient female tagging along behind. It wasn't much that way though; Phyl wouldn't spend the extra cash and my knee hurt enough to welcome the big seat in business class. They put me up in the bubble, though it was black, and we couldn't see anything all the way to our 2:30 landing at Papeete.

A cab took us to the Hyatt, which turned out to be the old Ta'ara at Matavai Bay, which Joe Long used to own.

To bed, grateful for the length to stretch out, having seen little of Papeete except the flash of balustrade and porch balconies amidst the tropical trees.

September 5, 1991

Tahiti, French Polynesia, Park Royal Hotel

My aching knee is doing a number, especially after the cramped positions of a flight of nine hours or so, so I was glad to stretch out, which helped some.

It's a lovely view from our hotel, out over the channel to Moorea, which means "yellow lizard." Moo is lizard and Rea is yellow. What an island!! Bali Hai. Jutting black pinnacles and sheer cliffs against verdant slopes and bright jade bay. A white penciling of surf in the fringing reef and then the deep oceanic blue sea.

From here it is all shades of gray, from the clouds and veils of rain to the disc of the sea—very flat.

We slept long, finally getting up to take a tour of the garden and then have dinner on the upper terrace overlooking the lights of Papeete, the lights of the Chilean training ship *Esmeralda* at the harbor, rigging let . . .

At 3:00 PM we caught a flight for Moorea—a 12-minute hop across the "Sea of the Moon," (I think), where we picked up a taxi and headed for the pump station. No Michael Poole there; no one else either. I plastered the place with notes of our whereabouts and headed for our hotel up toward the NW corner of the island. Moorea is building up a little, though it is still bucolic and slow. Mostly mopeds and chickens on the single road.

We checked in at our hotel, a big, upscale place, tastefully decorated with 14-15 thatched cabins out on a peninsula by the lagoon and manicured with crushed coral beaches, outriggers for rent, parasails, breakfast brought around by boat—we were in the low-rent district. A room complex. Nice, airy, well appointed. Good service.

Dinner and to bed.

September 6, 1991

Moorea

Michael found us (I hadn't given him decent info on our arrival), and so off we went in our rental Fiat around the island to see the places Michael works—his coves, the places he makes his counts. He showed us all the passes. They prefer the deep passes and once inside never violate Michael's rule, which is don't go shallower than 10 m, and Ken

Norris's rule: don't stay over dark bottom. So they are found over coral sand patches, just like Hawaii.

Michael counts about 100 animals in the Moorea population, and they move around the island in relation to the weather—staying on the calm side. At Haapite we found a big school, way out just behind the fringing reef, going back and forth just as spinners ought to do—very quietly. There were surfers there, too, a couple, who had paddled for 20 minutes to get to the nice wave break . . . far enough that the dolphins were very hard to make out with the naked eye. In some places, long, blue, deep-water channels ran behind the reef, and the dolphins used these, Michael said.

I asked what Michael's plans were—what was he going to write for a dissertation—*The Natural History of the Spinner Dolphin*, he replied . . . identifications, associations, movements, feeding. My impression is that a single person can only do a fraction of this, even with part-time assistance, especially if limited, as Michael is, to a truck and a rubber boat. He can start and he should and has, but much will remain unknown.

He is collecting solid information, I think, and will compile his thesis this next year.

We circled the island and Michael left us to go home, way around at the SW tip of the island.

We will meet tonight for dinner at the Tiki Village for dinner and to watch Mareva, his wife, dance. Mareva, by the way, is “with child,” due next March or so.

We had a bit of a nap, walked the beaches a little and then followed Michael to the Tiki Center, a sort of Moorean cultural center where we had a luau and a show including Mareva as part of a Tahitian dance review—much fast Tahitian dancing by perfect women and perfect men. Then some show dances—ones with torches, another scary one with a machete and “audience participation” designed largely to entertain prim ladies from Iowa.

Mareva is quite beautiful. Quiet, religious (part of the union with Michael, I know), and pregnant, but not so it shows.

Phylly drove us back and we collapsed very late. I take these late-night affairs less well these days, especially with a leg that objects.

September 7, 1991

Hyatt Regency Papeete (Matavai Bay)

Today Phyl and I made our way out to Michael and Mareva's house for lunch. Quite an experience. And then we headed for the Moorea Airport, flew to Papeete, and made our way back to the Hyatt.

We arose very early (5 AM) and went to the local early morning market with guide Douglas, thence back to the hotel where we took a rental car around the island, looking at appropriate points for dolphins.

September 8, 1991

French Polynesia, Tahiti

Up at 12 midnight to make our way down to the airport by bus at about 1 AM, and thence through customs to the plane and then through the night to Sydney where we landed in the morning, to be picked up by Don Norris and taken to Manly.

September 11, 1991

Australia, Sydney, Manly

This day we arose and took the ferry across the harbor and up to the Australian National Museum and then back to Manly late in the afternoon.

I took the time to check up on Bill Dawbin and found that he was still a Research Associate, but that he seldom came in. He and Janet have split, over alcoholism I am told. Poor Bill, he has struggled with this addiction for many years. I wanted him to visit us and to go out to the desert with me. I doubt that he can respond, but maybe the invitation, the friend out there, will mean something to him.

Phyl and I spent some time looking at the aboriginal exhibit. These people, so primitive looking, so ancient, were particularly vulnerable to “modern” society. Their dreaming, which is their way of conceiving their origins, is full of everything that our ancestors believed, the natural outcome of culture—the ability to see and conceive fore and aft in time. Since nothing is real except the present, all the rest is imagined, or based on the thread of traded information from generation to generation—the oral tradition, or what we have learned to write in books. No wonder that in the glass of the aboriginal’s time, it included much magic, and the things of their contemporary lives. These things are all they know.

We stopped off at a big department store and I bought a collapsible cane, a great boon that let me walk with little pain, back to the Ferry dock (10 blocks). My knee is feeling a little better, and perhaps before long I will be more mobile. But I am doing well, I think, and the trip will be successful.

We had a long, long dinner at a poorly staffed restaurant—apparently the labor laws protect wages to such an extent that help is too costly to use. So restaurants are very slow.

I’m reading Thomas Wolfe’s book on his writing of *Dr. Faustus*, a fascinating book about the writing profession.

He had erected a structure he wished to follow, the story he wanted to tell, and then its parts, scenes, avenues, and then worked his way through seeking integrity through finding those who knew and then literally working his way with them. He honed and researched and honed and moved on.

So tomorrow morning off on the train.

September 12, 1991

Enroute, Perth on Indian-Pacific Train

Well, this morning, crisp, 15 deg. C, a bit overcast, we packed up our things, left the nice apartment overlooking the sea, and took a cab for the ferry, which plies the bay to downtown Sydney. Phyl had brought a little wheeled luggage rack which helped a lot, but failed in the exercise under the weight of our four suitcases, its thin pipe frame folded and bent.

We had visited Don and Christine’s apartment the night before. A tiny apartment on a hill overlooking the Manly shore. Don can see the surf and decide whether or not to go out. Christine is due anytime now with their first child.

We had a good chat. Don is entertaining, a good conversationalist, and with many firm opinions and the artists’s eye. Christine, quiet around us, is also full of opinion when

she opens up, very much the Aussie, and I think a little uncomfortable among all the professors. If she only knew how simple we really are, but it's never that way, I fear. There is always oneself to overcome [??] class to leave behind with all the complications that brings. Christine, a brilliant French lit student, came right up to the brink of completion of her dissertation and stopped. Her way was not clear and she couldn't leave her past, her family, and her old friends, I suspect.

We piled in a large cab, all four of us and our luggage, and climbed up through glassy, shining avenues of downtown Sydney to the train station, where we boarded the very long Indian-Pacific train. We were in A-car, right next to Bob and Ginny—two bunks, a bathroom, shower, a sofa, three-folding arms and nice, but not too clear picture window and two fold-down beds, a little closet, a mirror, and appurtenances.

The trip took us over west of Sydney into the Blue Mountains, Triassic sediments dissected into canyons and battlements of banded stone, clothed with eucalypt forest. It's interesting to see that it has an understory of acacia, ferns, and other low vegetation, while typically in the US, eucalypt forests are bare except for fallen bark. The ecology is complete here. The Blues were something, over 1,000 m tall where we passed through. Not mountains really—the best an old, eroded continent, more ancient than nearly any other can produce . . . a flat plate of stone barely breaking the sea's surface, wrinkled stone and no more, clothed with sand and salt pans in its arid center and around the periphery a band of green sometimes jungle and sometimes turned to grassland.

The latter is the way it was all the way out to Bathhurst where we had dinner. New shorn sheep, white against the close-cropped green of the pastureland took over. An undulating land, divided into paddocks or runs for the livestock. Little towns and [?] farm centers of a few thousand people were the peoplescape.

We had a nice dinner of Aussie lamb, drank a Barossa Valley champagne in honor of Ken and Christine's 4th wedding anniversary, and retreated to our compartments, I grateful I would take my evening Naprosin pill to still the pains in my knee a little. Damn thing!! It makes me steal off away from the center of things and go silent, sometimes when the ache gets strong.

Sunset came over the increasingly flat land. The air is clear and crisp.

Phyl and I both were remarkably sleepy, looking at the clock which said 7:30. We finally pulled the bunks down, unfolded the little steel ladder, Phylly up and me down, for a change.

September 13, 1991

Australia, Broken Hill

With dawn we would see how flat the land had become and how sparse the trees were.

The sun came up just as it does over the sea, and we saw a land of low shrubs, pans, red soil, and red gums in the wandering washes. The latter are very beautiful, really.

We wandered into the dining car for an enormous breakfast. We sit three couples across and one Aussie couple. A menu, cereal of corn flakes, oatmeal, then heavier stuff, sausage, mashed potatoes, bacon, hash browns, then more, fruit juice, coffee, tea. The clientele is largely retirees. One couple was headed for Broken Hill to take a five-day outback tour, which they have done two or three times before; very open, very down to earth.

We've seen a good many kangaroos—the big, red ones, bounding across the landscape, told by smaller size and bounding gait from the ubiquitous sheep.

Cattle are here too, and the vegetation shows the effects to a degree. I find there is a grazing board to protect the land from overgrazing and so far I've seen no decimation like that of eastern Oregon.

Birds, so far, have not been especially conspicuous. A few magpies, an eagle, some gullahs.

We slid into Broken Hill, a lead-silver-zinc mining area now nearly played out. The town survives as a supply center—20,000 people—very much of the frontier, though generally tidy. The air is crisp and clear. We stay half an hour and slide on toward Adelaide and the Millarbos.

The countryside gradually becomes greener as one approaches Pt. Pirie, which is near the head of the Spencer Gulf adjacent to Adelaide. They smelt and ship lead, zinc, and silver from Broken Hill here.

As we approached the gulf, the rolling hills were checkerboarded with wheat fields, most of which seemed to house a flock of new-shorn sheep. I don't quite understand how you can graze and raise wheat. I'm sure I've missed something.

We've begun to see emus, big unkempt rattita birds, a bit smaller than the ostrich (1/3 down I'd guess), that run across the low hills. We passed the lower end of the Flinders Mts., battlements of banded rock formed into low mountains and [?] mulga and rucalypt [?] water courses at [?]. In this low land they are a point of real interest. At home, few would know their name.

Soon we will reach the upper Spencer Gulf, turn south to Adelaide, where a new crew comes on board for the segment to Kalgoorlie. Our stewards, the food, the company, have been splendid. Three times a day, sitting I am called out and heads for the dining car, a big menu of well-prepared food comes in courses, as we watch the scenery go by. The Aussies are mostly very in a friendly fashion that is open and easy to talk to, quick to "lay it on the Yanks" in a friendly fashion that is easy to ignore.

I tried an Emu beer at lunch and it was superb, from Perth, I think . . . like Pilsner. We're seeing pepper trees here, casuarinas, eucalypts, clothing some of the low hills, or in copses out in the green fields.

We stop at Adelaide at a new station a few miles from town—and so are restricted to its institutionalized precincts for our hour stay; quizzing locals about the man who hunts starlings with a hawk on the West Australia-South Australia border (they've heard of him), and about camels—wild up north and apparently raised at Alice Springs. Christine has a book about the woman who crossed Australia on a camel recently. I must find out about the foreign commerce in camels that's reported to have built up.

One of our informants on the platform while we waited for the train told me that they used to have a brothel on wheels on one of the cars of the train to Alice Springs—the Ghan. (Upon reexamination this turned out to be on a Canadian Railway. Just a casino on the Ghan.)

Gone now though, and on this one alcohol is strictly restricted to the club car and is little in evidence on this trip.

Lots of naps, reading about the aborigines, the plants, the birds. We're not yet half way!

The portion of land around Adelaide and north to the head of Spencer Gulf is lovely, tended and green; wheat, rolling hills, patches of eucalypts, neat houses, graveled and embanked roads, and more and more houses. Everything is well kept and looks prosperous. The Barossa Valley wine country is just to our east—it must be undulating country—[?] and watered.

Now out onto the Nullarbor. We will awake before the great straight stretch.

At 2:50 AM we'll pass the halfway point at just beyond Tarcoola, where the line goes off up the Simpson Desert to Alice Springs and we go on west, and then slide out toward the Nullarbor, where by about 1 PM at between Mirina and Loongara we start "the long straight"—the more than 400 km in an absolutely straight line across the flat limestone seafloor of the Nullarbor.

September 14, 1991

We woke up just before the Nullarbor, in the midst of very red stabilized dunes clothed in mulga, *Casuarina*, and low shrubs. A smattering of wildflowers clotted the sand, especially around the bases of bushes.

Gradually it flattened and the vegetation thinned, until now out west between Watson and Cook it is utterly flat, a disc of earth as far as you can see in any direction. Vision is limited by the curve of the earth. [?] Vegetation is mostly low, gray saltbush and every now and then a larger shrub—3-4 on the entire horizon.

Beard describes it as bluebush steppe (*Marreana sedifolia*); treeless in its center with low trees of *Acacia* and *Casuarina* towards the periphery.

Watson was just half a dozen wooden buildings, and a Lion's Club and Rotary Club from Port Augusta to the east.

The Nullarbor is about 350-400 km deep from the coast—over an extensive flat limestone bench.

The clouds are flat too, a thin sheet of broken cumulus with blue above, fading to pale greenish blue on the horizon all around.

There are, now and then, low pans, green with grass and other herbs with occasional shrubs, but mostly just bluebush and sky.

These solution depressions are called dongas or dongers according to Beard. Apparently, during the great rabbit plague, the bluebush was decimated.

At about 10 AM we slid into Cook, right in the middle of South Australian Nullarbor. "If you are crook come to Cook," declares a sign on a steel tank by the tracks. It is flat! Cook has probably four dozen houses and perhaps a hotel. The wind whipped in from the west, 18 knots, warm and pleasant. Peruvian pepper trees, umbrella trees, oleander (a lady said the Aussie name was "holeander." Two portable jails of stout wood called "brols" stood by, doors open with their peep holes and bars, for us to photograph.

I was told this was a place for section hands to stay and for watering trains.

Off we go now, toward the border of South Australia-West Australia. We'll see the hawk man or won't we. He's supposed to keep South Australia's starlings from going west to infest West Australia and these birds are supposed to be hopping the trains so we may see him, though the wind is picking up ferocity, blowing dust plumes 40 ft. in the air above the roads of downtown Cook.

Bob informs me that the Nullarbor limestones are Cenozoic, perhaps Miocene. Certainly they are full of fossils.

The train whistle blew and we all scurried back on board. Phylly pointed out a pair of ibises stalking along in the vegetation. I hauled out my trusty Australian bird book and found the straw-necked ibis [?]*—*sometimes called “the dry weather bird, farmer’s friend, or letter bird.” They are cricket, insect, frog, crustacean, and mollusk eaters and said to be rare or absent in the arid inland. Take that, bird book! This is the arid inland!

We wait for a freight to go by and then off to the border!

Now about 11:30, the trees or shrubs have all disappeared and it’s just bluebush (an *Atriplex*), air, cumulus, and sky. The horizon is as precisely drawn as by a ruler. A bush a foot high stands out 200 m away. We enter Denman. A radio tower, cement ties, we leave Denman. No houses on my side of the train. A smattering of wildflowers and long, supple bunchgrass bending and whipping in the wind. One bush four ft. high. Perhaps a eucalypt or *Acacia*.

A road sign made of a tire alongside the two-rut dirt track. A blackbird the size of a crow swoops half a mile away. Two falconiform birds swoop and whirl. Ten minutes later, another, like a sparrow hawk. We’re on what the Aussies call “the long straight” . . . the longest straight railway line in the world, more than 400 km absolutely flat and straight.

Here and there along the track edge enough water has gathered to produce a splash of yellow. Somehow this imperceptible moisture has unlocked the seeds and they are free to bloom. About 5 in. of rainfall falls annually. A white flower, like tiny popcorn, speckles the landscape, half beneath a giant cloud shadow and half in the sun. The soil, reddish tan, shows through in ruts and pans. It’s been a rainy year I’m told. These flowers wouldn’t be here, maybe not even the bluebush itself.

A mile later, two sparrows.

Two bushes, three ft. high on the horizon, yet so far apart they move in two different planes of motion. Relativity!

I had xeroxed the rules to Whist and had half designed a test of Einstein’s theory of relativity to relieve the boredom of the Nullarbor, but we set all these aside, at least temporarily, in favor of trying to see if the big stick nests that occupy every fourth or so electric pole alongside the tracks were occupied. Now and then we could see black babies sticking their heads up above the rim, or watching for wedge-tailed eagles that we see every few km, wheeling and dipping over the flat plain.

A single house of stone on a swell of the land, the first one we have seen except for the railroad hamlets, is great cause for wonder. Two windows and a portico, then we find it a mile out of the town of Forrest. Forrest is not much more. A radio tower dominates three houses and a skultch[?] pile of old cars, abandoned rails, and crushed cars.

The plain is rocky now, with slabs of limestone and seemingly this shallow soil has relegated the flora to animals and grass, for the most part. The bluebush is restricted to patches like jigsaw puzzle pieces.

One can almost see the sheet of hardpan emerge as we roll along. A swell of land passes, and it is a mosaic of rocks, while downslope in the swales the thin soil prevails; but now sheets of tan rock, and scattered fragments are everywhere.

A big dust devil swirls and boils away over the slope of the land and is gone except for the swirling opacity it leaves in the air above.

The steady wind, almost planetary in its constancy, presses its fingers against the grass, sending broad ripples across its sward as it hurries on.

Lord, there's not much here.

There is much that is wonderful about this pace. The land dictates our enthusiasms and excitements by what it sparingly presents us. This pace lets us focus down on the real things that make this land, the uprooted hardpan, the rippling wind, now and then a wheeling bird, the flat deck of clouds matching the flatness of the land below. We can doze, awake again, and pick up the story without a seam. I awake and it's become all nodding grass, dark-green below with awns of pale-green dipping and bending. A swath of this pale color bands the landscape far away toward the horizon and it's extinguished by the huge cloud shadow.

Somewhere west of Loongana still on the plain, the train stopped at what the announcer said was an old World War II prisoner of war camp . . . perhaps at Kybo south of the tracks, which shows on our map as a small red square. What a place for a POW camp. Let the prisoners wander and show up for meals, with no water. How could anyone escape?

We approach the end of "the long straight" at Haig, the place where the track bends about 20 degrees to the N.

The low scrub is creeping in, pocket by pocket, meandering watercourse by meandering watercourse. Phylly saw some cows. The soil is a [?] and the place looks beat up, grazed to the bone.

Now I see a windmill a mile or more away, and a truck, bluebush, [?], fences, no bunchgrass—the hard rusty earth showing through.

Next come Rawina and I believe we stop for a few minutes. The Nullarbor looked so healthy, if spare, two dozen miles back, and now it looks beaten and tattered.

Gradually the forest thickened and darkness came, rose light through black eucalypt limbs and then darkness.

After dinner (much good food all the way, good wine, good Emu beer), a fine conversation sitting in our cabin with Bob—retrospective of our careers. How fortunate we felt, how satisfied with what it had been, and with our families.

The train pulled in at Kalgoorlie, a gold town (20 tons of gold last year from open pit mines)—a walk around the town, few people out, not many cars. We drank at the bronzed Paddy Hanson who discovered gold, made our way back, and are off to Perth, which we reach tomorrow morning at 7 AM.

September 15, 1991

Perth, Australia

Dawn came some distance outside Perth in the rolling hills of wheat and sheep farms—well tended green and dotted with newly shorn sheep. Most of the eucalypts and scrub are gone, except an occasional tall clump or a hedgerow along the road's edge. Finally, an hour or so late we pulled into Perth Station, unloaded our bags and were met by Geoff Shaw, Bob's friend who runs education efforts at the National Museum of Western Australia. We went to his nice house, met his wife Jill and daughter Jan.

We had a nice visit at their nearby home, a homey place surrounded by a splendid garden of all sorts of plants, exotic and otherwise. Geoff trotted out books about this and that question we had. I asked him about my usual questions—the hawk man who is seeking to control starlings at the border. He told me that the Board of Agricultural Protection were shooting starlings and English sparrows with a troop of people. He wasn't sure if they employed the Hawk Man, or if he was real. A call should settle the matter.

I asked about camels. Yes, he said, Australian camels were abundant in the outback and being exported to the Middle East. The Middle East camels often carry camel syphilis and Aussie ones are free of it.

He told me of a giant meteor that was discovered on the Nullarbor—the Mundrabilla Meteor, found by surveyors in 1966. They saw a big lump on the flat land and when they investigated, it was a 11-ton part of the meteor. Later they found another piece weighing 5+/- tons that was sent to Adelaide. When sliced they found the characteristic Widmanstätten figures of iron meteorites.

There have also been considerable tektite finds on the Nullarbor. An asteroid hit the land and showered up glassy droplets in all directions, some like buttons and some with collars and other forms. Others occurred near Birdsville and Inaminke.

Geoff said the Nullarbor was 300-m-thick limestone, Cretaceous at the bottom and Pliocene/Miocene at the top. It's bottom margin marks the place where Gondwanaland split away to become Antarctica. The great crack marks the margin of the South Australian Bight where the land left Australia behind.

He told me of giant sinkholes and limestone caverns of huge size.

We check our reservation for a van and will pick it up tomorrow, spend the day here and then be off on Tuesday to Monkey Mia to the north.

It's been raining on and off today. The wind whipped across the Swan River as we drove around the broad body of water, looking at the broad vistas, houses, skyscrapers downtown—a lovely, clean town.

Back to the hotel, to let our lunch settle a little before we think further about food.

Finally we did go below for a good, if modest dinner, and much conversation. The Bloomes are waffling and may stay with our great venture to the south. I hope so. They're grand company.

September 16, 1991

Perth

The day was spent going around Perth, getting maps, finding out about starling control, visiting the museum. I sent my respects to John Bannister, who is director of the Museum of West Australia. He seems to be in committees most of the time, dealing with about 200 employees, and his IWC affairs. I didn't bother him—just left my respects.

We got a van and found out that there is now not a car to be had in Perth.

There is a big rally here. Sports are much bigger than the fate of Russia, Gorbachev, and the rest of the world. The Australian football team (the Hawks) did a number on Adelaide and now go to the finals.

Phylly had a long walk through the botanical gardens while we tended to the rest. Lucky to get our van, a six-seat Toyota with a roo-guard (bumper) and good luggage space.

We leave for the north tomorrow and will take a couple of days in the process, and finally heave up at Monkey Mia in Shark Bay, where I go to work. We'll visit some National Parks and see the stromatolites at Carneva in deep, saline Shark Bay and then head back on the inland road. Then south.

I found out a lot about starling control by calling the Agricultural Protection Board. I talked to Greg Pickles who is in charge of the starling program, which seeks to keep the starling and English sparrow out of the agricultural areas of west Australia. Greg felt they were succeeding. He had taken the offensive. Old efforts had established the West Australia-South Australia border as the battle line. He said: "Let's go gettun earlier, in South Australia before they even get here." So most of his work is there. He's established three control districts and knows where there are colonies. Then he and four men go after them with mist neets, cannon nets, and traps. I failed to ask him about the falconer, feeling a little silly about it (which is silly). He said he'd worked at UC Davis with Dr. Terry Salmon. He will send me a report through about 1986-7.

Thence back to our friendly, gracious little hotel by the park. We waited a long time for our free bus (free within the immediate Perth area). Bob took the wheel of our van and we went to dinner in [?] at a place called the Oyster Bed—on pilings over the estuary. Very pretty. The food was cutesy-poo and difficult to find a simple entrée. I ate oysters.

Back to the hotel.

September 17, 1991

Enroute North from Perth

We ambled down to breakfast, hauled our luggage down, ate breakfast, said our goodbyes to the pleasant staff of the Hotel Sullivans and shoved off to the north, Bob at the helm of our six-passenger Nissan van. It takes all of our luggage and leaves us a clear seat each, though with my gimpy knee the foot room on the middle seat leaves a good deal to be desired.

We traveled up the Swan River and inland to the Brand[?] Hwy. north, which took us out of town and into sheep farms dotted with eucalypts, green, green wheat fields, yellow with a pretty little daisy. A broad swath of bush accompanied the road on both sides and was alive with blossoming shrubs and animals. Phylly knew nearly every one, from a lovely little yellow orchid to the banksias, kangaroo paws, *Lechenaultia*, and dozens more. One new to me was the smoke plant, a curious bush whose stems were covered with a heavy tomentum with a tiny flower at the apex of each stem. There were two—one very white, the other somewhat less so. I'll bet they are pollinated perhaps by moths after dark.

Place names here are full of aboriginal words—Pamparup, Nerragup, Boongarra, etc. The farms grew larger and houses fewer. Some of the fields had emus "grazing" or at least searching for food, and we saw the occasional kangaroo. I'd think the scrub would be hard to hop in. It's a very dense equivalent of our Mediterranean scrub.

We are led to a cemetery out of Gin Gin where Ray Colett had told Phylly he would find *Anigozanthos*, the kangaroo paw. What a remarkable plant. It is a tall (1 m.) plant with a gaudy green, yellow, red, and black flower and red stems. A bird flies in, perches on the stem to sip nectar from an ovary set deep down a cleft. Overhead a rake of anthers pushes yellow pollen onto the bird's head. These plants occurred in three main

kinds in the cemetery—the main, tall one; a low, red one; and an orange, low one. Many other wildflowers were scattered among the bases of the larger flowerers—a brilliant and curious garden!

Down the road we went in our comfortable van to Nambung National Park, site of a remarkable collection of travertine pinnacles and a dense flora adjacent to the beach and blocked from it by big rolling beach dunes, crystal white and full of white fossils. The whiteness, I suspect, is because of a lack of feldspar as an iron source.

Spinifex, black boys, a curious relative of the lily, were scattered everywhere, and I am told, in some places in the outback, become dominant. It's in its own separate family—something like Xanthorreaceae, in honor of a yellowish gum secreted by the plant that can be used as a kind of hard glue for sticking implements together—stone axes, etc.

They stand up on a thick black trunk, 18 in. in diameter or so, and up to six ft. high at times, crowned by a radiating tuft of thin, sharp-pointed leaves . . . a landmark Australian plant.

At Eneabba we passed a major titanium source—in rutile sands. TiSO_4 ? I also used to love to peer into rutilated quartz crystals, the long amber crystals of rutile shooting through the clear quartz.

We cut off the main highway and headed toward the beach and Nambung National Park. A dirt road led us through the rich scrub back of white, white beach dunes. Phyllis was in her element as many of her old friends from the Arboretum were in bloom. the road took us to the pinnacles, which were ranks of tufa castles set in a saffron-yellow sand. I could locate the central water tube in most of the castles. All this runs counter to the official explanation in their handout—which seemed to miss the water, algae, precipitation [?] story that is likely to have been the case.

We headed through growing darkness to the wheat and fishing port of Geraldton, set on a peninsula, just inshore of the Albrojas Islands and reefs where the rock lobster is fished. Finally we reached town, and quickly turned off at the Larcoola Hotel and Caravan Park, where for \$50 base cost, we rented a cozy little house that took care of us all. Once we were situated (good we called ahead—there was no space left . . . The Chief of Police was using a house with no water) We all headed off to a local tavern where in back they ran a fish restaurant. We had the best dinner thus far in Australia—garlic prawns (a garlic sauce made with cream). Then off to bed, Ginny on a cot in the living room and the rest of us in two bedrooms.

September 18, 1991

Australia, West Australia, Kalbari (enroute)

A good and inexpensive sleep, a shower, then K. Bloome presided over breakfast, which he extracted from a great mysterious bag he is carrying—toast, coffee, marmalade, and what else? Then we were off up Banks Highway North.

The road takes one up past vacation beach homes, big grain silos, and out into the wheat fields and bush. It seems almost indiscriminate what land has been cleared and converted to grain and what is left native. The more I see of the latter, the more it resembles our chaparral in structure. Shrubby, dense, wood microphyllous plants often with low annuals back in amongst the branches of the perennials. My, what diversity! And essentially everything native to Australia. Except around habitation when many

exotics are obvious—bougainvillea, umbrella trees, oleanders, etc. I've seen or detected no introductions out in the scrub.

The road edge effect is very strong. I'd guess the stature of shrubs within about 10 m of the road are 3x as high as those beyond. I can't be sure but the species list seems to be larger, too.

Up the road a piece we came upon a big hilly field, a couple of hundred acres, I'd guess, totally dominated by salvation Jane—all around a lovely little pond, that reflected the blue of the flowers and became little azure gems. We got out to photograph and I was able to key it down to family—a hydrophyll is my guess, dark azure and purple-blue flowers in scorpioid cymes. Introduced? I dunno. Bob says that local lore has it that in bad times stock will eat the plant.

Grain is the big thing here. Our farmer's subsidies are big news here. We heard about Washington state, what was happening to corn, but very very little about the world at large, even though the USSR and Yugoslavia are being remade.

Up Gib Gib hill to Kalbarri National Park, a vast, rolling plain clothed with scrub. We stopped along the road a good many times to check out the botany. We saw so much. A big yellow *Grevillea* nodding on long stems, a dark-blue fringe lily (*Pattersonia*), a curious *Darwinia* with its flower head lying like a frying pan on the ground, the saintly little cypress pine *Callitris glaucophylla*, a fire-intolerant species that persists where fire can't get to it.

The company is fine. The Bloomes are soaking it all up in many dimensions and are of wonderful good spirits. Kenny is always caring for us in various ways and ready for every new adventure.

Bob and Ginny are both full of interest about the world we pass through and good company. I enjoy seeing little artistic things with Ginny—patterns, clouds, colors, imagination, and with Bob the landscape, its history, all the little foibles of the people, the signs, the land.

After visiting a bend in the Murchison River, incised bends down into ancient Cambrian and Silurian sediments in the ancient rolling landscape, we headed for Kalbarri for lunch—one gal did everything and it was good.

Now it's time to hit the trail to press on the six hours of driving we have left. It's low, rolling wheat land and scrub.

What do I want to learn at Monkey Mia?

I want to interview Jane and Andrew Richards and here are some questions:

- 1) Is the interaction between wild dolphins and people working?
- 2) What are problems?
- 3) What motivates the dolphins?
- 4) The people?
- 5) How much of the school is involved?
- 6) Dangers to either side?
- 7) What interest do you think motivates the human visitors?
- 8) How big is the local population of dolphins?
- 9) Who comes in?
- 10) Recount the history of the Monkey Mia dolphin-human interaction.

- 11) Talk about family interactions:
 - a) mother-young
 - b) food-sharing
 - c) exchange (do they give us things?)
 - d) male role
 - e) female role
- 12) Sponge behavior.
- 13) Fish capture and handling.
- 14) Die-off of dolphins.
- 15) Annual cycle.
- 16) Protection of animals.
 - a) What do they have?
 - b) What do they need?
- 17) Are more Monkey Mia's a good idea. Bunbury.
- 18) What do you expect to investigate? What have you learned?
- 19) Ethical questions.
- 20) Is Monkey Mia valuable? Why?
- 21) How do you feel about the question of dolphins being high-order mammals?

I asked many of these questions and found Janet Mann (Of Georgetown University) and Andrew Richards (University of Michigan) very much into their research. They didn't seem to be much engaged in the larger issues of conservation, public values, social attitudes, etc. Just like researchers everywhere. Young and mostly an island of ideas within the larger flux of society. They were well engaged in the dynamics of their dolphin population and asking questions within their paradigms.

Janet is both child psychologist and primatologist, and Andrew now a solid behaviorist. I tried for a while to find out about people's attitudes and the equation of exhibit versus this sort of interaction and didn't mine loose much ore. So, I switched to biology and found them looking at roles in dolphin society, thinking about animal networks over considerable areas of the sea, and the like. The underwater viewing is rather poor here though out to sea a bit it might be better. Only a handful of dolphins come in and some of these have been at it for years. Holeyfin brought her two-months-old baby in. It was a bouncy little soul, often wandering a couple of dozen meters from her. She seemed not to interpose herself between it and the people. Others came in including the pushy Nicky and others I didn't know.

The habituation is very limited with the lone population of a couple of hundred animals. The wardens frown on regular feeding, or habituation, not wanting to "lock the animals into this relation." They worry that we are an unreliable companion in such a relationship—like feeding chipmunks. I doubt that this is a real problem. The warden lined up everybody and pushed them back (with words) into shallower water, on the excuse that it induces the animals to come closer. I thought it was to keep her from being forced into water up high on her waders.

Holey Fin swam along with her, habituated as could be, turning on her side, probably looking for an intermittent handout of fish.

Nonetheless, the people did experience the animals and it was thrilling to some, especially I think to some women. I saw many hands outstretched and waiting, full of

anticipation, and the wonder in the eyes of some children. Conversely, there were some near, up the beach, who looked profoundly bored.

Christine was thrilled to touch one. My sense is that the experience is rich for some—a touching of a human to a friendly wild animal, unthreatening, unafraid and accepting. I even think the cultural dimension comes through for some—that these animals have chosen to come to us and not necessarily for food, but also because we are welcoming and open to them . . . their gift to us across the huge phylogenetic barrier between us.

The very lack of spreading of this tendency, I think, reflects badly on the means of cultural transmission in these animals. Why don't others learn? Well, Andrew says he thinks ownership of a "territory" to the handouts may be involved. A new animal joined the beach group a couple of years ago and there was some evident aggression. Most of the animals are Holey Fin's family.

I'd guess that if it is dolphin ownership, others will replace them if they die.

In the morning I interviewed Andrew Richards and Janet Mann about the dolphins. She is a new-minted Animal Behavior professor at Georgetown University.

Then, this afternoon, Andrew took me out on the boat again to see if we could see the sponge carrying dolphins and to watch how he does his work. Janet was in another boat with her assistant, Carrie Ann?

We boarded an aluminum skiff equipped with radio, oars, and fathometer, and took off out to sea. The bay is predominantly shallow with very extensive grass flats, channels in between and deepening slowly.

The dolphins are very scattered—a few loners, but mostly small groups of twos or threes—and fairly far apart—often a mile or more. Far out (3 miles) we came upon a crab trap boat laying double-buoyed traps over a grass flat. In this same area we came upon a loose assemblage of about 15 dugongs; they looked light, rusty, sand-colored and came remarkably close to the boat at times, swimming down a few feet, fairly close alongside and veering to surface. I saw adults and young. Their curious flattened snout and lack of a fin is very evident, and often enough I could see their very broad flukes slide right up to the water's surface as the animal's glided along. They blow a bit and can swim quite fast. Once we shut the engine down and one circled us curiously—15 yards out. What a pleasure to see a healthy population of this beleaguered species here in Shark Bay. It is, I was told, one of the healthiest populations of its species.

Richard Conner had left instructions for me to be shown everything. He told Andrew and Janet to be sure I was taken on a longitudinal follow, where you follow a single animal for a time and note behavior and associates. Much like a focal-animal method. We didn't do it. I begged off, pleading my fragile knee. I took an extra pill before going out and it pretty much saved me, I think, as I could feel twinges coming on.

To return to the lure of Monkey Mia. First it has received a lot of publicity and has become a destination. The run of the public now comes on tour buses and you get all kinds, especially a lot who are "tourists," who are spectators but not participating, even including not thinking much or even feeling much. I suspect many are not used to feeling, to thinking, to wondering. The Booboisie, perhaps. They probably aren't much engaged in issues about the degradation of the earth or the problems of wild animals. Others worry, but their sights are narrower, more trivial, closer to the little things in their lives. Then there are the young, into young things; girls who look laterally past the dolphins out

there to see if they are being noticed by the boy they saw. The juices run strong but not about the fate of their world.

Then, there are those who care terribly—bless ‘em—those that reached out in anticipation to these wild beings, who somehow took them on their own terms and came back for more. Holey Fin works it like a paper route. Her route. And she introduces her children to it, a family of cobblers, or the Great Zampeses, who were all aerialists. It’s a living. What does she think? The idea that they are not being conditioned seems ludicrous to me. We set rules, the dolphins get food.

So how does it stack up against an oceanarium show? There is the great plus of the animals being real wild animals coming in on their own terms, of leaving it up to them when to show and what to do. The visitor might or might not have contact, so contact becomes precious. The place is beautiful and the nearby sea a wild place of rays, fish, dugongs, turtle grass, etc. The beach is lovely. The education-protection message is generally well done.

The format allows visitors to imagine mostly about who these animals are.

It’s very simple so far. You don’t learn much about dolphins on the beach, though there were good posters in the interpretive center.

The scientific work I found rather bland and predictable and seemed not to use the beach situation very much. It was mostly a field study of accessible dolphins from a convenient place. To be sure they were following the genealogy and to some extent the behavior of the beach-frequenting animals.

September 20, 1991

The last morning. Clear, quiet, crisp, and lovely—the precursor to the warmth of the day. I walked down to the broad amber strand before my morning cup of coffee. In the morning light the hills shone almost tomato-red through their low clothing of scrub. The rolling land ended at the beach far to the north in a series of bluffs already distorted in the sun and then dipped into the haze and became a line or the horizon. Scrub formed dark gray-green patches interlaced with red over the low hills.

A scattering of people were already at the beach just north of the little pier, wading into the water and Holey Fin and her new child were there, too. Hands reached out in the search for connection.

Out past the thin crowd of dolphin-watchers, half a dozen small boats hung at anchor, the water still as glass around them, their retrieval lines, snaking ashore under the slowly moving dolphins.

This low land is exposed at every point of the compass and when the wind comes in from the Indian Ocean there is nothing at all to stop it, which it may do for weeks at a time. Right now I can see out past the glassy beach shallows to a dark band of grass, followed by a band of blue where the sponge-carrying dolphins work, and then still farther another dark grass patch where we had encountered dugongs the day before.

Sponge-carrying dolphins for some unknown reason, dive, retrieve, and carry sponges in their beaks. No one knows why.

A big, gracious caravan park has built up north of the pier, housing at least 200 people at capacity, featuring served meals in a big thatched ramada (the sides now closed by plastic curtains and heated by a big fireplace and hood).

A snackbar, a little store, and more, crisply run by a competent young man named Leith for the entrepreneur in Perth.

Denham too has felt the presence of these few dolphins. Once a sleepy fishing port, it now caters to tourists mostly and one can get an elegant sitdown meal with fine wine. Tour buses park end to end on the streets.

A day of goodbyes at Monkey Mia and travel. Many things happened in this simple scenario. We checked out, paid up, said goodbye to Andrew and Janet, and stopped long enough for me to write a description of Monkey Mia, which I had forgotten to write when I came. I photographed the Indian Ocean pelicans and off we went.

Before Denham we came to the Nine-hole Golf Course, which was very dessicated and the holes were sprayed with some kind of oil instead of green grass greens. As I stepped across a little band of scrub to get onto the fairway, I sighted a snake 18 in. long, tannish brown with blackish mottlings on its head and neck. It was eating what looked like a cigarette but which proved to be an insect, which the snake finally released and which flew away. The snake then reared up its head three inches above the ground facing us. I gave it wide berth as I suspected it was a brown snake, and therefore very venomous, even at this size. Sure enough, when I ran it down in my limited books it came out "West Australian Brown Snake, the world's second or third most venomous snake." It is supposed to be very aggressive and to strike two or three times in lightning succession, so fast one can hardly avoid it . . . like our racers. We gave it wide berth and drove on, later reading about a snake collector who had been bitten by a snake about this size and almost died—unconscious, great difficulty breathing, clotting destroyed . . . an awesome little beastie.

Into Denham where we straightened out things about our rental with Sandy Cooper, who turned out to be a nice guy. Ken got his deposit back. Then we got our act together and drove off down the road past "Useless Loop" to Hamelin Pool and Station. A dirt road takes off through the scrub toward the broad, arcing beach deep in the inner arm of Shark Bay. Soon it comes to the station building, with typical peaked galvanized roofs and screen porches, water tanks, and windmills, through ranch gates—metal mesh with bails for closing and down a dirt track to back of the beach dunes where one comes to an old (1884) telegraph station in which the station owners had managed to keep a stromatolite alive—under a grolux tube with an artificial tide.

The stromatolite is a castle of calcareous gravies and gelatinous blue green algae that form very slow-growing layers—less than a millimeter per year.

The algae bubble off oxygen and little fish, like larval snappers, clean off encrusting green algae that could shade off and kill the blue-greens. What did this before fish were evolved? These stromatolites are found in rocks at least 3.5 billion years old, along with other perhaps even more ancient forms, both of which must have been involved in the production of the original oxygen-rich atmosphere. We could see the algae bubble.

We hiked over a beach berm made almost entirely of a single pelycopod—a little ribbed shell. It dies and gas from decomposition causes it to float and it is blown ashore to be piled in windrows on the beach.

It was so thick and deep that beds, many 40+ ft.-thick had formed a pure coquina, which had been cut into building blocks at one time until a considerable quarry had been excavated. Lovely stuff, but not very strong.

Out beyond, in the intertidal, were the stromatolites—curious, knob-like, blackish castles up to a yard or two in diameter and perhaps two ft. high, surrounded by shallow, very saline pools, teeming with these little silvery fish and little else.

These stromatolites live only in places where hypersaline water occurs, apparently to protect it from competition and hence allowing their persistence in this complex modern ecology.

As we hiked over the berm and back down by the telegraph station, there on the road we encountered two lizards in combat. Each was on the order of 10-12 in. long, with a rather large head like a collared lizard, a dorsal-scale ridge colored tan like the sand. They had long, tapering, cylindrical tails. Each nipped at the tail of the other as they circled. Every now and then one would reach out toward the tail of the other, whirl in the air, with the effect that its tails wing around out of reach of the other just as it bit. This was very fast—a fraction of a second—and then they moved in to circle again. Finally, slightly smaller than the other [?], vanquished and moved away, still facing its opponent, who pursued. I think they were *Agamas*, but don't really know.

The hormonal rush gripped both of them, and their fight went on even though I was constantly photographing them. Unfortunately, I was having film-speed problems and I much doubt that my pictures are any good, even of the stromatolites. Sob! Sob!

On we went down to the main highway and then south. Our destination, Kalbarri, where we had rented two “two-star” motel rooms over the phone. Two star means there is a broken bulb in the bathroom light.

At Pindadano we came into mulga forest, having passed some ancient sand ridges clothed in a jagged fringe of cypress and pines.

Then as we approached the Murchison River, the low forest grew denser.

Spotting a little critter edged out onto the road, I said “Tiliqua! Skink! Pinecone Lizard!” It scuttled off into the dense bush before I could respond.

We cut off toward Kalbarri where we had a two-star hotel reservation (two rooms, three families) and down the road into Kalbarri Park in the late afternoon. We cut off to a lookout over the Murchison River Gorge. The ancient plain all covered with a rich scrub finally wrinkles a little and one can see the winding drainage of the Murchison cutting down through the red Silurian rocks toward the Proterozoic below river level here. An ancient winding course is still followed, now deeply incised in the land. Not far below us it flows into its gentle estuary at Kalbarri.

On the way back I saw a violet and black snake-like animal on the road and we stopped. I think it was a specimen of the endemic family of legless lizards, the Pygopodida. It had a very elongate pointed head, and I believe I could detect that it had once lost and regenerated its tail.

It thrashed from side to side ineffectively, very unlike a snake. I stopped hassling it and we drove on.

Mt. Pinatubo had thrown dust into the atmosphere, giving us a lovely red sunset which silhouetted grevilleas and black boys against the sky, precise filagreed black against the deep rose red. Elegant!

We holed up in a motel attached to a bar, sought out dinner, and went to sleep. I spent some of the night mulling over finances for the trip, in the dark—a fruitless activity.

Australia Caravan
September 21, 1991

We drove south along the coast, had lunch in a tea room at Northampton and headed inland at Geraldton, into the wheat belt. The country is an ancient landscape of low, rolling land, and it is ideal for wheat. Most of the land is cleared and solid grain pasture with big flocks of sheep. Most of the scrubland is in narrow bands along the roads. These are about one car wide with broad dirt shoulders for passing.

We looked at a tiger snake, dead on the road—about two ft. long (they reach 6½, I believe). This one was blackish mottled, rather thick, with a rather small, blunt head. It was still twitching so I was very wary with it. I pried up a lip and could see a rather small fang. Then we were on our way.

The Bloomes had come up with breakfast in the room so it wasn't until lunch that we stopped at a tea shoppe and then cut inland.

We passed some blue-tongued skinks[?] on the roads—and then drove through flocks of gullahs—lovely pink and whitish parrots, and then what may have been a flock of cockatiels and another of a big blackish parrot that I think was a white-tailed black cockatoo. Lovely big birds with a curious slow wingbeat. We found Phylly's low-growing, wild pomegranate in full bloom.

The land near Three Spring and the Yarra Yarra Lakes turned low, with salt, lakes, and pickleweed flats and stands of dead trees, all interspersed among the wheat fields.

The road cut through vast wheat fields, up over low hills and down to Carnamah alongside the Yarro Yarro lakes, which appear to be low, saline, ephemeral lakes ringed by salt-tolerant plants like *Salicornia*. We came to the little town of Carnamah, which seemed like a remnant town of the time when many people were on the land instead of a very few absentee landlords. The result is seedy towns just hanging on.

I spotted the hotel, a big two-story edifice with eucalyptus stairs out back, cavernous and dark halls, and spare rooms upstairs, a 1940s picture of Esther Williams hanging slightly askew from a bit of moulding, running seven ft. above the floor from which all pictures were hung. Esther *was* beautiful.

Our rooms had a single unshaded bulb, two single beds, an armoire with a sign inside that said "Stomp out Violence," and a door onto the second floor verandah that we couldn't lock.

Phyl's and my beds were OK, but apparently the Bloomes were sway-backed disasters. Not much sleep resulted.

The dining room was crowded and a single 30-year-old woman, frazzled hair in her eyes, cooked dinner for about 20 of us. She cooked double-thickness T-bones, one of which I had. A bottle of claret, and then a walk around town, such as it is, a stop by the bar with its pool table and TV showing the Aussie football championship, and then bed.

September 22, 1991
Australia, W. Australia, Busselton

We rose at 7:00 AM, scurried around paying our bill to the owner, a Vietnam vet, who moved out of Melbourne and loves it here, and coaches the local kids' football team, and does everything. The motel was full of Jehovah's witnesses, which he did not like, hence no rooms for us last night.

South we went, the countryside getting greener, the trees bigger and bigger, streams more and more evident, ponds here and there, and stock everywhere. By the time we skirted Perth we were in lovely eucalypt forest in bands among the fields, the marri, which looks like a big valley oak (*Eucalyptus calophylla*).

Everyone was a little tired and snappish, the Bloomes were puffy eyed, and Ginny seemed more on edge than usual. Phylly made a matter-of-fact assessment. Something like, "Everyone's on edge today. We better be careful or we'll be angry with each other from here on out." It said what needed to be said and we settled back.

We cut off to Bunbury to look for the wild dolphin place. Like Monkey Mia it had been started by a woman who took to feeding the animals and finally had them coming in regularly. Then began to falter because of the cost and the commitment. The Lions Club, sniffing a tourist attraction (they could see what was happening at Monkey Mia) stepped in to help out, but she was a renter and lost her lease, and then she died, in about 1979.

The dolphins began to wander off, and then in 1989 it was picked up again by a couple of dolphin handlers from a European oceanariums (Uridson, Germany and Luxembourg) who had come out to work at Atlantis University of Perth, Stephen and Jenny Honnor. A Dolphin Trust was set up (these animal things are not non-profit here in Australia), and they have been here ever since. Steve told me he thought this kind of interaction between people and dolphins was much better than an oceanarium.

He and his wife Jenny had supported the effort to bring the dolphins of Bunbury in to provide an exhibit. My guess is that they were sincere about their concern and care for the animals and also that they hope to build a tourist attraction as exists at Monkey Mia. They rather soon became enmeshed in two very different social forces: the fishermen, who think the animals take their fish and don't much want them in the harbor; and the arch-conservationists, who don't want to have the dolphins interact with people at all.

In between are these two, trying to provide an exhibit that tells about real wild animals instead of captives. They are pulled this way and that. Two dolphins (?) died and the arch-conservationists blamed it on the food they fed. In October last, they stopped feeding. The result is interesting. Attendance at the beach did not stop. Instead, they saw many dolphins who hadn't come in before out of the hundred animals they know. And they stayed a shorter period of time each day, usually in the morning. So, it seems probable some subset of the population claimed the beach for a food supply and kept the others, somehow, away.

But when food stopped, the attraction between dolphins and people did not go away. Interesting!

They have set up a trust of local people who help interpret and last year about 20,000 people stopped by.

We said our good wishes and goodbyes and left to Busselton where our hotel is located. I had John Dory for dinner—excellent firm white meat probably from New Zealand.

To bed.

September 23, 1999

Albany, West Australia

We stopped in to Busselton to exchange money and then made our way south along the coast, to the Margaret River, thence inland to the karri and jarrah forests. Actually the latter was much in evidence earlier, up along the Bunbury coast. Had a big lunch at Pemberton, thence through the karri forests and down along the coast to Denmark and Albany, where we stopped at the Dog Rock Hotel for a room and dinner, the last before Ken and Christine Bloome fly out tomorrow for Perth, thence to Melbourne for the football finals—a very big deal here.

Our trip took us down through the increasingly well-watered country at the extreme SW. The rain comes twice a year and may reach 80 in. in places. There are many streams, now; shallow ponds in green fields, melaleucas along slow-moving sloughs and ponds; and inland, a forest clothing the low, inland range of hills. Many streams are dammed and water everywhere abundant. The jarrah, a lovely red wood from a dark-furrow-trunked tree; tingles [?], large eucalypts; and then the giant statuesque karri, an elegant tree with a huge, mottled white and gray trunk, and often with its top blown away, presumably by lightning. Karris reach over 200 ft. (90 m.) and maybe 7-8 ft. through The wood is prized for structural timbers, because of its straightness and size.

We skirted along the shore at the Margaret River, forest opening to vineyards, and pretty streams and bluffs. White sand beaches in coves appeared now and then, and we could see surfers out in the curling waves.

It was rather a snippish day with Bob and Ginny at it, and this setting the others of us on edge. It's the clash of tempers—Ginny, artistic and loose, and Bob with everything figured out and organized. Ginny finally spoke up tearily and it subsided, to all of our relief.

We cut inland at the Brockman Road, traveling through a eucalypt forest with a dense understory of many perennial species; black boys; brilliant peas; proteaceous species; droseras on the ground, or some times appearing as climbing vines, their viscid insect traps gleaming with motes of brilliant light where the sun was caught. Many myrtaceous shrubs were there, too. Some of these were in flower—orange, red, deep deep blue, yellow, and white.

Even here in this deep forest, one found kangaroos and these often found the road and were killed. The toll is extreme for all of Australia, I would guess.

At Pemberton we stopped at the Shamrock Café, where we found Marron advertised. This is a huge freshwater crayfish, the size of a small California lobster. Some of us ordered it at \$20.00 a plate, to see how good it was. As good or better than our California lobster, I'd say. Phylly imperiously announced it wasn't up to *Homarus*. They raise them in a series of ponds. He talked of momma carrying eggs and spawning out a thousand young or so, who are put in big pools and fed up on pellet food. He also mentioned that when they get to size, they fight and males and females are separated. It takes seven years to raise up the size we were eating. He was a fine Irish guy and very knowledgeable. He was a refugee from town and doing a lot of wood turning using mostly the lovely jarrah wood. They had set up a nice gift shop which we perused. I was tempted by some of his wooden bowls, but didn't bite.

On we went toward the west, through lovely mixed karri forest. The jarrah here is being attacked by a fungus, and large tracts were infected.

We took a loop through giant eucalypts just at sunset and cruised on through the dusk and then the dark, seeing the lights of Albany looming under the overcast sky. Albany is the big town hereabouts. We've been quoted populations of 25,000-45,000. I'd guess close to the latter. We found our motel at Dog Rock, which is a big, sea-lionish or doggish rock across the street.

Then followed dinner, our last with the Bloomes, as they fly out to Perth tomorrow. We had some good Aussie wine and I had baked whiting with almonds, which was quite delicious.

To bed. My knee gradually, gradually improves.

September 24, 1991

Australia, Western Australia, Gowangemp

We decided to leave Albany because a coach's convention had snapped up all the rooms. I suggested we outranked Lacrosse coaches, but to no avail, and so we took the Bloomes to the tiny Albany airport, inspected Torbay Bay, then took off through the back country toward the Stirling Range. It was an elegant day.

We first drove out around the harbor at Albany, out where we could see over King George Sound.

Low, almost barren granite islands dot a huge harbor opening toward the southern sea. We spotted what I think was southern right whale moving slowly along, and a single bottlenose dolphin close alongshore. Then we headed for Torbay Peninsula, driving along swampy ground, all sedges, paperbark melaleucas, and open fields dotted with big flocks of newly shorn sheep, white as bed sheets.

Finally, we found a road off through farms that led us to Cape Home National Park, a little point of granite, clothed in native scrub, of a great many species, many in bloom: banksias, peas, orchids, daisies, and various [?] genera.

The park is really hidden. We found an unmarked dirt road in about the right place, turned out toward the peninsula, and sure enough, it became the main National Park road, and shortly took us up onto a rather high granitic peninsula, usually heavily clothed with a very diverse scrub, much of it in bloom. I can hardly list all the plants, but it ranged from tiny orchids to flowering banksias. We drove to a lookout high up over an absolutely white beach, the sea a dark jade, and then farther offshore darker still. It was a dripping or cloudy day that turned sunny later on as the sun burned through. I walked down a trail that cut across the face of the hill, usually waist deep or deeper in shrubbery. Phyl was off on a plant walk of her own as I poked down the trail.

Soon I noted a brown snake about 18 in. long, coiled in the tangle 2 ft. off the trail. I decided to test out the ferocity of this snake. They are reputed to be shy and to fade away if undisturbed, but if stepped on or provoked to attack with ferocity. I felt safe because I had my cane and was a good 5 ft. from the animal on a trail on which I could flee, faster, I hoped, than the snake.

I prodded it and instantly it lunged roughly in my direction, darting from side to side. I fled backward in a spasm of motion. The snake did not follow but faded away into the tangled brush. A larger animal with more range would be formidable indeed, and this

critter gets more than six ft. long, as I recall and is one of the two or three most venomous snakes in the world.

Back at the car we loaded up and headed for the airport where we left Kenny and Christine awaiting a plane to fly to Perth.

We looked beyond to the jagged Stirling Range jutting up over the low landscape to the north. Our plan was to spend some time there looking for plants and whatever else showed, and then to head for Gowangerup where we had reservations in the country hotel located there. These hotels are all old and clothed in the little farming hamlets of their towns. They have a pub, darts, TV, etc., a dining room, and rooms upstairs right out of the teens . . . bathroom down the hall, an armoire, a lightbulb, a bed, a towel, a bar of soap on the pillow.

The road north from Albany ("Ahlbany") goes through large sheep ranches, green with grass, and fields of wheat seeming close to maturity, down good paved roads often lined with shrubs and eucalypts of various kinds. Sheep by the hundreds dot the rolling landscape with white.

We entered Stirling Mountains National Park, one of the biggest in W. Australia . . . a whole isolated mountain range of ancient rocks, very abrupt in places and rising to more than 800 meters on some peaks (Mt. Trio). Phyl drove us through the very diverse scrub and low eucalypt forests to cut off on the Mt. Trio road. It is a garden: flowering eucalypts, proteid relatives, brilliant peas, composites, orchids, myrtles.

We drove up to the base of the mountains at Mt. Trio and walked a couple of nearby trails. A swarm of bees filled the air with humming and various unseen birds kept up a constant chatter. The flowers come in red, yellow, very intense indigo blue (*Dampiera*), and a remarkably brilliant *Leschenaultia*, white and yellow. Phyl was in her element.

We backtracked and made our way up to Bluff Knoll, at the base of an abrupt, banded peak capped with clouds. At the turnaround, I learned about grass girls, a tall, columnar plant topped by a pom-pom of thin, drooping leaves, with four or five knoblike flower projections. Alongside it were black boys, *Xanthorrhea*, which have a similar black column but a long, tapering rod-shaped flower stalk.

We met a curawong—an icterid bird—black and white or gray, with a long, curving beak and a cry something like "Curawong"—an egg and hatchling stealer about the size and disposition as our crow.

Under a low eucalypt we found two gray kangaroos taking a rest, one was mom and the other a joey, but a joey so big I doubt Mom could carry it any longer. They were amazingly tame—taking a nap with long legs outstretched and dozing. I crept closer and closer until they filled the whole frame of my camera, then closer still, just a head. Still they dozed. Finally, not wishing to disturb them, I left.

As elsewhere, *Drosera*, the sundew is here in many forms, notable a cauline red one of four leaves lying right on the ground.

We encouraged Phyl to backtrack and pick up a road that cuts across the park, almost from end to end, to Red Gum Pass. Several stops later we emerged heading across the farmlands to Cranbrook and finally Gnowangerup.

After a long drive just into dusk, we arrived at Gnowangerup and found our hotel—another two-story affair plastered with Swan Beer and Victoria Bitter signs, entered, and found the place was full enough that we had been shifted around. Phyl and I

took a room in the old hotel, Bob and Ginny in the motel out back. There didn't seem to be much to choose.

These outback hotels are of a type—about turn-of-the-century or 20 yrs. later, they have a high-walled and windowed cavern of a dining room, pretty much the same menu—fish, porterhouse, shrimp, soup, some desserts, drinks, and friendly Aussies running the show with only modest help and usually trying to remodel but a long way to go.

After more dinner than we needed, we spent a little time in the bar gabbing with patrons—most told us how odd our accents were—and then off to bed.

September 25, 1991

Hyden, West Australia, Wave Rock

The road took us north past the salt lakes. They vary a great deal in color and transparency but most seem fairly salty. Bob explains that sodium salts cause clay suspension while if calcium is preponderant, the water will be clear. The lakes are often surrounded by the dead and white trunks of trees. One informant calls this a “seepage effect,” but I still don't understand how it works.

Rather frequently we came across tiliquas (blue-tongued skinks) in the road, either killed or ambling along. They fled at our approach but still seem very slow. I suppose they are above the size susceptible to most birds (how about the wedge-tailed eagle and the emu?). Anyway, we never saw a young one. It sounds like the marine iguana, which becomes almost invulnerable on land when adult, but is very wary as a young lizard.

We pulled into Hyden, which is a considerable tourist destination—the motel and restaurant being full all summer. We signed on for the buffet, which fed us and two busloads of tourists.

The rooms were nicer than other outback accommodations and more expensive. We just got in under the wire by signing up first thing in the morning.

It was 3 km to Wave Rock. The granite domes had been seen most of the last half of the trip up . . . low, smooth, with very little exfoliation evident (though some).

Wave Rock is spectacular. A real wave in granite 30 ft. tall, streaked with broad bands of iron stains, black, light-tan, rust.

Needless to say, I had to hang ten with my cane. I did Geriatric “Charlie the Surfer.”

We hiked up on top, seepages and ponds and a reservoir were there as well as an awful, unsightly cement and rock retaining wall all along the top of the wave. I'd tear it out and move it back 30 ft. where no one could see it.

I saw the 28 parrot—the Port Lincoln parrot, *Bamarchius zonatus*, whose voice and call is supposed to be like “28.” They are a beautiful green, black, red, and blue bird, said to be a mu-[?].

We walked down to the Hippo's Smile, a great rock like the open mouth of a hippo. Pretty good, I have to admit.

Phyl and I walked back through the scrub, looking at just about everything and getting nipped by mosquitos for our pains.

A cup of tea in the gift shop and back to the motel for dinner, a shower, and bed. Nice place, though pretty tourist-riven.

September 26, 1991

Australia, Perth

A drive through rolling wheat and sheep land, banded with eucalypts, through colonnades of trees, down along the sandy, wandering trickle of the Avon to the town of York. It is an old and restored town; the first such town inland (1830s), very quaint and touristy. We had lunch and moved on, driving over the rolling Darling Range and then into Perth where we holed up in the Sullivans Hotel again, a friendly and comfortable haven just moments from downtown Perth, a short free bus ride in fact.

We had a nice dinner with the Shaws, Geoff and Jill. He has been our local contact and source of information and help and very good he is too. She is a calm, cool head who watches his various antics (storytelling) with the same bemusement Phylly directs at me.

September 27, 1991

Perth

A day in Perth, nearly all up at King's Park, where they were having a wildflower show. It was quite a lot of fun wandering around among the mostly inside exhibits where they had collected a remarkable array of flowering shrubs and some annuals, orchids, eucalypts, mulgas, black boys, fungus, and on and on. There were some elegant paintings by school children in the 10-11 grades, some good enough for publication.

The park is very short on amenities in my view. Two trailers provided lunch for dozens and dozens of people, but it is an elegant and lovely garden, beginning with a parade between towering, clean trunks of lemon gums, a sculpture of Queen Victoria, reliefs of the Boer War, WWI, Gallipoli, including some canons from the very early 1900s, and magnificent sweeping views of Perth and the Swan River estuary and river. It is a lovely, modern, unrushed place, sparkling clean, a combination of a modern city and parks and water, bluffs, and at our visit blue sky, puffy clouds, and crisp air.

My damn knee was painning me and the events of last night—a bit too much wine I suspect, bore down and it wasn't until lunch that I emerged into the living, being grumpy before.

Phyl and I hiked down the bluff face on a nice, gradual, asphalted trail, which I managed OK, almost right to our hotel.

We said our goodbyes to Bob and Ginny who are off to dinner with friends. We won't see them in the morning as we leave very early, catching a plane that stops in Adelaide, changes planes in Sydney, and thence on to Christchurch, where we stay overnight, leave 8:55 AM and fly to Dunedin where I give a seminar and check in with Steve Dawson.

It's been a very interesting and from my standpoint, successful trip. Phylly has been enjoying herself fully, too. We landed in the midst of one of their best recent wildflower years and she was never at a loss for something of interest as we drove through the countryside.

Now we are off to the South Island, New Zealand, for a look at the Akaroa Peninsula and perhaps a *Cephalorhynchus*, though I think I will have to be fairly lucky.

September 28, 1991

New Zealand, Christchurch

We packed up and left very early. An uneventful flight took us across the edge of the Great Australian Bight to Adelaide, where we landed and thence to Sydney, a change of planes and to Christchurch in the late evening. We checked in at the local posh hotel (Park Royal) (with an interior glass elevator) for a few hours of sleep.

September 29, 1991

Dunedin, New Zealand

About 9:00 AM we flew down the east coast to Dunedin, a University town set in gorse-covered hills, with patches of cultured Monterey pine forest and sheep, sheep.

We rented a car at the airport, being warned not to go on certain hazardous roads and drove (Phylly did) the ten miles or so into town.

Dunedin sits on a nice deep harbor near the south tip of the South Island, has an albatross colony, and is the site of the old University of Otago, the southernmost University in the world. We holed up at the quality "Quality Inn," a nice place on Moray Circle near the center of town and then walked around town on a quiet Sunday—almost no traffic, took in the exhibits at the Otago Museum, and thence back to the hotel for a delicious dinner—thin-sliced roast eye of lamb (the fillet) in a rosemary garlic sauce, and thence upstairs to read about New Zealand. No bites on my suggestion of a show.

September 30, 1991

New Zealand, Dunedin

I'm sitting here in the morning sun, which is predicted to give way to showers later today, preparing to see Steve Dawson about the Hector's dolphin. Here are questions for him:

- 1) What is the range of Hector's in N.Z.?
 - 2) Is it threatened everywhere or are there enclaves where no protection is needed?
 - 3) What are the worst threats?
 - a) Commercial?
 - b) Sport gill nets?
 - Any hope to ban the sport nets?
 - 4) Does the species migrate? Why?
 - 5) Any thoughts on how the genus dispersed to its present range?
 - 6) Where are your opinions about what makes *C. hectori* so vulnerable?
- Echolocation?
- 7) Describe life cycle of *C. hectori*; age to reproduce, growth, fecundity especially.
 - 8) Social structure.
 - 9) Prognosis for future.
 - 10) Questions about boatman at Akaroa. Advice on where to stay?
 - 11) What future work have you in mind?

Phyl and I went downtown in the morning, and did a little shopping, she to look for a special New Zealand plant book and I to look for a tweed coat. We didn't find a book but we did locate an elegant Harris tweed from the Hebrides that fit just fine and is

nice and heavy. It should last through a couple of additional owners. I intend to fly fish in it.

I went to the Zoology Building next to the Captain Cook Bar (broken glass all over the street) and went upstairs to find Drs. Steve Dawson and Elizabeth van Slooten. They met me in Steve's office—a typical old academic's office with pictures of the fusty former deans and professors outside the door. Not a single "Far Side" cartoon.

I gave a seminar on our spinner dolphin work—well received, I thought—to about 35 staff and students. R. Evan Fordya came. Then I interviewed Steve Dawson and Elizabeth Slooten about their work with *Cephalorhynchus hectori* at Banks Peninsula. They are both bright, open, committed, full of vigor, and I found Steve to go beyond even that. He is incisive and snapping bright and well informed. My guess is that he's among the top handful. He deals both in ideas and data. His training is in bioacoustics of bird vocalizations (chaffinches). She is doing ecologic-behavioral thing and was also sound, open, and excited.

I will fill in a piece on my interview later on.

They drove me back to the hotel in a quite spastic Datsun pickup, reminding me of my erstwhile own green one.

Then Phyl and I had a little rest and went downstairs at 6:30 to take everyone to dinner. Those attending were me and Phyl, Steve, Liz, two students (Susan Smith of U. Canterbury and Jan?, who works on the *Tursiops* of Doubtful Sound), and R. Evan and his wife Marylin.

We had a quite elegant dinner in a place with no liquor license (you brought your own). We had a fine time. R. Evan continues to find amazing discoveries at the time of the Mysticete-Odontocete split and has a new and exciting one from the Seymour Peninsula of Antarctica, plus others—a small mysticete with an elongate trough-shaped snout. I found out more about everyone's work. Steve has developed a means of measuring sperm whales using two cameras on a base bar, he says accurate to 1%.

We talked conservation too and I found him subtle and far ahead of most people. He emphasizes the need to get ahead on conservation problems—not wait for action until a species is in extremis. This is his view about *Cephalorhynchus*. He asked if I had yet seen the gill-net conference report, and I said no. It may be home now. He said some panels besides the one we were on took strong to even radical positions about oceanic gill netting.

He told me of a million gill nets off the Indian coast at any one time and of larval forms being caught and scraped from fine mesh nets in the Philippines. In the face of the population problem, the cheap available gill net has become the instrument of ecological destruction.

They took Phylly and me home to a hotel after a while, and we were quick to collapse. I'm deep in Tom Wicker's book about the Civil War.

October 1, 1991

New Zealand, Christchurch

It was a blustery, blowy, sometimes sprinkly day as we drove up from Dunedin (Phyl did). The trip is through many small towns, miles of sheep paddocks, all green this time of year and sprinkled with white sheep and their lambs. A few groups of deer were

seen. The road crosses a dozen braided, cobbly, glacial streams and is otherwise very civilized. Very little wildlife was in evidence, a couple of possums, black and white magpies, gulls, English sparrows (big, fat, sandy ones), and a few ducks.

Phyl was tense in the new car whose width was greater than her own, and we were on the wrong side of the street. We had a flat in the blustery cold. Thank goodness no rain.

A little sleuthing and we found the hotel, where the gracious staff whisked us off to our nice room—two beds so Phylly and I can sprawl.

Tomorrow we go out to Akaroa.

October 2, 1991

New Zealand, Akaroa

We drove out around the two calderas that make up the Banks Peninsula. The bustling Christchurch was left behind, and we found ourselves bowling along next to green pastures full of newsly shorn sheep. Very tall hedgerows, as neat and trimmed as green walls, protected many[?] of sea breezes flowing over the long sandbar that defines shallow Lake Ellesmere from the sea.

To our right were the first of the two mountainous calderas rising just under 1,000 m high, that make up the Banks Peninsula. The first is [?] from the north forming Ly Helton Harbor, and the outermost from the southeast forming Akaroa Harbor. Both are long, fairly shallow channels on the sea passing in past headlands and bays to the very center of the long, dead volcanic cores. One figure I heard was that volcanism was active 5½ million years ago, or during the mid Pliocene.

Lake Ellesmere (Waihora in Maori) is a huge expanse of shallow, tan water behind a low beach berm that stretches out of sight to the south. Hawks wheeled over adjacent flats of low, wind-pruned vegetation, while swans floated on the bay.

The road turns up a verdant valley past choppy Lake Forsythe and thence up over a steep ridge to the overlook down into the huge bowl that defines the perimeter of Akaroa Harbor.

If we had followed the shore a little farther, we would have come to Penaki Bay, where in the mid 1800s, a shore whaling station flourished, and beyond that a lava headland called Snufflenose.

The hillsides were clothed in light-green grass, so lush it spilled over the underlying soil like a green river interspersed with blocks of somber dark forest (green pines, planted so densely that they grew straight up, fighting at their crowns for a modicum of sunlight).

We wound down a switchbacky road in the inner caldera until we reached sea water, frosted jade beneath gray clouds.

Fingered Akaroa Harbor is deep enough (I haven't seen a chart) to take fishing boats, 20-40 ft. way up. I saw no larger craft. The occasional farmhouse is Victorian with utilitarian outbuildings. The jagged crater rim is heavy with gorse and from a distance rusty.

The land is well watered. Little streams gather and enter the Harbor at a dozen places.

The communities are small ones, Akaroa on the east slope being the biggest. I guess its population at a 2-3 thousand, swelling to twice that in mid summer tourist season, a couple of months hence. We are at earliest spring now.

The road is narrow and winding and Phyl was tense during it, especially since I admonished her to keep on the pavement, which she has a tendency to leave in her caution, as cars and trucks zip past.

A dozen times we could see Akaroa across the bay, tiered white houses up the slopes, a smattering of moored vessels in the bay, and two piers jutting out. The larger had three fishing vessels muzzled alongside, a swirl of gulls circling over them and standing expectantly on the old dock.

The town is heavily French in influence—Rue this and that. We holed up at a nice motel, the Wai Hi, right on the water, and then made our way down to the dock to catch a ride on the harbor tour aboard the *Canterbury Cat*, a nice 65-ft. catamaran rigged out for tourists, Captain Ron Bingham, skipper.

He gave an informative talk as we cruised along, about French history, the buildings, the old lighthouse, the cliffs, the nesting cormorants, little blue penguins in the bay, up against great lava bluffs and almost into the cavernous maws of the lava where he showed us the birds and an old sheep isolated by a fall into a cavern that she could not leave.

At the bay entrance, the afternoon wind had picked up, producing a little bump, which the big cat rode over easily enough. He said that this time of year the little dolphins were very scared and would come in later as summer approached. We would be lucky to see one, he said, and we didn't.

On the way back he nosed his craft close against the cages of a common salmon mariculture pen. There, a thousand big fish boiled up as the mate threw them trout chow pellets. A tiny tender's house on the hill behind housed two young men who fed the fish and protected the place.

The cages of the fish were of heavy galvanized pipe, more or less octagonal and articulated in the center to respond to the swell by bending. These held some kind of netting and floats. The articulations caused the cages to move easily in the low swell. I'd guess there were 8-10 pens. It's hard to see how the effort could be very lucrative, though I know little of the price of salmon and nothing about markets.

We passed a single big, fat southern fur seal (*Neophoca*??) on the rocks at the entrance to a lava cave and then made our way in.

Tomorrow is a day off waiting for the boat and then Friday I've arranged a morning charter on the cat. The skipper knows Steve Dawson well and likes him.

Bingham is middle-aged, trim, knows his stuff, and handles his ship with professionalism. If there are dolphins nearby we will find them, though I doubt my chances of success. The dolphin has been suffering seriously at entanglement—far more are being killed than can be produced locally. Steve says the problem is bad here and less in other places, but that he'd rather stop a problem before it got out of hand than later when it was critical. I see his information all over town—straight, unemotional, effective stuff.

I was curious about Akaroa history so as Phyl and I poked around town I picked up a good book called French Akaroa that told the story—different than the one in our tourist books. It told of competition for empire between England and France—and the

lucrative whaling trade of the 1830-40s that had moved into the distant Pacific—a two-three-year cruise away, in need of bases, of other commerce, flax, hemp, and more that became a competition with England. France played it clandestinely when one of its subjects signed a very dubious sale with the Maoris for the Banks Peninsula—for a pittance—\$1,000 of gear of one sort or another. The government, after considerable temporizing, backed him with two vessels and the materials for a colony and then a solicitation went out for colonists and about 600[?] people responded.

At the same time, England had moved into North Island and through a somewhat similar treaty, moved in.

This was all after the French Revolution and much of the fight was gone out of France, it seemed, so she did not prevail.

Anyway, we sit at the heart of that thrust, now a century and a half old. It's hard to realize how the world has changed since then. Some things haven't. The plan fell into the commercial competition of nations, an old, less urbanized culture was ground under the heel of the new one and dealt with in a cavalier fashion. One culture replaced another, and just as in the idea evolution in science, it did so by trampling the old idea structure and its people, who were left adrift to adjust or be cast aside in the rush of social evolution.

One reason France was interested in the colonial enterprise was to establish a penal colony on the Chatham Islands where its dross could be sent and made to fend for themselves. Society would thus be purged. But would it? A new culture, as good as the old one rose out of such castoffs in Australia, as good and vital as its parent.

In France's case, poverty in 1830s was rife in the countryside; the poor were at the edge of starvation and glad to leave. A contingent of laborers, craftspeople, carpenters, butchers, farmers, and such left their single-room, dirt-floored houses in France, which they shared with the stock, in hopes of better food than millet and chestnut flour . . . for a better hope, even if they had to build it from scratch.

France used the church. Priests came too, along with Catholicism, which could be pitted against the English Protestantism as a weapon of colonialism. Doctrine against doctrine. Indoctrinate the children in their juvenile time and they would build their lives on its tenets and be the church's forever. If one church was different enough from the other, the purposes of nations could be served by such doctrinal war. We will explain the world whether we can or not and we will build our lives on the resulting constructs.

Well, Phylly and I went off to a local hotel, the Madeira Hotel and Bistro, and we had a grand fish meal and some local wine—a little thin, I thought, and a Madeira ice cream dessert and thence to our warm room. A bit brisk here these spring days.

October 4, 1991

New Zealand, South Island, Akaroa

Today Phyl and I wandered Akaroa, soaking up the ambiance of this quaint historic place, visiting a *Protea* nursery (we obtained an autographed book by the author of *The Proteaceae—New Zealand*, Lewis Matthews, photography). Then we dropped by the pub for a little garlic bread and soup.

We checked out the museum, which chronicled the English-French struggle, the whaling, the incorporation into British empire, the plight of the Maori, who were cast aside in these imperatives.

It was a blustery day so we pulled our coats tight and drove along through this quaint, lovely place.

The museum had a slide show that among much else said that Langlois, the person who started the colony here, was influenced more by beauty than practicality. There is very little flat land to cultivate, but an elegant harbor.

So we sit here in the afternoon after the drive, catching up on notes and clustering around the wall heater. If all goes well I go out to sea at dawn.

[Drawing of area]

October 5, 1991

New Zealand, Canterbury, New Brighton Beach

All didn't go well and I didn't go out on the *Canterbury Cat*. As we were walking to dinner at the Chez La Rue down by the harbor, Captain Ron Bingham of the *Cat* drove up and told me that the weather was predicted to turn bad and we shouldn't go out. He was certainly right, as it proved. So instead of staying in Akaroa, we packed up and said our goodbyes to Marie, the young girl who had cared for us in the motel, plying us with literature, towels, and other bits of help.

With Phylly at the helm, we headed across Banks Peninsula to Lyttleton and ultimately Christchurch. The road took us back over the ancient crater lip, now a bowl of sheep farms, down to the village of Little River, once again just the vestige of a town, a store, houses, some old Victorians on sheep-dotted pastures. Old trees lined the road, including the ubiquitous Lombardy poplar. Then we wound along the shore of Forsythe Lake, which ends at Lake Ellesmere, which seems to be a huge brackish estuary bounded on the sea side by a long barrier dune. I think it's partly fresh as sedges formed clumps along its edge. But the real interest for me was that it was dotted with hundreds and hundreds of medium-sized, gray-black swans, both on the sedge land and in the water, tipping up or just floating. We saw one momma swan followed by a tiny signet as if she was towing a toy boat in her bath. The road then took us inland at Motukarara, up the Gebbies Pass Road and over the crest. Some modest patches of native forest and scrub remain, flax patches in the gullies and short trees up on the hills.

Soon the road edged around a corner and we looked down on magnificent Lyttleton Harbor with "Back of the Bay" and Quail Island in the foreground and the shipping port of Lyttleton across the bay in the background. A container ship edged in with a heavy deck load of red-painted containers, to a dock with long cranes to take them off and stack them on the spacious dock behind.

We headed out on the east side toward the residential community of Diamond Harbor and there found a park where we could walk down close to the water. The bay is milky jade, surely with glacial flour from the two big rivers that drain the high mountains that form the spine of South Island, and that one can see, cloaked in white almost down to the level of the Canterbury Plain. These rivers are the Rakaia River to the south of Canterbury and the Waimakariri River to the north. The result is a plume of reasonably opaque water in both the Canterbury Bight to the south and the Pegasus Bay to the north of the Banks Peninsula and enveloping the entire Banks Peninsula. It is in this murky

water that Hector's dolphin lives, and where its curious, high-frequency 1120-1130 mHz, narrow-band pulses find their utility.

Both Steve and I feel that this is a facultative convergence with the very similar sounds of the Phocoenids. My guess is that dolphin sounds are labile and that they are pushed up to high-frequency registers in murky water and that Phocoenids may have fixed such sounds there but perhaps these delphinids might not be fixed. The structure of the Phocoenid forehead may have changed to make only these sounds. This may not be the case with *Cephalorhynchus*, whose skull is very delphinid.

At any rate, I scanned the bay at some length and may, just may have seen Hector's dolphins amidst some feeding terns far across Lyttleton Harbor and out from the towns. I rather suspect I didn't though.

We went as far out on the east shore as we could go, to Purau and a little beyond on a dirt road where we were finally admonished not to go farther (by a sign) that announced it was lambing time. Purau is a lovely little calm nook dotted with small sailing craft at mooring.

From the back of Purau we took a winding, narrow, two-lane road to Pt. Levy, the next cove to the south, a long, narrow bay between the fingers of the crater and probably a Maori village in that it had a meeting house, a little pier, and a cluster of houses. At the back of the bay was a big, old, two-story house, gabled and elegant with green fields and a herd of red deer, and allees of big trees.

We looked and looked but no dolphins and then Phyl picked her way nervously back toward Lyttleton. We had lunch, drove through the teeming port, and finally over the hill to New Brighton, the beach community of Canterbury, finally finding a motel and holing up just as the wind and rain hit.

It whipped around our snug room as we tried to warm up by the little electric heater and then made for a local disco for a meal just as Phearless Phreddy was warming up and testing his light show for the onslaught at 8:00 PM. We left at 7:59.

The Future of Wildlife on the California Desert: Management Options and Dilemmas

There is a constant running battle on the deserts between those who would manage for orderly human use and growth and those who would preserve ancient prehuman patterns and life.

1. Often enough, though by no means always, the real cause of the struggle is neither stated nor understood by either party.
2. As I see it, the struggle boils down to this:

The wildlife and the patterns of diversity they take on the deserts is the result of the history of the earth and its evolution.

The origins and life patterns of the lizards that patrol the rocks in front of this cabin, of the cacomistle that climbs these rocks, of the Mojave yucca down on the gravel apron below is connected directly to the history of everything that makes up the desert.

It is intricate, intermeshed, and interdependent, far beyond the little we now know. Most, maybe 90% of how desert things survive, where they came from, and what they do, and even who they are is still unknown.

These patterns and most of the life involved cannot stand human intervention. We know far, far too little to in any real sense manage human impacts upon the totality of desert wildlife.

For many human and many wildlife patterns there seems no real middle ground possible.

The last desert wolf was seen in the early 1920s on the flats to the east of this cabin, part of a regular, long-gone influx from the mountains of Mexico. In these yuccas, not too long ago, wandered the 5-ft.-high ground sloth of long, red hair.

For many we can guess how to preserve samples that may survive, but always we guess. The more we intervene the more we guess, and the more we can be sure we will lose. The life patterns of the individual animals are too complex, and their age-old interactions and interdependencies, totally unknown for us to do more than suggest a plan, and if we haven't planned right, back off when we prove wrong.

If we want to preserve this record of past life, all we can do is to provide lands and waters of sufficient size, habitat diversity, and artful placement that the animals and plants that make up this ancient life can make a living surrounded by the other mostly unknown interactants of their lives.

So we must guess and tinker very lightly, learn to back away when we prove wrong.

One other thing. For the most part, these guesses are for ever, at least for as long as we value this past history of life and attempt to save it as a history of our world. Ours is the last chance.

This, as I see it, is why politicians, planners, and environmentalists are so often at odds.

Politicians and planners live by artful compromise with shaping of a reasonable and acceptable process of change as a goal. Their goals are almost always homocentric.

Conservationists know in their souls that it will not work, to manage, the wise amongst them know is simply to save the land, to cover the gross patterns of life as they understand them.

Many conservationists feel and their perception is correct that what has been saved cannot persist in the face of multiple use management, because above all, continuity of the land and the patterns of life it provides is the final arbiter of survival. Reasonable men and women cannot jigger in their vast, pervasive ignorance with the very source of life itself, the land.

So how, in my view, is BLM doing? How is the Forest Service doing? How is the Park Service doing?

Marginally in all cases, I think, and not at all because these organizations do not have people of enormous goodwill and skill involved. I, for one, look on our desert

district with something akin to awe at the depth of commitment, the steady hands at the helm, and the collective skills.

The success in protecting wildlife and ancient patterns and processes is directly related to how much land is left alone in relation to how much is exposed to the . . .

Natural Values

It is possible to envision a desert future in which the essential scenic and natural values of the existing desert are preserved into the indefinite future, and in which much of the diversity of use remains possible. This differs from other schemes of land management in which land is devoted largely to a single value to the exclusion of others, as for example in a park.

But this cannot be done without modification of the way in which the mandate laid down with the establishment of the CDCA is presently carried out. Specifically, the natural values of the desert are the modern endpoints of processes as old as the desert itself and once gone they cannot be reconstituted, so a commitment to manage them is a permanent one. Also, if BLM wishes to make a permanent commitment to these values, a plan should be put in place as soon as various changes are underway, especially in western deserts that are limiting options with considerable rapidity.

The opportunity for BLM is a groundbreaking one. Instead of establishing a preserve in which the diversity of public use is narrowly controlled (scenic, narrow recreation areas, as in National Parks), a more generous goal can be sought that includes the values listed above and also accommodates a broader range of recreation, education, research, carefully controlled mineral extraction, and some level of range use. The key criterion is that the integrity of the basic habitat and its life should govern the management of such lands.

What form across the desert would such a plan take?

The BLM must develop as a basic order of business an ongoing quantitative database that describes the changes occurring on the desert from the many important standpoints. These should include such items as population patterns, transportation, utility use, mineral extraction patterns, grazing use, military use, and agriculture.

Evaluate the state of CDCA in order to secure protection for the wildlife of each of the three major physiographic divisions of the California desert. Such protection absolutely requires that the ecosystem of which the wildlife forms are members be protected as a primary order of business.

This does not mean that other uses of such protected lands cannot go on. It means that the health of the desert biota is primary and that such other uses need to be managed with the health of the biota as primary.

It needs to be remembered that once the ecosystem is destroyed it cannot with any present management method be reconstituted. Such ecosystems are simply too complex and too completely the product of millions of years of history, for such management to work.

It seems likely that true ecosystem protection of this sort can mostly be achieved on the eastern sections of the Mojave, Great Basin, and Sonoran deserts, while lands closer to urban centers have already impacted the land sufficiently that such major protection will be less than perfect. Even so, wherever important wildlife elements exist,

in heavily impacted areas, attempts to protect these elements, if not the entire system to which they belong, should go forward to protect as well as possible the wildlife as it presently exists.

The range of compatible uses can possibly include recreation, carefully controlled grazing, utility corridors, mineral extraction, and other elements.

This will amount to permanent zoning. If such permanency cannot be assured, then the very probable result will be that the BLM cannot provide permanent stewardship for wildlife.

November 5, 1991

California, Contra Costa County, UC Berkeley Campus, Men's Faculty Club

Tonight our dear colleague these many years, Roger Samuelsen, retires. Most of the rest of us who fought the battles and shaped the form and fate of the University of California's Natural Reserve System are already retired and watching now, from the sidelines, as this creation of ours takes its own course beyond us and our time.

That, of course, is good. No such creation is worth much if it dies with its creators. Me, Mildred, Brother Bob, Dan, Bill Mayhew, Bob, who lined up all those budget projections for us to puzzle over, Sarah and so many more have ended their skeins, and now Roger, too, takes his place with us.

I feel fulfilled and good. We have together used our very different and sometimes contrasting talents in remarkable unanimity of purpose, to do a job that could be the most important thing any one of us could do—to provide a living baseline against which to measure and understand the flood of change which now envelops our world and all in it. NRS, under our diverse hands, has already become a place where the best young minds and spirits can learn the real shape of the larger world. It promises so much more, not just for a single campus, the University, or the state of California, but for the larger world, without such artificial boundaries.

It is already a place to ponder in and to teach these things without peer or parallel.

This has been Roger's professional life these last decades. It could not have happened without him and it bears the stamp of his deep professionalism in a thousand places.

The vision formed in the crucible of change at UCLA, where the megalopolis was swallowing up our human contact with nature. It became, in time, an enormously complex venture beyond, I think, the scope of any of us alone to develop.

Roger's special genius and crucial talent was, I think, that he brought us together for the task, however much any of us might, individually, press our own viewpoints. He kept us pointing forward, all of us, and in deep comradeship and commitment. The mission we were on was never obscure, nor was the commitment and integrity of any of us a question.

Roger shaped that. He cared for us all and for the hundreds of diverse people who, for hundreds of reasons, touched our affairs.

The faltering old woman who loved her little cluster of oaks and the tiny rills that ran under them in springtime, but who could understand neither the larger imperatives of NRS, nor the faceless and huge University, was as carefully cared for as the young woman who thanked us all for helping her study her precious ants, or the reserve manager who saw the lack of a truck as central to all wrong things on his reserve.

Roger never would, never did, do, or allow to be done, a piece of work halfway, and if it meant waiting, the wait was a secondary problem and the integrity of what he did primary.

That, not infrequently, drove various of his friends up a tree, and sometimes brought about floods of postcards, one a day, each bearing the simple imperative: "Onward Roger."

Never mind that his task was staggeringly complex and became huge as the list of reserves burgeoned to close to 30, and the impending legal, land, and fiscal decisions stretched out as long as your arm.

But Roger built well and as solidly as any one ever could. A recent high-level review recognized our work for what it is—a monumental resource like none in any university here or abroad.

So, it is a good time to stand back. It is a grand time to feel proud of what we, and most of all you, have done.

It's a time to feel the warmth of all of us around you who love you for the humanity with which these working years have been spent.

Now, Rog, let me tell you about retirement and the things I have planned for you. I've already addressed the postcards.

Granite Mountains

The Global Field Theory of Sand Dune Song K.S. Norris, E. C. Evans III, Flip Nicklin

A variety of observations together come very close to explaining why some sand dunes "sing." Put simply, the "song" results from the activating-force of dry sand cascading or slumping down the slip face of some dunes, setting the surface layer of sand into an oscillation that is especially strong at the toe of a sliding stream of sand, but which is also produced more widely in the slipping cascade, perhaps on its bottom surface where it contacts the still often moist sand beneath.

The moving sand oscillates between a dense packing state and a loose state, and this oscillation can often be seen as a wave on the surface whose crests are separated by a measurable distance, 12-18 mm (a stamped foot).

The maximum amplitude of sound was 2-3 ft. ahead of a moving person or disturbance. The supposition is that the slumping or sliding sand provides the force, the sand stream is set into oscillation and a sound emanates from the dune.

Now, why should some sands sing and others not? Kelso sand is only modestly clean, being rather heavily contaminated with aeolian material including magnetite from

the adjacent Granite Mts. and perhaps other sources. Its grains are also relatively rough compared to say, the Imperial Sand Dunes, which do not sing. The implication is that the grains are “doped” as if one put rosin on a bow, so that they cause the grains to excite each other to motion as they move past one another.

The oscillation, we propose, results from the grains shifting back and forth between the two packing states as restrained by the weight of the overlying sand and the packed or moist sand beneath, and by the consequent oscillation of interstitial air pressure that results, smoothing the shift in pressure to a clean oscillation.

The weight of the overburden of sand may well cause the interstitial air pressure to override that produced by the simple change of packing state alone, thus promoting the clean oscillation of the grain pore spaces.

We clearly observed that a wide range of frequencies of sound could be produced from this single dune. The primary source of such change in frequency seems due to the velocity difference of grains against one another. A stick thrust in sand produced a squeak, a slower moving hand sliced against a dune a lower bark, and slicing[?] sand lower sounds still, until just above the point at which movement of slipping sand ceased, the sound could be very deep indeed, perhaps below our ability to hear.

When watching a sliding tongue of sand, it could be seen to ripple, the wavelength matching the frequency ranges 200-250, perhaps to infrasound. 30-40 Hz? Dominant near 90 Hz and the fifth above is 126 Hz.

This effect could also be produced by kicking a boot against the slipface, with the sand rippling to the lower side of the boot.

When a tongue of sand slides down a slip face, this wrinkling can be observed at the lower half, about, of the tongue. As it comes to a stop, one often observed a more rapid upward moving wave, as the downward sand stream came to a halt. I assume this wave to represent the last downward movement of sand in the absence of a new sand supply, moving into the loose packing state.

Perhaps the oscillation of the sand “heterodynes” the sounds of the grains rubbing against one another, producing a subharmonic note of purity and strength. That is, the sound of grains moving against one another is “played against” the oscillation of interstitial air which imposes its note upon the other vibration.

“The pursuit of science is the nexus of points of failure peppered about a single point of success.”—Evan C. Evans III

“I can do it. You can do it. You can tell me how to do it. But you can’t expect me to do it how you wish I’d do it.”—Flip Nicklin. Great statement on human relations.

“Measure it with calipers. Mark it with a grease pencil. Cut it with an axe.” —Comment on Corps of Engineers from ECE III

“The only thing worse than being wrong is being right and having nobody listen.”—Flip Nicklin

Evan says earthworms are possibly considered as snakes according to California Law.

“Is there an overabundant species act?”—Flip Nicklin

“All law is teleological, based on intent.”—ECE III

“The three blind men and the elephant. The first stuck his hand up the asshole and reported a hot spring, the reports of the other two were unfortunately lost in the ensuing environmental readjustment.”—ECE III

“You can lead a horse to water, but you can’t teach him the backstroke.”

Protecting Wildlife Values of the California Desert Into the Indefinite Future

The major impetus for the proposal of alternate laws for the management of the Californina desert is the perception that the present management regime for the CDCA will be unable to protect the integrity of the wild lands, plants, and animals of the desert into the inndefinite future.

The reasons for this perception seem simple:

1) The BLM process is the most open among federal land-management agencies, allowing for continual review of its procedures and conclusions by the user public. The ancient natural patterns on the land are the result of millions of years of evolution and cannot be reassembled once gone. This includes such things as migration patterns, ecosystem structures, seasonal emergence patterns, and species composition.”

Thus the open BLM process is a constant threat to natural values. The means of designating and providing long-lasting protection for a carefully selected sample of these values is therefore critical.

2) The usual solution to such longterm provisions for the wild values of the desert is almost always conceived as being to lock them up away from the meddling hands of man. Such a solution typically removes the chance for a multiplicity of user classes that BLM specifically supports. There is almost certainly considerable room for melding many of these uses with management and [?].

For example, power transmission and generation, recreation, mining, and livestock activity can in many cases be carried on alongside cocnservation of the biota with the proper planning, and in a climate of conciliation. The new science of conservation biology is beginning to show the way for such artful compromises to be developed.

3) But foremost in the minds of those who would plan for such a future, must be the preservation and perpetuation of the ecosystems of which the desert is composed. There is, I repeat, only one chance for them.

To lose them is not trivial. Contained in such systems are all the compromises and balances that have resulted from history and there are a great many things to gain and learn from them that we must not lose. The only sensible alternate to such artful planning is to lock up large parts of the desert without such thought. . . .

By Saving Patterns on the Land—
You save both what you know and what you don't know

What are the patterns?

- 1) Protect migratory paths.
 - a) Stopovers for birds.
 - b) Bighorns to butterflies
- 2) Protect samples of the three great physiographic divisions.
 - a) Colorado-Sonora
 - b) Mojave
 - c) Great Basin
- 3) Protect water sources and life.
 - a) Amargosa
 - b) Springs
 - c) Mojave River
 - d) Colorado
- 4) Protect marks of the past.
 - a) Ice advances
 - b) Interglacial
 - c) East-West
- 5) High-Low
- 6) Protect specialties.
 - a) Calcophytes
 - b) Lake beds
 - c) Burros[?] Deer
 - d) Salamanders and frogs
 - e) Maturango tohee
 - f) fish populations
 - g) falcons, mountain lions, cacomistles, lizards, snakes, insect faunas, etc.

Most has been protected to a degree, but not recognized in a desert-wide plan.

Problem of continuity. A matrix in conservatorship with private sector conservancy.

One third of the nation's land is managed by the government. This means it belongs to all of us, and we should say how it is used and how it is managed.

Who are we? We are 23 senior environmental studies students from UCSC about to launch into careers dealing in various ways with the fate of the land. What, then, do we public landowners want? We will list:

1) No public land that is being preserved or used primarily for its natural values should be subjected to any use that degrades those values.

To give examples, no national forest lands whose values have been decided to be timber should be cut in such a way or at such a rate that the basic forest resource degrades.

Cutting that degrades the soil or that occurs faster than the trees can replace themselves should not be allowed, but instead new means of forestry sought that do not cause such unreplaced[?] disruption. No immediate economic benefit should be allowed to disrupt this policy. We must not "mine" these values, but must recognize that they are finite.

Another example can be found in our parks. The natural land and its biota are a park's basic value. Such parkland as is preserved for its natural values must be protected from degradation, both from within the park and from outside its boundaries.

This does not say that certain amenities that are locally disruptive of a park's natural resource should be [?]. It says instead that parks should be zoned and such amenities placed outside park boundaries whenever possible, and when inside it should be clearly understood that part of the park is being sacrificed at its most basic level to such needs.

2) It is a myth that public lands can better be managed by the private than the public sector.

Land management, at its very core, requires applications of a philosophy that is selfless, and that puts the public trust ahead of private gain. What is needed is a protective presence that is free from the daily tug and haul of the economic pressures that guide the private entrepreneur. At many points it will be crucial to be able to put the fate of the land ahead of private gain. That cannot be achieved in private hands in a capitalistic system.

3) Where economic considerations and the integrity of the public land collide, let the land win.

This will drive the extractive disciplines to seek new techniques. That will perpetuate the value of the land for future generations and not allow them to degrade it for short-term benefit. This is not simply visionary, it provides for the long-term stability of our country.

Manifesto for All Public Lands

A balance should be struck between lands devoted to agroforestry (where the complex ecology is suppressed in favor of monoculture) and ecoforestry (where the

dynamics of the forest ecology is made an integral part of forest exploration.) Normally steep and remote mountain lands will require ecoforestry.

Forest lands are required to be managed for multiple uses, which include wildlife values as well as production of forest products and hence the life patterns of wildlife such as migration and home ranges must be considered as basic to forest use.

A [?] of statutes and rules governing federal land management should be made with the aim of removing incentives and disincentives that force management practices to be driven by motives other than care for the living natural resources in perpetuity. Example: subsidies for road construction and mining.

Mineral Extraction—best left unexploited until need is strong, then used to stimulate national economy. We must face finiteness of land and its resources and therefore priorities should be on restraint.

The provisions of NEPA are being widely violated on Federal Lands. This should be revised.

April 5, 1992

New York

Burroughs Award

[Take 1]

During my years as a working scientist I did not imagine that I could one day write interestingly enough to join the distinguished company of other Burroughs awardees.

It was enough to hope that being a scientist hadn't wrung all the poetry and sense of beauty from my soul. When, from time to time a journal editor would object because my scientific prose was too simple and unadorned, I didn't know whether I was failing or winning.

A year and a half ago, at the age of 68, I graduated for the 6th or 7th time in my career to full-time emeritushood. The restraints of science were behind me. Yowie!!

Now, I said to myself, I can tell my stories with whatever sense of beauty, pathos, humor, pain, exaltation, hope, fear, and love that I have felt all along. I tried to leap and click my heels, but sadly I reached only 6 in. above the ground. . . .

[Take 2]

During my years as a working scientist I did not imagine that I could one day write interestingly enough to join the distinguished company of the other Burroughs awardees.

It was enough to unsnarl the obscurantism of science and now and then to be accused of writing too simply.

Yet here I am, and of all the credits I have received, this is the most exciting to me.

I am now a 68-year-old naturalist who has experienced many things all over the earth, and more than anything else I want to tell these stories, to sum up my naturalist's view of things.

You probably know me only as a dolphin specialist, but my intellectual wanderings have taken me much more widely than that, as first a chemist (a brief and desperate venture, at best); then a geomorphologist of deserts (wonderful fun, a time of camps and hikes all over the west); then a student of desert animals (even better fun), and my introduction to evolutionary processes and their histories and adaptations. Then an ichthyologist (my PhD was an exciting study of the life of a nearshore fish). . . .

[Take 3]

As a working scientist I never imagined that I could one day write interestingly or well enough to join in the distinguished company of your other awardees.

Yet here I am, and of all the credits I have received in my lifetime, this is the most exciting to me because it is so unexpected, and says that if I work hard enough I have a chance of doing better still.

At the age of 68, that is a very exciting and intriguing vista, coming as it does at a time when the rigidities of science number the days I wish to spend with that cumbersome process.

I fit your template because I have felt throughout my career that science should not be the precinct for a few, but its discoveries about how the world works should be made accessible to everyone who is interested, and should thereby become an integral part of our social process.

After all, we scientists, as I know very well from my own experience, are not some special breed. We are just people. We cannot with honesty set ourselves up as priests and then cloak our work in a hidden code designed to exclude those who have taken other paths.

It is in fact common among those I travel with to bay at the moon, to cuss, to dance to mariachi music, to orbit in the magnetism of women—or women in the orbits of men—or to resonate to the beauty of a hidden pool up some untrodden fold of the mountain, up where a yellow brushstroke shows where mimulus grows, against the green of horsetail rushes.

It seems to me that poetry and science often have the same roots. Whether each may start by observing with as clear eyes as can be achieved, asking nature questions, asking again, clarifying until something comes clean and true. In such a way each, the poet and the scientist, attempts to be a truthsayer. In my remaining years I want to explore this nexus, here so inadequately outlined. What I will write will likely be part of both, but I do not intend that it should be science and I cannot aspire to poetry. I can, at this stage, be a storyteller.

My book *Dolphin Days*, which you have honored, is I suppose familiar to most of you. So, it has been suggested that I talk mostly about other things, especially my plans for new works of natural history, if I have this in my future.

Let me say that the spinner dolphin work goes on today. My boat is at sea off the Kona Coast of the island of Hawaii and students continue to learn about the remarkable lives of spinner dolphins, animals who live in the almost totally foreign, open sea and whose minds in some ways rival our own. The question is how do they, living totally in 3D open water, do so with such capability?

One new thing we have found is that these animals seem to regulate everything they do by rhythms or oscillations, more completely than any other animals I know.

(Explain rhythms, zig-zag, social concourse bouts.)

Does this pervasive use of rhythmic patterning perhaps relate to the occurrence of rhythmic behavior in other animals, including us?

Let me take you back for a few moments to my own history and then to the stories of dolphins, which brought me here, and then finally to sketch briefly my next project.

In my career as a naturalist, I personally have refused to be spindled and filed as this or that sort of observer of nature, even though how I am known to the larger public may have done that.

I have always, I think, wanted to take it whole.

As a boy under my father's wing, I started as a hunter and fisherman, where that is what you do, take it whole. Then I became fascinated with the elemental building blocks of nature and aspired to be a chemist, but I needed to be outdoors. So I spent some years as a geologist, a geomorphologist fascinated especially with the majesty, beauty, and life of dunes, but once again, with the earth as a whole, beneath it all.

Then I fell under the spell—there is no other word for it—of the old South African naturalist, Ray Cowles.

. . .

[Take 4]

In these few minutes we have together let me tell you where my views of this world came from, then catch you up very briefly on the spinner dolphins of Hawaii, which I am told many of you will have sampled through my book *Dolphin Days*, and finally tell you what is next.

In my career as a naturalist I have refused to be spindled and filed as to what sort of scientist I was supposed to be, beyond assuming the self-anointing of "Professor of Natural History"—one of two in the UC system.

As a boy under my father's wing, I started as a hunter and fisherman. In some ways that start was irreplaceable. One took the world whole, one pitted wits against the quarry. Where were they? What did they sense of you? How did they use their world? There was so much there that most scientists never see. But the game became too unequal. It became a chase.

The discoveries and power of science fascinated me when I grew old enough to understand its process. Piece by piece I have blocked in the larger world. I became fascinated with chemistry . . . with the search for elements, the building blocks of nature. But it was indoors with the world "out there" somewhere.

Then I spent some wonderful years as a geologist—a geomorphologist, attracted to the majesty and beauty of landforms, especially dunes, their mathematical loveliness and perfection, and with the larger earth over which they moved.

To many of my geologist colleagues of that time, the life of the land was a thing to be ignored, the fields of flowers spread on the springtime desert and the nesting birds were hardly seen.

Quite naturally, I think, I fell under the spell—there is no other word for it—of a remarkable South African naturalist, Ray Cowles. He would introduce me to the worlds of birds, reptiles, and the beginnings of ecology.

I went from there to complete a doctorate on fishes and do much field work in Mexico under Carl Hubbs at Scripps Institution and from there, because of my interests in public education, to the second oceanarium in the world, at Los Angeles, where I became curator.

There I caught the first whale to be brought into captivity and began to learn about those remarkable mammals, the dolphins, with whom I have spent much of the next 30 years. I have been part of learning how they swim, echolocate, form societies, and what their culture may consist of.

Now I have come to the time when I want to put these [?] together, . . . to look beyond the various viewpoints—and that is what my book-in-formation is all about—*Mountain Time* it is called.

The scientist-naturalist tries first and foremost to perceive how the natural world works. How very important it is for us humans so typically wrapped in delusions of our own making to know these things! In the workings of the wild world lie the keys to understanding our own.

In our cities we are buffered in all sorts of ways, buffered from the torrential rush of water following a storm, the bite of the cold wind, the searing heat of summertime on a desert rock face. We are shielded from predators lurking just beyond our shield, whatever it may [?], and we are provided with food and shelter as if they were given rights.

None of that is true in nature. What's it like out there? What are the rules, really? What can they tell us about where we are steering our society from within the glass-walled, carpeted, heated chambers where we make our decisions about the future? What right have I to talk about these things? I don't think I'm smarter than most of the decisionmakers, but I am, routinely, closer to the real world. So maybe I have something important to say. We'll see.

[Take 5 is too messy to transcribe]

May 29, 1991

Sweden, Kolmardens Djurpark

At Amsterdam my bag is lost and there proves not to be time to retrieve it. I run back and forth down a long, echoey hallway between security and the Aussie girl at the TWA desk as the time to board ticks closer. Gimlet-eyed security guards suspect me at every turn, making sure we never set our bags down where a terrorist could slip in a bomb. I'm pleased to cooperate. But my bag never appears, and I finally run for the plane and board for the flight to Arlanda Airport at Stockholm. There I file a missing-bag report with a pretty, efficient stewardess and head for the entrance, where Mats is waiting. He is far from calm about the coming dissertation exam, but our conversation runs smoothly in an old friendly way as we arrow south to his zoo at Kolmardens at Nordkoping we stop to shop for some interim clothing for me for the exam, since I had arrived in an open shirt and with no luggage to improve things. I finally select a summer coat, some socks and shorts, and a sexy necktie covered with butterfly scales.

Off we go to the zoo, a few miles south. Mats and his family live in a little house a short distance from the zoo parking lot. Wife Birgid, sturdy, has her own space, loving, two sons, Jonas, into cars and Eskil, an animal prson. Both in their teens. We have a snack and deposit me at the nearby hotel overlooking a sea channel back of the Baltic, small freighters and tankers ply by, sea birds, including a big raft of swans, dot the surface and call from the air. The hotel is on a cliff amidst the elms, oaks, and pines. Very beautiful. I immediately crash and don't wake up till 3:30 AM to the northern dawn light. After a while I drift back to sleep and arise at 5:30 to accompany Mats north to the University of Stockholm where his exam is scheduled.

May 30, 1991

Kolmardens, Sweden

We knife up the open roads to Kolmarden (1½ hrs. S. of Stockholm) through copses of forest and fields, some of rape and others fallow or green with new green.

Mats had had his PhD work printed up in a volume of seven papers, centered around the issue of odontocete cetacean phonation. It is an elegant little volume with many color plates in the back and one on the cover, all of phonation anatomy. I had reviewed each including a long introductory piece that summarized his overall views.

The University of Stockholm sits in an old farmstead and is composed about half of some of the ugliest modern buildings I have ever seen. Functional architecture at its worst. Mats agreed with me. It was hard to tell it was a university or a methyl cellulose extract factory. Tinny and cheap looking from a bad choice of materials. Airy inside and perhaps functional but filled with pipes and blanketed vents and exhaust lines without imaginative painting.

The exam was public. I was the outside examiner and main controler of the flow of the exam.

I met with the committee in the chairman's office: Dick Nassel, a young neurophysiologist, a fish endocrinologist, a behaviorist (Scholander—no relative of Per), a gaunt ethologist population man from U. Gobeurg to the south, and I.

The rules were laid down and off we went to the hall, the biggest amphitheatre in the University. I guess 100 people attended including Henry Truby.

I first introduced the field since attendees were public and people from other fields, and that went on for 15 minutes. Then I summarized the importance and contribution of each paper and then led into a series of questions to Mats. The chairman Nassel then opened it to the public for a good general discussion.

Mats was composed and increasingly relaxed as the exam went on, fielding questions openly and directly. The best discussion came when we got onto the mechanism of sound production and whether or not simple impact could produce the intense clicks dolphins make.

Then, two hours later, it was over, the committee met in solemn conclave. Clearly he was one of the better students in recent years, and signed the crucial paper. We found him in the hall, shook his hand, and called him "Dockter." (One committee member dissembled, noting that one requirement, some classes and readings remained. Mats objects and will fight it.) Then a long lunch, mostly spent waiting for the waitress, and then Mats hauled me over to a building where I gave a lecture on spinner dolphins in a stifling room, and thence to Kolmardens where we had dinner with Mats's parents. Father

is a gracious, gaunt electrical engineer and Mom a small, smiley woman. All speak English and well. I suspect the English on TV does much of this as they use unaccented English for the most part and haven't traveled extensively beyond Sweden.

They took me to the hotel where I was pleased to collapse after a short hike to the water's edge to watch swans feed. Long necks are to reach the bottom.

It was quite an experience. The system is good if the details and nuances of a person's research are what one wishes to use to determine passage to the PhD. The method brings out little about the broader aspects of biology. It was a very much more professional exam than the ones I've been used to at UCSC.

We had a long lunch at a kind of faculty club and then my seminar in a very hot seminar room. It went OK.

Then Mats and I fled Stockholm down the almost vacant freeway at 120 km. Mats was drained, as was I, and anxious to get home.

May 31, 1991

Sweden, Kolmarden

Bertel Mohl and Saren Anderson with respective wives Lotte and Charlotte arrived and were greeted warmly. Such wonderful colleagues! Bertel wanted me to join them in Greenland (at Thule, way up on top at 77 deg. N latitude) for studies of the narwhal, not this next summer, but the summer after. He is trying to obtain underwater videos of their feeding. How do they do it with the tusk in the way?

Lotte and Charlotte, two favorite women if one needs to class people, were full of life.

Lotte weaves mostly. She says with her children grown, baking is cut back severely. Charlotte is still a journalist, writing local news at the coastal town of Strib, Denmark. Both Soren and Bertel seem fine. Bertel retires in five years and Soren struggles for money at his Odense zoo.

We walked various parts of Kolmardens, which has an elegant, open parkland full of antelopes—black bucks, impalas, and others, a fine chimp island, and a great deal more. A great troop of tigers stalked around their moated compound. It's set in hilly terrain in forest land. Quite lovely and the animals seem very well cared for.

In the evening a fine dinner for about 100, much prepared by Mrs. Amundin Birgitte—appetizers, much liquor, roast beef, cheeses, vegetables, a fancy dessert of whipped cream, and thin sheets of chocolate, all interspersed with speeches about Mats. What emerged was how monastic Mats has been to do his work, prepare the book, mostly without direction, and originally, actively in the face of opposition from his zoo director. A new direction was supportive. I told about my troubles at being a stern, serious “opponent” when we knew each other so well.

Finally, at about 1:30 AM, I found my way to the hotel. Tomorrow at about 7:00 AM I leave for the airport and Texas.

June 1, 1991

Enroute, Houston, Texas

While I think about it, Bernd, in his usual incisive way, explained cavitation to me—what I think to be the key to understanding how dolphins make sound. It is in two parts—one is the effect which causes extremely high temperatures in cavitation bubbles

and the other is the noise. The heat can reach the surface of the sun, I recall, and noises are similarly intense. The heat comes as pressure is suddenly relieved and is the same effect as lowering the boiling point of water with increased altitude. At high altitude the change in state occurs at lower and lower temperatures as pressure reduces. There is more molecular space at high altitude, so going from liquid to gas phase releases less heat. the molecules collide less often. The deeper you go the more molecular per unit volume in a gas, so the higher the temperature (more collisions per unit time) occur. So the temperature rises. The other separate effect results from pulling apart the matrix of a fluid and its resultant collapse and oscillation. This makes loud noise. So the higher the ambient pressure, the higher the temperature upon release, while the collapse oscillation resultant upon pulling apart the matrix ought to be approximately the same at any depth, as I now conceive it. At any depth is it the relative or absolute pressure differential that produces the phenomenon? I think it is the latter. Thus, when you lower a glass ball to a 1,000 ft. and implode it with a steel stylus, the sea collapses over it, a 30-atmosphere pressure difference results and a great noise results as the bubble oscillates wildly.

If the pressure differential is less, say 1-1.5 atm., a loud but much lesser noise results, pulling against the molecular matrix of the water and at about that point pulling it apart in cavitation. Why then, if I have all this right are submarines silent at depth since their propellers don't seem to cavitate. I think it is because the fractional pressure change of an atmosphere changes with depth. That is a rapid 1 at m [?] change at the surface may pull a fluid or gas apart, creating a vacuum but the same change becomes less and less a percentage of total pressure with depth, so it is harder to create true cavitation, so heat is not usually released, but the oscillation of pressure around ambient, at whatever depth still creates a loud, oscillating source. It's the amplitude of the oscillation that counts, not whether it crosses zero. If I am right the abruptness and amplitude of a shift is crucial, not whether it cavitates.

So, it should be the loading on the source and its elastic rebound that counts to make a loud sonic using an airstream differential. How much pressure is available on the passing airstream? How big an oscillation is the question and that is not dependent on depth.

So if 1-1.5 atm pressure can be exerted low in the superior nasal passages and if it can push against a controlled blockage point with elasticity (rebound), so that as pressure is released it will build up again, be released again, etc. Now, if this is done by breaking an airstream into packets or bubbles it can be made to pulse. Now if the initiation of a bubble is separated from the next bubble by a different time to the next bubble it can be made to produce different repetition rates.

Perhaps this is why the museau is wedge shaped—high rep rates at the narrow end, low rep rates at wide end, and both related to the velocity of air stream (pressure differential) over the museau.

So by muscular means, an air pressure is built up behind the museau and the airstream directed at specific point at the back of the museau. The airstream pressure forces the lips apart at that point allowing a little air to pass, which uses up a little of the source air reducing pressure and allowing it momentarily to close—thus breaking up the airstream into pulses. these are released just beyond the lip margin into a tissue-enclosed space that is both vented to take air away and restricted so that the oscillating gas bubble will drive a compliant portion of the tissue wall—the wall of the dorsal bursa—which

transduces sound into the fat and thence out the melon. This produces the tissue [?] click. the vented oscillating gas produces the low-frequency position of the signal a very short time after the HF signal is propagated.

Now what does that space beyond the lips look like? How does it trap a released, oscillating bubble? How is it vented? Into what?

By playing or directing an airstream against the back of the museau, rep rates can be modulated.

Now why should one MLDB complex be at right angles and the other slanted at 40 degrees? If both are used simultaneously, path length through a melon in one can be varied against the other, thus varying interference. This of course can adjust directionality of the beam, and can cause frequency shifts within the beam. Thus a click could be adjusted to a given inspection problem.

I wonder if this is how it works?

My plane is about two hours late. I'll probably miss my connection to Dallas-Fort Worth, but at least I'll be in the air soon and on the way home. It's been a fine jaunt. I feel very good for Mats and his family. He's done very useful things.

February 13, 1991

Notes, Japan Trip

Koji Nakamura and Flip and I went to the Institute of Cetacean Biology, a long, long drive through huge Tokyo, street after street of glittering buildings, [?], traffic, well-dressed people, slim girls with bangs, and cars nudging up close against other cars for a place in line, then a wave of thanks to the car who gave way, fleets and fleets of big, blunt-nosed trucks, and tiers and tiers of windows, striped with fluorescents.

We finally found the Institute over near the docks somewhere. I could see a big vessel's bridge.

We met Director Yamamura, an affable, endlessly helpful person. He is an administrator, not a scientist. Most of our time was spent on schedule. We will go south to the Far Seas Institute and to Izu (Taiji is farther south) and stay at Koji's log-cabin villa.

Koji has been squiring us around. He and Flip are close, old divers to the last. He is a heavy-set guy from northern Japan, very comfortable with Americans, who runs a TV business for underwater film segments. We will pay all his expenses, I'm pleased to say. I like him a lot. Very open and honest. Flip says he's a great diver and photographer. With Koji driving his Subaru we thread our way around easily, especially with his car phone to call ahead.

We sat in Yamamura's office worrying about schedules and then began to discuss fisheries, including the Dall porpoise harpoon fishery. There are thought to be five or six stocks out to and above the Aleutians, three near northern Japan. We will see the southern one, which has been so strongly impacted. As I gather it, the fishery severely reduced the population at Area 1 where we will visit at _____, and has adjusted the kill by limiting the fishing season and by limited entry on boats.

February 14, 1991

Tokyo Hilton

Flip and Mr. Yamamura, operations officer of Institute of Cetacean Research took us in a blustery day to the government fisheries center—a very governmental gray building over by the [?]. We went by subway—neat, quick, crowded. We were taken out of the desk-to-desk office into a conference room where a row of blue-suited, grave Japanese waited for my questions. Flip sat back soaking it all in. He has considerable sensitivity and is not afraid to come in to help steer things. I tried to still fears, to tell them I support fisheries and have for years—what I would like to be is a balanced voice. . . . no comment.

I asked in detail about the Dall porpoise harpoon fishery. I got the regulations and their imposition. I found little out about the fishermen, their strength and attitudes, where the catch goes (I think it goes south to the porpoise-eating regions). I found that they limited seasons, landing ports, numbers of vessels, and that they imposed reporting requirements. I was given some important literature.

I switched in midstream to the squid fishery and confused my bureaucratic colleagues. My intent was to explore the bay catch, but they concentrated on squid. Flip brought us back on track.

I found that the boats are separate for the two fisheries. The harpooners fish for marlin, salmon, a few other fish, and dolphins, while the drift netters concentrate on gill netting and are sometimes tied up when the season is off. The big boats have fished since 1979 on flying squid, having moved over when a more local squid fishery declined.

The mothership fishery was cancelled a year ago. It worked mostly for salmon as I recall.

One interesting point. Pan is not allowed according to International agreement to sell by catch dolphins inside Japan. So the fishery cannot benefit from the killing of these dolphins. I want to understand this agreement, but do not.

All in all I came away with the following feelings. The overall feeling is that things are very bureaucratic. One can't ask people to wander too far.

Sociology, for instance, doesn't seem to enter the Fishery Building. I saw them as working on not very different levels, scope, and commitment to our own fishery people, who can also be narrow, but I think it could be said that they are attempting to solve these problems, just as we do. I see a bit of chauvinism, I think, a bit of defensiveness as these rules and methods change and as the Japanese face international pressure. But I do see response. The Dall porpoise fishery was unregulated until 1989. In 1988 40,000 animals were killed. It is now down to 20,000 after regulations were instituted. Whether this population can withstand a 20,000 animal take seems far from secure to me.

The fishery people talk of five populations, one around southern Hokkaido-N. Honshu and others to the north and east and in the Bering Sea. I tried to find the basis of this determination but failed. I'm not sure they know. I want to know what the population level is thought to be and if 20,000 can be withstood. I doubt it. I want to be sure I believe their figures and that these populations are not mobile entities.

I see Japan emerging. Whale decals are around, and there are evidences of an emerging environmental view. I will watch carefully.

I think I stilled their fears of me a little. They gave me literature on Japan and world fisheries ([?] is first, if I read it right), and then Flip and I went off to a sushi dinner and prawns, sea urchin gonads, fish eggs, octopus, squid, whelks, herring.

We collapsed in our rooms, a bit of the jet lag still with us.

February 15, 1991

Japan, Izu Peninsula, Ho City, overlooking Oshima Island

We are sitting in Koji Nakamura's wonderful log cabin overlooking Sagami Bay, our feet on a wonderful electrically warmed rug, after driving south from Tokyo to the Far Seas Research Institute, in Shimizu City. We skirted the base of Mt. Fuji, all decked with snow, halfway down the mountain.

Koji Nakamura drove in his new Subaru and he can drive. He also regaled us with information about just about everything.

On our way to Far Seas Fisheries Institute we stopped at Tokai University Aquarium and looked at the lovely fish and met the Curator. The tank features 24-ft. slabs of Mitsubishi plastic and a modestly interesting fish exhibit. A long, striped cleaner fish with a red tail (looked like a relative of the sea horse), garden eels—they have fine little faces and maintain the walls of their burrows in remarkably precise cylinders even though they jerk in and out. I was much taken with an exhibit of scabbard fish, elegant, shiny silver fish that stand up on their spike-like tails. I want to know more about how they live. They kept jellyfish and had made a modest attempt to do so by cylindrical flow but I understand they just replace them every few weeks.

On we went to Far Seas, which is nearby. We met Dr. Oshimi who is director, and he said, near retirement. He will retire to a position at the Institute of Cetacean Research. We traded a few stories about our earlier contacts and then went upstairs to see Toshio Kasuya who greeted me warmly and answered all my questions quickly, precisely, and directly. He is amazing and seemingly impossible to fool. I asked him first about the Dall porpoise harpoon fishery. It is concentrated in winter on the coast of northern Honshu and in summer on Hokkaido.

He said stock size had been determined by line transect cruises in the Sea of Japan, Sea of Okhotsk, and farther offshore, including the Bering Sea. His present view of the stocks were that there were two in northern Japan with a maximum estimate of 110,000 animals, and that the figure could be 3x this. One stock, which includes *P. truei* type animals is found on the east coast of northern Honshu. In winter it moves north and northeast of Hokkaido to breed (calve?). The second stock is found in the northern Sea of Japan-Okhotsk Sea in winter and moves directly north of Hokkaido to breed (calve?).

Toshio had recommended to IWC that the kill be reduced to 10,000 per year, and he expected this to be followed. This he felt would protect the population from decline.

1988: 40,000 harpooned, mostly sent south to prefectures where eating dolphins is traditional and where dive fishery had declined.

1989: Kill regulation not to exceed 20,000 by a combination of methods: 1) restriction of harbors for landing; 2) time restriction; 3) restriction in number of vessels; 4) reporting requirements differed.

1991: IWC limitation to 10,000 will be instituted (next year?)

The impression is that unregulated kill was quickly out of hand, probably severely reducing stock, but that the 10,000 regulation will bring it back to equilibrium.

I asked Toshio about the fisherman's villages and what they controlled. He said their "ownership was restricted to the shoreline and all on it and that this worked pretty well." He said the villages did not claim ownership of open water Dall porpoise stock or fisheries farther at sea, and that these were common property resources as a result and had to be regulated by his organization.

I asked about my old Scripps classmate Nonyku Nasu and he is retired and in Tokyo at NHK Broadcasting University—whatever that might be.

I asked about the drive fishery. Toshio thought it had declined because of overfishing. A century ago ten villages did it at Izu Peninsula, and only one at Futo operated two years ago. And even it did not operate last year. The catch was very heavy after war—10,000/yr. or so; by 1960s down to 9,000/yr. but declined in recent years to only two villages and less than 1,000 animals and then none. Mostly *S. c.*

Taiji to the south has had similar history in a way. In the 1960s and before it was a harpoon fishery, but switched in 1970s to Oikomi, or drive techniques. It is regulated by the prefectural government. It rose when Oikomi was introduced and has now declined due, Toshio says, to overfishing. Toshio published a paper on all this in 1985 in the Whale Research Institute Bulletin.

We left Far Seas and drove through the lowlands and up over the Izu Peninsula to Koji's villa. The place is crowded with stores, construction, people, signs in Japanese, in three kinds of characters, occasional English, well-dressed people, very few bicycles, a continual flow of trucks large and small, round mirrors to let you look down obstructed roadways, narrow streets and sidewalks, deep gutters, and big, open, high-speed freeways and flyovers. Koji drives his Subaru fast, 120 km frequently, even though 80 km may be the speed limit. He is a very affable, open, bright guy, a little heavy like me, mid 40s, [?] a successful underwater film, TV, and publishing effort with a staff in Tokyo. He is an organizer who runs things by car phone and is busy doing 10 things at once. He is just splendid to be around and a wonderful guide for us. We have saved days of time by having him help us.

What a day! We got up early (5:50 AM) and left for Mimazu Fish Market, which is about a two hour's drive from here. Koji did another splendid driving job. On the way I listened to Flip calling the *Geographic* from the car phone, and since it was Feb. 14th, St. Valentine's Day, I decided to call Phylly. It was so simple. We just dialed as were driving along the edge of Suruga Bay. Just moments before we had seen Mt. Fuji off to the left. Fred and Sus came on (Phylly was at the Arboretum). It was great. I told them when we came to a stop sign and what the weather was like, etc.

Not long after we located the big regional fish market. It consists of a couple of broad waterways, capable of handling 250 ft. (or more) of fishing vessels, and two long galvanized sheds, perhaps 1,000 ft. long and 200 ft. wide, the dock on one side and a busy truck-loading road on the other. Across the broad, crowded street were the wholesale shops, freezers, a series of tight little streets and alleys. It was bustling with trucks, hand-carts, and busy people, many in hard hats, aprons, verey intent. One had to watch out to keep out of the way and to avoid being run over.

The other impression was of neatness and the splendid condition of the fish and other products. Styrofoam boxes have taken over. We walked the length of one barn, past tiers of ice-filled styrofoam boxes, each with a perfect yellowtail, or a group of smaller

fish, shrimp, squid, even krill, seaweed, halfbeaks, groupers, [?], and large numbers of tuna, some marlin, and broadbell[?], and some deep-sea fish, squids, prawns, brotulids, cods, octopus, all iced, and in perfect shape.

Hideo Miyamoto, Futo Fisherman's Association.

There was little of the mess and smell of the usual fish market. The tunas were in the round, gill covers, and gills and tails missing, usually a line to lift them, frozen so solid they were frosted white with a coating of ice. They were sometimes stacked up like cord wood, the frost steaming like smoke. Koji thinks they are frozen at the other dock.

One area was given over to living seafood, all in green plastic containers, each supplied by a bubbler. There were puffers for fugu, snappers, and a variety of fish and crabs. Apparently this live food is increasingly popular.

We drove to the other dock—found it by accident actually, and it was devoted to seine and hook-and line-fisheries offshore. Two modern hook and line boats were full of very large, plump mackerel that were taken off in a chute and beltway and sorted and boxed. The other was a big vessel 40 m long, with at least half-a-dozen holds in the well deck that were filled with skipjack, jack mackerel, sardines, and some other schooling fish. They were brailing out 400-500 lbs. at a dip, draining it and putting it on the belt for sorting. The skipjack were gleaming and clean and perhaps 5-6 lbs. The dock was spread with large fish boxes, perhaps ready for a cannery.

We saw a little dolphin meat but no whole animals. It was cut and dark and in the ubiquitous styrofoam boxes.

Over all, I felt much in the middle of something important at the dock, and one could feel the pulse—so much greater in scope than anything I know in California—richer, more vital, and in fact, our diet since being here has been heavily from the sea, and I believe that it is correct that Japan is the No. 1 fishing nation. One realizes the importance to the people, and then one realizes the degree of importance of fisheries problems and agreement, and of problems related to dolphins that have come to affect those agreements and regulations.

On the way back to Koji's villa, he took us down through the elegant houses and corporate villas to the coast at a diving facility where Koji had worked. It was right next to Futo Harbor, which is a cement hook against a rather steep lava boulder slope and shoreline; not very large—big enough to house perhaps 30 vessels up to 50-60 ft. or so, the shore slope having been paved in about half the shore so that boats could be block and tackled up about 30-50 ft. above water laterally and maybe 20 ft. above tide, their bows against the hill slope and restrained by heavy lines. I presume this is protections from storms but it could also be used for boat repair.

The rain sheeted down, dappling the greenish gray water offshore, 20 miles or so away is Oshima Island, out where the Kuroshio Current bends in and the dolphin herds migrate by (largely *S. coreuleoalba*). It is from out there that they are maneuvered in the drive fishery, into the harbor.

We drove around the base of the harbor on a narrow, lava-margined road and out on the breakwater where the porpoise vesssel lay up against the cemented slope. She was perhaps 35-40 ft. long, open deck cabin, slim and ready to go.

Against the other shore where the opposite breakwater extended, we were able to walk down to the entrance. Piled on the breakwater was the net used to close the harbor

once the dolphins had been driven in and at the end under the harbor beacon a series of the noise makers—10-ft. pipes, a bell at the end, and a solid rod at the top to pound on, a bolt that could be loosened to let water into the lower end of the pipe, and a hook to affix it over the sail.

Hideo Miyanoko, Koji's friend, met us and told us a good deal. They were ready to fish, but hadn't this season. The market was still there, but it was difficult to drive the dolphins because of the great increase of ship traffic out by China. He said there was a reduction in the number of dolphins, but he laid it at the feet of reduced squid in northern Honshu, not population decrease of the dolphins. He knew about the various species.

We were invited up into the Fishermen's Cooperative Quarters, where three of them were having a snack and a little saki and beer. It sits in a partly ramshackle building at the dock. We were invited in by the fishermen sitting around low tables on tatami mats, split and smoked jack mackerel in a pile, and a big jug of beer and some saki, which one of the fishermen drank from a tumbler. He had a good slug.

We talked easily, especially to an older man who knew all about oikomi. It isn't very old. Only in the late 1970s it came in, replacing a harpoon fishery.

All three liked to talk about fish and dolphins. They said bottlenose were smart, sperm whales were tried, but just dived out of sight, *S. attenuata* was "stupid" as was *S. coeruleoalba*. They had caught false killer whales, pilot whales, and rough-tooth dolphins. They seemed to know what *Feresa* was. I drew them pictures.

The drive bell (pounder) had been suggested by a metal worker from down the coast, working with the fishermen.

The conversation was lively and open. Koji told me the fishermen at first welcomed divers but then banned them, but finally, given a piece of the action, the climate of opinion changed again and now their relationship was good, as it clearly seemed to be. It's hard not to like Koji.

He told me the bottom is very rich, good-sized abalones, alcyonarians, shellfish, kelp, all carefully guarded by the fishermen's cooperatives. Their success stops at the shore, though, and migratory resources aren't conserved. The fishermen probably don't understand the problem or the difference in growth of a dolphin and a fish and what it means.

One told me about seeing a dolphin in a drive give birth and then watching it try to nurse. He said this with evident compassion, even though his fishery is designed to kill dolphins. Such tangles of the human spirit.

We said our thanks and left in a downpour, grateful for this time with the men of the fishery—on back to Koji's place to listen to what may be a cease fire in Iraq-Kuwait, and thence out for a splendid tempura dinner and home to hang over the Japanese-speaking TV for hints. We all want it to end according to the United Nations' sanction.

Off to bed, after a full day.

February 16, 1991

Japan, Tokyo, Imperial Hotel

I asked Koji to tell me about currents around Japan as we drove back to Tokyo. I was interested because there seems to be rich fishing water on both coasts and it is doubtless related to the currents.

He drew this [drawing]:

I've distorted his islands quite a lot. But the current situation is indicated correctly. There is much fishing on both coasts where the currents meet and mix, and much opportunity for productivity in upwelling, downwelling, mixing, eddies, etc. the deep, or mid-depth rich water is continually or seasonally brought to the surface by one means or another and rich fisheries result. The Sea of Japan richness is seasonal. I suspect the Kuroshio is a divergence-zone phenomenon and probably relatively continual though clearly the dolphins migrate seasonally.

Together these things make Japan extremely rich in things of the sea, turn her toward it, globally. Tradition ties the nation to food sources, and they move across the seas of the earth in search of it . . . the ultimate mechanized hunter-gatherers of the sea, joined by Taiwan and South Korea, who also have traditions. Neither we nor they have learned how to treat these global resources as more than for the taking. All of us must learn to consider their health in our equations, just as the Japanese coastal fishermen have learned to care for theirs.

What about the whales. The Institute for Cetacean Research is dedicated to utilizing the whales, especially the minke. This says nothing about past depredations on whales in which we all took part, in which all our nations failed to respect the wild populations. It says these Japanese scientists remain unconvinced that whales should not be fished. I understand what they say.

Presuming that we have learned to exploit wild populations at sea in such a way that the populations are not harmed, the Japanese call for a return to selective whaling for minke whales is a balanced one—balanced with our two societies' heavy reliance upon animal protein. There is little moral justification for us, it seems to me, to condemn such whaling in view of our own sources of food. In the process we condemn Japan from a shaky platform, and one that does not, I believe, include a majority of people.

Can we exploit in such a way? Any of us? Maybe. We've been very bad at it so far. Should we? I find it hard to condemn the Japanese in this case, so long as we have learned our lesson enough to assume the integrity of minke whale populations.

To me, the call in the USA for the cessation of whaling is a symbolic call for care for our world. It falls in a world deep in the throes of a population flush so great that it threatens just about everything else we try to do. but, we must not apply our moral indignation unequally upon our friends, especially when we violate what we try to impress on others.

Hideo Miyamoto told me of watching a birth and a first suckling of a young amidst those trapped in Futo Harbor. He said it with compassion, with knowledge of his role in the death of the school and with reflection back on his own position in this drama. His voice was wistful, but he moved on to show me how he helped accomplish the capture of the school. How like me and my sheep flock, I thought. We were, indeed, in a position of manipulating death and survival according to our own needs, whether we did it with fish, squid, dolphins, sheep, or cattle.

February 17, 1991

Japan, Iwate Prefecture, Ozuchi, Hotel Otsuchi

Flip and I retreated to our posh (they should be for \$300/night) rooms in the Imperial and Koji went home. We watch CNN TV on the Gulf War, sanitized in the extreme, but with pictures from Baghdad of the bunker bombing and the move toward

retreat by Saddam Hussein. It must truly be hell in those bunkers occupied by his troops as mission after mission of bombers goes over. Koji and his very "akamai" wife Miaki took us to a Vietnamese place for dinner. Six cooks and about 20 customers and the place was nearly full. Good time, good food. Then to bed to leave early for Ozuchi up on the northeast coast of Honshu at a town devoted to the Dall porpoise harpoon fishery.

We sorted our gear down to a suitcase and took a taxi to the train station where with Koji's help we descended about five levels to the platform for the bullet train north—it travels about 230 km/hr.

Crowds of well-dressed people, a spotless station, and a spotless train. It runs due north on Honshu and may go to Hokkaido, I don't know. We went $\frac{3}{4}$ of the way up from Tokyo. It was blustery and overcast, but not cold (7 degrees C), when we boarded, each of us having a double seat to ourselves.

Tokyo is ringed by suburbs, whose main features are lower buildings and reduced crowds. Then rice paddies began to appear among the buildings, almost every space over $\frac{1}{4}$ acre has its rice. Cemeteries with big monuments and sculpture appeared on other bits of land, little tiny ones. Off to the west the land rose to snowy, tree-covered hills. As we went north the snow line came down to meet us. By the time we got off at Shinhanamaki there were patches on the road edge.

Koji took us in a rental car toward the coast, first through rolling hills with sizeable streams, little rivers really, pouring along in cobbled streambeds, and then into the mountains where the snow had fallen in earnest. Trees had limbs white banked and the road was slush. We thanked the rental lords that we were in a 4x Subaru and made the coast easily enough on a rocky coved coast, lined with buildings and docks, through a long tunnel and out into Ozuchi Bay. The town is mostly in the north area of a Y-shaped bay, protected by a cement jetty and a curved entrance. Even so, a heavy swell surged in, swashing at high tide against the quay where the porpoise boats were moored and sending a sheet of salt water up between our feet. Forest-clothed mountains, white with snow through the map of trees rise perhaps 2,000 ft. back of the bay. The town occupies nooks and river bottoms along the arms of the bay. The rafts of oyster, scallop, and seaweed mariculture pepper much of the surface of the bay with little black patches, like the heads of sea otters napping.

Koji took us down to the dock where the Dall porpoise boats are moored. They are high-flaring-bowed vessels about 70 ft. long, with a bridge and superstructure amidships and a half dozen or more dolphin darts leaned against the rigging up near the bow. Some were double pronged (the double-prongers, like [?] spears, are apparently primarily for marlin, but also serve the porpoise fishery), and more single, with an 18-ft. shaft of wood tipped with a metal rod perhaps five ft. long and then the dart. I did not note the gear used once the animal is harpooned. As I took a couple of pictures my motor drive made its winding noise and a man on the dock turned toward me silently, with body language that said "Wary, wary, I'm not sure I like you."

We made our way up the hill to our hotel set on the promontory over the harbor entrance, spun down into the snow and slush-covered entrance area, and checked in. It's Ozuchi's best—Japanese tatami mats and a low table, mats for sleeping, and slippers in a rack by the door. We will meet for dinner in a special room right next to mine.

It's cold in this place, regardless of the febrile Hitachi heater thrumming away. One has to remove shoes and don slippers. I've put on woolen socks over my other wool

socks and my feet no longer fit the slippers. I've closed the screens on the bleak, cold bay, all foam filled with the offshore storm.

So, what do I think? I'm glad I don't have Flip's job. He doesn't like it either, being pushy and [?] in a place where you're not wanted is not his cup of tea.

What I think is that a fisherman probably cannot be expected to understand why his catch has been restricted to 10,000. I don't expect him to be engaged with the question that he kills a sentient animal. What rubbish, who says? What's so different between them and a fish? They don't make you rich, either. Only a part of the Japanese like them.

What do I think about the kill in the first place? Should they take them at all? If we prey on mammals at all, I find it hard to draw the line. I'm not at all sure I hold more of a brief for Dall's porpoises than I do for cattle and sheep and pigs, especially pigs, and my society is addicted to them. As a commentator, can I condemn another society when my own so blatantly disagrees? Am I of the dissenters? I think not. I too am addicted to these animals as food and I do not believe it has ever been different between us except when animal protein was in short supply.

Well, what about their minds? Well, what about a pig's mind? By every evidence they are high in terms of mind among mammals, and yet the cubes of crisp pork I was served last night were delicious fare. I doubt very much that the Dall's porpoise is so high in the scale of mammals as the pig.

So where are we? Deep in the tangles of social values, of cultural change where things don't often make sense except viscerally, where we know things are wrong and we call for change that may or may not fit or apply to the root cause.

What all this says, I think, is that we sense on every hand that our race tears at the fabric of the earth and everything that lives in it, and we seek change by righting some wrong while dealing not at all with other equally visceral problems. What is being asked for is the larger "righting" that makes these examples cumulative. These are examples, cries of pain at that, which we wreak by the cumulative impact of our members. A Dall's porpoise's death singly, we would not worry. Done to a single species our worry would be more, but would still not engage a country, a rising swell of societies, not just in the USA, but in Europe, New Zealand, Australia, and increasingly in Japan itself, wherever people still have space to think.

It is the same in the Far Seas Research Institute as in the Institute for Cetacean Research here in Japan. They understand as well as I do.

In important ways Japan has found out how to deal with its coastal living resources and the U.S. is behind. They even have more tools for offshore fisheries, the restriction of fishing vessel entry for one. Limited entry protects species and also protects fishermen.

But for species that no one can really count, that live and move in currents and over the sea floor they never see, intersecting only now and then invisible boundaries, with no mark on land or water, we don't yet know enough. The best we can do is to touch such species, measure what we have done, and preserve the option to back up if the signs suggest we should. We probably cannot yet know with any precision what precisely to do. Yet can we back off utterly? Leaving the sea and its animals alone? Should we

condemn Japan and Korea and Taiwan and [?] ourselves for reaching out for resources from the global commons?

I don't see it in the works. I see us, humans that is, coming slowly to terms with who we are, what we need, what we eat, where it must come from. This is a buffeting ride and all around us we see limits and cautions and ecological destruction and excess. But we also see backing away, we comprehend limits, impacts, the needs of our partners. This is what the row is about.

In a curious way, cultural change seems to be done by metaphor. We seldom solve this or that. We play with the stage on which events have played themselves out. We deal with values. We argue over them. We maneuver them. We deal with ideas, not things. So it is with all cultural change, I think.

February 18, 1991

Japan, Ozuchi

Last night we had a remarkable (for me), sit-down (on the floor) Japanese dinner at the hotel. My knees shortly got the better of me, and I asked to use a chair, which seemed fine with everybody and the dinner went on.

We had a variety of raw or pickled seafood, abalone (sliced but in its shell), scallop, squid (cut ¼-in. strips), fish, shellfish, pickled shallow-water algae, lovely sticky rice and soy sauce, good beer, Suntory whisky, tea, and a big steaming pot in the table center containing onions, some kind of red meat (sliced thin), fish, and a very small, long-stalked mushroom.

Somehow we got around most of this. A very gracious, tidy woman in kimono and obe served us.

Off to the tatami mat in a cold room, warmed only modestly by the wall heater. I closed the screens against the chill world outside and slid onto the mat under a big down comforter and off to sleep.

This morning at about 5:30 AM, Koji thrust his head in the door and woke me. I was up and dressed as warmly as I could against the chill dawn 15 minutes later. Koji's loaned cashmere long johns and heavy down coat helped immeasurably. Now all I need are rubber boots. My leather field boots are already damp from the sea water [?] on the dock last night, but with two pairs of dry socks they aren't bad.

Soon we were navigating down the hill road, Koji navigating very carefully over the vitreous sheets of glare ice and onto the flat where the fish docks are located. The sun was just rising, slanting across the 1,000-ft.-long concrete market floor. We were alone. The same boats were alongside the dock as last night, breastlines outboard to pull them away from the dock in the heaving sea. The sea had been rough enough last night to break a section of the inner breakwater loose.

I took a more detailed look over the dolphin boat tied up along the quay. They are limited to 20 tons and the biggest are about 5 ft. or so, a 15-ft. pulpit extending from the high, flaring bows. The harpooner stands up on this pulpit, which is broad, perhaps eight ft. and narrowing to five ft. at the tip. I assume with his long harpoon down under the platform as a dolphin rises to blow, darts it, the flagged buoy is thrown overboard as he goes for the next animal with a new harpoon and buoy, until all available on a nearby rack are used.

There is a considerable well deck forward, with no hatches visible under the snow, the bridge house with assorted radios and radar atop and then a boxy stern with another smaller well deck, but shorter and with boards across the stern that might allow a net to be payed out at some other season in some other fishery.

A truck drove up with two True's porpoises in its open back, caught, so we were told, 15 miles offshore north of here. Flip swung into action with the two Institute of Cetacean Research biologists ____ Kawasaki, a quite remarkable free diver (did I hear he descended to 70 m?) and his assistant ____, who had previously worked as a dolphin trainer at one of the big exhibits near Tokyo.

They obliged Flip by taking samples and notes as the morning sun slanted in under the overhanging girders of the sheet-metal roof. Flip became utterly intent, a state I had never seen before, as he composed his pictures and people—enough so that conversation was not in order, only help running lenses and film. His big Nikon (F-4, I think) whispered, his flash blinked, and slide after slide was taken, his story picture. He was after a market or inspector shot that told a story, not a blood picture of cutting up.

We were given courtesy of the dock, but regarded with caution. They had been lied to before and the best we could expect was to let us be.

Flip took shots with his 15-mm wide angle, an impressive, almost spherical hunk of glass that got almost everything in one shot.

I left him working away and wandered the dock, talking to the ravens, who had gathered at an offal pile nearby, pieces of dolphins flensed out, piled, I presume, for burning.

Later, four more dolphins that had been brought up from the south appeared from under a tarp and cutting up began. Flip asked for a staged picture by the flenser and was refused on the grounds that if it was misused and he had given permission, it could go against him.

He was dexterous in the extreme, slicing off the two epaxial muscles in two long strokes of a very sharp knife, right up against the skull and spines of the vertebrae, and then the hypaxial muscles were cut loose, the ribs chopped free at their bases and then the next animal. The fins and flippers were saved and considered a delicacy, presumably because of their gelatin content (my guess).

Once Flip was satisfied and with two or three rolls taken, we drove back to the hotel for breakfast, a little coffee, and green tea and then to a break in our rooms. I try to find out what's happened in the Gulf War. It seems to be winding down. I hope so. The damage to the Iraqi army must have been horrendous. I can image those soldiers down in those underground bunkers, being pounded by carpet bombing with little food or water, [?]

I wonder how long the images will persist for them? Probably for their lives, as it was for many Viet Nam veterans.

After a noodle lunch (Koji is very high on noodle lunches with tempura) and fish tempura in broth and some green tea. Koji is remarkably fast. I just get started unsnarling the things when he is done.

A word or two about Koji. He is a very open, social person, porky, even more than me, very smart, very observant and energetic, and apparently a splendid driver and photographer. He has a company that provides films for a big TV quiz program about animals. He's a fixer and entrepreneur and world traveler, as a photographer. He is

wonderfully direct and uncomplicated about all my questions. He's into publishing, writing, TV, photography, and more, and a positively wonderful guide. I have such a feel of things from him. He's also subtle and ahead of us much of the time, I think. Wonderful getting to know him. He and Flip have done many things together and there is obvious trust between them. So pleasant to see that such values and approaches work across between our two cultures. I'm afraid the Japanese expect us to try to cheat them when there can be another way.

We took a drive to the big steel[?] town one cove to the south, walked through a fine fish market and then cruised the docks and had our noodles.

I suggested a drive to the north would be good fun, so off we went to a town that has an old whaling station (we are holding it in reserve as Yamamura of the Institute of Cetacean Research will join us on our last day).

The hills are being very actively forested, cut, planted for conifers at least—cedars and a lovely red-barked pine. We stopped at an almost perfectly circular bay with a narrow entrance between mountains, off to the north.

I'd guess the bay as two miles across. It is literally peppered with the rafts and floats of mariculture—oysters, scallops, algae, I'm told, and the shores are protected for tsunamis by big cement walls, behind which the highway runs and villages hide. The beaches are clustered with piles of cement "jacks" to absorb wave shock. The towns are clean, roads well maintained, and the place has a progressive, well-tended look.

I've seen almost no slums or poorly tended areas or buildings decaying, even though we are far out in the hinterlands.

When I asked Koji how they regarded children, he replied, "as angels." They are indulged even into their 20s, when many try to find their own way, but the family remains. He worried about the high cost of housing, saying that a retiring executive of a big company could not afford a place in downtown Tokyo and that new families, of course, were much worse off.

Tonight the two biologists from the Institute of Cetacean Biology join us for dinner, and tomorrow Flip will give another try at photographing the market. He's pretty satisfied that he may have a publishable picture. He's very interesting to watch. He watches light carefully, knows how to fill in and choose the time and place to do it, and what problems a particular subject poses. Especially, he composes the picture in his head to tell a story. He's subtle about being intrusive. Given a chance, he will spend days winning people to his side and then photograph, but if he needs to be will photograph in a difficult social situation, though that hasn't yet happened.

He said a rule is "F8 and be there"—that is being at where things are happening is more important than photographic technique. He keeps few slides. He says his whole collection may number no more than 1,500. He certainly doesn't burn up film or deeply cherish cameras. He uses them. I find him very perceptive, honorable, and a super guy to be associated with. Things at the main headquarters seem tense, however, in the wake of the recent shake-up. I have few illusions that my deathless prose will survive close inspection.

February 19, 1991
Japan, Ozuchi

It began snowing toward afternoon last night and continued all night and is still snowing now at 4:00 PM. The hotel, which sits on a promontory up above the harbor entrance, is banked with snow and the forest is decked and bent with lumps of snow that fall and scatter in white cascades and the limbs spring up again.

The bay is all but obscured though we can watch a lone fisherman in an open boat tending his mariculture rafts through the swirling snow and then beyond all is white.

This morning at 9:30, we drove down the hill following a bulldozer truck between the banked edges of the road. Animal tracks wandered in the fresh snow. The 4-wheel drive Subaru we had rented negotiated it all without a hitch. At the Fishermen's Cooperative Building we met with a fisherman, the owner of a vessel, to talk about conditions in the fishery. I was expected to ask questions and must say I found it an arid event at first, not having much in my mind, but later it became interesting.

I asked about harpooning and harpoon boats.

The most interesting thing I learned was that the boats did not fish for much besides dolphin and marlin and once the season and quota was up, they might not fish at all and the fishermen got other jobs, such as those in construction.

Nearly all the answers came from the owner of a dolphin vessel, who told me his family had been involved for four generations. Later, he told us he was pessimistic it would continue for long into the future.

He expressed gratitude that we were not activists, whom he obviously was disturbed by. I asked about how far they could fish and he indicated they might venture to Hokkaido.

He told me that the older fishery used guns to kill the dolphins, but had turned to the more secure harpoon. The porpoises in this area ate mostly small squid though elsewhere they ate sardines or larger squid. He said they were easily caught when they started feeding.

He told us that the fishermen had built a buddhist shrine to the dolphins, which spoke of a relation between the fishermen and the dolphins and its continuance.

He questioned the new regulations (10,000 annually) and whether Toshio Kasuya could be trusted to change his views if facts indicated it. He was not sure his fishery could survive the new rules. I mentioned that dolphins are not like fish and may have only 8-10 babies in a lifetime, the first baby at 7-8 years, and the last at 30 or so, but not every year.

I was corrected by Saino, who said that new info for Phocoenids indicated a lifespan of about 15 years and a first pregnancy as early as 3 years, when it reaches 6 ft., though still about the same number of young.

We left about noon and headed north with Mr. Yamamura to visit a whaling station (mostly for sperm whales) north of here, with Kawasaki and Saino.

First we stopped at the Shinto shrine, very close by the fish docks. Three polished basalt slabs inscribed with characters were in front of an old lacquered house. One had the names of contributors, which included townspeople. The second, elegantly inscribed, said something like, celebrate and pray for 1) a good catch of dolphins into the future, and 2) a good death of the dolphin, and a happy afterlife.

The impression was of a tight, animistic relation between fisherman and dolphin that tied the welfare of one to the welfare of the other. Shinto is tied closely to the emperor-god and can be chauvinistic at times, I'm told.

Once the Oikomi fishery declined and whale meat became hard to get, there was a new demand for dolphins, which became satisfied by the rejuvenated Dall porpoise fishery, the meat being shipped south. The kill, which had been hovering around 8-10,000, skyrocketed to 40,000/yr., which alarmed the fishery biologists at Far Seas.

Kasua and crew began a study that outlined populations and movements by lane transect means. The fishery was first limited to 20,000 and then to 10,000. Population estimates were as low as 100,000 if I understand it correctly. This corresponds reasonably closely to the old take during the earlier kill that was sustained for a very long time. Certainly this level is likely to be sustainable, but our fisherman told us he doubted that his 4th generation could go on for long. Perhaps the problem is simply economic. Dolphin meat is not prized. In 1991, it brought 150-350-370 yen, or 500/kg at the highest, while salmon brought 800-900 yen/kg. And hamachi (young yellowtail) brought 3,000-10,000 yen/kg. Dolphin meat is cheap meat, can be very strong, is very dark, and only used in some places. I suspect the fishery hangs in the balance, but I also think the Japanese research establishment and fishery people have acted responsibly.

The conformance of the fishery to these rules is enforced to a degree by the market, which can be faced with severe consequences if it buys banned products. It can be sold illegally, but both seller and buyer face severe consequences and in such a traditional society with traditional fishing groups, one has to be a renegade to buck the rules. I suspect they do conform.

Like fishermen everywhere, ours didn't like the state of affairs much and doubted that he would continue.

We drove north in the falling snow to a planned whaling exhibit, finally found it next to a field white and deep with snow. We went inside for tea. The company provides McDonald's with fillet o' fish, which is cod or pollack, some Russian, and some jobbed through N. Korea. They fillet it, pick the bones out, stack it up, freeze it, and stamp out square pieces.

We drove back through the snow to our cold rooms, for dinner at 6:00 PM. I had pork cutlets for lunch and am not sure how much more I can eat. The amount of food, 85% from the sea, one can eat begins to be a question. I had tunicates in kim chee sauce last night.

It's cold in this room. I've closed the screens and the heater barely warms my hand and the TV is all in Japanese, mostly men in business suits sitting side by side discussing I know not what or sweet-smiling girls in bangs advertising drain cleaner. Bangs are very big here. There are remarkable examples to be seen that blow up in the windy streets but fall back absolutely in place. Ears are big, too.

All in all, I like Japan and admire the orderly society and its gentility, though I know what competition lies just beneath the surface and what chauvinism as well. But I also think a lack of understanding of the rules on both sides has led to Japanese expecting to be cheated by Americans, and vice versa. Not a good situation in people as similar as we two are.

Flip and Koji and I had dinner with Mr. Yamamura of the Institute of Cetacean Research. He has been on a catcher boat and then on a mother ship in the Antarctic on five expeditions. We talked over many things and listened to him tell us his experiences.

He said that the Fisherman ____ Ogomi we talked to this morning is the best supporter of scientists in this Fishermen's Cooperative, very traditional and very concerned about the fate of the fishery. Gradually, the traditional boats and their fishery are begin invaded by others with no tradition. His is four generations long and he cares for the dolphin and the resource.

The use of dolphins took its burst to 40,000/yr. at a time when more than just the decline of the oikomi fishery was occurring. It also coincided with the reduction of the sperm-whale quota by the IWC and the replacement of this food by dolphin meal, and by the reduction in minke whale meat and its replacement too.

He told us of Taiji whose tradition goes back 13 generations and then disappears in antiquity. The Taiji whalers were licensed by the shogun and were his secret navy. Their coordinated maneuvers, which were accomplished with flags, have evolved into the maneuvers used in Oikomi, or the drive fishery. I find this melding of tradition with the obtaining of food, and its melding with the almost animistic aspects of Buddhism a fascinating exercise. The realization is that even though you take food from an environment, you too are part of it and its [?]. It is timeless and what the dolphin harpooner talked about.

Mr. Yamamura told of how brave the Taiji whalers became. When first they set to sea to catch whales, after finding that Russians and US? were fishing off their coast, they tried and their traditional boats were broken up. But finally they succeeded. One brave whaler was charged with pumping on the whale's head before it died from lancing, cutting the frenum of the nostrils and tying a rope through to prevent the whale from sinking. Then the whale was killed with a sword thrust to the brain.

I am struck by the dimension of time in the culture here, so often lacking from our own and how tradition can work to protect the world because it involves stewardship, participation, responsibility, that is so often lacking in our own raw approach to the natural world.

Hopefully, the Iraqi war is winding down, now that Gorbachev sees a role and a responsibility. I hope so.

A word about food. there has been so much of such variety that I've had to hang on by watching how much I ate, or else I would have had trouble simply from overeating. Most food has been traditional and most except rice, from the sea. All is served with grace and beauty. The bowls, the miso soup bowls, made to squeeze a little and break the vacuum as the soup cools, the shaving of onion, the sprigs of algae, the tiny clams or gastropods, a piece of fish, soft salt salmon was a favorite, sticky rice, dispensed with chopsticks, sea squirts like big vegetables—roots that went in among the rocks and a soft, iodine-tasting interior—green tea, side dishes of vegetables, cabbage, okra, a little packet of tasty nori to wrap around rice in a single, swift maneuver of the chopsticks, Asahi beer, and a beautifully designed bottle of Suntory whisky on the side. Very tasty yellowtail, slabs of deep red bluefin tuna (ahi), scallop sashimi (delicious), oysters, prawns in their shell, a big pot set in the middle of the table with an alcohol burner underneath in which a collection of seafoods were dumped in a kind of broth cooked till steaming, and we all shared.

There was much more that slips the mind. All was graceful and gracious and the conversation good. Koji is a fine translator, not at all slowed by his accent as some are. He was more than that—a sharer and interpreter for us. With the fishermen he gave them a considerable lecture that did much to clear the air and open the way for us. The climate was noticeably more open and accepting the next day.

February 20, 1991

Enroute to Tokyo on the bullet train

We were up at first light. It was cold and clear and the storm was gone. In its place was a deep blanket of glittering snow, branches laden, the roadside banked three ft. deep, the road itself slick and treacherous with ice under the snow. The harbor lay calm in the apricot light of first day.

There were no boats out last night so our hopes were slight, but down to the market we went anyway, all bundled in our down jackets, long johns, and caps. I walked the dock in the frosty morning through the glittering snow to photograph the idle catcher boats. A little boat, a single fisherman at the tiller, putted up and put a hoop-net full of eels ashore. A pickup with two bushels of flatfish and sulkin came up, their catches weighed and accepted.

Then surprise, surprise, the crew of the Oikomi dolphin boat drove up, after what looked like a night of partying and said they were about to unload 15 Dall's porpoise caught five days before.

Soon the hold was opened and the dolphins swung out one after the other to be picked up by a big, long-forked dolly, and rolled up and arranged in a row for sale. Only three buyers were there, but all were bought. Flip was in his element. He became very intent and professional, bracketing shots, changing lenses and light, and nothing seemed to escape him, even though a wind swept down from the mountains of the bay and it became fearfully cold—cold enough that my power winder only worked fitfully. The fishermen in blue foul-weather gear, the red harpoon flags, the black-and-white dolphins against the glittering snow in the slanting morning light were indeed a scene. Once lined up inside, Sanio and Kawasaki started work sampling the animals and Flip moved in.

His best shot he thinks is of a woman buyer pulling her newly bought porpoise out of the row with a gaff hook.

Flip was visibly elated since he thinks his picture is “in the can” of a market shot in Japan. I'm very pleased about this as I was at least partly responsible for the tight schedule that allowed little slack for waiting, a thing a good photographer of subjects such as these must do.

Back to the hotel for a big, diverse Japanese breakfast, checkout, the drive through the snow in our 4-wheel Subaru and then aboard the swift bullet train (they leave about every hour—we waited 15 minutes). These things go 240 km/hr. and they are gracious and nearly completely smooth. The directions are given in both English and Japanese.

May 8, 1991

Hawaii, Honolulu

I drove to San Francisco, boarded a plane, and flew to Honolulu. I was met by Ken Marten, who took me to his lovely little stash at Lanikai Beach, where we met Annie. I think they are doing well, though Annie is shifting jobs because her position at Castle as a psychiatric nurse had become a difficult physical holding action of very long hours. She'll move into a quality assurance program.

After lunch we headed for Sea Life Park where Ken works in the basement of Bateson's Bay with four *Tursiops*, under sponsorship with Earth Trust environmental group.

It was well worth my time. They are hard at work on the driftnet issue and gave me much material.

The three principles were Donald White, Susan White, a lawyer-biologist. They are also working on the Taiwanese drive fishery.

I support Ken. I thought they were very bright and knowledgeable. They had broken away from Greenpeace, which they felt had become undirected and not cost effective. They were obviously lean and directed. I thought they were pretty formidable. The director was planning expansion. I wondered if his organization would one day be swallowed up as Greenpeace is becoming [?]. I may send material to them for checking.

I came away realizing anew the vital part these citizens groups have begun to play. They are increasingly informed watchdogs, and increasingly one sees their names associated with United Nations and other governmental decisions as participants rather than merely as irritants. I say their role is vital because there is a critical need for proponents of other than exploitation of resources in human terms to have a say about the fate of the natural world.

Fisheries Commissions and agencies are, in a word, too much in bed with the fisheries they regulate to be effective in world terms. These Earthwatch people are sophisticated and critical observers.

May 9, 1991

Hawaii, Kona Coast

Jan and Ania live up the hill from the Kona Airport—up 700 ft. or so, above the lowland heat where breezes blow and it seems 10-15 degrees C cooler, showers every afternoon, in a nice, open, three-bedroom house. Jan has a room below for his scars and marks work. He has identified 200 dolphins about, and Ania pursues her work on the afternoon arousal. I haven't yet pressed for details but will soon.

The weather is beautiful, not yet summer, and very comfortable.

May 10, 1991

Hawaii, Kona Coast

I spent the morning reading material given me by Earth Watch and getting my act together. I'll go out to the Waikaloa facility in an hour or so, with Holly Green. Holly is preparing for her impending wedding and waitressing on the side to survive. Her pal lost his job with troubled children in the Santa Cruz school system in a general educational cutback. Tough times. Jan and Ania seem to be doing pretty well—the Musgraves are a major support.

My impression of Ken's work was that he is to some extent "released to do his own thing" and doing better than at UCSC. His work still lacks scientific forms—he is shying away from conditioned-response training for ideological reasons.

We watched some elegant bubble behavior. The dolphin seems to blow a bubble and catch it in a boil of turbulence, which spreads the air into rings, some long and necklace-like.

Sometimes these bubbles become entrained in the oscillatory flow past the flukes, and become long, very beautiful trains.

We were met by Ernie and Rog Corgell for dinner. Rog is retiring and will retain a position on the Sea Life Park board. Ernie is doing very well as a Vice President in a 350-person company with six stores. Lovely to see them.

Well, soon I'll get my act together and go out to the hotel, which Pam told us is an American Taj Mahal.

In the afternoon we went out to visit the Hyatt Regency Waikaloa and Dolphin Quest, on whose board I sit and whose facility I have never visited. It is a Taj Mahal without an evident theme. There is a lot of Asian staff and a few grand-scale staircases, a lot of lovely plantings, a beautiful lagoon, a tram, a canal boat, and no evident theme unless it is a low-level Angkor Wat without gilt (guilt?).

The dolphins were splendid. They are held in an upper 20-ft.-deep lagoon with a shelving sand beach on one side and the building and lawn on the other side. It's maybe an acre of water, clear as crystal, with little fish cruising about.

The female training staff was arrayed in spiffy orange suits that don't conceal much noteworthy. They do much work in shallow wading-depth water and the animals are puppy dogs.

May 11, 1991

Hawaii, Kona, Kula Nai'a Project

We got up at 7:00 AM or so, had a little breakfast, and made our way down to Honokohau Harbor, where we loaded our gear onto the *Smygtittar'n*, who lay at a mooring below the restaurant at the Coast Guard dock.

Hanalalai was decked in clouds halfway up but the sea lay shining below us as we drove down the long lava fan to the shore.

We carried our gear down the dock, loaded it aboard, cast off, and made our way slowly out of Honokohau Harbor. On board were Tom Freeman, a psychologist from Massachusetts who works with self-abusive adults. He's here on the Herman Humpback project—under Alan Frankel; Holly Green, who has moved here to help with Kula Nai'a, Jan, and Ania.

We took the *Smyg* out, and cruised northwestward 200 m offshore toward Keahole Point. We doubled the point, skirting along the OTEC referral power facility that extracts energy from the warm surface water above the thermocline and then generates power in a low-pressure turbine.

On the north side we entered Ho'ona Bay, a little bay that drops to 30-40 fathoms very close to the edge of the lava flow (100-240 ft.).

Soon we sighted a school of spinners coming into the bay from the north. A few animals left and one or two spun as we closed on them. Jan gave the command to lower

the chamber. Tom, Ania, and Holly knew exactly what to do. Jan and Ania lifted a little winch into its collar, taking weight off the locking bolts, which were then removed. Jan and Ania winch the chamber down into its combing where it finally sits. All four place big stainless locking bolts and tighten them in place against the ship motion, with big wrenches. Once done the air and exhaust hoses are put in place and the air system turned on so that a constant stream of clean air flows over the windows deep in the chamber.

The hatch is opened and bungeed in place against the swell. Blue light from the clear sea floods the chamber as I climb down the aluminum rungs and take my seat, don headphones and microphone. Jan and I check our communication link, which the lookout forward can hear. Holly, the lookout, across the cabin talks us in to the big school. Jan says there are 50-60 dolphins coming into Ho'ona Bay. They move daintily, little quiet surfacing, scattered in clusters of 2, 6, 8, 12, as we approach, and soon I see them, gray shapes resolving out of the blue veil, gliding, and then beating their flukes, and swooping in within a yard of my window. So close I can see the dolphin's eye fix on me as it passes.

It is an immaculate animal of dark back, white belly, long, slim black-tipped beak, of remarkable grace moving in hydrospace.

8:00 AM.

I came up and surrendered my place below to Jan, grateful for the air and the steady horizon. Two years away from the water have edged me back toward landlubber status.

The view from the chamber is spectacular—full view from the nearby surface to deep below down to the gleaming and shadowy coral sand about 180 ft. down. Animals are full frame. It is no trick at all to see their sex, to watch as far as you can see to each side. But I'm glad to be topside to recover a little.

The sun slants down from Hanalalei, its top hidden in a veil of mist. Ho'ona Bay is edged in black, jagged lava, a bluff not much more than 10 ft. high, yet giving and receiving the swell from the blue oceanic sea. A pencil line of turquoise lines the black and then the [?] glinting sun. The sea heaves and sighs. At its peak it rushes white and spurting through the manifold crevices of the lava, jetting high in plumes of foam, to flood back in cascading rivers and falls of foamy water.

Dolphins crisscross the bow, Ania and Jan on ID know 200 of them personally. There's Wart and Forenip and Nubby, Low Notch, Sharky, Big Fin, Tweaky (who has the tip of his fin tweaked as if a tie on a loaf of bread were twisted).

The dolphins are brown-backed, colored by the reflected light of the blue sea. they slow and flow around us, a yard or two from the window down below. We can see that ahead is a group of 12 adult males, a coalition, their tall, triangular dorsal fins obvious and their muscular humped tail is clear to us after our time of learning to know them, but obscure to the newcomer. Our eyes have come to see, just as we learn eachother's faces.

We enter a mixed school, mothers with young tacked against their sides, or riding high on momma's side, the drafting position where they get a free ride. Four Nips is there where he was a decade ago, an adult male then, and still an alloparent, a male caretaker of the young.

Ania hands the camera through the cabin window for more film, and then turns to the school, her motor drive muttering as she documents the tiny nicks and scars of all the dolphins that will let the couple reconstruct the dolphin society slide by slide, over months' time.

A dolphin spins dead ahead of the bow in a blur of [?] as it spins and falls back, and the observer below watches [?] its spiral of form, 12 ft. down, a designed sonar target for the other dolphins that can define the moving fluid dimension of the school

Back on shore, we wander through the giant stores of Kona for food and a toothbrush and a bottle of wine and then back to the comfortable house on the haunch of Hanalalau.

May 12, 1991

Hawaii, Kona, At sea on Smygtittar'n

It's a not-quite-blue morning-haze and a cloud deck offshore and haze in the air over the harbor as we climb aboard the *Smyg* and head for sea. Though there may be a swell, the air is all but still, waving the hale koa but not much more.

We load and head out. The *Smyg* is waterline level with the sea. Only under full power does the bow come up and even then the 4,000 lbs. of ballast anchors her like a rock in the water, resistant to forces that would rock a normal boat.

We're at the entrance now, traversing the turquoise water for the deep blue beyond.

We cruise north in low swell and chop toward Ho'ona Bay and beyond and encounter the school at Kakapa Bay just south of Kihola Bay, which was the northernmost place we saw dolphins in my study.

The bay is a shallow indentation north of the Cinder Cone above Makalawena. The dolphins were found 200-300 yards offshore moving slowly south. There was Four Nip in his group of juveniles and adults. The haze is dissipating a little though clouds hang over Hanalalau and Kohala and a veil of haze lies in the gap between Mauna Loa and Mauna Kea.

Jan commands lowering of the [?], a tricky business in the swell. Tom and I take out the retaining bolts and stand back as Jan takes the strain of them and then the chamber goes down restrained by the whining winds and then once down in its collar, the big bolts are run in place and the chamber is secure in the down position, a flat indicating "[?] percent" is attached and the air hoses put in place, and the hatch secured open with a bungee cord.

Holly, at the helm, runs the *Smyg* into the swell. The water is blue and oceanic though I can see a mottling of dark coral on the bottom, perhaps 30 ft. below.

The sun glints off the blue swells now, a thousand mirror flashes as the day grows clearer.

Up ahead is hotel now and the Hyatt Regency Wakaloa, the Taj of all Tajs.

A half-grown baby spins, silhouetted black against the sky. The shallow water, the swell, and the great weight [?] water chamber down jerk us this way and that. The motion is more uncomfortable topside than down in the chamber, since the vessel totes about the lead-tipped chamber. Jan goes below to sex dolphins, his work more important

than tending to the whines of his Sr. professor. I like that. The baby salmon leaps ahead of us and now spins, its pink stomach evident on every burst from the water. Head over tail combined with a spin, a crazy melange of flukes, flippers, and motion. Another motor boat ahead of us, splashing staccato blots of white against the blue sea.

They came to the chamber, little dots of dolphins, the [?] grown spins on the beam, 40 yards from the nearest other dolphin, a sure sign that all is well. Thereafter [?] bunch tight at fin-tip distance and maneuver as one. That distance is also a measure of their society. Only when they are undisturbed does dolphin sociality intrude, caressing that the Hawaiians call "porpoise work"—Hana Nai'a [?] Frightened they become a fish school, a group organism capable of creating illusions in the minds of predators that defeat their attacks.

Four Nip goes by in the company of a sleek juvenile. Only one loose tab of flesh remains on the trailing edge of his dorsal fin when a shark attacked him. When I knew him a decade ago, there were four, and even then his job seemed to be with the juveniles—an alloparent, the behaviorists call him.

The [?] dolphins laze along at our bow. When they descend into rest later in the morning they will turn shy, their sounds will stop, and they will enter what passes for spinner sleep. They will bunch and one eye or the other will close, and they will go all but silent. They will leave the inboard-looking eye open, the events of their school more important than environmental information, since other dolphins are alert. Only a low crackle of occasional clicks will guide their way. We move south now.

The baby still spins, obviously in an aerial bout, its leaps mostly head slaps now. I haven't seen a decent spin for a few moments. A phalanx of dolphins races in the face of a swell that sweeps past us from astern, the tips of their beaks breaking the face of the swell, or even their foreheads as they rise for a breath, or they race along inside the swell face, the tip of their dorsal projecting [?] arch into the air sending a trail of white, like water squirted from a bottle. The fin tip is a fender guard!

We're off Makalawena now, where Jody had her great adventure, I can see no trace of Sam and Kinu's beach shelter or Jody's dancing platform. Time, time. It passes and things change.

The little dolphin, if it is the same one, still leaps and spins on our beam. I think it's the same animal. It's in the same place in the school and the same small size.

A chase ahead of us leaves a rooster tail of foam and the rapid beats of flukes on foam. No spins for a while now. Some animals at 50 yards apart and some always seem to be flirting with our bow. A larger animal spins ahead of the starboard bow, nine times in a row, some good, some a single [?]. Another burst of four.

We watch and lose the dolphins. Have they turned back? Some looked as if they might try to evade us, so we circle and then turn back, but no dolphins. On down to Ho'ona Bay, and there we find them again, hand against the southern shore of the bay—tightly clustered this time. They dive and are gone for four minutes and reappear clear across the bay to the north. Another couple of dives, random surfacings in the bay and the rest pattern was obvious, 3-4 minutes down, zig and zag slowly, no aerial patterns and no plan. Jan decides to leave them to their rest and so we break off contact, haul up the chamber, secure it, and head for home port.

We skirt around blustery Keahole Point past the Pine Trees and into Honokohan Harbor, where we moor in the ship to Coast Guard reserves for confiscated boats.

Jan directs the cleaning of the boat, wash down windows, lock her up and flush the engines and then home at about 3:00 PM. I'll finish interviewing Jan and Ania, probably today.

May 13, 1991

Hawaii, Kona

Catch-up day at Jan and Ania's.

Quote from Cynthia Moss re impalas.

M. Jarman showed that the original isolation of the mother and young at the time of births is important, not only as an anti-predator device, but in allowing the mother and fawn to learn to recognize one another. When a fawn was born in the vicinity of the herd, the female was harrassed by the territorial male, and by bachelors, females, other youngsters, who immediately surrounded the newborn fawn and confused it. In these cases the fawn tried to suckle and follow animals other than its mother, and it was clear that it could easily "imprint" on the wrong animal.

Perhaps the parts of this one are as follows. When a baby is born in a school of dolphins it is an event in which the anonymity of close-to-identical school members is badly disrupted by the inappropriate size and behavior of the young. It must be a very vulnerable time in open hydrospace, not only for the young but also for nearby school-members who can be fixated upon because there is a place to fix attention in the school (the blue fish). So one would expect segregation to occur within the school. There should be a "place" in the school where moms and babies go, and where they receive support from the school. Is this in a "playpen." Do males and others shunt the female young to this area? Is this also happening with impalas?

Is there a testing of the fitness of the young, at this time. Investment is least at this time. "How realistic is this, considering the very considerable investment of a mother for her new fetus?" Are young to some extent expendable?

So what does the school do at birth? What do adult animals, male coalitions, do at birth. Wouldn't it be exciting to observe!

Back to the story. A couple-team of young behaviorists learns about the lives of wild dolphins. They do so with their and my vessel, *Smygtittar'n*.

They search for understanding about who these almost alien mammals-on-earth are. Who are [?] that in other sectors of the human equation deal so cavalierly with them, [?] in gossamer nets as strong as steel and discarding them back to the sea by the hundreds of thousands and now no place is safe on our globe, no remote fastness of untenanted sea can their evolved ancient pattern of life go on without the heavy and thoughtless hand of a removed civilization from ashore blotting out uncomprehended lives and societies at sea without a backward glance. Who are these ciphers?

Jan and Ania patiently pile piece upon tiny piece of the equation, a jigsaw puzzle moving toward understanding. She the pattern thinker, he the careful builder of pattern.

She who dreams of what dolphin society is like and he who patiently learns the players, who they are, where they go, who they associate with.

What does their search tell them?

All of these, my students and their and my colleagues, build upon my own past explorations, 38 years spent mostly with spinner dolphins, and yet the picture is only now coming into focus for us.

A mammalian society in 3D hydrospace.

A society that works on and off, not it is here and now under threat disappears into the anonymity formation like of a fish school, where all animals are as alike as they can be and the predator mind and eyes blink in confusion confronted with faceless passing ranks, all alike. The headlong predatory rush fails as its mind blinks, dotting and predicting the course of its trajectory, to fail as prediction fails, and it wallows in uncertainty, fins fanning, precious energy that cannot be often spared, lost.

May 14, 1991

Hawaii, Kona

Up this morning at 7:00 AM, a quick breakfast. Say goodbye to Java and Harpo and listen to Midori the male parrot scream because we are leaving him.

We drop down under the cloud deck that clothes the upper slopes of Hualalai. We board *Smyg* and head out the harbor where we meet a small school of spinners—perhaps 20 animals at the entrance. Jan circles and we do a little ID and then head off up north. The day is quite calm and save where the ocean rides up over shallow banks and reefs the water is rather quiet. Even so, tosscaps prick the water at the tip of Keahole.

We pass by two mantas, the tips of their fins bent up like [?] as they laze near the surface.

A big school of spinners was encountered at Mahauila just south of Jody's Makalawena. Jan goes below first. He takes his captaining seriously and the water is shallow enough for him to worry about the capsule hitting bottom—so I come second. I don't object, knowing how important it is not to insert myself into a well-oiled, careful and efficient operation. He is careful from A to Z, the boat and engines are washed and flushed at the end of the day and two dozen other details checked.

I go below in the chamber, clambering my difficult way to the bottom, where I settle in to the swivel chair, the big rectangular ports ahead and to the sides (the back two are blocked with a towel to prevent reflections).

The water is clear blue, the banked coral heads gleaming and each with a halo of reef fish, kiki-kikis, surgeon fish, black triggers (humu humu ele eles). The immaculate long-snouted spinners are now all around me, they flirt with my capsule, look in at me, and on some unknown signal, they angle downward at 45 degrees toward the distant coral and sand 100 ft. below, turn a dozen ft. above it, and cruise, [?] as ghosts to level out 20 ft. above the heads and slide along in what we came to call a "carpet formation."

They head for Ho'ona Bay, a favorite sleep spot. Half an hour later we are there. They slow and tighten their schools into silent knots of dolphins, at fin-tip distance. The school becomes wary of us, half its members alert and on watch and the other half with one eye closed. They maneuver away from us.

May 15, 1991

Kona

Tesseract day. We spend the morning hours cleaning the Tesseract (actually Jan and Tom Freeman do it). Ania wrassles with accounts and I read about baboons and lions in Cynthia Moss's good book. We will stay with the dolphins until dusk to see if we can record the evening chorus. I sign over checks to Kula Na'ia.

I invite Toni to come visit us in Santa Cruz, and Holly prepares for her August wedding. Much peering at wedding dresses and talks with seamstresses.

It's much hotter today, seems to me, than earlier in the week. But the sea is calm and the dolphins accessible. Ania has a new hydrophone, obtained from John Ford's wife that Ania will use. It's reportedly good up to 25 kHz.

Tonight John Stern has invited us to his house for dinner. He says he has a grand fish recipe and allows as how he loves to cook.

The clouds begin to sweep down off Hualalai and here on the hillside, it grows cooler, but I can still look out over the lawn fan to the sea edge and tell that the sun beats down there with unremittant force. We'll be hot, I suspect, aboard the Tesseract.

So much detailing.

May 16, 1991

Kona

We're in Tesseract at entrance to Honokohau Harbor. Jan stops to talk weather into a tape recorder. Wind shoots to W.

We go north, the Tesseract slapping along. She's twice as fuel efficient as a similar Deep [?] boat but she's also an aquatic skateboard with little to promote stability. The way one deals with her is to imbalance the boat so the chine digs in a little.

We headed north into a considerable chop and swell. Tom had seen a "wind line" to the north—a choppy horizon and over it a wispy lower margin of the cloud deck. The sport fleet of white bobbing boats with dipping outriggers and white bow waves, had made its way south off Keahole. We slapped and bannged our way north, and no dolphins appeared.

We backtracked to Ho'ona Bay, where we bobbed quietly waiting for the furtive sleeping dolphin school to surface. It never did.

Jan steered the Tesseract south along Kailua shore, along the hotels, to Maihi Bay and Red Hill (a cinder cone sliced in half, exposing the inner core of the vent.) On down to Kealakeakwa point and light. It all seemed very much the way except that upslope a couple of long golf courses had been hacked out of the Hale Koa.

Finally under lowering clouds we rounded into Kealakeakwa and up under the black cliff. The water itself was dark ink in the sinking late afternoon light.

Black fins and backs appeared not far offshore and soon we were in a considerable school of 40-60 dolphins, including some quite small ones. They were in the first stages of zig-zag swimming. A few head slapped, a desultory spin or two, they move laterally, speeding, then slowing, and back into quiescence, then another burst. In and out, out to the bay mouth and back again. We followed them until 5:45 PM when it was perhaps $\frac{3}{4}$ hr. to dusk, but the sun was low in the west.

The dolphins oscillated faster, slowed, raced again, with concerted leaps forward. Then, as we cruised ½ a mile outside of the mouth of the bay in the gathering darkness, the school burst from the water in cascading floods of animals, moving at high speed.

The change was startling to all of us. "Wow, look at that!!" We cruised along as the school raced in a magnificent arc around us. Black silhouettes cascaded against the black mountain and the dark rainclouds. As they arced, they became better [?] and their patterns became evident then, abruptly, no more than a minute later they subsided into the sea and resumed their slower progression northward along the shore, half a mile out.

The big peak in the oscillatory course of zig-zag swimming. I'll bet if one plotted the oscillation one would find that they nearly reached crossover speed four or five times before, and on this occasional they did it wholly, and then, as before, oscillated back to a lower state.

The crew of the boat was getting antsy about being so far south with so little gas. So, we turned north, Tom at the helm now with Jan below trying to fix up the running lights (he did).

We made it to Honokohau after darkness. The green buoy guided us in to the red buoy (red right returning). We put the boat on the trailer, washed everything down and headed for home. It's all the 4-wheel International Scout could do to haul it up the hill.

A good day.

I prepare for the Breese visit this evening. I'll do some shopping and cooking.

It was good seeing Paul and Jeanne, who is wonderfully good for him. He has control of alcohol now and seems very clear headed with his memory as intact as ever. He immediately told us all about the eclectus parrot, where it came from, problems with keeping it, and so on. John Stern was there too, a very nice guy and Jan says, his best friend.

Well, tomorrow I head home. What's it been like?

Well, Jan is wonderfully capable and so is Ania, in very different ways. Their lives are wonderful in their way—the two loving dogs barking when they come home, obediently staying on the porch, but with front feet as far in the living room as possible. The parrot cheers when they come home too and plays a wonderful game of peek-a-boo around a brown bag on the living room table. Everything organized and well cared for. The house pleasant up on the slope of Hualalai where it is cool and the sprinkles come in the afternoon, red plumerias and bouganvilleas bloom, tulip trees and everywhere one looks, flowers of some sort. A peaceful, ordered, clean haoli neighborhood, and close to the harbor.

They struggle for money, but just now they are in good shape. The program goes methodically and well. Jan has more than 200 animals catalogued and recognized, some on sight with the best of them. The new video has excellent definition and one can see scars and marks and sex. The viewing boat works well, but needs a new and higher bow. It is very well cared for. Chamber operation is clean and direct. Climbing up and down is for the agile but even I could do it. The windows are glorious. One forgets one is looking out through a port and instead one is in the blue world with the dolphins. The communication, by headphone, is excellent between the skipper and the observer. The blowers

work well, and seasickness is only a modest problem. I think I would soon become hardy to the motion, which is much less than either the SSSM or the MOC. So it's working well, and berthing seems to be working the Coast Guard slip.

Ania is the conceptualizer, Jan the methodical worker. He knows a great deal about terrestrial animal behavior and while I found him tough he is not frozen but instead thinking hard. So is Ania. Her data on the afternoon oscillation is coming along. She's trying to make sense of it all at once, just as I would do. Both are very bright, contentious, judgmental as graduate students (good ones) usually are.

So, I go home and write up a little piece for the *Geographic*. Good time.

Now to see Phylly and Sus and Fred. I buy leis and head for the plane. A long-delayed flight, and I'm on my way to San Francisco.

May 26, 1991

Massachusetts, Falmouth, above Woods Hole

Up this morning and down to the bus stop with Sus, at the Barn Theater. There I waited for the Airport Shuttle, which was late, and when it arrived it was seething with tension. An older lady motioned me to sit beside her and in the back a curious couple was grumbling incoherently. The man was a hunk, Mr. Universe I found out, a product of steroids for sure and a slimmer, taut, young woman, flax-colored hair pulled tightly back, breasts flat and sternum in view under a thin blouse.

He had left his ticket on the dresser of his motel and had erupted in a volcano of profanity that almost dislodged my seatmate, a nurse. The driver took us to the motel, not too far off line, the ticket was retrieved, and we shot like an arrow over the hill. Opposite Memorial Day traffic was building, but we arrived not too far from time. I checked in and made it to the gate on time and into the plain where I occupied a nice business-class seat and lay back a little to gather my wits. This trip is a hurried one. Woods Hole to see and interview Peter Tyack and see Dick and Teresa and Ben and thence to Stockholm to Mats's graduation, then to Houston-Galveston to interview Bernd Wursig about worldwide pollution issues and marine mammals.

Dick and Tre met me at Boston airport, and we drove together out to Falmouth where their very nice little house is located. It has a pond out front that connects with the sea at the other end and features various birds. I watched a cormorant catch and eat an eel, [?] swans flew in, huge and white.

The house is three bedrooms, with a tended lawn, rhododendrons bank against the garages, stacks of firewood inside the garage, trim and white in a controlled trim and white street amidst the mixed forest with a tight middle-class regulation about it. Not many overt smiles around from neighbors that I could see.

Down the block is Vineyard Sound and trickles of polluted water from the various ponds, shallow warm sea across eelgrass flats, and a winding string of summer-clad bicyclists or parties sitting on the beach.

Ben is walking now, the unsteady walk of a 1½ year old, huge smile, cranky from a molar coming in, words jelling out of the babble—his “more” is very clear now and other words that his parents discern, assembling out of the babble. The babble is a child's wordless mimic of adult speech I think and settles around commonest things, not all

norms by any means (witness “more”). Parents reinforce strongly for success and help shape words by repeating models to Ben. “More, Ben, more,” amidst reinforcing smiles. The clasp of parents is a haven, and I barely broach it, telgraphing my own uncertainty to him. He stiffens and soon slides into a wail, reaching out to his father with outstretched arms, fingers wide.

Dick and I visited his lab in Clark Hall. He works very hard and monastically, telling his iterative evolution story in the tests of forams stuck to SEM stubs and sprayed with metal dust for photographing. A [?] SEM-icroscope is across the hall where he can see his subject on a video screen and photograph it on polaroid.

His story fills in. he is carefully tracing the lives of his pelagic protozoans, then ontogeny (they have a complicated one, for a one-celled organism) telling a story of repeated [?] through the same trace, over millions [?], over and over again.

We barbecue on the lawn and watch the Canada geese troops come up little trails to the lawn where they clip off new grass. Mom and pop bracketing the troop of fledglings ahead and behind, heads erect and alert, launch and swim off in the same formation.

We put our feet up after dinner and talk of the difficult, competitive world of the soft-money scientist at a time when funds are drying up and a dearth of new positions are appearing. It’s tough and getting tougher, but Dick is making his way on sheer talent and drive. Teresa holds down the house and child, is full with the next one, due in July. Faced backward it may give her pain unless it can be rotated. We talk of names and family and go to bed.

May 28, 1991

Enroute, Stockholm, Sweden

This morning Dick and I find the new acoustic lab in an old Victorian just off Woods Hole docks. There Bill Watkins and company have set up their domain. Wat’s work has been to upgrade the lab and its collections. He has built two or more acoustic reduction labs, all digital and modern, doing at a stroke what I could never do myself—77T’s, etc. printouts in various formats, and down the hall a climate-controlled vault where the tapes are kept. I donated Gregory Bateson’s old tapes of the Whaler’s Cove spinner school experiment. I’ll transfer the library as fully as I can. This is where it belongs.

I interview Peter Tyack up in his office before lunch. We had such an exciting time that I got through one out of six questions. Peter sees very far, ties his work to other theory and both accepts the specialty of dolphins and rejects Lilly’s simplistic view. They are remarkable acoustic-social animals, but they emphatically are not people. He, like me, lodged this specialty in their sociality. He sees more uniqueness than I have—the whistle learning a use is a cultural system [??], he says is evidence of remarkable flexibility of mind. Primates, save most anthropoids, seem to have signals lodged in the genome—the cries of vervets about snakes and hawks may be there in isolation. I’m not sure this is primitive, though, only deep freezing a very useful pattern.

We have lunch at the Hole, a fine little nook on the bay with all the ships and the canal bridge into the Hole next door.

Then off I go with Dick and Tre for a last time. Dick takes me to the Falmouth bus. I sat next to Alexander Langmuir, an epidemiologist MD who had worked all over.

he told me many things about disease theories. He seemed peaceful and philosophical though less than pleased that he now had to weed his lawn. He is the nephew of Ernest Langmuir of Langmuir Cells and so much more—Nobel laureate.

I make the plane and out over the Atlantic in the dark—fields of white clouds hiding the water.

Gulf of St. Lawrence

Note: These notes are different than my usual daily log. Here I attempt to record all things that will be useful in writing a magazine piece.

--Kenneth Norris

July 10, 1992

California, San Jose Airport

I wait for my flight to Newark and thence on to Quebec. There I will be met by Robert Michaud for a trip up to Ladoussac and other points on the north shore of the Gulf of St. Lawrence. This trip is the first stop on an exploration of the states of the North American and Greenland populations of the belukha or white whale, *Delphinapterus leucas* for a *National Geographic* story.

After St. Lawrence I head for Montreal and then a flight to Resolute Bay, up on Cornwallis Island, where I will meet Flip Micklin. We then meet Dr. Tom Smith the next day to helicopter down to his camp at Somerset Island, where he will attempt to satellite tag a belukha that is expected to make the traverse across Baffin Bay to the Greenland coast, probably to the area of Pisko Bay. We'll be there too, in late September, coming in from Frobisher Bay on Baffin Island to Muuk, the capital of Greenland, and Eric-the-Red's old housing development. It was he that gave the name "Greenland" I believe—to lure settlers to this seldom green, icy place.

I'm sleepy and ready to travel after a long gathering of clothing and supplies for this trip that takes me into a latitude I've never visited (75 degrees N. at Resolute), and hence with only secondhand ideas of how to prepare. Weather? Cold or hot? Will we have mattresses for the dome tent? Will the new gold-colored fly fit? Did I get the one that matches openings in the tent?

July 11, 1992

Quebec City, Quebec Province, Canada

I sit in the Holiday Inn restaurant after a good night's sleep, but no dinner, waiting to be picked up by Pierre Beland and taken up the Gulf of St. Lawrence to look at the situation of belukhas in this waterway.

It's muggy out. I don't know the temperature.

I'll visit L'Isle Aux Condres where the old belukha traps were, and then Ladoussac and thence up to Lac St. Jean where the two aluminum plants use hydropower to make beer cans, and which are purported to be partly responsible for the sickness of the belukha population. I'm told the reproductive potential of the belukhas is dropping.

Being dropped in the midst of a French-speaking populace and having little French, I'm impressed at how language is the ultimate definer of the tribe (amongst a good many others). Changes in the nuances of language define local moities and as they change so does language. One always knows the "in" group and whether one belongs or not. I watched a French-speaking group in the elevator, watched the responses of facial signals (smiles, frowns, uncertainties, signals of reception, and comprehension of the words)—all incomprehensible to me. All I could do was to smile in a low-key way to indicate I was benign but not of their language group. No wonder Quebec is separatist—

they are constantly reminded of the fact. The nuance of signal-response is their own and welds them together—the damn Anglos give all the wrong signals.

So it is with Jews, who have wandered most of their history among foreign tribes, with different sign systems—and always they have been foreigners in a foreign land.

Well, on to belukhas. I meet Dr. Pierre Beland here in a few moments, then off to change money and thence out the Gulf.

At this stage I'm a bit shocked, alerted to the fact that the juxtaposition of USA industrial culture spreads its toxins in a halo around its margins like a seeping sore, indicative of the problems within.

It goes both ways, too. The destruction of Canada's forests is more blatant than our own. Forestry is more economically central and hence its forces more powerful than our own—but we both manage to change, to deplete, to destroy.

July 11, 1992

Canada, Quebec, Tadoussac

After breakfast this morning, Dr. Pierre Beland, director of the St. Lawrence National Institute of Ecotoxicology, a private nonprofit institute devoted heavily to ceteacean studies, picked me up at the hotel and after abortive attempts to change my money (it is Saturday)—Pierre says “no need, everyone takes dollars”—we drove off down the coast of Gulf of St. Lawrence toward the [?] where there used to be pole traps for belugas. They use “beluga” here, and “beluhkha” in Alaska, according to Pierre.

He is a compact, energetic, very smart, synthetic, outspoken guy of drive and imagination. He has a background in biology, paleontology (dinosaurs), qualitative biology, and belugas. He was raised here and has been all over the world on one project or another. His work ranges from studies of the Gulf of St. Lawrence belugas to using albatrosses to sample ocean pollutants. His team works widely on the whales of the Gulf and the sources of toxics. If he needs a method he gets it and uses it.

One problem he told me about was the high incidence of a toxic called mirex in beluga fat, used to control fire ants in the south but made in a Magra[?] River plant. It has higher concentrations in eels of the Great Lakes but belugas aren't known to eat eels to any extent. He thinks they must, because they are the major source migrating by. He checked and such information as there is on beluga feeding was all taken at seasons when eels were not migrating—so he lays in wait for a dead beluga during the proper season.

Robert Michand is an MA from the Quebec area who has had much to do with counting belugas and with setting up the whale-watching program and facility at Tadoussac.

Robert's lady is Jamie, who works on blue whale IDs and group size.

Richard Sears is way out at the end of the road working on large whales.

Pierre told me all the problems of running a private non-profit research institute—déjà vu—so much was the same as Oceanic Institute, except that they seemed to have kept good financial control.

L'Ile Aux Conodres is a largely shale and granite island—23 miles long—a hogback . . .

July 12, 1992

Canada, Quebec, Tadoussac

Up this morning before the hotel breakfast and down to the car and thence to the boulangerie for a cup of coffee and a sweet roll and thence off down the shore toward the

dock of their vessel, the *Bleuvert*, named for the gray young of the belukha. The harbor is a little man-made nook that holds maybe 40-60 vessels and has a little restaurant and a repair facility.

The vessel, made in Iceland, has a hull like the *Nai'a* (25 ft. fiberglass) but with a larger enclosed cabin, very suitable to the weather. The captain has a nice control panel and can stand up with his head through a hatch when tracking animals or docking. It has a head and a bit of a galley, a volvo diesel (very nice), and a through-hull propeller.

The day was absolutely flat calm—only the peaked water of tide rips marked a flow, in some places up to 7 kts at times. Robert was to do photo ID—he has managed perhaps 100 already even though his animals have no dorsal fins to speak of, just a ridge.

We set out on a pattern of stops at places where the belugas were known to congregate four or five in all for the day. The places in between are apparently all but vacant of animals.

Captain Daniel LeLevre piloted. He is a big, tanned man of 35 or so, VP of the St. Lawrence National Institute of Ecotoxicology, which is the home of a few young entrepreneurs in science looking for a way past the system. They do pretty well, I think. No. 1, I think they are technically sound, though this is not to say that they aren't also opportunistic. Richard Sears is their big whale man and he is way out at the end of the north shore miles and miles away.

Robert Michaud is the ID man on belugas and one of the forces behind the new whale center at Tadoussac. He worked at whale watching for a while. His lady friend is named Jamie and she works on blue whales. Pierre is president and lives in Montreal, working from his home there. He is either separated or divorced and has two children. His self-possessed, 15-year-old girl, Martin is with us. She takes the world's measure.

I asked Pierre about how they ran the finances of his institute. It's fairly simple. Half of a grant goes to the institute to do a project and half runs the PI and his direct expenses. They have a bookkeeper and are audited. When they run out on a project, no pay. So they live from project to project. But they do [?] and they maintain much independence. They are a force in interpreting what is happening to belugas and the whales.

The beluga population apparently has dropped dramatically, judging from early records of the beluga fishery here when ____ animals over ____ years were taken. Now, an estimated 469 +/- 5% remain. It is a question whether or not they are declining further. Pierre will look at the proportion of young, a figure independent of the total population, to find out.

He investigates pollution effects from the once damned aluminum plants above Chicoutimi on the Saguenay River—I say “once damned” because it is now thought that they can only be part of the problem.

Food from belugas taken locally and bottom samples show low levels of pollutants from the Great Lakes upstream. Yet the whales have very high loads of some chemicals in the blubber; mirex (a chemical used in the south to control fire ants), PCBs, mercury, DDT, etc. How come? Maybe it's the food chain? Maybe the eels, *Argulla*, migrating to the Sargasso Sea. They carry those chemicals including mirex. Eels have not been implicated as a major a major part of belukha food. In fact they've only been recorded occasionally. But such samples have been at the wrong season for eels, which just pass through. So he suspects but doesn't know.

After the long day's run, bread and cheese on board, a snooze in the cuddy cabin, back to the aging elegance of the Hotel Tadoussac—a huge old place all shiny red roof,

widow's walks, gleaming white siding, croquet courts, and then the beach and modest rooms above, with little dormer windows and motel art, wagonwheel lamps, and blond furniture. Tasteless sprawl and a touch of the past.

Tomorrow Chicoutimi to look at the aluminum plants, and a creek where some say belukhas swim to give birth. Pierre says, "Poppycok." No evidence. But in places white whales go into rivers—why? Food? Temperature? To slough skin? Why?

Here are notes from on the channel.

A dozen belugas (Canadian spelling) including young stages including the bleuvet and all the way up to pure white animals, and the stage one size smaller that looks like dirty linen. Absolutely flat. Animals are evident all around us.

Robert Michaud is busy photo ID'ing from top of cabin. He uses a 300-mm lens on a camera mounted on a shoulder harness normally used for a TV camera. It leaves his hands free to take notes.

Traffic plying back and forth in the deep channel where the belugas go.

They seldom throw their flukes. They come up and the tail bends and they go down.

The head pushes a bow wave that looks like a black "bone in the teeth."

Animals moving very slowly—1.5 knots—even though they are 40-50 yards apart, they obviously are in communication.

It is a greenish coppery [?] day (is it my new dark glasses?).

The St. Lawrence runs in a fault channel in the Laurentian plateau—the ancient granite 1.5 billion years old covered with on order of 10,000 feet of ice, says Pierre. Sounds excessive to me.

There are animals with obvious pockmarks in their sides—used for ID. Are they lamprey scars? We've seen lamprey hanging on. Indentations.

Identifying these animals is an order of magnitude more difficult than most dolphins, except age is clearly marked by color stages.

Robert says he saw a herd of about 35 animals in about a 500 m radius.

He says 15-18 subherds, one calf and at least 5-7 grays of various stages.

In summer Robert says there is a fairly strict geographic separation of age classes. How separate are the sexes?

Robert says herd size varies with position in the channel. Downstream it is small herd size. Here (off Cape Angle) age classes are also segregated in Gulf and estuary. They separate the two, the gulf is out to sea farther. This is estuary at Tadoussac.

Robert: Animals that we are seeing here are never seen downstream. We have animals that are so obvious they are sighted 10, 12, 15 times, downstream 50 km from Tadoussac. The obvious and well known animals have never been seen here in last ten years in summer. On the other hand I have six matches from here and downstream and of those five grays—juveniles. I think there is a strong site fidelity. The males are in the downstream area. They are typically in herds of up to 150 animals radius 500 m to 1 km. Tight formation, up to 16 [?] up to hours and hours.

Ken: When do they mate?

Robert: We don't know. If there is a peak in calving we figure that mating will occur in early spring.

Ken: A bit brisk?

Robert: Yes, quite windy. I've done six aerial surveys and most sightings were at ice edge in the Gulf. In this time they are out in the Gulf, out of Sagenay and I'le Aux Condres. It's about half the size of the summer range.

K: Including males?

R: All animals. I know that the whales are there but I have never made observations.

K: It sounds like the time they should be mating.

R: It might be. They could be mating in March-April. It's still something that is unclear.

K: Like my story, after 25 years it's still full of holes. God, it's slow.

R: This summer we're putting all that we know about these patterns together and from there we will look at other things.

K: For a degree?

R: Yes, after that a doctorate.

K: Are you publishing?

R: No, not yet. I've published agency reports and [?] three papers.

K: What do you folks think about the fate of these animals? Are they in trouble?

R: From Pierre's work they seem to be in trouble. If there have been only 500 animals for the last 25 years something is happening to the whales down the line.

K: You mean because the numbers are not increasing?

R: Yes.

K: Why do you want them to increase?

R: From all the numbers there seems to be a fairly stable population. We have only found the carcass of one known whale.

K: Gee, that's surprising.

R: Yes, the ratio of known to dead whales.

K: Does that make you suspect your numbers?

R: It raises a question. (A long discussion of what they're seeing about percentage of calves. I think it means they are uncertain about the percentage.) Except this season when we see a number of new calves.

K: How long through gray stage?

R: Six to eight years old they will be all white. Some animals are white at five years and some are gray at ten. Six to eight coincides pretty well with sexual maturity.

K: Well they are pretty marvelous and what a day! You can hardly beat this.

Robert will stick around 1-1½ hr with a group like we just left and then try to find other animals. We had a nice lunch on the afterdeck sucking up our juice and eating our french bread and cheese. It's absolutely glassy calm. The water is greenish and the sky partly overcast with the sun coming in. It is in fact as close to glass as you can come. We can see whales a very long way.

The adults that come up are immaculate white. You can see the low ridge of a fin on their back and then the muscular tail that bulges through the blubber layer. As I said before, very seldom do they throw their flukes. I recall one that did.

A little fin of rock with a low scrub of trees on top (Grand Ile).

R: See the tower on top? We use it for observations.

We see a single beluga. Robert tells me it is where that one belongs, at the end of the island. Robert says the island is great for berries.

I was asking Pierre about the structure of his organization. He's the President and Daniel is the Vice President, whom he describes as a guy who can do anything, very practical and sharp but untrained.

Richard Sears is Secretary, I think, and then I forget Robert's position. They pay for all their own supplies out of grants.

Tight fiscal control. Somebody's pretty smart. I suspect that it's Pierre. If he consults he charges \$600/day and he keeps \$300.

A black guillemot just flew by. A fast wingbeat with white wing specula. Robert says feet and mouth are bright red.

A widespread group of belugas being lazily circled by birds—just a few. I haven't seen a bird get anything to eat. Once I saw the birds settle around a beluga and I saw one of the latter with its head plastered with greenish mud. Three belugas plastered with greenish mud, on their heads and down sides of body.

In the Saguenay the bar gets up to 11 m while upstream it drops to 270 m. A terminal moraine defines deep channel end from the Gulf. This defines where belugas feed. Upwelling and high productivity.

They can predict where the belugas can be found. Larger areas are untenanted.

We move back into the harbor now that the day is over.

The days are very long here. The sun sets at 9:00.

The St. Lawrence Institute is a repository for projects. You put one in and then you get paid. No money, no pay. So they don't go in arears. For example, Daniel is on a project now so he doesn't get paid.

July 13, 1992

Canada, Quebec, Tadoussac

I take off with Pierre and Martin to Chicoutimi and Joniquier where the aluminum plants are, St. ____ du Nord about halfway up. A beautiful channel 200 m deep with ancient sea water at bottom that creeps over the bar at the terminal moraine.

It's a little village of white and red houses tucked up against the forests and rocky bluffs. The tide line is way up the cliff. There are a few little yatches at anchor. The water is like the Rio Negro—a bad grade of tea—and a considerable freshwater layer at the surface.

Pierre says this is a remnant of when the Laurentian ice sheet was south in this area. There is a fauna of Arctic cod and sleeper sharks still here. These animals have been left behind along with the beluga.

One [?] wonder that these belugas can stand fresh water when in fact over the surface of many of the estuaries they live in is a layer of fresh water—so they spend a lot of time in fresh water. Prehistorically that is the norm. The fact they can stand fresh water and most of the dolphins can't isn't so surprising. The fact that they may run up river may have little to do with fresh water.

Churchill River

Summer belugas, Pierre says, should be fatter so buoyancy supports them in fresh water.

He thinks buoyancy is why they are fat. He says fat percentage remains fairly constant even if body shape and size may vary. They must be trimmed to neutral buoyancy first and foremost or the cost of swimming will be too high.

Pierre: We allow the use of DDT because the experiments didn't show its use was dangerous. But if we had done it the other way, wanting people to prove it was not dangerous . . . the burden of proof.

K: I'll find it.

P: You can reject the [?] hypothesis or accept it.

P: When I'm writing I'm a different person. I'm in a different world. I get very bright. I think and then I write it down. People read what you have written and they come to you: "You are brilliant. What do you think of this?" But the brightness is gone. I'm sorry the light is off.

K: How familiar. It's what happens at 4 AM.

P: That's what people call inspiration. Some people have to take drugs. I don't have to do that. These moments of creativity are more important than anything else.

An artist doesn't subject his work to falsification. A scientist has the same idea and comes up with an idea and then says to other "destroy it, please." If you can I'd go to something else. If you cannot, I've found it.

K: Elegant.

P: A scientist should love criticism. If they hide data and evade it, I'm sorry they're not scientists.

K: Right. They're technicians.

We reach the uppermost reach of belugas in the Saguenay.

P: Every year we see a couple up here.

K: They're mostly in the entrance area.

P: Yes, first five miles.

These little towns we've come to. The hills are lower and the canal is shallower, . A lot of oil tanks, industries, 80,000 people. Pierre says. Birches more than conifers, alders, willows, here on hilltops. Gray or jack pines here, Pierre says. Larches, tamarack.

P: Mostly its deciduous conifer. I was a diver once. I'd get hot. You have to stop. If belugas swam fast they would just melt. (I mention Carleton Ray's walrus stuff.)

We're in Chicoutini—

Were going through suburbs of little neat houses with tricycles on the lawns and beds of flowers and patches of green lawn.

Pierre says maybe a mile of ice here at the peak of glaciation. Speaks of elastic rebound of land. Isostasy. Edge of ice was here 11,000 years ago and this was equivalent to Ellesmere Island in the Arctic today.

P: Some remained here. Water is very cold here. In the winter it's the Arctic. It's just that we have warmer summers. It gets down to 40 below.

What keeps this Gulf of St. Lawrence so cold is that process of winter. Winter. Water is densest at 4 degrees. During the winter it cools to zero degrees and when it warms up it sinks.

K: Hey the red paint salesman has been here. That big red roof.

P: I think this may be the biggest aluminum producing complex in the world.

We're at the old Alcan aluminum plant. There are four lines of high tension towers leading in a big condenser-transformer. We're going up on the road in back of the plant.

On a promontory to look over plant. Bushwacking. Whole row of railroad lines down the center—on order of 100 stacks. Trailer housing. Refractory stacks, brown smoke, protective fencing. What is main contribution to local environment?

P: Benzo-a-pyrene, a polycyclic aromatic hydrocarbon produced at high temperatures in forest fires, cigarettes, and aluminum plants. [?] electrolytic process with two electrodes and a bath of aluminum current burns electrodes and builds of Al^{++} on other and this releases benzo-a-pyrene—one of the most potent carcinogens known.

It used to be poured into the Saguenay in liquid form and later it was released mostly in stack gas or smoke.

An experiment was done measuring benzo-a-pyrene in mussels and it was found concentrated in direct relation to Aluminum plant. Mussels at the Gaspé had only the background level. The closer to Saguenay the more benzo-a-pyrene the closer to the plant. They transplanted mussels to mouth of Saguenay and in no time at all they accumulated very high levels of benzo-a-pyrene.

We found benzo-a-pyrene adducts in the beluga whale—metabolic degradation products. Some metabolites will hook up with your DNA—that's what we call an adduct. Chemically bonded to DNA. There's good argument now that relates the adduction of foreign compounds to DNA with increased and eventual promotion and induction of cancers.

We are finding in our whales a very high rate of cancer. I think there in the whales of the world there have been described something like 10 cancers, and we have eight of them.

K: Does that mean 20 kinds of cancer?

P: Different kinds. Among all the tumor found in whales of the world, half of them come from beluga whales. We have autopsied about 40 belugas and we have found about half of the cancers known from all marine mammals comes from our population. So there is something happening.

Benzo-a-pyrene seems not to be the only agent, because if it were, we would presumably find a syndrome—a single kind of cancer—but we don't.

What's coming from upstream are other compounds than this one. The other compounds are probably affecting the immune system of the whale. When your immune system is affected you may be susceptible to certain types of cancer if promoted by the substance (benzo-a-pyrene). A very complicated picture.

Why this has become the [?] of problems of the beluga is because in 1985 the first cancer we described was a bladder cancer. This industry is linked to a very high level of bladder cancer among its workers.

We said "aha"—our beluga lives just downstream of the plant and bladder cancers are rare in animals and unknown in wild animals. This region here has the highest rate of cancers in Quebec. So that's the link. So we cannot prove that the cancers we have observed come from benzo-a-pyrene, or that the benzo-a-pyrene we observe comes from this plant.

We can say that in this area there is a very high level of benzo-a-pyrene in the environment, higher than anywhere else in Quebec, and that it comes from this plant.

You find it also in cooking plants, any place where burning of carbon goes on at high temperatures. Or in a smoke-filled room.

K: Right.

We're looking at these stacks across the width of these plants. Stack gas is brownish. Other stacks exhaust steam.

P: The biggest stacks are where the electrolytic process, the Soderberg process, is going on. Named after a Swedish engineer. It's not used any more. The new plant north of here uses a new, cleaner process with very little benzo-a-pyrene products.

K: So the company itself has developed a new process but they are still using the old plant.

P: Yes, when they advertised it, it put a lot of pressure on them. When we started advertising beluga problems they announced that they were opening a new plant and that as this plant was getting into operation then they would close down one of those stack units at the same rate as they were opening new capacity, but as you can see most of these stacks are still running.

K: There's one that doesn't seem to be doing anything at the moment. It looks like repairs are going on around it.

P: In my view they should all be closed. This company in 1989, its profit after taxes was 1 billion U.S. dollars. So you can imagine. These guys have much more power than I have.

When they are discussing with the government and who can do what and whether they are having an affect, these people can put five million dollars in publicity and public relations tomorrow morning to demonstrate with all sorts of experts and data that belugas are not linked to this plant. I cannot muster that amount of money.

K: (laughter)

P: They eventually win.

K: I'm not so sure.

P: I'm not so sure either. Eventually they will lose. I told them four years ago. Robert and I went with some of the big bosses in Montreal and we told them what they should do is associate with one institute. They should give us millions of dollars a year for proper research and correct their problems and be open about it and say, "We're not controlling this institute. We're giving them money to do the job and in ten years we will solve the problem." They didn't do it of course. They have a lot of problems with the public now. Everyone is on their back.

K: Times are a-changin', Pierre. It's amazing to me the strength of a person like yourself in a situation like this. [?] People that get their facts together. It's not the ones that just shout, it's the ones that honest to god know what they are talking about. There is a David and Goliath thing going on there. Also there is a generational change going on. The old generation is going, and it's because of guys like you.

P: I've learned over the years that within this company there are hawks and doves. There's a group of people in that company that believe that there is a problem and are trying to do something. But, they haven't won. They gave a Tadoussac Conference on belukhas. The doors were closed. The old guard was . . .

K: Behind those doors what is happening is ferment and it takes a little while for the ferment to replace those old values. The old values don't go easily. You wish it would hurry up.

P: I don't know what happens but there is fluorine released here (we pass a fluorine plant here).

He tells me about etched windows in Jonquievre.

P: The cows eat the grass and get fluorosis. Affects teeth and bones. They hired a vet whose job it was to travel the countryside looking for cows with fluorine effects and to buy them. They would kill the cows. Our beluga have teeth problems and bone problems but it may be an immune system thing, or it could be due to fluorine. I don't know what happens to it.

(We're now in back.) Those are ore cars coming in, rust-red with bauxite. There is a spoil pile back there abuzz with skiploaders. The ones come in by ship to a port on Saguenay. (An absolutely huge plant. We're driving around it now. There are hopper cars. The fluoride plant is in back. Reynolds aluminum is Baie Comeau.)

The plants in Mohawk Reservation, New York have produced fluoride problems in cows.

(We're back in Skitch Yard. We're still driving around. Piles of carbonaceous material. A tube plant.)

K: Tell me about old population of beluga. Randall Reeves and Ed Mitchell's calculation to turn of century. There were years of kill with 700 animals killed (almost 2X present population).

P: Derived from skins and barrels of oil a population of 5,000 animals. The standing stock was 5,000 and they were taking about 500/year and the stock was dwindling.

(Now passing industrial research section and Centre Analytique. We turn around in a guarded gate.)

P: I think Reeves and Mitchell used too high a rate of natural increase in their paper. There may have been 2X as many animals as they projected. It was not sustainable.

(We are going down road to La Terriere toward new plant. Not a forest of stacks, 15 instead of about 100. Blue and aluminum. Smaller but also power lines going in as a single one instead of four—probably smaller.

....

July 14, 1992

Canada, Quebec, Tadoussac

I spent the day at the Hotel Tadoussac transcribing notes from the tape recorder. I took a walk at noon, out on the dock for a lousy hamburger and ossified french fries and then headed back for the room, past the oldest church in North America (1603?), which is right to the side of the hotel and by the water. Its cemetery has a lot of old, thin marble gravestones, but none of them seem very old. I don't remember a 1700s one. Then back to work.

In the evening we drove out to Robert and Jamie's place out along the north shore. A neat little house in the birches at the water's edge. One could look out over the tidal flat to the drop-off into the deep channel and there they had been seeing a sperm whale today and for a matter of weeks—diving for 40 minutes or so, and then surfacing—alone.

We saw a minke and saw Jamie coming in high-speed by Zodiac from her work with blue whales. She had followed one today. She is an MD who now works only part time to survive and chases whales the rest. She is Robert's friend-in-residence—a hard-driving, almost obsessed person from outward appearances, though that may be superficial—pleasant, harried looking.

Robert is a compact, muscular man, once on the Canadian downhill ski team, but he tore up his knee. He works very hard, fine-grain stuff, methodical, usually late, a skeptic, and not one to draw the broad conclusion—like Randy. Honorable, straightforward. I like him and Jamie too.

I talked to the group at the new interpretive center at Tadoussac—a very nice facility full of whale stuff, T-shirts, auditorium, offices above where Robert perches, right on the water. My talk on the history of studying whales and dolphins went very well. A good group (35 interpreters).

July 15, 1992

Hilton Hotel

We drive in—Pierre, Martin, and I. Five to six hours through the Quebec countryside talking of this and that. It's hard to realize Martin is 15; a little girl, really, but self-possessed and making her own way, very much in love with her "papa," interested in religious history—just budding, fine luminous face.

We met Pierre's new lady, Maria, a pretty, blonde, blue-eyed, slim lady who works in TV, kinetic, swags bugs (no fieldperson is my guess). In the newsroom doing soundbites, two minutes, four minutes. We had an Afghani meal (interesting) and Pierre took me to the airport where I am now at the Hilton catching up. Tomorrow morning I head for Resolute Bay where the high today was 2 degrees F. Sounds brisk. I wonder if my rig is warm enough, but how does one haul all this stuff? Maybe I'll rent it at Resolute.

July 16, 1992

Montreal

I spent the day at the airport hotel with a brief trip out to buy a good field coat. I got a double one.

Then back at the hotel, watching the Democratic Convention, I began to develop a belly ache, then diarrhea, and I feared for dysentery, called the hotel security, got nowhere. Paramedics couldn't prescribe anything, and I wasn't sure I could take it anyway. But gradually Pepto Bismol slowed things, and I warily lay back, hoping for the best. It's better now, though iffy.

I was impressed by the hope in the Clinton-Gore message. We'll see.

July 17, 1992

Enroute, Resolute Bay, Cornwallis Island, Canadian Arctic

I sit at the Montreal airport, a kind of pre-drizzle in the sky and the plane (Canada North) is being loaded to take us to Resolute. We will stop at Frobisher Bay, Baffin

Island, first, and I may change planes though my ticket doesn't indicate it. My belly ache is settled down to a sort of internal unease, as if I better watch it carefully.

The passengers include only one identifiable Eskimo—or Inuit—long-haired [?]-writing a crossword puzzle, most look like they have business or live there in some capacity.

We lift off. The cabin is at least half cargo, in front of a white wall, with us behind. We've been told about exits, life jackets, oxygen, and the like, and I sit with a mom and her lively 2½ year old (Emma) enroute to Resolute Bay. Her husband helps to maintain the airfield and its support. The land fades in the mist, flickers into view and disappears in a blanket of white. We're above it now, enroute to Kaliut (Frobisher Bay). I doze—what's ahead?

We fly over N. Quebec and out over Baffin Island. It's a low, creased land of tundra-covered hills, long, partially frozen lakes, sounds dotted with ice floes and skim ice and open water. The snow lines ridges with white tufts and defines the shape of the land. I look at the Frobisher Bay newspaper—half Inuit and half English, like no other language I've seen. Something an anthropologist invented. There is a three-bedroom house (small) for \$129,000. They have trouble hiring J.P.s (justices of the peace). The pay is too low and Inuits don't judge each other—only tribunals do. They have a loose sled-dog problem. One man says it's simple—the owner pitches a tent with the dogs and lives there. Don't tease them or they turn mean. There is a narcotics anonymous program and a home violence counselor, and Arctic char, which take decades to grow up get scarce in the Sylvia [?]. Another talks of a char derby and for the winners are three gutted fish weighing 50 lbs. Jobs are open for someone to write a curriculum, but must be fluent in English and Inuktitut for grades 10, 11, 12. . . .

We come in at Iqaliut (Frobisher Bay). The plane sets down on a long, cement runway patched with a webwork of tar lines—I suppose the result of winter cold. We roll up alongside a bright yellow-orange terminal building on cement legs above the permafrost. It's of metal with vestibules. Inside are the counters of local flying services—a service to Nuuk, Greenland (twice a week), a tourist counter, and a little food nook. We spend our 25 minutes, move back out into the crisp but not cold air, nearly overcast sky. The landscape is rounded.

Two hours and 15 minutes to Resolute, at 31,000 ft., up into the overcast again and into the bright light.

Baffin, larger than Texas, has 10,000 people, 3,000 of them in Iqaliut. The rest are in little camps around the margins of the great island—Pont Inlet, Arctic Bay. It doesn't make any difference to this plane if it goes to Resolute except when it lands.

Out over the pack ice we fly—a landscape choked with ice and due to the whims of currents and eddies and patches of open water or [?], far below. Islands now, a dark landscape of sedge and frozen lakes, of permafrost and polygonal ground and of rounded outcrops of rock smoothed by the now-gone ice caps, I'd guess, though due to lack of precipitation some of the Arctic remained iceless. I don't know.

The steward just provided me with a window just as Somerset Island passes to the left 31,000 ft. below. The ice is drifting in great polygonal slabs that somehow retain [?] linearity although miles across.

We passed inland from the coast—bluffed, bare, and eroded. A dark glacier dumps into a jade bay. The land is low and rounded streaked with snow where the wind has dropped it. An almost black glacial river choked with sediment winds its way across the smoothed landscape. More snow now, but still ¾ dark buff rock. The drainages aren't

as obviously dendritic as some lower on the planet but they do branch. Now a shore choked with ice and its river with long cracks—not maps of Iowa or polygons, but the cracks of larger-scale rotations against the shore, pieces 20 acres in extent rolling like plates on the surface sea, their edges battered and fractured. The ice surface is mottled black and white. The white are drifts of windblown snow, I think and like barchans vaguely crescentic. It's more like tectonic plates and rotational forces of the crust.

I may see bowheads and belugas (no, too high). Now the ice blocks are a pale lucent gray-blue with snow patches.

The high Arctic! We drop down to Resolute. I think I may see clusters of belugas in one place. The continuous sun. It's bright out.

As far as one can see—ice polygons until they disappear under the clouds. Bright white and dark ultramarine water. Ahead the olive gray land, the heaped clouds like puffs of wool cast on the shearing deck. Now the snow-streaked bluffs. Cornwallis is low and planed down here. Now the sea beyond the land shining in the constant sun. A tan pyramid 1,000 ft. high sweeps under the wing, largely clear of snow. The sea bottom jade green, a longitudinal pool of red, like blood, just back of the beach. Was it?

We land over hummocky ground. Rectangular houses—on a gravel runway in a cloud of dust, metal building, tan red, green, power lines, drums of fuel, blast fences, trucks with lights on the roof. Quonsets, oil tanks.

We head for the Narwhal after Flip meets me. He seems a bit preoccupied. Lisa of the Film Division at *National Geographic* is with him.

The Narwhal is a trailer house writ very large. Pool table, dining, 50 rooms maybe. You enter and leave your boots in the vestibule. Down the street half a block is the store. I picked up a pair of wind pants. It's sunny out but with a little breeze. It cuts like a knife. Subtropical beasts like me feel it even under these best of conditions. Flip's had wind and snow and has one roll of good underwater stuff so far. He's been here since mid-June. Tough going.

I may take a snooze. Lisa is out for a run. It's comfortable. Resolute's not much but I'll take it. Flip says they located it here because this is as far as the supply ship could get—windy, bleak. We are in the company town part, and down the road is the scruffy village. Arctic Bay is better, Flip says.

But, I'm here, and it's the Arctic, and tomorrow Tom Smith's group comes here and we learn the next detail.

Somerset Island is to the south. I'm reluctant to go out and wander around without supervision so I'll wait, and besides it's a bit brisk and I don't much want to have my cold-weather rig out just yet. I called home and talked to Phylly and Fred and all's well.

I talked to a young German computer scientist and he had walked inland six hours and had come upon many flowers and had no sightings of bears, which he says cluster on the shoreline.

I'll sign off now and go to my room for a bit of rest. The curtains look like they can close out most light even at 9:45 PM, which is what it is, and its bright sunlight.

July 18, 1992

Canada, Cornwallis Island, 75 degrees N.

What a day! The Arctic creeps in as I begin to understand it a little.

It's remote up here, a frontier with very little ancient human presence, even from Inuits. Most of them have been brought in or have followed the imperatives of the nation

who controls this austere land. Most has to do with geopolitics and potential resources—flying the flag.

North of us on Ellesmere is Eureka, a weather station, or Grise Fjord, another new community. Resolute and the native village down the road are new, constructed here because sea access for large ships and a field for planes to land. The DEW line has closed down and Canada has its own for Cruise missiles. The story is most of the junk remains, bulldozers, oil drums, etc. or has been pushed into the bay, or through the ice.

The real native villages and life are to the south. So what's the land like? I took a walk up to the top of the nearby hill—perhaps 100 [?] high, part of a long, rounded bluff that defines the land of the village of Resolute. I went with Peter Banta, a New Jersey lawyer whom I met at the Narwhal. He's a real nature buff and an interesting guy. He's been before the supreme court.

We walked across the end of the gravel field—a field piled and graded on top of the permafrost, perhaps 10 ft. deep. On each island is polygonal ground, puffy in the center with clay and lichen-moss cover and of frost-shattered rock defining the polygons and lower. So as thawing occurs the water runs around the webwork of polygons, carrying away the dustlike cross of ice degradation of the rock. As I see it, the freezing squeezes the rocky soil onto polygonal shapes and lifts the central soil, thus grinding the water around the periphery and washing away the flour. The flour, by the way, in my view, is far from being mostly produced by glacial ice grinding. I think there is a powdering off process here by thawing and freezing in homogeneous rock.

The boggy places are really boggy. The moss mats sink and squish under your feet. Many flowers were about but only of a few kinds. One looked like a magenta gentian, a pincushion (*Saxifraga*) of purple horns like a Victrola, a little yellow *Draba*, and what I took for a pasque flower (Arctic poppy). Hairy stems with glands, pale-yellow corolla, many stamens. There were cushions of grass—very low, little green more than five in. high, some lichens but more exposed soil and fractured rock. I'd expected a sedge cover but it wasn't there.

We scrambled up the shingle and finally stood on the rounded top and could look around. A bench mark was there and a rectangular rock cairn seven ft. high with a weathered wooden ladder to the top. I expect it was used by surveyors.

We looked around—low hills eroded and marked by white snow streaks and fractured rock. Here and there are cushions of flowers bravely showing off in the cutting wind down close to freezing. I did not have gloves and Peter lent me his windproof mittens, while he kept the mittens themselves. I was glad for my dark sunglasses that stop UV, even though my disparate eyes take a while to adjust so I don't blink in the bright sun. Gratefully, after half an hour or so they did adjust enough so I could see well.

From the hilltop the landscape is simple, austere, beautiful, and a little threatening though now bathed in 24 hours of sunlight. Resolute is tiny—the airport and a cluster of buildings, vehicles, a whole farm of oil drums—very utilitarian and very tiny in the landscape.

Fields of ice flow to the east in the channel, dark indigo water to the west, scudding low clouds, pale arctic light, one feels the heat on one's skin.

The plane comes into the terminal—a 35-ft. room with two shops, a baggage rack, free coffee pot, and control.

Tom Smith, weatherbeaten, taciturn, tough field man and his crew arrive and we pick up their battered gear, including a satellite tag. Fisheries and Oceans, like some of our field people NMFS. They know how to do their own thing, and I feel lucky to be

included. Tomorrow we may make the helicopter crossing to Cunningham Inlet. I talk to a couple of fine Saskatchewan wheat farmers up to look at the Arctic. Robert and Blair Anderson from Swift Current.

9:25 PM and it's as light as noon.

Tom tells me they catch the belugas when they work their way into the shallows at highest tide and may strand. They can be netted and then give little trouble. Some thought that they may be feeding in the shallows where food has become rich under the ice and then push it as edge feeding. Smith says they seldom are taken by bears. The bears are too scattered to matter much, but he does remember when eight died. The last satellite tag lasted, I think, 52 days, and the whale went out south of Ellesmere on a course to Greenland. We'll see what happens.

July 19, 1992

Resolute Bay

Hurry up and wait. The fog at Cunningham Inlet got us and we'll try again after noon. We aroused ourselves at 6 AM, packed, had breakfast, loaded duffels into a pickup, which reappeared at the Polar Shelf warehouse where various research efforts are staged out of it. There are two floors of Skidoos (snowmobiles), tents, cannisters, etc.—all the support of field science to be placed by helicopter or Twin Otter.

So, we're back at the Narwhal watching a golf tournament in Scotland. I write a little.

This morning we looked out the window of the Narwhal and out by the runway was a great white rabbit, at least as big as a cocker spaniel—hopping along, sitting up, nibbling—an Arctic hare. Pure white so far as I could tell.

This town is unlovely—a cluster of utilitarian boxes in which people and their stuff can be found. No amount of colored paint seems capable of making it fit in with the wild scene around us. The pack ice flowing in and out between the low, snow-flecked islands.

There are creature comforts—lots of good food, fuel, communication, and I suppose medical attention. But we have to get out of here to experience the place. I wonder will my clothes work

Smith is a wiry, ginger-haired man, lined face from much time in the Arctic—softspoken, self-deprecating. He says he has to have these big camps now because he is getting forgetful and has to stay in one place instead of doing new things all the time, because all the stuff he would forget is already here.

He'll probably move from Cunningham Inlet, where his tower is up, to a smaller estuary on the east shore—Elwin Bay.

A golf tournament on TV (British Open, Nick Faldo winds), lunch, and the word comes that we can go. Lisa, Flip, and I board a Kinn Borez airlines Twin Otter and sit in a row of seats with a row of drums: "Shell Jet B with anti-icing additive" smelling dully. It's bright out now.

Tom Smith says somebody added a zero to their orders for flour and vinegar. We have 200 kg of flour and some gallons of vinegar. I imagine a giant loaf of bread with all ten of us burrowing out from inside, brandishing vinegar bottles to drive off the polar bears.

We left off quickly as Otters do. We have big squishy tires which I suspect are good for rough terrain landings. We circle and head south. Cunningham is almost across Barrow Strait, Peary Channel.

The brown, barren land plays past below us streaked with rotting snow. We hit the ridge of the channel, banded with white ice. The sea is dark greenish blue, deep, apparently lacking transparency.

The ice is alive and an integral part of life up here. It opens, closes, blocks, and fills bays or locks them tight and when it leaves the life accumulated below it becomes available. Perhaps that is what belukhas seek in the shallows and the high-tide strand and find it worth it to strand occasionally even if the occasional polar bear may find a beluga now and then.

Flat, polygonal blocks of ice, snow-covered, and pure white scatter the sound. [?] near the opposite shore where much of the ice has docked. It's a blue and white world streaked with a low-lying deck of gray fog. How far to the shore? When will it open? When will belugas come?

We begin our descent from the bright sun. It's all gray.

The cloud deck reflects the colors below it. Gray for water, white for sea ice, so you can learn it, read it like reading turquoise atoll water under the tropical clouds.

We drop in. I can see our plane's silhouette on the cloud's below, ringed in rainbow light. We pass over a flow now, dark water, and gray clouds. Now the ice is pale blue green and white flecks—snow patched scattered like barchan dunes across it over slick sea ice. We come in low over a point of tidal mud—no it's dark-brown water. The bluff looms under the cloud deck. A fast flock of dark birds Vs over 15 ft. above the ice.

We pass over four white belugas. We cross the gravelly beach, the marsh, and polygonal ground behind. There's water near shore greenish coming from the braided mouth of a river. The countervailing flows of tide and stream runoff have written its vagaries. The stream is milky blue now. I see a drum on a bluff. We land in a grad clatter of tire impact and quickly slow to a stop.

We are at the posh camp of Arctic Watch run by Peter and Judy Jess and their two remarkable kids, Matthew and Teddy. Teddy, the naturalist, age nine I'd say. Matt, the artist, age 11.

They've set up a tourist operation full blown here. They've set up a little city where they can cook gourmet meals with wine, Drambuie, Arctic char, carafes of red and white. The "Herman Nelson" was on the fritz. I personally have never heard a Herman Nelson that worked properly. Actually, it's a heat blower, built for people repairing aircraft in the Arctic winter.

Judy and Peter are from Calgary and they've obtained a lease on a couple of acres of gravel beach for their operation. The huts are anchored in the permafrost. They drill, put a rod in, and it freezes in, and that's that.

The structures are something like mylar or Kevlar, taut over an aluminum frame, [?], aerodynamic. Inside a big dining room, kitchen, foyer where drinks are served, and a sleeping quarters, all divided into canvas cubicles.

We were [?] over dinner but first went N. to our camp where there are just nine of us. The camp is above the mouth of the river of Cunningham Inlet—a braided Arctic stream over gravel bars between low bluffs streaked with snow.

We put up a radio tower and antenna, assembled what is called a "Park All"—a padded, Quonset-hut-like structure, a sectional wooden floor, a demountable pole frame, rocks all around on the cover. Once set up with a propane stove inside, it's cozy and spacious. The nine of us fit O.K.

I wandered the hill slopes looking at rocks, and the place is full of fossils—corals, bryozoans, brachyopods are everywhere, a trilobite now and then, stromatolites. I'm already getting loaded down.

Supposedly there's a fish fossil locality inland. The rocks are fractured by ice into piles of shards.

The fossils are from the upper Silurian Duero formation.

At the Elwin Cape Storm Formation, it's Middle Silurian and supposed to be full of Ostracoderms, the cephalic shields can be found.

July 20, 1992

Elwin Bay, Canadian High Arctic

We're up and away, off the gravel bar at Cunningham Inlet across the dun hills striped on the slopes with rivulets from melting snow. Blue, white, dun, bogs. A low, rounded land really. The bluffs are down drainage channels. We head for Elwin Bay—five of us in a Twin Otter—the two young men from the Inuit villages, Lisa, Flip, and me, and a huge pile of baggage ahead.

Snow polygons on the land where it lies over polygonal ground.

The stream water is clear jade blue.

The snow stays longest on the land next to rivulets. I suppose there's ice there instead of soil. Dark bottle-green glass of little lakes trapped on the land, usually margined with ice and snow.

We go east across Somerset to Elwin Bay where there are, we are told, many belugas. Wisps of gray cloud at eye level and Barrow Channel beyond, dark blue with 200-acre polygons of white ice.

A bay choked with ice passes under us, a long, ox-bowed stream ending in the braiding of a gravel-choked mouth hits the bay. The patterns of snow on the land have to do, I think, with slope. They are on steep land, bluffs, escarpment. I see no animal life. Later, I took the helicopter from the Elwin camp and tried to understand the art of flying such a contraption. Both feet and both hands are used in a very subtle dance that sends the helicopter dipping over a bluff or poises it hovering like a dragonfly to settle in a cloud of downdrift-driven dust.

The pilot is grizzled, 10 years younger than me. Hardly any words.

These Twin Otters are amazingly agile but capable of high loads too. We took off from Cunningham on a gravel bar—better than the airstrip and leapt into the air, 100 yards before the bluff, banked and were “outa there” in a roar.

Deeper canyons now, darker earth, polygonal ground on highlands.

Rectangular ground below. Big maps of Iowa, five acres each. What is that all about? The edges are drained channels off the calving ice I think. Caribou. I didn't see them. In a broad river valley, maps of Iowa on flat, broad river bottom. The braided stream green and then blue and then the shallows of Elwin. We land in a roar and swaying bounces in a bright, barren river valley—on the alluvium.

After a considerable bit of hauling gear in helicopters and a little four-wheel “quad runner”, a soft-tired vehicle, and after a long cogitation with a new tent whose pile of aluminum poles bent this way and that, we weren't short a ridge pole and everything did hook together.

Our camp is a windy one—on the shingle above the upper arm of the bay.

Six hundred belugas, or 1/40 of the Arctic population is deep in Elwin bay right in front of us. They are diving and turning in the shallows, and this afternoon an attempt

will be made to catch one. Tony's satellite transmitters are working. Word came in by fax from Cambridge that all were sending in signals clearly.

The tents are up. We wolfed down a little salami and were to go up over the belugas but I would have been in the middle crowding Flip severely so asked not to go and am back on the shingle with the helicopter scouting the animals for a possible catch. They go right up in the shallows at hightide and that's the time they try to drive them in shallower and two people put a buoyed hoop net over the animal's head.

I've hitched a ride in the helicopter that will circle over the belugas. They are collected like schooling fish, many with backs partly out of water, rolling and driving up boils of mud. Maybe a hundred are up in the blue water or the freshwater river, once again in water so shallow they are partly out.

These belugas have heads bent in the mud and the mud stirring is mostly in an embayment just beyond the mouth of a freshwater distributary. The ones upstream are not so obviously stirring the bottom.

One can see long smoke trails of mud in this particular area. I'd say 30% of the bottom is stirred with mud boils.

Here is an embayment just opening to the animals this season. The ice has gone out and they can come in. Has food built up, or is the animal in a molt as it enters fresh water, or is it in a seasonal molt like an elephant seal? I'm not sure. I'd want to know what food was in the mud, in their stomachs, the state of their skin, etc. It's up for grabs for me at my state of knowledge.

Whatever it is, there is obviously a great attraction to this shallow bay and even to going into the flowing freshwater stream itself, the whole school was there—the big, hump-shouldered males, the gray young, and the big white adults. I saw a bit of group behavior involving about six animals in a flat chevron. Others were much more scattered or oriented in the river flow.

Visually, the scene was blue water, ice margins or floating, the greenish shallow boils of brown mud and then the winding bluish channel of the brown stream, white whales, and the shingled stone riverbank.

What a sight. There were maybe 300 animals left in the bay.

Our chopper seemed not to disturb them, remarkably, I thought, given the noise we created. We stayed above 500 ft.

The camp is different than any I have known. The main cook tent is two tents inside one another—12 x 15, shingle floor. The frame is aluminum pipe with interlocking fittings to a ridgepole, braced with metal, a rectangle of pipe at the bottom. Then the guys were placed—polypro—loaded with big rocks and then covered with shingle until buried. An aerial for the radio transmitter was strong. A biffy facing the cove—a triangle of tarp to break the wind and a three-gallon plastic bucket. The wind must come a'plenty. It's 10 degrees C. now. I've been pretty comfortable so far, double jacket, hi-tech long johns, cap (always) dark glasses (no UV) always, waterproof ankle boots (always).

Tom: an old Arctic hand, master of the practical things one needs to survive and work in the Arctic. We can't figure out the frame of the new tent. He doesn't get angry, freak out, or lose confidence. He plus away at it, thinks about it, and finally it comes to him—the ridge pole is up wrong. Everything comes clear but it takes half an hour. He makes his own tents, canvas wall tents. In winter he cuts snow blocks and stacked against the tent, a tarp over all, and they shed the rain, and he's inside with the wind blocked.

He's red-bearded, lined face, easy, in charge, at home out here, I think. He began his work in Baffin in the early 60s. Then he was alone up here. Him and the Inuit. My how things have changed. We've seen three helicopters, came in on an Otter, a tourist place up the island, the Narwhal at Resolute Bay, etc. etc. Tom was a student of Max Dunbar at McGill.

Tony Martin sits beside me doping his transmitters with liquid neoprene. He puts a light shield on to black sunlight as the beluga surfaces. He's full of life, very hard working.

July 21, 1992

Canada, Somerset Island, Elwin Bay

We lay plans for the beluga capture this afternoon—or I should say, Tom and Crew do while we watch.

The detail, as I understand it, goes like this. They get the boat as close as they can. This time they will walk the Zodiac around the base of the hill and when they are as close as possible to seaward they rev it up and rush into behind the whale and when in waste-deep water at the most, two guys are in the bow each with hoops. The closest one jumps in and puts the net over its head. There is a line with a big buoy in case the animal gets free. The net slows the animal dramatically. Then the animal is beached (2,800 lbs estimated for a female).

These guys don't swipe sideways with their tails. Three people can handle one of these belugas. Imagine that!

They are pretty quiet once they get past the idea of trying to get back in the water.

Tony then puts his satellite tag on with four nylon pins.

Tony has a local radio good for 5 km or so and then it goes over to Cambridge and the Arggos signal. So after that happens all between us and the whale is the FAX machine.

Lithium batteries, Tony says, have the same energy density as TNT. He had one explode next door at Cambridge, a tiny one that filled the room with smoke and blew parts through his disk. We use D cells, 20x bigger. They send 300 signals a day to a 800 km up—120 days with elephant seals (400 signals a day) +/- 50,000 signals and microprocessors during its lifetime. Wow, what a battery. The one that blew up slipped over and had a coin cross the terminals, heated up, and blew up.

Finished a little lunch and we see Jack running down the spit. Tom thinks something must have gone wrong with the motor, which they were rigging up. Tom came back saying "There's a whale in shallow against the outer spit!"

So we tumbled out grabbing cameras and coats and headed up across the spit. There it was, cutting in close to shore—a big male, with the small head and fatty ruff. Jack and Tom and Larry maneuvered him down and in, in against the gravelly beach. Jack jumped in, straddled his head and got the hoop over. Tom worked on the tail and slipped a rope covered with garden hose over the tail and then cinched it up. There was a large amount of thrashing from the tail beats. By then I was down the beach to lend a hand, taking the tail line and beginning to inch the big (more than a ton) beast backward onto the beach. By this time Tony arrived with the transmitter package and was soon fitting it in place. He armed it, so pulses were going out.

Then boring four holes through the dorsal ridge—all blubber and connective tissue—then four nylon pins are inserted and locked in place.

The whale was measured (a big male). He was white except for a yellowish film and not deeply scarred.

Soon the animal was freed, head net first and then the tail noose was loosened and off he went back toward Elwin Bay, close in shore, finally to curve out a little as the narrows were approached. A smooth operation, with a remarkably docile animal.

Now we're back at camp and having coffee and waiting for another try later as the tide comes in, back in the bay.

Tom says he can't find any belugas in the bay. Did our big male go squealing and squealing in and did they all flee? Right now we don't know.

It's been calm and 55 degrees F. out today. Clean blue sky and bright sunshine.

Let me tell you where we are. We're around on the northeast coast of Somerset Island. A braided glacial river springing from the low, rounded, tan hills winds down across gravel flats to the upper bay. There much of it gathers into a channel, which is blue from above and empties into the upper bay—a fairly extensive body of water—one mile across to the gravel bar, on which our camp sits. The bay opens to the south over against a rounded mountain, which is often topped by a veil of clouds. Our bar is a long pyramid of gravel and cobbles, riven with great rectangular grooves a foot deep sometimes and usually filled with a row of Arctic plants—sprawling Arctic willow, *Dryas*, etc. The gravel is flat enough to take the Twin Otter, which bounces in and off for amazingly short takeoffs and landings. These planes, especially in a good headwind, dance on their tires, impatient to fly, in spite of carrying large loads.

It blows like hell out now and canvas flaps. The outer bay is choked with moving ice cakes and now the [?] is clear, except for the band of ice on the beaches. I found out that there are ostracoderm fossils here—up on the bluff and so off I went, driving a Kawasaki four-wheel ATV—a little squat motorcycle and big fat tires that bounced across streams, gravel bars, and up against a 500-ft. high scree slope. I looked and looked and clambered a way up—but nothing more than gastropods, worm tubes, mud cracks.

Now I sit in the flapping tent waiting for it to calm and for the incoming tide to ring the animals in. A nap would be nice.

This 24-hr. daylight has its unexpected aspects. One never wants for vision. It's always light enough to see everywhere, even when the sun is rather low. One forgets. And so the wind roars and someone outside shovels gravel on the tent stakes.

July 23, 1992

Canada, Somerset Island, Elwin Bay

Another one of those days! Actually we caught five whales, though two went unscathed and took off out of the bay.

Up at 7 AM or so (my new tent was a joy last night—I can spread my junk out to my heart's content, instead of having it in the cook tent). A bowl of oatmeal and raisins and then off to see how a whale might be caught. We go out toward the point and ahead of me the Zodiac cut along the outer edge and just at the tip they encountered a big beluga and ran him in circles, but finally he escaped. Then the boats took off across the bay to the stream entrance at the head of the bay. I stayed on the point and in about 45 minute's time about half a dozen animals went by me—singles and in one case three together in the channel that runs by the spit.

I could see a gaggle of people over at the river entrance and could finally make out what looked like two animals (it was three). I watched one get tagged—tail flipping and then the boat moved deeper in the bay to work on another. Actually, it was a mother and her little gray calf.

Finally, Jack Orr (he lives in Winnipeg) came over and offered me a ride in the Zodiac. The bay is remarkably shallow and we bumped on the bottom a time or two and then onto the mud-flat. There was a pair of medium-sized animals high and dry, one with a tag in place. Down the beach deeper in the bay was an enormous old male—curled pectoral fins, a band of muscle and blubber epraxially and below a huge, sacky body—stranded hard and fast, tail toward the beach (3,200-3,500 lbs.).

On down still farther was a mother and gray calf pair, out on a sand bar, that Tony and Tom soon worked on.

I waited on the beach a long time waiting for the tide to rise. It finally came up a little just as I had a chance to go back to camp. Larry and I headed for lunch.

All the strandings were the direct result of the intervention of the Zodiac, and only two were netted.

The old male, who must have weighed 3,500 lbs., thrashed and bent his body and seemed thoroughly unequipped behaviorally to wriggle off. Only once did I think he used his curled old fins to scoop with. The sideways wriggle of the tail seemed to inch him forward but not much, and certainly not enough to do any good. He was feisty and bit Jack on the ankle, which left a bruise but nothing more (through a boot).

I looked at the bottom where the whales had been leaving the mud plumes when we came in. It was gravel covered with mud with a yellowish diatom film. Pockmarked everywhere were the burrows of an amphipod—the biggest I saw were ½ in. or a bit longer. I kicked my boot in the pools and at times was able to dislodge buried amphipods so that a pool would contain four to five dozen swimming. Then, later, I began to note inch-deep piles of cast exoskeletons of these crustaceans in ripple marks. No, I'll wage those belugas were feeding up there. Others were up the river and not apparently feeding, so maybe more than one thing was going on up there, like the skin sloughing mentioned.

Later, all animals were off the beach but one tagged animal, and so Tom and Larry and Jack and Gary went back in the Zodiac and tried to take the animal off the beach. It repeatedly went back on the beach even though towed out in five ft. of water. No other beluga was then in the bay by that time. Finally, Tony cut the transmitter loose as he was afraid the animal would repeatedly strand. So, two radios are out to sea today, not three.

Flip and I cook dinner. Steak fried onions and cabbage and bread. Well received. The tent got very hot with the cooking and I had to go outside for air.

Tom says Inuit “know” things they've experienced—hence elders become priceless sources of wisdom. Not like us who learn things from books, lectures. Hence it's hard to ask them to explain, or reason out a solution, or to tell them about stuff in books.

July 23, 1992

Canada, Somerset Island, Elwin Bay

A few words about belugas (which is what they call them in the Canadian Arctic—belukha, in Alaska). They strike me as incredibly vulnerable. A crew in an

outboard skiff can, I think, take them almost at will. A big beach semi might catch them all. Net them and they give up almost entirely, especially if their head is covered. They swim in very shallow water habitually and one often sees them on the flats with part of their back exposed. They bolt upon hearing a motor, but the next day they are back and can be caught again. They hang at the ice edge where they can be shot.

I'm interested in how aggressive the old male was. He calmed right down with a net over his head. The smaller animals are sleek and not sacky like the male. He was mountainous.

The animal kill in the Canadian Arctic is 60. In Greenland, 700, and at least [?] 1,000, since they are shot.

Then there is ice entrapment and the kill goes up and this happens sporadically.

July 24, 1992

Canada, Somerset Island, Elwin Bay

Today is a day off, both for us and the whales, and it's a wonderful one, bright sun, sharp with UV, I'm sure. It was clothes washing day and lots of skivvies, long johns etc. dangle from the stays. It's calm so far and that helps a lot.

I took off on the ATV to see if I could find one of the ostracoderms in the Cape [?] Formation (Upper Silurian) that forms most of the cliffs around here—battlements of stone 1,000 ft. up, and long scree shingles of sandstone, dolomite, and limestone.

My aim was to get up among the rocks to see if I could find the cephalic shields of the ostracoderms they say are here. Jim Savelle, a sometime geologist, says over in the next bay every fourth rock from the top of the section will have a shield. He says the marker is the presence of stromatolites.

I wended my way up the rock plain and up at the base of the escarpment, and at one place where it got steep tipped the ATV over. I easily righted it and was undamaged by the event. It took a while to get it going again though. I had visions of walking back to camp.

The escarpment is marked by a glacial bench that extends up the valley, perhaps 100 ft. up from the spit-airfield level.

I picked and picked and found nary a shield but I did grow wary of the rock slides which seemed right at the edge of instability to me. Once I pulled a rock and heard a grinding from other rocks. I looked up at the towering 100 ft. slide of rocks at what might have been close to the maximum angle of repose. After that no hiking up the slope and no pulling unless I just had to see.

Down on the lower slope I could see that it was formed by water runoff and ice—standard alluvial fans with little streamlets playing across the fan-like surface. Then on the flats a rectangular set of grooves marked the landscape. These grooves, when there was a little gradient, grew deep enough that I had to slow the ATV way down and bump across. On the flat they were shallower. I see them as being formed by melting and shrinking of an ice-snow sheet. The first crack guides water, the edge thaws and splits, etc.—a tensional system.

I obtained a copy of *Common Arctic Wildflowers of the Northwest Territories* with Dr. Sylvia Edlund as artist.

The flowering plants I saw here: *Papaver lapponicum* (Arctic poppy), *Draba corymbosa* (Arctic draba), *Saxifraga caespitosa* (tufted saxifrage), *Saxifraga flagellaris*, *S. oppositifolia* (purple saxifrage), *Dryas lutearifolia* (Arctic avens), and *Pedicularis sudetica*.

Now for a nap in the bright sunny day; now that lunch of onion and peanut butter sandwich is past. Then stew for dinner and cake and cabbage.

I'm outside sitting on the radio antenna box, which is full of shingle to hold up the wire. It's absolutely still. We have buried the outhouse contents in three garbage bags. It wasn't more than 15 inches down to permafrost. Tom tells me they dig frost pits, put a little house around them and anything will keep. The sun skirts low over the Elwin Valley and up toward the rounded bluffs. I look over the gleaming flat bay and can see the blows of dozens of belugas up in the river mouth—columns of vapor maybe five ft. high at times.

It's a little nippy on the back of my neck now. So, I go inside and sit in the cook tent, where it's warm. Tomorrow we try for another animal.

Tony has heard back from the first of our tags and it transmitted and then quit. The others are transmitting and the animals are reported to be going south. Though just now Gary came in from the end of the spit and lo and behold one of our tagged animals swam back around the spit and into the bay. Imagine that!! What to make of that? Was he not frightened enough to stay out? Was the school attraction so great it didn't matter. I think the latter.

Well, I think I'll quit for the day. If this is the whale whose transmitter isn't working, Tony will try to catch it. Tony is something! A very kinetic guy, always in motion, always with the slangy, rapier comment said in good spirits. Always first in the water, knows his stuff, and gives everything he's got. Good company indeed!

July 25, 1992

Canada, Somerset Island, Elwin Bay

Today we make an attempt to place another tag. This will take place about four in the afternoon when the tide comes up. Two whales with working tags are here again and perhaps the one whose tag quit on us.

It's a pretty good calm day again, though with a 50% overcast of cumulostratus clouds. I had a snooze this morning and then went out for a last try at finding an ostracoderm.

I clambered all over the lower slopes of the bluff, below the place where anything falling off the castellated bluffs and spires up on the upper cliff. Sure enough the rock was there—dolostone—according to the Canadian Geological Survey report, but aside from trace fossils and most abundant, a small bean-like organism, I found nothing. No stromatolites were in evidence.

I think they are at Port Leopold, 30 miles to the north.

But it was a good little ride on the ATV—out along the airstrip and thence back to the bluffs where I was able to work on blocks of rock from up the cliffs. No ostracoderms and not even any stromatolites.

I came bumping back to find Tom Smith on his way out, worrying about me a little. I'd been gone two hours and there was still 1.5-2 hours to go till beluga capture. Sorry, I was, but feeling they were antsier than they need have been.

We set an Arctic char gill net to see if we can catch fish for dinner tomorrow. So, another day of tagging. The net caught huge blocks of ice and failed dismally.

[Map]

What are these belugas like? They lollygag along in a loose school, moving maybe one knot as a group. Animals putter along occasionally a head is thrown out, a back appears very briefly, and mostly one hears blows and occasionally sees a columnar vapor spout. only when they are in shallow water—the river mouth—does their visibility pick up and their backs appear frequently. Mostly you pick them up by noting a streak or slick on the surface and then a bit of a head.

The old male we tagged was an enormous pile, just monstrous on the beach, and angry too. When the head net was off he went for Jack's ankle and only the boot saved him.

In the water they flow along as if they were greased. When they fled the bay they streamed out as singles and by twos and threes. They obviously knew the channel well.

It is remarkable how simply they can be stranded. One female and gray young seems to have have stranded on its own with no major intervention from us, just the general disruption of our capture attempt.

They are incredibly vulnerable—surely unable to withstand the increased incursion of man in the Arctic without some degree of regulation and protection.

Tony tried out his Telonix receiver, which picks up a direcct radio signal as it simultaneously goes up to the satellite. I was surprised at how brief the blip was—just a click of sound, but then the receiver identifies which radio (animal) is involved.

When they are trapped by freezing sea ice they may be killed by dozens or even hundreds. The rule is that if not shot they will die anyway, which is probably not true.

We're about ready to make an attempt. It will be Tony, Jack, Larry, and Gary. Tom, who is recovering from a bit of laryngitis or whatever, will stay on the bench. He's usually first in the water. Ginger beard streaked with gray, lined face weathered, raw-boned, stainless revolver on his belt, canvas pants. Independent mind, very welcoming to us, a respecer of competence, a dog breeder and trainer.

Well, the tagging of the day apparently went well. Tony, Gary, Jack, and Larry headed out in the Zodiac for the stream mouth in upper bay. I rush for the sand spit to see the belugas round it and bend out to sea once they got the word. We could see the capture, the tail splashes, the group standing in the water, presumably as the tag was going on.

Soon the whales came racing out of the bay turning close along the point on which I stood.

Soon the waves were washing on the beach enough to roll the gravel and cobbles. The whole channel close to us was awash with waves and beneath them the long, slim, white shapes going as fast as a beluga can. They seldom breathed until well out of the bay, except for the gray babies bucking along.

Now we're back in the Park All, the smell of roast pork in our nostrils, waiting for the boys to return.

It seems remarkable to me that these whales returned today—not the wariness I'd expect of animals with members just tagged.

I keep thinking how to describe this land. Austere? Bleak? No, not for the things that live here. They find a way. They choose a time and a place like desert animals and then wait it out. They are full of strategies to deal with the climate and to find things to eat. Those three polar bears coming up the bacon-odor trail, were as fit as any animal. It's we anthropoids who invade by our wits and our impedimenta of tents, jackets, down

borrowed from birds, carbon skins to sleep on—the air-filled hair magnificent insulation. We see the world as bleak.

Simple it is. Scree slopes of ice-parted stone, rounded and carved by an unimaginable burden of ice—more than a mile. Now in July streaks of rotting snow remain and the scree gives forth the sound of tumbling water, hidden somewhere down beneath the blue bay, dun cliffs, white streaked [?] and almost no plants. yet the bay teems with life. Belugas bob and bray like cattle and beneath the surface a cacophony.

We read *U.S. News and World Report* about the U.S. election and look at the clothing and car ads and jaw endlessly inside the flapping tent, a capsule of warmth set on bleak rocky shingle—held at the end of a lifeline composed of Resolute Bay, the Narwhal Hotel with showers and plentiful food. Leave your boots and jackets at the door and the Twin Otter that tomorrow will bounce on huge soft tires across the ice cracks engraved in the shingle and swallow us and our gear up for the half hour flight across the Barrow Channel to Resolute. Then on the 28th—a 737 to Montreal.

I came out of the tent to head down the spit to photograph the belugas coming out of the bay, since Tony and crew were about to head across the bay to the river mouth. Instead, as I came out, the team cornered a 12 ft., 8 in. beluga—a gray animal almost completely transformed to white—just remnant gray on edges of tail stock, right beyond camp toward the spit. The animal ran along the shore and it seemed to me with a little agility could have escaped. Instead it almost ran into the Zodiac prop and then when Gary and Larry were trying to get a net on it, it poked against the Zodiac itself on the other side. Keystone cops!! Shortly they had the head net on and shortly the tail noose was in place and a line run up the beach to a little danforth anchor set in the beach shingle.

I cranked away with my camera and may have caught the whole sequence on film, except that I had to change film at the crucial moment. The little critter put up something of a fuss as the transmitter was on and was then released out into the bay. At first she curved upbay, but soon enough turned for the entrance. I hope she could hear her school and return to them.

Tony first checked transmission on the local receiver (it worked) and then contacted Cambridge to let them know their last transmitter was on.

I am in a constant state of surprise over how easy it is to catch belugas. Their imperative is with their school and I suppose the sound communication going on constantly. It seems to have few safeguards against boats and man. I wonder what these same safeguards consist of for things more pertinent in its world, such as polar bears. I don't think they get taken often.

For us it proved almost ridiculously easy to catch these huge beasts. They must keep together and alone they are lost and they must navigate the complex channels of this shallow bay—both of which make them vulnerable.

So before lunch we've finished! Tomorrow we pack up and head back, 136 journal pages later. I head for Boston after cleaning up a little at Resolute.

An old Arctic hand, now, of course (don't listen).

July 27, 1992

Canada, Cornwallis Island, Resolute Bay, The Narwhal

I got up about 3 AM and it was absolutely flat calm. The streaks of snow were so faithfully reflected in the shallow bay that it is difficult to tell reflection from reality.

At 7 AM we're up to break camp, take the long house down, divide gear into two piles, one for Cunningham where Flip will go with Tom, and another for Resolute where

Tony and I and Gary and Larry will go. We said our goodbyes—the Cunningham crew went first. The Twin Otter came in and I went up the shingle bank to photograph it coming in. I tried to get out of its line but no luck. It was really low so I moved down the slope with the plane apparently coming right at me—its big, soft tires hanging down.

Finally, I threw myself down on the slope and the plane roared overhead, so close it knocked over the 7½ ft. radio antenna, six feet from me. The guys down the hill were laughing their heads off. I picked myself up and dusted the glacial clay and we walked over to load the plane, which had taxied down the cobble berm and swung around near the duffel piles. Out stepped Duncan Grant, or should I say, out crabbed Duncan, a rawboned ancient pilot who has been up here for many years. He has an almost spastic walk. He smokes like a chimney and cusses constantly.

Was it a knock down? And then he circled and buzzed us again as he cut out to sea. Anyway, soon enough the plane was loaded and away. Flip will head for Creswell Bay to the south. As for me it has been a magnificent, varied experience, but I'm glad to be on my way. I need a bath and most everything I could gain we have done. One is rather limited in movement because of bears and I especially, because of my age (not my ability, really), my chance to move very far is limited. I behaved myself pretty much, but I was watched, too. So, now on down to Boston and the lower 48, Dick, Teresa, Ben and Thomas, and the Schevills. I wrote and wrote and wrote and interviewed and the story is clear enough. The curious, gentle beluga is in trouble, the familiar trouble of facing the spread of human culture and its technology. The contest is in no way equal and we must learn to control ourselves. The beluga may be the most vulnerable of whales. What other could be caught by two men with a three-ft. head net and a tail rope?

Tony Martin says he has been working at developing a satellite tag for seven years, among other things he has done. His background is partly at least in computing and he is a tinkerer. He shaves this, fiddles with that, tests this and that—a good instrumentationist. Like all such tags a percentage work and a percentage don't. We have one out there from this trip that sent one position and quit.

The team at Cunningham Inlet saw a tagged animal. One of ours? From last year? (Yes, the one that's not working.)

Flip photographed it with a very long lens and thinks it is the tag that didn't work long from Elwin.

July 28, 1992

Resolute

Packing up, palaver with a retired friend from Boeing in Seattle. Been everywhere. The Narwhal has about 40 rooms all told, including some doubles upstairs. It's a typical Arctic desert day—sharp, bright sun now over the austere landscape.

My plane leaves for Montreal at a little after 2 PM. I stay there a night and head for Boston and the Schevills and then out to the Cape and Dick and Teresa, Ben and Thomas.

The Canadian North plane comes in, circling once because of a low ground fog and then comes in and lands. The terminal is full of people, many from Peter Jess's camp.

I sit up front with Tony. He talks about the construction of the satellite tag. Much is done in his own lab—he gets one piece—a RF oscillator that goes beep. The other is the control unit.

Pure tone (access) ID code followed 356 binary bits of data. Tony takes a piece of paper from me and tells me all about the marvels of this tag of his. The lithium battery is equivalent to TNT. A 1% battery shorted out [?], blew up and went through three drawers in his Cambridge lab.

[Tony's notes about his transmitter.]

Tom—

I found I was with the quintessential Arctic man, one most comfortable camped beside some bleak bay where the wind will howl and his tent ropes thrum in the icy wind. One who knows to watch downwind where the bears may come in on the wafted odor of bacon being cooked and who would fire his everpresent revolver in the air when they were 50 ft. from the cook tent and then expertly edge them away, back toward the ice-choked sea until they splashed into it, turned, and swam toward the far shore half a mile away.

This is his land. He is complete here, ginger beard spiking out past bright eyes showing through a creased and wrinkled face. He's of this land in his bones, I thought, and that's all a man can ask.

July 29, 1992

I headed down to Boston and rented a little car and drove out to the Schevill's and then to Alan and Carrie's. A fine evening with the Schevills, and then over for brunch at Carrie's.

Tibby was there, writing a book about William Paley's daughter and her conversion. She is a clinical case.

Then on down to the Cape to Teresa, Dick, and Ben and Thomas. Good time melding in with their lives for a while. Then home on August 4th to prepare for Alaska-Greenland.

Belugas

The ___ -ft. white whale of Beluga blew a bubble from its blowhole atop its head, rolled and sucked it into its mouth through big, expressive eyes and then spat out a work of art worthy of Cellini, a shining bubble, gleaming silver and spinning slowly in the water like an elegant Christmas tree ornament. The big whale turned a little to view it with a critical eye. The bubble rose, expanded and fragmented. The whale casually pursed its lips and sucked it in—transitory art that the huge animal seemed to appraise.

September 8, 1992

Alaska, Anchorage

I'm in my Holiday Inn hotel room in Anchorage on the first day of a long trip, which will go through Fairbanks to Nome to Montreal to Greenland and then home. The mission is to look into various aspects of the status of the belukha (beluga outside Alaska) or white whale.

I'll be joined by E. C. Evans and then give some lectures at U. Alaska, where I have been invited as the seasonal invitee by the students. Then we're off with Lloyd Lowry to do a spotting study of Norton Sound.

We'll stay at Nome, and then off to Baffin Island and Greenland. We'll go up the coast, but at this point I don't intend to go to the hunt at Upernavik because of hostility of the Inuits there during the hunt, which Bertel [?] describes as "murder." The members have suggested that twice as many are being killed as the population will stand. Ken Bloome, and Brother Bob will be on this Greenland leg. Tomorrow I attend the Rural Community Action program, which includes a group proposing how to keep Alaskan-W. Canadian populations healthy.

I'll stop now and watch the ballgame.

September 9, 1992
Anchorage, Alaska

Massive, direct Matthew Iya of Nome, the Chairman of this section of Rural Community Action Program, and a carpenter when he is not representing his people in meetings such as this, starts the afternoon session by saying:

"Before we begin, I propose that we honor Lloyd Lowry by giving him a plaque or something. In all the scientific work he does, he never forgets the welfare of the animals he studies, and he never forgets the needs of our people either."

The deep voice of Burton Rexford, Chairman of the Alaska Eskimo Whaling Commission broke in: "By acclamation."

Lloyd Lowry, gray-templed and steady, always looks as if he was ready for a flight over some cold Arctic sea. I suspect he is most comfortable there, most whole. He likes the Eskimo reps who sought to honor him, and is direct and low key.

. . . . a bushy-browed man with a deeply lined, wise face capable of giving itself over to wholesale humor. He, I knew, had stood off the U.S. government on behalf of the Eskimo values of his people—the traditional hunt of the bowhead whale, and today the villages he represents vie for a quota of whales on which much of the fabric of their society, he said, depends.

Lloyd kept his feelings to himself and faded into the group heading for coffee.

The meeting today was held in the big meeting room of Rural CAP, which is a program from the old OEO of Lyndon Johnson's great society. Here it fills a crucial niche. A whole society of native peoples struggles with the almost desperate equation of finding their way, in a generation or two, from a time when they knew everything needed to wrest a living from a desperately difficult part of the world, one where few plants grow and where the lights go out all winter and outside is glacial cold and dark, almost that of space. They now found themselves in a subtle conflict with a network of foreign laws that bit by bit bid fare to strip them of identity and connection.

Some like Matthew and Burton had learned well how to fight back. I admired their rock-hard audacity and their willingness to reach out to Lloyd, whom they had grown to trust, but who was not one of their own. It didn't matter, like them he was practical, direct, and his word was clear.

Everybody seemed to like and trust Rural CAP director Bob Polasky. He was the only one in the room with a tie. His domain dealt with headstart programs, resource issues, these avenues for native people to find their way into the 20th Century. Ways to winterize their houses, drug problems, and more. Much came and went through his doors.

September 11, 1992

Alaska, Fairbanks

Evan arrived yesterday and we've been having a grand time wrassling with this and that. I will try to get down some of Evan's grand thoughts that poured out like rain during breakfast.

I told him I was going to write a chapter on population control and he reminded me of several things and gave me some new ones.

He talked of the Polynesian people who controlled their population by selectively killing young people of a chosen class. They were allowed to live with the others but not to reproduce and then killed (by clubbing or strangulation).

Arabian nomads (Tuareg?) and Eskimos . . . these were formalized in social rules.

Edward W. Applewhite wrote about Buckminster Fuller in *Paradise Misland*. Contains a chapter on abortion that Evan says is good.

The Polynesians, faced with the absolutely finite universe of an atoll or island, institutionalized population control, at least in part, by selecting a cadre of young people who were ritually killed at a certain age. How members in this group were determined isn't clear to me.

Something similar existed among some desert Arabs (Tuareg) and among the Eskimos and Inuits—I need to learn more. In each of these cases, the control was ritualized and approved by all including those who were sacrificed. Bushmen would go along and leave the old behind, and they expected it, as did the old Eskimos, who were put out in the snow when they became unable to keep up the rhythms of society.

Denali slips by the west wing—20,000 ft.+—a huge, complex, snow-covered mass piercing the highest clouds and ringed with glacial valleys. In the north a great valley glacier swings around the mountain. Below are glacial-fluted hills and stream-crossed lowlands. The hills are dotted with cirque lakes and only dusted with snow except in the deepest cirques that hold what looks to be permanent snow. Clouds deck the lowlands and we see little more.

Now the clouds open and a white range is below, all glacial topography, snow fields, lakes, scree, and rivers braided with gravel. Now it is gone again and we slope down into the cloud deck as Fairbanks on the banks of the Tanana[?] approaches.

A long glide in the clouds, bright at first. It darkens at 1,000-1,500 ft., breaks [?] after the yellowing forest and twisting streams of the Alaskan interior. Now Fairbanks looms, rectilinear, much water in the squares, freeways, trailers, houses, the oval of the school's track, industrial plants, the ballfield gone yellow, the aggregate plant, with shoals and draglines in a bow of the river, a pond for float planes next to the runway as we touch down.

We land and are met by MA student Jill Anthony, who is working on the sea otters of Valdez, I expect as a way of having a baseline should there be another spill there. She is intense, wound up, nice, a list maker. She tends to us and dumps us in the Wedgewood Manor, a sprawling studio apartment complex fairly near campus.

We go out to U. of Alaska. It is up on the high ground—a fairly undistinguished looking campus, with now and then the interesting building. It's very much a campus of its staff, and in northern biology, physiology it has excellent people.

We met with the dean, Vera Alexander, who worked on sub-ice ecosystems and she is a grand lady of wonderful presence. I liked her immediately and could see a real light in her eyes.

I gave a talk on spinner dolphin society. I've done better. I'm tired. Then to Mike Catellini's lab, where we took it easy, Ev and I, and then went to meet the grad students, who gave us a potluck at "Copper House," a nice place for such a function—like a nice, gracious house. The students showed us slides of their work.

Then to the Wedgewood Manor, where I prepared tomorrow's talk on how I do science.

Time to quit. I'm pooped!

September 12, 1992

Fairbanks, Alaska

Saturday! Ev and I are stashed at the "Wedgewood Manor," a great, sprawling, shlocky apartment complex erected for pipeline laborers and technicians and their families.

It had snowed last night, covering the walks and the car windshields and hoods. On the way back, without the slightest difficulty in doing so, I slipped on the walk and landed on my hip and shoulder. The hip is only slightly dented, but my shoulder took a good crack and is pretty sore. I'm on anti-inflammatories and exercises (painful) to keep my range of motion up. It takes ten minutes to swell and set up and then I can lift it only through considerable pain. Keep it up, Knute and you'll be OK. Let it set up and you'll have trouble.

I've had a couple of student appointments today and talk tonight about the philosophy of science, as if I had deep things to say there.

September 13, 1992

Fairbanks, Alaska

Today is Sunday. It snowed all night, very early unseasonable snow but continuous. We scrape it from the windshield, it slides off the roof, and we do it all over again later on.

Last night I went through a time with my shoulder but thanks to a heating pad provided by ever-attentive Jill Anthony, I wasn't desperately uncomfortable. I have trouble raising the arm, but with a little effort I make it to maintain degrees of motion as it heals. It is getting better.

We picked up lunch stuff at a local store—a huge barn of a food and convenience store and then headed for campus for a "picnic." The long trip was out because of snow so we toured Fairbanks instead. We stopped at the Chena River, which becomes the Lanana—a big, burling stream ¼ mile across, brown and turbulent.

We saw larches, black spruce in bogs and on permafrost, and white spruce on the uplands where there is no permafrost.

Then we hit downtown Fairbanks, the usual plastic eateries—Denny's, McDonalds, etc., and most businesses in largely windowless, warehousy buildings—pretty soulless really. Nothing seemed built to last. Downtown we saw the Polaris Hotel in the low rent district—only now and then did we see much of nature. The black spruce flats are spindly dark bean pole trees, very small really and very dense.

Then we visited the University Museum, a densely packed place with a sort of hodge-podgy exhibit space. Much nice stuff. I was tired by that time from the pace and because of light sleep last night.

Then a potluck at Copper House and home. Tomorrow we move over to John Burns's place.

I want to see him socially, but he is also reckoned as a beluga authority. He's retired now and still doing contract work—this time for Kathy Frost. I sense some difficulty somewhere.

Then we had a potluck with some of Lloyd Lowry's halibut salad—elegant, wine, desert.

Kathy gave me quite a dissertation on her work—much opinion. The Canadian numbers are very conservative and the allowable take very low. Kathy mentioned 6% as acceptable. Canada is closer to 3%. I don't know enough to comment. She had earned the trust or at least acceptance of the Inuit people on the Eskimo beluga commission. Kathy spoke of the Eskimo use of consensus as a means of decision making and said it worked if the group was modest. She mentioned 100 people. They all have to come to agree or the deal is postponed. For larger numbers it doesn't work.

She says peer pressure in this process is crucial.

She spoke of the very longstanding opposition of Inuits to officials who did "stupid" things, did things in incomprehensible ways. I wonder how far one can bend and still protect the animals. All seemed to agree decision making needed to be local.

It was a nice affair at Copper House. We had a good time and Jill was relaxed. She's been our shepherd on a tight, full schedule and has been very attentive to us and to making sure all went well. Very nice person.

Oh yes. Vladimir Burkenoff of Petropaulusk Kamchatka has invited us to Bering Island to do a story. He was very welcoming. It could be good.

September 15, 1992

Alaska, Fairbanks

The storm has broken! It has left behind icy streets, frozen brakes, and very treacherous footing. But the sky is clear and you can see the V's of birds against the blue, the still-leafed birches and willows are bowed with clumps of snow, but they begin to fall. Will the albedo of the earth be enough to melt away the ice and snow on the ground, or do we plunge directly into winter?

The light slants in, low and peach-colored over the horizon. Nome, we are told, is clear, so it seems as if our survey will go ahead on schedule.

Today I give my last talk on schools, flocks, and herds, and then, on Wednesday, we have a free day to regroup before heading out by plane to the Seward Peninsula, and the Nome Nugget Hotel.

Last night we went to dinner with Lloyd and Kathy, and both Ev and I felt that intense Kathy began to come off of it—and emerged as a person of strength and commitment, very pro-Eskimo, but with her feet on the ground. Ev wondered if she read much. I pointed out that she and Lloyd both have published a good deal and are the authorities on beluga populations in Alaska.

Kathy described her installation on the Eskimo beluga commission or committee. She was at first opposed by Marie Adams, an Eskimo activist friend from . . . but she was voted in.

Wayne, Testa, Ev, and I went off to lunch at a local ice cream/jazz parlor and had a bowl of soup and an ice cream cone.

Wayne has worked with Weddell seals in the Antarctic—done a good underwater in Schevill's upside-down cocktail-shaker viewing chamber. He told us even with five

feet of ice there was enough light to see so long as there was no snow cover. A blindfold test had not worked.

We returned to campus where Jill has provided us with a table and two chairs and where I meet with various students. I met Ben, a mainland Chinese doing chemical ecology. Mostly he wanted to know about exams.

Then I met Gay Sheffield, who has done much fieldwork with walruses on Round Island and on the Diomedes. She was an interesting field person, full of humor, and not at all sure about the academic side.

Then lunch with Wayne and back to my table. I gave a seminar on schooling at noon. Whew! What a schedule.

September 16, 1992
Alaska, Fairbanks

This morning we moved from the Wedgewood (comfortable, dark) to John Burns's house. I wanted to see John after all these years, and I had been told he knew more about belukhas than anyone—and so it proved.

He met us after breakfast and took us up into the birch forest on the hills above town to his place. By the time we reached it we were in snow. The road ran through the banks and without John's four-wheel Subaru, we wouldn't have made it. He's retired from Alaska Fish and Game and much involved in education. He is finishing a volume for the Society for Marine Mammalogy on bowheads.

The conversation poured out. He's 55 and retired as head of the marine mammal unit when a budget crunch hit—not because he had to, but his retirement and salary savings saved the unit. Sounds like John.

His home is a very nice place in the light and airy forest. Trim, full of mementos of his many travels. John lived at Nome and speaks very fondly of it. The Bering Straits sluices animals in between the Arctic and the Bering Sea.

John is a real field man . . . more, he is one of the real synthetic thinkers in my view. Ev concurs and mentions his elegant use of language.

We talked of many things about the people and the animals. Let me now list some questions I want to ask so I can generate a good tape:

1) Is the Alaska beluga in reasonable shape? 2) What about Canada? Greenland? 3) Tell me about the Alaskan subsistence fishery. Are the animals essential to a way of life? Is that way of life ending? 4) We have instituted some welfare programs for Eskimos. What is their effect on belukhas? 5) What do these Alaska "Eskimos" call themselves? 6) Describe the appearance of regional centers v. villages. 7) What is the level of population increase amongst natives in Alaska, Canada, Greenland? 8) What can you say about the proposed independent homeland, Nunavut, in Greenland, Alaska? 9) When did belukha hunting start? Basques, Norwegians 10) How do you spell belukha? What do you prefer? 11) How do you describe the zoo—[?] of the beluga? 12) Tell me about "availability" and "abundance." 13) Much belukha is used for muktuk. What is it? How do you spell it? How do you cook or eat it? Is it a staple or a luxury? 14) When belukhas arrive, is it true that all that can be caught are—and that if the neighboring village is in need, food will be shared. What happens to the heart? Is there waste? 15) What are belukhas doing when they go up rivers? 16) What is the status and prospect of the native male? 17) Are Cook Inlet and St. Lawrence the result of the Little Ice Age?

I was never able to ask all these seriatim but our discussions did cover many of them.

September 17, 1992
Alaska, Fairbanks

The latest word is that Mt. Spurr has erupted again and Anchorage Airport is closed. Our plane may not get out. So we: “mill about smartly,” “stand by to stand by,” and “remain flexible but don’t go limp.”

John and I discuss: We will explain the world whether we can or not! It applies to water-witchers and priests and very much else. I say it lies at the basis of culture, of the formation of value systems by which we can live in the absence of real understanding of the universe. Now, science intervenes and begins explanation and conflict is inevitable, until science wipes away the last demon or god.

Polar bear population increases. It has perhaps doubled [in the last?] 30 years about. So now they have increased take of belukhas—savsaa in Eskimo—“animals whose way is blocked,” in western writing translated as “animals who are trapped.” These are predictable.

Fresh water freezes at 32 degrees F., seawater at 28 degrees F.

So when belukhas go up a river mouth to feed the freshwater plume overriding the seawater may freeze and trap the animals. The distance to open water may be so great they can’t escape. John concurs that five miles of ice can trap them. That’s about what we saw at Cunningham Inlet on Somerset Island, Canada. An animal swimming under ice cannot use all its capacity to escape. It must either have a perceived goal that will allow it to breathe at the end, or search and return to base.

What, to a belukha, indicates a place for breathing? Is it light shining down? Is it noise of ice grinding, is it both of the above? What happens in winter?

John says belukhas winter in the central Bering sea. How much do they feed? Do they live on their blubber store? I’d guess their sophisticated close-up, clutter-resistant echolocation would allow them to feed easily all winter.

Mt. Spurr erupts. The Anchorage area is blanketed with ash on and off and our Fish and Game plane can’t take off. So Ev and I plan to head for Nome anyway to see the land and the Norton Sound. So we are going by Frontier Air, which costs about \$500 each. We will fly down the Yukon Delta to Galena and then transfer to Nome. It’s 1:45 PM. We board a Beech Craft 99D that holds 15 passengers.

We head for Galena down 1½ hours toward the ocean on the Yukon and then transfer to hit Nome. I sit right behind the pilot—a slim, sandy-haired guy with captain’s bars—50-55, the co-pilot—slim, moustached, 32.

It’s overcast here, snowing in Galena. Here the ground is covered with snow among the forest trees—alders, aspens, and willows—a touch of yellow here and there—and dark foliage of white and black spruce. Others are going to a potlatch for the deceased, and some native people are hunters, I’d guess. We swing into the runway, a Delta jet turns away as we rev and take off. The rooftops of Fairbanks are snow-covered rectangles, the [?] still and gray, fields are white. We circle up into the mist.

The hope is to get to the Seward Peninsula, to see Nome and to meet Lloyd Findley. There tomorrow—this will let us fly in to the Seward Peninsula and at least see the place before we have to leave for Montreal and Greenland. I’ve already had a rich and valuable time in terms of the story here in Alaska, both Fairbanks and Anchorage, so seeing the belugas is an added hope, but not I feel I know important personalities in the

beluga equation, a good deal I didn't know about the animal, and a good many of its trials and prospects—all good stuff. The time with John was especially valuable, as was Rural CAP. So up in the cloud deck, time for a snooze.

We land at Galena. a great big hangar tower and long, well-lighted field and river-bottom willows, braided stream, and a slushy mixture of rain and snow. Into the Frontier terminal room—plywood, coffee, notices about the potlatch at Huslin for six people—memorials “In loving memory of Auntie, etc. etc.” And a notice at the bottom—“No alcohol please.” The schedule of ladies basketball for Malakleet and some other towns.

We transfer to a Piper Navajo with pilot Larry—38. I'll bet this big airfield has a military history somewhere when I see the covered radar dome and air force helicopters and trucks at the big hangar.

Low alders blowing, gray sky, flashing runway lights reflecting from the slick runway.

We're off in moments, the wheels whack into their wells. Eutrophic bogs below, dark spruce and willows, tendrils of water plants and sphagnum creep out into the open water. We're at 300 ft. and merging into the haze. Bleak below, dark filagree of water and streaks of snow, bars[?], and half snowy ponds, a tangle of brown channels. All gray now. 400 ft. The sky lightens as we nose upward. The propeller tip draws a pure circle, faintly rainbow-hued. A front came in last night, but it may be better now as we are about to skim along the south shore of the Seward Peninsula. Jim's all jokes in the terminal and all business up here—air chart on his lap. Snow still clings to the corners of the windows at 145 knots.

An old indian man who seemed to tend the terminal and our pilot both mistook me. One said, “You live out there, don't you? (Nome)” Larry said: “Run the pizza parlor, don't you? Or was it Medevac?” “No, just quaint to the core folks.” Advice: For fine cuisine the Nome Nugget, for good food Fast Freddie.

It's not far to the Bering Sea here. We'll encounter it at the base of Norton Sound, not far from Unalakleet.

We'll get to Nome all right, but will we get out to make connections to Montreal and Greenland? . . . Too tight!!

The snowy land appears below—river bends, black loess-cut banks and white whites. Jim looks at the aeronautic sheet, pokes his well-worked hand calculator, and his graphs in a taped pocket, dog-eared with use. The sun glints on the engine [?]. The land is gone again. Jim's glasses are missing an ear piece. He has it tied together with carpet thread. Out comes the airport directory. He adjusts the radio direction finder. Maybe it isn't carpet thread. Turbulence bounces a bit. Is that the coast? It's all white. Larry talks quietly into his mouth mike, thumbs through the thick book of airport instruction. Loose leaf all right but each is ensheathed in tough plastic so it won't tear out with use. On an instrument right in front of Jim with compass designations on it, a little white card flip-flops up and down across what might be the horizon. He steadies it with a twist of the dial. “We're at 1,000 ft. over Moses Point.” It's clearer at Nome. I see clouds stream and above, still all white below. Gradually, gradually the white dissipates. A pale streak of blue sky shows, off up high. There's texture in the white below—mostly long, smoothed shapes of white.

4:51. We'll be in Nome in 20 minutes. Gray decks ahead. Jim used to run a leather shop in Santa Cruz.

I see land below, rounded hills bloom with snow black in the canyons. A stream now, bars, forested slopes. We're not on the tundra yet. The trees are in the canyons and the hills bald. I can see the Bering Sea under the cloud deck now off to the left.

Braided blue river banked with rich brown and a liner of white at the water's edge. Tundra ponds peppered across the brown. Oxbows and bars, like out of a text book.

"Go to Bering Air? Is that OK?" Jim asks. "They're the most colorful one. I used to work for them."

"OK. Can we get a taxi?"

"Yup."

The land is wrinkled and etched into families of parallel lines by the snow. I wonder what earth process did that?

We pass Council and head along the bluffed coast, sand beaches and now coastal lagoons we can look up ahead and see the barrier bar and the big lagoon at Nome.

Pt. Safety and Nome straight ahead. A dark, flat-topped island lies offshore. Somewhere out there is St. Lawrence Island to the WSW.

The inland mountains of Beringia are on our left, snow-decked and apricot in the afternoon light, their heads nudging a skin of clouds. The sea is government-issue green. The tundra ponds are banded in lovely rich yellows and browns.

Do I see belugas below? I think so, lying like white sausages, helter skelter every which way, not far off shore.

We can see the road across to Teller now, ducking up a broad glacial valley toward the snowy peaks, a winding stream in its bottom.

I see a gold dredge sitting like a giant duck in its little made-up pond, gray spoil behind it, wandering over the tundra flat.

We circle out over the Bering Sea (Norton Sound) to land, gray, white-capped, foam trails away from the wind. The sea is dark greenish gray—no transparency at all.

Then Nome, a wedge of buildings, white tanks, red, blue, tan roofs, a rock jetty, and some landing barges perhaps abandoned, 4-5 dozen private planes are tied down on the gravel. Cranes, light towers, hangars, a partially paved runway. Offshore we can see Sledge Island, that looks like a volcanic, flat-topped sea mount—but a lot of these islands look that way and it may be glacial or even interglacial. I dunno.

We went into Bering Air Service and called a taxi—an orange van with a great, mountainous, impassive, fur-clad, mustached Eskimo riding shotgun.

The Nome Nugget Hotel is on the main drag as you turn into town. It is on the water. Fat Freddie's is the restaurant—and it is a mass of gold rush and other artifacts, gold pans, old newspapers, dredge scoops, kayaks, polar bear rugs, etc. The rooms are small, clean. We have a shower and can look out over the Bering Sea. It's bleak out there, dark green, and rather calm, though streaked with wind.

We walked the length of town. Old, scruffy buildings sinking into the muskeg alternate with a new town hall, an armory, a kind of mall, a northern brand of U. Alaska, really devoted to education of the local people. We went inside and talked to the science-math instructor and Ev looked at their terminals.

We had an Italian dinner—frozen veal scallopini and spags, and a couple of glasses of wine. I called home (all's well). Now 10 PM, it's getting pretty dark and we have quit for the day. Tomorrow we rent a car and head up the Teller Road. Maybe Lloyd Lowry will come in in the afternoon and maybe not, but we have to leave the following morning.

My camera, which had been in the nose of the charter plane, refused to function because its batteries were cold. So, I'm warming it.
Off to a shower and bed.

September 18, 1992

Nome, Alaska

Ev and I have boarded an Aerocommander with Lloyd Lowry and Dave Weintraub pilot to do a spotting flight for belukhas along the north shore of Norton Sound, into Norton Bay and S. to about Unalaklec and return. We have more than 20 kts. of wind on the sound so it will be difficult spotting.

We arc on the tundra, the big placer dredges and out south to the shoreline. The Aerocommander leaps off the runway. We pass along the shore and the Eskimo summer cabins. [?] is the name of the game, both in Nome and on the beach. We fly a ½ mile off the beach at 1,000 ft. We pass Cape Nome—a quarry site used here and at the Pribilofs. Now we pass Safety Lagoon. John Bockstoce has a house here. He built his Umiak here.

Safety Lagoon is a mix of skim ice, open water, and snow margins, and behind tundra of blueberries and willows and alders.

In spite of wind our flight is not much bumpier than a good dirt road.

We go by a murre and killiwakes. We pass Table Rock, the low hills have snow-dusted bald tops where the weather has stripped the land.

Saffron cod are incredibly abundant here.

We pass Golovin Bay, a [?] dotted with largha seals (spotted seals). It breeds on ice, close to leopard seal.

The coast becomes more precipitous and behind is a big, deep bay—Golovan Bay.

We fly over the village at Golovan Bay on a spit that blocks the lovely bay. Lloyd says they hunt a few belugas. They are mostly reindeer herders.

The muddy plume of the [?] bay is below us, marked by foam line from clearer greener water.

Seems like 5,500-6,000 belugas (Spring-June). We pass Cape Darby. Walruses haul out here. Males. We move into Norton Bay. there are two villages in the bay, Elam and Koyak—the latter back up the bay. We cross the tree line. Here comes the spruce forest, white spruce, and perhaps willow.

The belugas concentrate on the coast so the offshore lines are apt to be [?] except in ice time.

Lloyd thinks belugas have extreme site fidelity, and come back and back. What makes them attractive is—what?

We pass Elam—150 people, and an airstrip, mountains behind. this is a shorefast ice. Good [?] seals are in the winter. Good place for [?] dens.

Bald Head looms. The bay turns muddy. Kwik River, a broad-winding river, ice-margined, shallow mud bars.

Bald Head abeam. The water clears and deepens a bit. Granite Mt. Deep in snow to the north.

Dave says a big gold mine is up there. We come up on Koyuk, a beluga-hunting village on the big Koyuk River—big, broad, muddy, icy. Not a rich area because shorefast ice anchors to the bottom. Finely penciled foam streaks line the water.

The ice locks to the shore, over the mud. It's 500-m wide here. Thermokarst ponds, a piece of ice in the sediments melted out leaving a roundish pond. The flats are dotted with them. It's getting muddier and muddier.

We pass over Shaktoolik on a bar—a beluga-hunting village on the ocean edge on a giant flat below the distant, snow-frosted hills. We pass a gleaming gold bluff, like mica, or gold.

"Dependent independence." that's what John Burns calls these Eskimo homelands. What the northern people seek.

We come upon Unalkeet, the Unalkeet River is very good king salmon fishing. A real metropolis amidst snowy hills at the mouth of a river. About the size of Nome, I guess.

We turn out across Norton Sound and head directly for Nome about an hour away. The sea is dappled with tumbling white caps and low swell. There's little fetch with this wind so oceanic rollers weren't here. Cloud shadows on the sea made gold by the low sun.

Lloyd has kept us informed all the way along. He knows this place, as does Dave the pilot. There are whales here somewhere over this shallow sea and an enormous area to search for food. So where are they?

Fine flight. We settle in over the airport and stop 50 yards short of end of the pavement.

The last time they found the whales they were off the Yukon Delta, which we did not reach—part in brown and part in the green water, scattered across some miles of sea.

Why do they school together? They have such a rich acoustic system, one wonders if they have some group process as protection from killer whales or other predators. I heard a little mention of a group action against polar bears. Any animal that makes such an enormous amount of noise as a beluga automatically advertises itself. So its protection lies elsewhere. Polar bears, to be sure, may not hear well underwater, but killer whales do. White whales fear killers and run from them—a group-dwelling predator against group [?], so there must be failure by the belugas, at least sometimes. Sometimes is enough. But they . . .

I take a break to hold Samuel's saline solution, an Eskimo guy going to Humana Hospital in Anchorage. He's a old guy with some senior's problem going in for treatment. He tells us he is a welder and that where he worked is too cold—up between Barrow and Deadhorse. He looks a little jaundiced. He says he can climb into the plane . . .

But they seem to deal with bears. Gang up, I'm told. But they are killed sometimes, too. Knowing would unfold a fascinating story, I think. We know so little about what belugas are really like. We know numbers. The specifics of hunting, the outlines of population dynamics, but of their behavior—very little. People think they know belugas. They don't at all. The trainers know best.

All this was in the afternoon. In the morning, Ev and I rented a car from the Polaris Hotel. Go in past the laundromat signs, turn left through the door saying "No Admittance" and enter an office where you rent the car.

We unfolded our Geological Survey Quadrangle maps and headed up the Nome River into the rounded, tundra-covered hills, the higher very bald and dusted with snow.

Our road led toward Salmon Lake and was an elegant gravel one—a berm piled. The slopes are gold with low willows, only a few reaching a meter and a half high. Most

of the slopes up to the barren ground and snow were rose with low-growing blueberries in full, ripe fruit.

I stained my pants lying down to take a picture up into a bleak, windswept canyon.

A few dozen shacks dotted the landscape and a system of flumes, now abandoned lead along the west slope, going, I suppose, out to the flats above Nome to provide water for the dredge to swim in. Down the canyon purred a river, the Nome River, 50 yards across, purling over stones and often enough margined with an ice rime.

On up we went until the snow blanketed the hills almost to the valley floor. There we met a slope flanked with dark alders, four- to five-ft. high. One could see the solifluction lines in the trees, but much better over more sparsely vegetated slopes. It is lined more or less along contours—a soil crack propelled by ice freezing and thawing, whose lines drip and move down hill slopes.

We came to Salmon Lake—water in the valley bottom, pale blue, low, vegetated slopes and hills beyond. The wind shipped unmercifully and was very cold. We went in an abandoned miner's shack—30 years old, maybe—flapping tin, bedsprings, an old bicycle, a distributor cap, tarred seams, single plywood not much more than head high. A bleak two rooms and an entry. Cold, bleak, elemental.

We returned for the afternoon flight and had 30 minutes to spare.

That night, after the flight, we had dinner at Bob Nelson's house. I liked him a lot. He's married to a Shismaref Eskimo woman, Mal—as nice as she could be.

We went up the back street of Nome past churches. I'll bet there are 10 or more kinds in town. Bob's house is rather new, up on permafrost piles (they lift the houses above the ground so it doesn't thaw and do in the foundations and tear the house apart as it sags and sinks).

We had red salmon and a good bit of wine and fine conversation with Lloyd and Dave, the pilot. The Nelsons have bought a small coffee plantation near Captain Cook and they will retire there in a couple of years. I want to send them a spinner book.

About 10 we drove back to the Golden Nugget, showered, and got ready for tomorrow's trip. Ev had to see the Board of Trade, the local bar of wildest repute—a few doors down. It has an electric light show dance floor, "Sin City" was playing loud, synthesizer drums and guitar and a few Eskimos dancing up a storm. Ev and I had a couple of rums, played bingo—or scratcher—and he won \$20 and me \$4. We watched the pool (not very good) and hit the hay.

But to little avail. For the second night in a row the paper-thin walls let us in on a bachanal next door. An Eskimo woman, drunk but coherent: "Fuck you, Fuck me, bang, thump, but only once, and low male voices of no passion, a child's wail, more from the woman, and on and on for hours."

I pondered pounding on the wall but thought better of it. I didn't want them pounding on our door. Finally, after midnight sometime it subsided. We're both a little the loss for wear today for lack of good sleep.

We board Alaska Airlines very nice DeHaviland commuter plane and head over the clouds for Kotzebue on the Kobuk.

We landed, coming out of the clouds over the nearly flat Beaufort Sea, the sun low and copper, the snowy hills low and rounded, great shallow lagoons and flats inland—all pale blue, brown, gold, with white, white, planed-down mountains behind. The town is pretty big and rather neat, compared to home. The light was coppery—the sun low. Once out of the plane the cold wind cut in. We headed for the warm terminal.

Our plane was having trouble in Anchorage and so we waited. Ev and I walked into town in search of a restaurant—the first was Chinese and not really ready for patrons. The second was unmarked, a great three-story facing the flat sound. Kittiwakes flew by and some glaucous gulls. We are quite a bit above the Arctic Circle here and it feels it.

We had an ample breakfast looking out the window past the bowhead bones on the esplanade—pickups everywhere. We hitched a ride, three of us, from a gracious Eskimo girl. She dumped Ev and me off and we went in and boarded soon after in a big jet.

Soon, Anchorage, a long wait. Roger Genny walked by and we had a fine chat. Then off for Chicago. No serious hitches yet, except I left my long johns inside a pack that I used as a spare pillow to cushion my sore shoulder. A guy ran into the Nome terminal with it—praises be, so I don't have to buy more long johns.

Now comes the long (six hours) flight to Chicago.

Gasp. We're in Toronto heading for Montreal. Both Ev and I are zombies. We'll hope to meet Bob at the airport, but if not he has the hotel name.

We fly over the Great Lakes. I wonder what it's like to own an island, if we can meet Bob easily, and then Moosemeat. Bob comes in at 5:19. Ev is up straightening out his return ticket and once that is done we can head for the hotel.

A good night's sleep will help and then we go out tomorrow at . . .

Baffin Island--Iqaluit

September 20, 1992

Canada, Montreal

We did meet Bob OK, had a grand horsemeat, Caesar salad, cheesecake dinner, and then up this morning to meet Danny, who had driven taxis for 48 years.

He drove Hudson Terraplains, Packards, etc., married 47 years, he seemed to think this was a Catholic attribute. All us non-Catholics nearly equaled him, however. Now we wait for the Iqaluit flight. The weather is balmy here but we hear of snow at Iqaluit, -4 degrees C. at Resolute.

Kenny Bloome came in on schedule so we headed for the Frobisher Inn—a great condo project six stories tall with perhaps 100 rooms set aside for a hotel and with a fine restaurant downstairs.

I contracted with a tour guide, Matty McNair, to take us around the local area and show us the sights. Matty proved to be an ebullient young woman, a teacher, a real Arctic buff, a runner of dog teams, and general tour guide to the area. We saw Iqaluit (pronounced Ikaluit), its stores and sights. Its buildings, dirt roads, squatters on the beach, dogs staked out among the kelp. The tide is over 40 ft. here and this makes the harbor of only modest use (they run in with tankers, pump hard, and get out before the tide drops them on the flat). The result is poor supply for the town, except by air. They wait for lumber, etc.

We had a great first dinner (Arctic char) overlooking the harbor, the fuel tanks, the cemetery (We looked for plants there). Good white wine, Arctic char, and company. It's a grand crew. I'll say more later. Now it's the Giants and Bears on TV. Moose is in the shower, and it's 9 PM.

We watch the NY Giants and Chicago Bears on TV. The Giants take 'em easily.

September 21, 1992
Baffin Island, Iqaliut

Iqaliut is a collection of about 3,300 people, living along Frobisher Bay, a long cut in the southeast coast of Baffin Island. It's here because of the need for refueling for the WWII, so it had little to do with natural resources or even how you can service it by sea. It still shows. The Inuits make their camps where one or another resource is available, often seasonally.

So these military, mining, or weather-station towns are always dislocating for the native people who must live in them.

The area has much exposed bedrock but even so the houses and buildings are on pilings, allowing air circulation underneath and preventing melting from occurring, the cause of houses going all out of true and sometimes destroying themselves as they sag and slump.

There is a trim, prestressed concrete school, in full swing with two dozen kids kicking balls and squealing away. There are barges stranded in the harbor now as the tide recedes and a pickup has driven out on what was once the harbor bottom. The bigger fishing vessels are way out, a mile further.

We hiked in Sylvia Grinnell Park looking at plants in the low vegetation—much *Selaginella*, lichens of various sorts, *Ledum* (Labrador tea), *Draba*, a *Pyrola*, three or four willows, a *Ranunculus*, Arctic poppy, and some others. We visited the cemetery down in a gravel outwash plain above tide line—all crosses of wood, plastic flowers, and wreaths.

September 22, 1992
Canada, Baffin Island, Iqaluit

We got up, had breakfast, and I stayed in the Frobisher Inn—nice rooms, a big institutional building, three or four floors, half apartments for rent, the rest hotel rooms. There is a good dining room, a little pricy, but good food. The others went around town while I got my accounts straight—receipts, etc., and then we walked around town looking for muktuk for me to taste.

We found a fishery sales building—a Scandinavian-looking guy who said mostly he sold locally. He had some Arctic char—big, beautiful, red-spotted fish, like huge brook trout. He had some narwhal muktuk in squares about 10 in. on a side, mottled skin showing. I didn't buy any. The man said most of their catch was *Mallotus*, or a couple of kinds of Arctic flat fish, molas, wolf eels, zoarcid eels, enchalon.

It had begun snowing fairly briskly. The lady at the hotel counter said, "Oh, that's all right." They seem not to worry about a snow like this one, and apparently winds are more likely to stop them.

The others have walked uptown while I stay with gear and nurse a headache—too much gaiety at last night's dinner. The plane has been delayed until about 5 PM.

Then, with luck, out across Baffin Bay to Nuuk.

The Naarwhal came in from up north, not so often around here so we were told—Grisc Fjord.

Lots of children and many young women with babies, often in parkas carried in a sack on their mothers backs over the long apron-like affair that hangs down in back further than the front. So we were told it's not much of a sin to have babies out of wedlock and population increase is among the highest in the world—over 3%.

So welfarism is here with its consequent release of population numbers, and very little pressure base to support it. Housing here is very dear. One hundred and thirty

thousand for a very small frame house. Many use subsidized housing. So it's hard to see how it all can be sustained, and at the bottom of the pyramid, the wildlife including the beluga.

Musk ox and reindeer farming may help some, mineral extraction a bit more, but in the last analysis the place cannot accommodate the flood of new people except by welfare for very long.

TV enters. Everyone watches the game shows, the ball games, the world news. For the first time they are connected to the rest of the world. They enter the 20th Century, ready or not. The land and its life, harsh and resistant, or naïve and vulnerable are swept along too.

September 23, 1992
Muuk, Greenland

We made our way down to the airport through an increasingly heavy snowfall. I couldn't imagine that First Air would fly in this stuff, but I asked the girl at the counter, and she said "First Air? Oh, sure," as if nothing like this little storm, where you couldn't see across the runway, would stop them. It didn't either, and it didn't let up.

But after looking over the art warehouse where the owner, a big fat guy, said, "Bring your gold cards," we went aboard a [?] (prop jet), about 20 of us, and we raced into the sky, up through a cloud deck and on over the invisible Baffin Bay to Nuuk, Greenland. A bit over two hours later we dropped down and soon could see the land without snow, long fingers of land and channels of the sea with craggy snow-dusted mountains behind, disappearing up into the clouds. The lights of the town were gleaming as we landed and soon enough we were in town.

It is very Danish—spotlessly clean and with strong colors on the simple buildings—many long row houses of 2-4 stories. The Hotel Hans Eede is spotless, very well appointed, smart Danish furniture, solid smart fixtures in the bath, fluffy down comforters, house plants, all carpeted, a big dining room overlooking the town.

Nuuk itself, 13,000 people, has a buzz of traffic, including busses and a good many taxis. We walked the square, past banks, to a convenience store with everything from licorice whips to social tea biscuits. The proprietor is very Danish, while Anna, the smiley house lady in the hotel is from the Faroes.

The spaces between stores and banks are often paved with interlocking bricks and walkways of asphalt. The people are either Scandinavian or Inuit, or often enough, a combination. Truly Inuit people are maybe 1/3 of the pedestrians. A skateboarder rocketed over the cobbles and a cat meowed.

We straightened out our tickets—mine hadn't been reconfirmed so I was dropped from the manifest. The travel agent, Mary Ann, part Inuit, had spent a year in Santa Cruz, fixed things up even though I was on stand-by.

We contemplated renting a helicopter but it had to dead head from Illulisat and would have cost \$10,000, so we decided to try a boat instead, out of Illulisat for \$2,000. Better anyhow.

But the weather closed in and we are back in Nuuk since high winds are predicted and the plane to Illulisat won't fly.

And they came. We went off to the Icelandic Restaurant—"Exquisite cuisine in a delightful ambiance"—tux-clad waiters abound. Imagine your agent getting you a gig in Greenland.

We had an elegant dinner—reindeer, I had whale steak, red fish. My whale was fried with onions, huge (two times as much as I could eat), very beef-like in color, brussel sprouts from Santa Cruz (I guess), and then back to the hotel through the wind, which had picked up a great deal.

I can see why we didn't fly. We will make it to Illulissat tomorrow and a plane goes to Uummannaq on the 25th. Now to see if we can charter a boat to sail back to Illulissat. The air charter cost \$10,000 or a bit more and I begged off.

Well, off to bed in our ever-so-elegant feather beds.

September 24, 1992

Greenland, Nuuk Airport

Well, we're giving it another try. I stewed about everything last night and came to the conclusion as the storm raged outside, that it was impractical to go to Uummannaq since we couldn't get back easily and our schedule out of Nuuk is frozen.

I had bestirred myself yesterday and gone over to the Department of Fisheries and Industry to look up two people recommended to me by [?]-Peter Heidi Jorgensen—one was gone and Amalie Jessen was about to go home. Small, almost furtive, black eyes, expressionless mask of a face, she told me she was going home and couldn't talk. I told her I was coming back next week. My personal introduction was good enough for her to learn more than that I was writing about the white whale. I told her I would be back later to check in.

The result was that this morning in the lobby of the hotel, a great impressive deputation. Dennis Sandberg, Deputy Chief of Mission, US Embassy, Copenhagen—a huge, bluff man, and Jens Paulsen, Einor Lemche, Amalie Jessen.

It was very "high noonish." I told them my mission and there were questions such as "Do you know about the joint Canada-Greenland beluga commission?" I did, but not deeply enough? Had I seen [?] Peter Heidi Jorgensen's papers, which contained it all.

"Yes, I had them, but wasn't it true that statistics on the catch hadn't been turned in since 1989?"

"Well, yes."

We left it pretty much at that with me telling them I wanted to know about population increases in Greenland and that I would return.

We parted in good form, I thought.

Now we are at the airport waiting to see if the plane will fly in this windy weather. It whips down off the bleak snow-dusted mountain and blows the rain pools this way and that. Now and then a shower comes and is also blown about.

We collected rocks from around the airport, which are, Gustav tells me, 3.76 billion years old—the oldest dated rocks on earth. They are gneisses, granites, with amphibolite inclusions.

So, will be off to Illulissat, maybe.

50,000 people in Greenland. AIDS is here, 25-30 cases in all of Greenland, and 15,000 tests a year.

We sat all afternoon at the airport while the wind howled and it rained or sleeted. We were supposed to board at 1412, and that was passed up and then it became apparent that there was a mechanical problem—a landing guidance system problem—many delays. Finally, they unloaded a stretcher-born person and began to unhitch blowers and things.

There were some grand people that we became acquainted with—a woman vet in charge of the subsistence animal industries in Greenland, just out of Denmark; a Norwegian doctor in charge of communicable diseases, and a northern Inuit fellow with green eyes who told us he had come from Tule, way up in the north and got a job at Ummannak way to the south and didn't want to leave his dog team, so he drove it all the way down across Melville Sound and on, stopping at the Inuit villages and to Ummannak where he is now a construction supervisor for Home Rule Housing.

He did this enormous trek alone, just he and his dogs. Mostly he fed them fish. And he had done the trip three times since—an odyssey of maybe 1,000 miles. I wonder how many such odysseys of necessity we never hear about.

The Doc said AIDS was under control but other problems such as TB were rising.

The Home Rule group met with us for dinner and we discussed monetary dynamics and Greenland. Tomorrow we try again. Ken and Ev have gone off to the Seaman's home for a \$40 room. The weather is clearing. Now if the plane works. We leave at 8 AM.

It occurred to me that these people, the Inuits, have been a part of the Arctic ecosystem where the rules are simple and [?] whatever you can to sustain your population.

And now, by adopting crucial parts of a foreign cultural system that has almost totally escaped into a new systemic relationship to the earth and its life—the welfare, the commerce, the health systems, the value structure, they are now outside the belukha's world and they hardly realize it. The relationship cannot be supported if these new people with new support systems regard the beluga as they once did.

The give and take is no longer anywhere near in balance and destruction of the less-equipped partner is inevitable unless checked by cultural adjustments derived from the adopted culture.

While having dinner Moose reminded me of some extra things about the Inuit Odyssey I described earlier. The man—about 40 I'd say—had told the home rule people he wanted to bring his dogs. He said he told them he would be there in three months because he was going to drive his dogs. He also mentioned his pleasure at having an air mattress to sit on and mentioned that, "you could also sleep on it." Such a revelation. Going across Melville Bay he stayed near shore, which got him into "screw ice," which because of ice movement builds up around rocks. He did it all alone, and it must be 800 miles in mid-winter.

September 25, 1992

Ilulissat, Greenland

We were up early. Actually I was restless and up at 3 AM or so, and fitfully back to bed. It had calmed and the snow melted until toward dawn, when it came again.

We piled down to breakfast (Bob and I)—Moose and Evan were at the Seaman's Home, and then into a cab on the now snowy, icy streets and up the rocky hill toward the airport, which is hacked out of the hillside, and is a very windy place, but at least the wind blows preponderantly down the runway. Our driver skillfully took us up over the slick, snowy road and rather soon we were on board in the dancing, moving plane.

The sky was white and opaque until about Sondre Stromfjord, where we landed up a great glacial river valley. The huge U.S. field and the SAS strip were on opposite sides. Though the US flag still flies and some of our planes were there, we are told it reverts to the Danes at the end of this month.

The loess from glacial flour in the braided stream bottom had been piled by the wind against the canyon walls in places, and Bob tells me that dust storms of monumental proportions can result.

The SAS terminal here was crowded with travelers, knick-knack stores, glass, baggage racks, etc. It's hard to realize that outside just a smile or two up the fjord valley lies the great ice shield of Greenland stretching interminably on to the opposite coast.

The clouds seemed to lie flat over it, forcing perspective as the bulge of ice rose and curved and disappeared.

We photographed the inevitable, radial pointer pole telling how far it is to Rome or Taipei or wherever. We were first in line back on board our Hawker Siddley to head north to Disko Bay. My seat faced the center of Greenland, so I could look up the [?] to the ice shield and look back toward the low sun over the rounded rock of the mountains at the gleaming tarn lakes collected in rock depressions. When the gneiss itself wasn't exposed the rock was skinned with rose-red—from *Vaccinium* bushes, I'd guess, or splotches of topaz yellow and tan.

The ice shield swelled down canyons, became fissured by systems of cracks at right angles to the flow, and then ended in a jumble of ice over sediment-choked valleys.

Moraines weren't very much in evidence. I think the smooth rock mountains have been picked clean and the ice mostly slides down slick rock canyons, polished like glass.

We slipped out over Disko Bay just north of the Arctic Circle and headed up the east shore and as we dropped down for a landing at Ilulissat, we passed close over a 1½-mile-wide fjord choked with a jumble of ice blocks, so thick little water could be seen except at the entrance where icebergs as big as Radio City stood like white castles, immobile, so far as we could see, in the quiet ocean.

We circled in over the village and then the crowded harbor down in the rocky cleft of a fjord and onto the runway. We were met by a bright young woman driving a Hotel Arctic van and taken to the nearby hostelry high on a ridge of rock overlooking the harbor, town, and fjord. Contrary to advertising, it was not the optimum place for looking at icebergs, the best being in the town itself, which edges onto the ice fjord.

Soon we found that our delay at Nuuk had put us on the Arctic waiting list and there were no rooms, so off we went by van down into Ilulissat—¾ mile away, or so.

We were directed into the Hotel Juide Falk, which has two fine white falcons over the door. This place is right at the entrance to the fjord and one sees icebergs moving past the big plate windows from the excellent dining room.

The day was sunny and bright so the glaring white of ice contrasted to the deep blue ice interior as they drifted by. We had an elegant lunch—crystal, folded napkins of wine color, silverware, and tablecloths—and thence out for a walk around town. It's a marvelous, busy, dog-filled place of trim, vari-colored houses, sharp sloping roofs, vivid red, blue, and white walls. Most houses are built on exposed rock. Often a big concrete wall defines a basement, and then the house above. Triple-glazed windows, heavy doors, vestibules, a spired church down above the ice fjord, the Knud Rasmussen Museum, an old sod house, a three-parted [?] works of three vats, an arch of bowhead bones, and dogs, dogs, dogs. They are little, light, almost coyote-like, pale dogs, mostly chained in fields or up on the rocks. They sit or sleep and wait for winter when they can run and pull for eight hours at a stretch. They got into howling contests and sang back and forth. Usually there was a sled or a Comatik nearby and a fish-drying rack, often festooned with shingled rows of northern halibut.

Downtown there are stores, bars (where beer can be had, or hard liquor, but it's very dear). Bob and I wandered down into the cleft-walled harbor, the busiest place in town. A raft of small boats clustered on their moorings deep in the harbor and out beyond. The big coastal ferry was moored at a dock—I'd guess it at 200 ft. long and 35 ft. high at the waterline—bright red and immaculate, Inuit people waving from the railings.

Forklifts and trucks raced about—a true and constant hazard for the wandering visitors to the dock.

In between, fishermen patched drag nets and balloon trawls; others adjusted chain lines and doors to trawls or lashed floats on the upper throat of nets.

There was an ancient, very, very battered Russian stern trawler, long-haired Russian crew hanging cigarettes over the rail. I wondered what life as such a crew was like.

The catch was ground fish—halibuts, wolf eels, shrimp (a big deal here). Bob and I escaped not being run over and headed back for town. We met Evan and Moose, who are holed up over a bar and full of joy, near as I can tell. It looks like snow is coming though it's been a bright, sunshiny day.

September 26, 1992

Ilulissat, Greenland

It snowed last night, and we have the tail end of the overcast now. Icebergs have crowded into the harbor mouth so deeply I wonder if boats can get in and out. What a curious place for a harbor.

Twenty million tons of ice go by every day from the ice fjord, and it must block up constantly. But it is beautiful. (The reason is that it is an especially productive fishing area.)

The battered Russian trawler tried to come out and ran into a berg almost as high as its bow (20 ft. or more) and there was a cascade of shattered ice, but the big trawler stopped and pushed a while. No dice. They backed up and tried to go around. Still, no dice. (There were big rust trails up the berg.)

I stayed in the warmth of the Hvide Falk this morning and wrote, did accounts, etc. I prepared my views on the beluga problem for the Director of Home Rule, found him downstairs, and gave it to him.

I asked for some materials for the story—demography, etc.—and told them Mads Peter Heide Jorgensen's work deserved support, and that I didn't know him. Nosy! Why not? I didn't like some of what I heard (if a human constituency yelled louder, they might deserve a larger kill, or quota).

The Director, Eniar Lemche, is a big, blocky guy, obviously very smart and penetrating.

He will, I think refer my wisdom to Amalie Jessen. I don't expect much. I told them that it looked to me like the present Greenland belukha kill was twice as high as could be sustained and that selling mattack (bluber and skin) just locked the animals and the hunters in an unsustainable commerce. Well, why not? They know I'm writing a story for *National Geographic*.

This afternoon, Ev and I walked out past the heliport, past a big field where dozens of dogs were chained and waited to be fed—mostly the remains of Arctic halibut minus the fillets. Then past the cemetery—bleak in the snow, a tight little plot of wooden crosses decorated with sodden paper flowers, up in a snowy cove in the rounded gneiss.

We slogged on, picking our way up toward a rock cairn on a hill overlooking the ice fjord.

Bob, Kenny, and Ev had previously blazed the trail. Dog music was everywhere. We picked our way up amid sedges, prostrate willows, cotton grass, blueberries, and lichens.

A black lichen predominated, punctuated here and there by rings of gold stars—another yellow lichen. In the rocks were pools and it was easy to break through the ice crust and sink into them. Caution, caution, no wet feet please! One pool, larger than the rest, had an ice skin except where protuberant rocks kept thawed circles open—very elegant. Finally we reached the crest and could look over at the ice-choked fjord . . . a parade of huge ice ships making their way in succession out to sea. The big ones were 120 ft. high and 1,200 ft. deep. Imagine that! What huge shapes. These big ones may plow the Disko Bay bottom as they sail, twist, and steer, and unless they go hard aground, they sail off. A dozen pure white shapes—vertical walled, some with fluted peaks, some flat on top, sailed along, the Disko Island in the background.

The low sun is pale copper, the high sun clear blue. Colors appear on the bergs, pale pink on top, deep rich blue in crevices, and at sunset some off our hotel were almost lemon yellow, perhaps from reflection of the town's houses—I don't know.

The town is full of kids, [?] bundled up, and rosy cheeked. Lifespan has doubled here since 1951—32 years for boys, 37½ for girls to about 60 now. The row house out my window is lined with [?] and sleds careen down the streets. Slick, slick, dangerous, but the locals seem to pay it no heed at all.

My impression is of a truly serious population spurt here. The kids (and many adults) are quite beautiful people, mixed as they are between Nordic and Inuit ancestry.

We were invited to a dinner to be held at the Hotel Arctic. There was to be native dancing and the Vice Consul Dennis Sandberg and Director of Home Rule Lemche were to be there with Roberta Sandberg, as well as two groups of businessmen from Denmark. So I decided to take my team. We had a Greenland plate, which included a lot of local food in tiny samples: mattak from a beluga, dried cod, herring, lumpfish roe, salmon, and reindeer jerky. The mattak was tough as my boot sole, rather flavorless and oily, not something I'd go very far for—fainly nutty in flavor. After that, musk ox steak—rather coarse but good. I thought it would make fine pot roasts.

The Eskimo (Inuit) dancers were a real surprise—it was to polkas, or square dances, and I could recognize the tune of "Little Brown Jug."

I was told by one person the music came from the Dutch, and another from the Scotch. I know the Scotch were here.

We talked to the Lemche/Sandberg party quite a lot. Lemche—he is a lawyer and began to work in home rule issues. He's been here a while, maybe a decade—very bright and subtle. He went into a long conversation directed at identifying who I was and what my views were. This, I believe, was directed at seeing if I was an activist, especially Greenpeace, who are reviled here as knowing nothing of the needs of the people. I thought he warmed noticeably after our initial contact. I didn't press him.

September 27, 1992

Greenland, Ilulissat

We take a boat ride today. We were met at the hotel by the van and taken down the icy hill to the dock by Flemming Nicholsson. The boat, the *Nika*, is a little fishing boat of about 37 ft., made in Denmark in 1956, diesel powered, a bit battered, but smooth

running. Capt. Thorvald Jensen—pale and peering over [?] glasses, blue-eyed, a nordic, “square” head with a fringe of red hair and bald pate, squat, with a remarkable twinkle in his eye and sense of the absurd.

He handled the boat alone. We clambered over the bow into the forward deck where the winch, stack, and spare ancient stock anchor were located.

Coffee, tea, and sugar were available and Ev had brought along a loaf of bread, so no problems about food.

We edged out of the harbor with Capt. Jensen plotting course on a satellite positioning rig, combined with fathometer. He sat perched on a high swivel seat in front of tight rectangular windows.

The head was located on the stern bulkhead of the bridge and the galley below. The day was still clear and bright, cold but not seriously so.

He headed the vessel right into the glacier field from Isfjord—choked with colossal ice castles, some looming 150 ft. high. Since they go down about 10x as far as up, that’s a huge hunk of ice. Some were acres in extent. Their walls were glazed like nubbly, irregular porcelain, pure white except where cracks had healed blue—the difference in color is in air content of the ice—white with air, blue congealed and vitreous. Some bergs were sheer-walled and craggy, others sloping up from the water. The waves had marked an indented ring just above the sea, and doubtless when these bergs grow older it would cut in and deepen.

These huge jelled islands were moving of course from water movements around them and from the ice moving into the sea from behind, so to go down the sea corridors between them was a subject for caution. Capt. Jensen replied to my question about danger. He said they would tip, but slowly, with much sound, and providing you had some place to go, these tipping events were slow enough to be evaded.

Skiffs and small gill netters patrolled these channels—the first one seal hunting—ring and harp seals.

Jensen avoided talk about harp seals, I suppose because he was uncertain whether or not I was “Greenpeace,” which is anathema up here. They fish here in the ice, too. Jensen said the town was here because of the good fishing and sealing and worth dealing with ice in the harbor on a regular basis because of this.

Ravens flew and tumbled off the crests of bergs. They are amazing, adaptable birds! A few gulls went by.

We learned the fjord was 1,500 meters deep (Can this be real?)—not feet as I had supposed. He told us the upper ice fjord was a place where the ice was launched over water—some say it goes far back under the central ice shield inland.

The beauty of these immaculate chilly castles grasps one, tying your gaze to the varied forms before you.

Captain Jensen stopped to dipnet himself up two ice chests full of sea ice, which he will put in his whisky. It’s contained air crackles and snaps in his drink like carbonated water.

We were on our way again, I thought, to a village across the fjord channel called Clanshavn (Ilimanaq), but we turned north toward Rodeby (Oqaitsut), a village 3-5 miles or so north of Ilulissat. The bergs were spread, and the big ones mostly over toward Disko Island, so it was pretty clear sailing. Ev spotted the spouts of a whale, but we could not find it, and so continued along the coastal hills, scoured rounded rocks, and clefts dusted with snow.

Then we ducked in a channel blocked by two rocks awash at [?]. The captain hugged the right cliffed channel wall so closely we could almost touch it. Past the rocks we turned into a still bay and beheld the village of Rodeby—maybe 85 Inuits lived there—fishing, sealing, and whaling people.

The town of scattered houses rests on a sloping, gneissic hill, polished and striated by ice. The houses are built on the bedrock, a wall of concrete on the rock to level and then a trim house, usually rectangular sloping roofs, wood siding, often tar-paper roofs, metal sheds, wooden or gravel walkways that now and then gave out, a little store, and a fine collection of dogs singing their greeting with barks and yelps.

Later when their masters brought food they stood on hind legs at the end of their chains pawing the air and singing in anticipation. A collection of wiggly puppies clustered around us, while older sled dogs, thin-faced, wolf-like, but too small, usually tan or off-white, without pattern, small hunter's eyes.

Torvald had told us about the Spanish Embassy, a blue building on the sloping rocks, a sign was bolted to it proclaiming it to be the Spanish Chancery (it said "Embajada de Espana, Chanceleria Honario, El pobles, Lunes, Viernes, de 9a 14h"), obviously lifted and brought home. The little dock, store, Greenland and Danish flag flying, the snow-dusted rocks, the yellow frozen ice and dog droppings, the fish racks with dogs resting beneath.

A small boat came in with a young man at the helm, pipe clutched in his teeth and a very handsome, dark-haired young woman in the boat. They were greeted by the dog chorus. They began to throw gutted fish of a couple of species onto the shore rocks—a cod and some sort of bottom fish. They took very little notice of us although we clustered close to the boat. We were summer people or tourists, not yet so odious as to be a distinct pain, but I suspect the time is not far off.

Our party included Einar Lemche, the director of Greenland Home Rule and Dennis Sandberg and his wife Roberta, Deputy Consul General of the U.S. Diplomatic Corps. for Greenland. Roberta is an artist, doing geometric acrylics, of which she gave us one, nicely inscribed.

As we walked gingerly downhill over the polished rock, I suddenly realized that the moment of action had come—the time for a true founding of La Cueva de la Topa Chisera. We had with us a man I had previously referred to as "God"—Einar Lemche, the ukimuk of Greenland, we were above the Arctic Circle, there were four founding members together—three geriatric cases and their doctor.

So I have my camera to God, we stood back on the lawn of the Spanish Embassy—at 69 degrees 17 min. north, as far north as we would go on this trip, and he took a group picture.

Ev spoke the imprimatur of the society as follows: LCDTS is devoted to the totally unrefined but deeply penetrating accessories of science.

It was a moment to remember—there under the low Arctic sun, on the polished rock amid the dog shit. We made our way back down to the boat past fish racks where Arctic halibut hung drying, down past the scattered houses, almost all silent and closed, some with Danish or Greenland flags flying, past the little red corrugated metal store, bags of potato chips and a stack of Hostess Twinkies showing through the window and back on board our boat.

We sailed out past the sloping smooth rock face where the Inuits mounted their hauled whales up for flensing—just inside the narrow rocky channel through which we

had entered. [Drawing] (I later, in Canada, learned that there had been a recent expedition to Greenland from Spain and doubtless they brought the sign.)

The boat squeezed through under Captain Jensen's skilled hand, just feet from the rock wall to our port. Then we made our way back to Ilulissat through calm seas. Both Evan and Roberta saw a minke whale blow.

We had a fine dinner at the Huide Falk Hotel with the Director and the Sandbergs. It emerged that Einar had been a representative to the IWC, and knew many of the figures in that curious organization whom I knew.

He very kindly took me aside to comment on my note to him. We were in substantial agreement on most points—the 4% annual exploitation figure, the need for quotas and more. He said he hadn't heard of any kill here of more than a few hundred animals. He didn't follow my analysis of the problem being underlain by population increases, saying that now they had quotas that should protect the animal. (I didn't know they did.) He felt that the society was reorganizing itself, and that self-regulation would produce a solution. We both agreed that self regulation was the best route, since there was little hope of any external policing. The Inuit would need to be educated on how many belugas they could safely take and then enforce the regulations themselves—the only thing that would work in my estimation, there being no enforcement arm here.

He knew Sidney Holt, said he was very clever, but agreed that the IWC would fall apart under the impact of his maneuverings.

Einar felt the kill of the northern population of belugas was not 2x what could be tolerated—but less. Say a thousand a year now from a population of 20,000—or 1/20—or 5% so, only modestly higher than could be tolerated if you don't account for animals shot and lost. Judging from the mayhem involved in a chase, I doubt very much if a 6-8% kill is far from the mark.

“Even though you are starving, you save the last seed till spring”—Ev's ethic of conservation of resources. Ah, but this is not agriculture. It is hunting and the game is to take what you can from the passing flood of animals because tomorrow they are all gone by and you must wait for them to return as the ice front thaws back again.

Now, as methods make the battle more and more unequal, the guns shot by hunters waiting on seaside rocks, or from boats, or the nets laid to entangle the fleeing animals, the balance is tipping beyond the gregarious beluga's ability to recoup and they must decline and become so scarce the game becomes no longer central to the people. Right now, beluga mattak is the most treasured food on the coast. The bowl of mattak empties first at their gatherings.

So, I think it likely that a decline in these whales may well be underway and may be rapid. It is heartening to learn that measures are underway to redress the imbalance. The means they must use involve a deep shift in the rules of Inuit society, and at the same time as these people come into 20th Century lives, with all the trappings of “civilized society.” Now they must somehow confront what that shift means. They must cope with discos, television, health care, food stamps, baseball, exotic foods, and all the rest. But the history of whales shows that the beluga can be expected to change but little. It will swim its old migration routes at the ice front though it must pass by rocky promontories and bays from which hunters will issue and where a white back exposed as a whale rises to breathe will be a target for a bullet that may kill, or merely wound, so an animal may later sink and not be counted. This is what they do, sink when mortally wounded. The time for retrieval is moments only and the water turbid.

We took a walk before lunch—up the icy streets, a big silver tank truck ground up the hill by us and a familiar figure waved in greeting. It was Torvald Jensen, driving the town “honey bucket” truck. Later, Dennis Sandberg labeled him as a fraud and found out somehow that he had been a primary school teacher. Dennis professed to be terrified by some of Torvald Jensen’s seamanship, though I could point no such finger. Dennis said our captain’s name was not really “Torvald,” which has connotations of nobility, but “Torgus,” a name of the common people. Oh, well. I thought he was grand, we didn’t run into anything, and the day was one to remember. Torvald lived on his boat, and I thought it could use a little dusting up, but the holding down of three jobs requires one to make compromises, doesn’t it?

We caught our plane after a long wait up at the airport. A helicopter (a big Sikorsky) left for Uumneang and then ours for Nuuk. It was a while before we were called out to board our Hawker. It was equipped with only about 20 seats and then ahead of us, a bare floor.

We swooped over the ice-choked bay and after a long while we came into Sondre Stromfjord on just about the last day of U.S. occupancy of the big airbase here. Then another wait in the SAS terminal and then on in the darkening sky toward Nuuk.

On the way in to Nuuk we saw our first aurora—a pale drapery, and later Bob and I saw a bit larger one in the dark sky in the late night.

September 29, 1992

Greenland, Nuuk

Today I’m scheduled to have a conversation over at the Home Rule office with Amalie and Jens Paulsen about the beluga and narwhal situation.

Statistics: Population young, 42% less than 25 years of age. Crude birth rate of the native population is 24.5/1,000. Life expectancy is 10 years below Danish, due to high infant mortality. 16,691 Inuit, 8,842 Danes.

First we tried to reconfirm our air tickets and couldn’t. You have to do that, remarkably enough, through Iqualuit. Then we headed for the bookstore, where I picked up a piece on the animal rights tangle.

Then I abandoned my pals and had a light lunch and then headed for the Home Rule office to meet Amalie Jessen about the white whale status and plans. I walked over and Amalie met me graciously and took me up to a conference room. Jens Paulsen, a biologist, came in. I asked if I could record the conversation. Amalie was agreeable but Jens demurred. So I tucked it away, knowing how incomplete the record would be. But, I did my best. Here’s what I learned:

In 1989 the first general meeting of the Joint Committee on the beluga and narwhal was held at Iquluit and the second in Ilulissat in January 1991.

The Joint Committee agreed to regulate the catches of these species. They agreed to begin by gathering catch data, while the catch-limit action is coming up.

Amalie is looking at the whole question of the technology of catch and its effects in society. One catch-limiting method is to restructure the use of larger vessels that can travel relatively great distances from port.

The population of Greenland is changing. The Danes are slowly moving out. The populations of the distant communities are either stable or going down. The life expectancy in Greenland is almost like in Europe now.

Paulsen sees gear as the problem. New equipment, such as faster, larger boats, nets, and rifles can be regulated and will control the kill.

The nation, he says, is obliged to cooperate on protection of species if “endangered.” I’m not sure what he means by endangered.

He sees following trends in the population of animals, rather than actual counts as the appropriate means of management. I’d agree, but also think attempts at making counts are important to give the outer boundaries of the required actions.

Amalie felt the first thing to do was to understand the traditional knowledge of the people. I suspect she is at least partly Inuit. A small, bright-eyed woman, she first impressed me as cold; now I see her as a little shy but very direct and honest. Not complicated, is my present guess.

There is a quota for fin and minke whales from IWC. Then in cooperation with community associations and local hunting and fishing organizations, they prepare a quota figure for a municipality.

But management can occur without quotas. Quotas require one to know population numbers and these may be all but unobtainable. The last method, Paulsen thinks, are quotas. He lists before quotas: gear, number of boats, size, persons who can hunt, and time of hunt.

He thinks their big whale management system is effective and good.

A key feature in making these things work is the social disapproval of community members against those who violate the rules.

[?] The system may be very cumbersome—many bureaucrats from Denmark in community I suppose, but I’m impressed with it nonetheless. There is much emphasis on local control, Inuit control, and certainly they are everywhere throughout this society, and not obviously subservient.

Jens says, “Who is nearest to you is yourself,” i.e., self-interest rules in the last analysis, but here the social pressure of the group is also vital.

The hunters are closest to the hunt and about the need for conservation they say, “We see the problem.”

Up at Tule the municipality has rules that keep the kill in check. They do this even though they have no real understanding of whale stocks. Jens says, “What this means is that they care.”

Most of the perception of a need for regulation comes from the municipalities. The Inuit Circumpolar Conference (ICC) has been negative to the rules produced by IWC. The municipalities can’t do enough to manage fully but must help improve the regulations. Nuuk and the small villages around it is a municipality. The laws for hunting and catching come from municipality, and the Home Rule government can, if it wishes, override.

They (Jens and Amalie) regarded the Greenpeace harp seal initiative as ridiculous. Such events generated by distant people with distant views. Their effects on the settlements has been disastrous because of loss of income from seal skins.

The Greenland National Radio links all parts of Greenland together. Each division (3) has ½ hour to which most people listen each day. There is an MC who has people on and reports local news: North/Middle/South. “We caught a minke whale yesterday,” etc., etc., etc. Kalaktitut is Greenlandic language and way of speaking.

I walked out into the brisk air and down to the water. I passed the open market. Lots of gutted reindeer, a couple of seals (harp seals, I think). All the fish were gone but a couple of small cod.

Down at the water I came upon some boys being instructed in the use of the kayak. they donned the skin hood, which attached to the ring around the hole in the kayak in which they sat, legs thrust forward. The skin hood went to the wrists and tied there, and up over the head. A drawstring around the face pulled tight and tied around the forehead and back of the head. Their paddle, double-bladed, had tiny blades, but it thrust them forward.

They had an instructor in chest waders, wandering around in the shallow water. When beaching, the kayak could be pulled, occupant and all, clear out of the water up onto the sand.

I'd guess the kayak had six inches of freeboard. It was very flexible.

I walked back up to the hotel and soon our crew gathered to exchange adventures. Moose had found the museum where the mummies were and a collection of *Ichthyostegia* fossils.

We had dinner at a combination bar and dinner place. Ev and I had eider duck breasts in gravy and a little salad. Dark and a bit gamey but very good, I thought.

Outside we were greeted by our first full-scale aurora. The sky hung with luminous white veils, while long snakes of luminous white, curved and twisted across the sky, grew, became brighter and faced while we watched. A hint of green and occasionally a little rose on the margins. We stopped and gawked like the tourists we were while the local folk flooded by looking down, unconcerned.

Then off to our respective rooms, getting ready for the homeward flight tomorrow.

On the plane to Iqaluit my seatmate is a fisherman, Marc La Meque, from New Brunswick. He fishes shrimp. He told me about the harp seals, all along the Newfoundland-Labrador coast—millions of seals he says. As a result of keeping the kill [?] 40,000 last year. In the water when trawl is pulled along, heads all over the place. This is the result of ceasing the kill.

I look down from the plane—30 minutes out of Iqaluit, through a stratus gauze and can see a scattering of icebergs on the blue sea, some I'm sure spit out by the ice fjord at Ilulissat.

July 16, 1993

Canada, Alberta, Edmonton

Phylly drove me to San Jose to catch my plane at 8:30 AM. I had too many bags (6), but they let me get away with it because I carried two. Too much junk, but then you need a tent and boots and lots of socks and clothes, a camera, tapes, for a month in the outback Arctic.

I'll fly tomorrow up to Yellow Knife, Cambridge Bay (on ____ Island) and then to Resolute.

The trip is with Dr. Tom Smith to Somerset Island where he studies the white whales and narwhals. We will hit Cunningham Bay for the annual coming of the belugas—as many as 2,000 in a 1½-mile-long bay—all scratching their backs and some

stranding—then south to an Inuit camp at Oreswell Bay, where we will watch an Inuit hunt for narwhals and belugas, and then, after my month, home to write it up.

Cloud decked and no land as we head straight north from Edmonton. I learned that there actually is a waterfall in town that can be shut on and off, and a big indoor mall and an artificial beach.

July 17, 1993

Resolute Bay, N. Canada

The flight north took me over almost untenanted land, so far as I could see from the air. The very occasional line of a road but mostly shining lakes and ponds, the braided, twisting courses of nameless rivers, green, yellow, amber-clothed forests—all but interminable muskeg forest and stream.

Our destination is Yellow Knife on the north shore of Great Slave Lake, a huge remnant of the Pleistocene ice now gone, and of the earth beneath rebounding from the weight.

I was in the company, mostly, of an elder hostel group headed for Cambridge Bay on Victoria Island and then northeast over the channels and islands to Resolute Bay on the Barrow Channel.

Yellow Knife sits on the north shore in a bend of rounded rock and gravel of Great Slave Lake on the planed-down rock. Scrubby spruce and aspen forest clings and fills the crevices. The lake seems shallow and dotted with what looks like rotten, dirty ice.

The town of two to three thousand has some high rises, quite a spread of houses, and broad, curving streets. It's on the MacKenzie and a shipping point north, and a transportation center for the northwest territory. The plane flights focus here.

15 degrees C. and not much in the air terminal. Thirty minutes later we were back in the air.

A new seat mate, Steve Mercer, a teacher at Cambridge Bay, joined me. He teaches 10th graders and only eight students got that far last year. He teaches everything. He was trained in economics in Toronto but teaches a lot of science. He didn't much like chemistry, he said. "What do the students do after they graduate?" I asked. "Nothing," he replied. He had a fishing and hunting camp near town—he had a \$5 license and could catch char and freeze them or dry them. [?] Victoria Island Caribou herd camp right around town at one season of the year. Now they are on the north end of the island. The migration is quite regular.

The town is small—1,200 people or so. They crowd into the terminal—affable people and smiling children. It was 17 degrees C. and the mosquitos had hatched in droves—big ones too. The elder hostel folks were looking a bit dismayed and swatting away.

Parallel ridges and strand lines from elastic rebound-related rising of the land above sea level. Victoria Island is very flat, a patchwork quilt of lake and ponds and low ridges. Alongshore is a rotten field of ice cracked into rectangular blocks and leads.

We rise quickly above the clouds, and a little later we come in at Resolute. the temperature has dropped to 5 deg. C. and light rain falls. May the mosquitos be stilled until they merely walk upon the shingle.

July 18, 1993

Canada, Somerset Island, Cunningham Inlet

We are in a 6-person helicopter about to take off. Lisa, Flip, Tom, the pilot, and I. We are going up to spot belukhas and narwhals. 700 animals in the inlet. 2,000+ last year max. We are going to fly to Garner Bay and east to Elwin Bay.

We are refueling now and will now take off to the coast. The gas is in yellow drums and we had to leave the cabin, snap our seat belts closed so they don't catch in the doors, and we are now back on board, the rotor going faster, beating hard, noise and pitch go up, and we are bouncing on finger tips, lift off, rotate, and away off the alluvial bench, out over the braided stream.

Tan mud, brown shingle, pale blue water winding, intersecting. Haze is low, patches of snow shining through, rounded, castellated bluffs, scree, and patches of white, the jade bay, rounded jigsaws of white ice. Raindrops jitter along the windows. A rank of male belugas below.

Males in ranks, tight nearly against each other, groups of 7-12, big shoulders, pale cream, wheeling together, a slow pavan. Four head to tail traveling with backs above water, inside fragmented ice in clear water at river mouth.

A few diving and rolling. Out we go. The animals are all at rivermouth. The number of belugas in the mouth is rising day to day. Build to 29th, first rapidly decline, by 5th they may be gone, by 15th all gone, all down in [?] Sound.

Flying east on Somerset. The ice is piled up against the shore fissured with green, against darkest ultramarine—angular broken, the mottled bottom showing clear through 20 ft. of water.

We fly parallel to a ribbon of fog. Twenty-one belugas moving toward Cunningham. The bluffs rise—sea bird country, Tom says. The alluvium bench ringed with rising land from elastic rebound. The topographic ridges go at least 500 ft. up mountain bluffs.

Ice—pools of jade water and dark rifts where plates of ice have broken into leads. We fly into haze and the island is obliterated. Kittiwakes white against dark water. Pale yellow sky against fog. Limestone cliff, vertical for 150 ft. Narwhal country—wide leads.

Irvine Bay, usually no animals here. Round rosettes in ice. Old ice providing breathing holes for walrus. Ring seals abundant here. Good population of polar bears that feed on them. Ice dotted with seals in June almost to Elwin Bay now. Narwhal more dispersed and solitary than beluga.

Elwin Bay. We fly along at cliff top height, back into bay and across river. Belugas to lift in dark water. Many in entrance in shallow water, grays, one rolling in bottom shingle. In little groups of 6-12, a few 2-3's. Streams of Elwin beach follow rectangular lines as do trenches without water.

We are coming to Batty Bay and will continue down to Creswell Bay and back. We'll refuel at a cache. Belugas in black water 6-10. There's a whole house full of belugas—100 or more.

Guillemot cliffs at Batty. Narwhals usually stay offshore but Tom saw a couple stranded. Tom scared off eight bears feeding on stranded animals—eight animals, ripped up by bears, still alive, but chewed on badly. One had its spine exposed. Maybe Creswell belugas are separate.

Inuits brought up from East Baffin Pond to Resolute but didn't like it and moved south to Creswell. Archaeology says thule people once lived there.

Andrew a minister in Anglican church at Creswell. He's taken over summer narwhal hunt.

Fury wreck, musket balls, salt beef cans, house where crew overwintered. They got out with whalers. Strewn all along beach berm, anchor chain, at water lines.

Melville Island at Bridgeport. Wreck, muskets, etc. Boarded up by Canadian National Museum. Fifty-six separate expeditions went out looking for Franklin.

Creswell Bay—Fury Pt. Entering outer bay. We will stay at Inuit Camp. [?]-Fletcher parachuted in to see if DC3 could land and I presume to select a landing site.

We land at a cache of five yellow fuel drums.

John Revanboer, young, affable, an excellent pilot, lands us at a cache of fuel drums at Creswell Bay. He hauled out a fuel pump and filter system that runs off of a battery. He put in 500 lbs. of fuel in a very short time, and we are off into Creswell Bay. It's brisk now. The clouds have lowered and it is near freezing. I find a crane fly walking jerkily along like a six-legged drunk. We take off up bay.

The big bay is choked with platy sea ice, rotting, pools of melt water atop the rectangular pieces and often enough perforated with round holes showing dark water through.

"Another week and there will be 4,000 animals in here," says Tom. "Go along the shore," says Tom.

We cruise 500 ft. over the shore, low-lying mist now and then blotting out our view.

We pass over the Creswell River, jade against brick-colored banks, then again over misty flats, rimmed with white ice.

"This is going to break up pretty nicely," says Tom. "By the time we arrive, there may be 4,000 belugas here."

We turn north and pierce through an opaque cloud and head for Cunningham. Peter Jess promises us dinner tonight. We all wonder how he can be making any money, given the number of visitors he can accommodate. His season is pretty much over by August 5th, when the belugas leave. He's put up a series of sleeping tents now so his people don't have to sleep in the dense bunk stacks he had last year. He has put up what looks like a plastic greenhouse now occupied by artist Mary Valentine.

Lisa Truitt, producer. They are doing *Life on the Edge*, *Edge of the Ice*, *Edge of the World*, etc. Good bunch. Lisa looks at the whales in the inlet and is blown away. Tom thinks there are 900 animals here now.

We set up camp in a light drizzle—then after the helicopter flight described earlier go down to Peter Jess's camp for dinner. I talk to the guests and to Peter's two great kids, Matt and Ted.

The trip around the island was splendid, fairly long. I got sleepy toward the end, but a great day all in all.

The clouds hung low. Creswell was full of ice, and on the way back we flew over the rounded, planed-down land, over the metamorphic section of the islands, where lichens turned the land dark. The land is lined with patterns—rectangles from ice and snowmelt, polygonal ground, swollen knolls (pingoes), and sweeping families of rivulets down the slopes. Now and then an erratic boulder could be seen lying on what was otherwise a field of mud.

We go down the channel of Cunningham Inlet to Pete Jess's camp. We all wonder how he can make it. Too short a season, too big a nut, too few entertainments. Yet Jess is

building a 24-unit hotel at Resolute and talking about helicopter skiing and a wildlife experience at Trulove on Devon Island.

[. . . notes]

Later on, at Creswell, I learn the wellsprings of the sharing system. There is no other way possible for an intimate village such as these are, nor was it possible in our tent even with no Inuits at all. We were much too close, too interdependent, too social.

July 19, 1993

Canada, Somerset Island, Cunningham Inlet

Good conversation over coffee. Tom tells of Holman, where he has a house—a town on Victoria Island, and when Adam, the general fix-it guy and much respected, killed himself with a rifle. Tom had heard a whistle—an air leak of some port, and this was instantly incorporated into the causality of the event—he had been taken, said some villagers.

The comment and problem in town with the thinking people—those who synthesize and look at gestalts of society—is “how boring it has become.” This in the face of this startling social change has left these people rudderless and without a thing to do. Sadness reigns.

Tom talks of his friend, Jimmie, with whom he was hunting that day and who slipped off the ice. Tom lay down on the ice and pulled him to safety and then they went into town to find the suicide and the whistle.

Tom says the problem of assimilation of Inuits into our culture stems from their resistance to changing their pattern of sharing, of entering into the pattern of monetary exchange for things that in their society were institutionalized patterns of sharing. They don't want to put values on things such as the supply of food, and hence the hunter who supplies 60% of the food of a village is technically “unemployed.”

The shamanistic system, with real roles, was not boring.

Tony says the giving patterns are first familial—the old receive food first and then the family, and then others. Tom points out that this is good evolution. I went off on altruism in society and the selfish gene, etc.

It is a gray day. Lisa struggles with the realities of trying to capture this event of belugas flooding into the estuary and the weather of the Arctic and the realities of helicopter schedules. It's a crap shoot at some level. Lisa wisely says, “Shoot a little—get something in the can.”

Today we may put up the tower (we don't). It will go on a bar out by a channel where the belugas pass close below. They don't seem to mind.

Lisa finally concludes to get film coming through the mist, of the animals, and not to pine for the stark, clear days when the sun shines down. I agree—more interesting, more evocative of the place.

I want to describe this place and our situation.

Cunningham Inlet is a two-mile wide slot in the northwest shore of Somerset Island, leading back to the south from Barrow Strait about four miles to where the braided, twisting channels of the Cunningham River reach the sea. Here on the west shore I look down from a bluff 200 ft. more or less above the water. Behind me the land rises still farther up to about a thousand feet when the swelling highlands of Somerset are reached. Riven with winding streams and lichen, gentle contours [?] where the highest

land is a bit over 1,300 ft. Everywhere the rock or soil define the landscape and even where lichen cover is strongly expressed, every feature of the underlying island shows through. Polygonal ground dapples patches of the land of the highland and where water runs in may trickle to the valleys down families of streams as if someone had raked the land curving downstream.

The thousand-foot bluffs and steps that define Cunningham are dark-dun streaked with white snow, a gray cloud deck above.

The water of the sound is still now; the ice has moved away and out where the river meets the sea, cluster almost a thousand belugas, scattered white against the pale, greenish-blue water. They move slowly, some splashing, many accompanied by young who throw their heads and now and then push their flukes into the chill air.

Most are near the main river mouth. A few have ventured up the stream channel half a mile. I can hear the snores and pops and squawks of the animals—the first a sound uncommonly like that of a tuba.

They loll and maneuver in the shallows. Some ranks of a dozen or more big animals move slowly, almost abreast together—big males, Tom says.

Tom will erect his tower on the main channel edge tomorrow—a conflict for the photographers who want no such structures in their scene.

They don't want our camp in their photographs either—206 ft. up the bluff we have a Parkall cook tent. Tom has a tight little wooden cabin (two bunks, a desk, shelves, a Coleman stove, and cooktable, and diesel heater, small windows, and thick insulated walls—all anchored with cables and 30-gallon drums full of rocks and gravel. A sign inside the door says: "Before going outside, check all windows around doorway for bears." The enormous forearm of a bear, just bones and ligaments is in a rock crevice outside. A shotgun is leaned inside, four shells in its magazine, to scare the bears away. We have seen none. I'm in a pop tent and so are most of the others.

The wind picks up a little. Scattered clusters of whales rise and blow a mile out the inlet. Where snow stripes on the defining bluffs stand white they leave reflections so like pillars of smoke that I, at first, puzzled about the source, and then I saw it.

Tom shows me where he will catch whales—a hook right below us and protected by an intervening bar from the main mass of whales in the main river channel.

He will do 3-5 animals—suction cups and dissolvable [?] that lasts 50 minutes.

Later, with the tide rising. If it is too high they must quit as the water over the bar is too deep. Bob and Russ are the capture team—the entire Jess camp is here up on a bench 30 ft. high, watching. Tom seems OK with this. Flip says that today the problem is that everybody passes judgment. Some in the camp may do so. Well said.

About five male belugas hang at the outside edge of the hook—too far out to pursue. They wait. Tom cancels.

Down below us in the hook are several belugas on the shallow bar—almost shallow enough to strand. I watched them for perhaps 20 minutes, focal animal-wise. There was mild interaction between what I took to be a group of adult males. My focal animal traveled very little distance—in two to three body lengths and only turned when another came within pectoral fin distance. It blew underwater in one such encounter.

In deeper water, groups of males traveled together at pectoral fin distance—six to twelve animals, often with backs (necks) arched at the neck and melon and upper jaw continuously out of water—what Tom calls "scanning." The animals in such a rank are slightly in echelon—one animal at another's eye.

These males drive around the bay purposefully, staying together—obvious groups. I can see four such groups right now, all out in deeper water away from the main channel.

The tide is going down and the gravel bars are appearing to define the river channel. A bleuvet tried to swim across in shallow water and for a few moments became stranded. There followed a wild thrashing of flukes, the spray white five feet above the animal. Whack, whack, whack. The animal made it off but so alerted the others that they all fled the channel out into the open inlet, leaving the river vacant.

The males travel in blind ranks, often [?] abreast. They move slowly along at the surface, heads arched up so most of their head and anterior back is in air—scanning, Tom calls it. They are covered with a tan film now, which Tom says will change to white as the two weeks they are here move along. The way they move is unique to these whales—cruising along like logs at the surface, heads bent up. Are they looking into the air? Maybe. I could see an eye from time to time.

Now and then the sounds from the whales rise as if there was some pulsation or contagion to them. Tuba sounds, balloon rubbing, squeals, then it goes quiet for a while with only the odd sounds can be heard.

The tide is dropping and maybe we'll try again. The people from Jess's camp are back. As Tom says, "All you can do is lose." Better to work alone. "You don't know who they are." Will someone pass judgment even though this is benign—suction cups and a release mechanism timed by a life saver. Some of them asked if we were going to bolt transmitters through the dorsal ridge. They know.

July 20, 1993

Canada, Somerset, Cunningham

Last evening I had dinner at Peter Jess's camp, rapped with the visitors, and gave them a talk about dolphins. They loved it. Jess has perhaps a dozen people there, now, sleeping in little tents outside. They include a usual crew of adventurous sorts, the daughter of Dick Leonard of the Sierra Club, and her pal, another teacher. Nice folks, doctors, an ant photographer, a retired doctor now photographer-essayist, and so on. I had three drinks and a glass of wine, a bit too much so I was glad to drink some water and go to bed.

Tom attempted a capture yesterday for Russ's instruments, but the shear pin on the outboard separated—it was nearly gone and the people from Jess's camp gave their glasses and cups back to the rolling bar (hot chocolate, drinks, snacks) and left.

I'm stashed in my pop tent just outside the Parkall and very comfortable up on two foam mattresses. So I drifted off to a good sleep after a lot of talk. Much of that around here.

Lisa and team have lifted off to make some runs over the bay. The weather is clear for them now and no one is on the bar so it will all look natural. I expect them any moment now to make a pass. They work on "Life on the Edge,"—a film.

So there are three teams here with Tom coordinating: Flip and me, Russ and Doug and Bob and Lisa, and then Tom, who will participate in the science involved in the captures. He tells me he's nearly run out of things to do here. The rubbing and shedding is what they do here. No mating, calving, etc.

Peter Jess, a smooth, entrepreneurial sort—bright, politic, organized—came in with the news that three belugas had stranded at Cape Anne—not far west—and that they had attracted a polar bear who had ripped one in half and was eating pieces. Tom will go down for an autopsy.

The helicopter makes passes over the channel just high enough that the belugas stay put. I hope Lisa gets her footage.

Word comes in that four belugas had been found with a polar bear ripping at them over at Cape Ann. Art Wolfe said there were 12 whales, 10 mortally wounded, and 2 were scared and swam off. We loaded the helicopter and landed at Cape Anne on a gravel bar. When we arrived, one was reachable by hook and rope and the divers had to go after the rest who were in three ft. of water or more.

Flip had his dive gear on and went in with a hook to retrieve one old white guy with a terribly scarred melon. Clawed and tattered with bites, a large (10 lb.) chunk of its back drifted on the bottom. Flip and Tom went in after others. Art Wole, wildlife artist, said “When we flew over, the bear was next to a young whale’s head and when we landed it ran off. there were 12 whales aground; only 2 seemed still alive, 10 of which have varying degrees of injury, blood, bites, and two were unscathed. Of 10 that had marks, 2-3 were still swimming.”

Lance waded out and found several were underwater and no longer mooring.

Jeff MacGinnis came in with the second crew. The fog whips by four of the animals now hauled into the shallows.

Tom talks to John, the helicopter pilot. There’s a lot of work to do here and I may have to stay all night. “Bring me a tent and a Coleman stove and some food and a sleeping bag when you come back.”

The whales are tattered with scratches and pustulated cratered skin and one with shallow rows . . .

“The whales are lined up like salmon spawning in a river.”—Flip Nicklin

The whales are now lined up on the shallows, blood streams from their head wounds. Tom says, “the bear normally jumps directly for the head—down into the water and grabs the whale under the chin and bites down.”

Their skins are pustulated and tattered, probably they are ready for the year’s shedding.

Tom: “You eak muktuk and you never get cold.”

“Why did they die?” I ask Tom. I think the whale bites down and crushes the skull. I hope to find out here.”

Tom: “The muktuk is good for you. This is great stuff.”

I try a piece he slices off the skin, blubber and a little of the underlying tissue. It is sweet, slightly nutty, and clear oil runs down my lips. It is tough and requires concerted chewing. I can see eating it would coagulate the mind.

Tom readies himself for dissection and measurements and sampling. He will sample various tissues for pesticides, PCBs, etc., as well as for pathology.

Two of the animals he will sample are grays and two white adults—one a male and one a female.

Tom looks up the shallow channel toward the heaped ice and the far black ridge along shore. “If the bears come back they will probably come from that direction,” he

says pointing down shore. He takes his 30'06 out of its sheath and carefully lays the gun on top.

The whales certainly died quickly. The kill was an efficient one.

A thule site lies up the hill, bowhead perhaps, 70-100 vertical feet above the sea, a house site with bowhead whale bones rising above the sea by the elastic rebound of the earth since the 6,000 ft. of Pleistocene ice left these planed-down hills.

Tom starts his work. He and Russ measure and record from a bleuvet terribly torn back of the head and on the flank. The whole side of the brain case is exposed. I cannot make out any punctures but they may well be there. The pectoral is sliced into three parts, probably by the bear's long claws.

I examined the wounds of all the belugas. All were the same. The whale had been held with claws on the anterior body. Families of five claw marks streaked the anterior chest. Thee bear in each case had bit down over the occiput, just back of the now dead, opaque eye. Two canine wounds ripped in above and two below as the bear took the whale's head in its mouth. Two were below, ___ apart, and then the bear bit down, probably piercing the skull and into the brain (maybe, maybe not). Each was the same. Efficient and likely quick and the ten animals lay dead on the flat.

While Tom and Russ sampled the four belugas—flensed them, opened the body cavity, etc., Art Wolfe and I walked up to a thule Eskimo house site about ¼ mile up onto the island slope. It lay at the mouth of a small gorge, on the flat that had once been the shore, three tiers up from the present beach—perhaps 50-70 ft. above the present shore. It is composed of perhaps six small living spaces reached through crawl holes. Rock slabs seem to have formed the walls and perhaps the floor [drawing].

Art had a tent up there—served us a cup of hot coffee and then I walked back down to the flats to the beach, where Tom and Russ were on their third animal. The wind is picking up. Bob comes in with the chopper, and in a little while we will take off for camp. Quite a day.

The bear took all he could—far more than he could eat, I suspect, and that may be the way of things up here.

I sat up in the copilot's place with Bob the pilot on the way back. He showed me the turbine jet engine that weighs 125 lbs. A gas jet bends around, generates a fire ball that goes through the pipe to the turbine blade that run at 600-700 ft.

I helped bag all the whale heads, fairly covering myself with beluga blood and oil in the process on my coat and boots. So what else is new? The view from the front baffle just flat out blew me away.

We rose off the shingle strand where the belukhas' carcasses lay, carved into sections, blood arcing out of the stream behind the berm toward the main entrance at Cape Anne.

We carried all our gear back to the chopper. The heads and buckets of [?] and bagged samples were put in the locker aft end, gear piled high, the personnel compartment. Somehow three men fit in and I slid up front surrounded by gear, trying to not to block a breather pipe with my foot.

We lifted off and tipped down a little, cutting along the shore at 500-700 ft. We traveled along the shore ice—white, lined with pattern—dark leads and malachite caverns under the higher ice. Old second-year ice formed round niches, polygonal cracks, and in between longitudinal lines of blue cracks.

We lifted off up over Somerset. It was starkly beautiful, a bit like Death Valley—tinted, vacant land, formed by water brushed by rivulets in families following the contours. The shadows of the winding canyons were black, almost purplish blue, the streams green, the sea jade, the snow immaculate white, the land pale brick red or tan, and where lichens grew the land was black. I watched carefully for life—caribou or muskox, but saw none—a moonscape. We lifted over the ridge, past a small lake and down over Pete Jess's camp, and then along Cunningham to camp. Most whales were gone and the tide was high.

We landed not 40 ft. from my tent.

Tom doubts that the bears' teeth broke the skulls of the whales, and I did not see it either, only cleaving the bone will show a cracking or piercing. If not, it's blocking their breathing in a welter of blood.

To go back to that beautiful flight—the light was stark—light hills, deep shadow—like the moon with water. I can't seem to describe it somehow.

Then came the task of getting rid of beluga blood on my clothes, and Russ's and Tom's. We rubbed our hands and blood spots with hand cleaner. Now, temporarily, we smell like gasoline instead of beluga blood.

Muktuk: Tom stood over the beluga, his flensing knife in one hand, with deft strokes peeling back the six-inch-thick blubber blanket of the whale as he explored his way through its body, taking samples of various tissues, kidney, muscle, liver, etc., which would later be examined for chemical contaminants and parasites.

"Want some muktuk?" Tom asked.

"Sure," I replied.

He sliced off a three-inch strip of epidermis bearing about an inch of blubber, handing it to me on the blade of his knife. I took it, avoiding the razor-sharp edge, and bit down hard. The gristly epidermis resisted like rubber, while the blubber ran from teeth with clear, sweet oil and down my chin, where I wiped it away with the back of my hand. (Deep in a beluga dissection, one cannot, it seems, keep clean.)

"You'll never get cold, if you eat muktuk," Tom commented, referring I assumed to living on a diet of beluga blubber and oil.

Killing a beluga: Art Wolfe said "When he first saw the kill, the bear was sprawled across the top of a beluga's head, biting down, "its front legs spread wide, holding the beluga's blubbery skin," and that it had left when the Twin Otter soared over. The beluga had circled the shallow water in a hopeless arc, streaming blood, and soon lay quiet on the shingly bottom of the cove, inert.

I could see by where the huge canines had entered that the bear had taken the whole side of the whale's head in its mouth, its upper canines piercing over the hapless whale's blowhole and the top of its skull and the lower canines far down the side of its head, below the line of the mouth. Families of five claw marks sliced into the whale's blubber from the spread-eagled paws, holding on.

"I don't think the teeth pierced the brain case, but we will have to look later when I clean the skull," Tom commented, as he severed and carefully tagged the . . .

The Annual Animal

Light in the Arctic is annual, and so are the plants and animals that live there. By July, when I arrived at 74 degrees N latitude, there was little difference between midday and 3 AM. It was one interminable crisp day, the ice cover had already broken and the Barrow Strait was full of drifting, rotting ice. Once the winter pack that choked Cunningham had begun to fragment in early July, the whales begin to straggle in. They seem to come from the east first, at the east end of Devon Island, from either the Greenland coast or the polynuas of uppermost Baffin Bay. Thence their move across to Prince Leopold Point on Somerset and then seem to follow a long east-west crack in the ice, or "lead" as Arctic folk call it. They reach Cunningham in early July, when the ice-choking Cunningham begins to leave.

If these whales, and it remains a question in the minds of scientists such as Tom, go across to Greenland then it is across the very top of Baffin Bay, up where Greenland and Canada tip together, leaving only the narrow between them. As fall avalanches toward the north, the whales move south. By October 1st, it is half day and half light and soon enough the sun will go below the horizon altogether, and on ____ later show over the horizon again.

Their first Canadian landfall may have been on the east end of Devon Island. Then they filtered[?] across toward the island on which I stood, Somerset Island, and made their way innto Cunningham Inlet. They had followed an east-west lead along shore that develops at this time of year, cracking along shore like a crack shooting through plate glass. They turn in at Cuningham, the first few appearing at clear water where the Cunningham River enters the sea, while behind them 4 km of ice chokes the mouth.

This coming is no casual thing. They must. They come in yellow with film and covered with old skin wrinkled and pitted, ready, it seems, to be shed. It is a dangerous time.

Many whales cruise slowly along with heads bent up and eyes in air, perhaps to keep watch for the polar bears that have learned to patrol the beaches beside the river mouth. Many, maybe most, belugas cruise with their heads up this way. They are alert in some group sense and yet one can walk the river edge a few yards from them and they do not leave. Yet they are on edge annd any signal from one of them will send the entire collection of animals fleeing to open water. A whale thrashing its tail because the tide had dropped and nearly left it stranded—an outboard started coughing to life. It is usually 12 hours later before they return, tiptoeing back into the shallow rivermouth.

The whales rub and roll over the shingle bottom, sending up plumes of mud. In 10-15 days, the yellow caste is gone, and the big animals are again white, and the shore drift contains skin fragments that have scrubbed free. They go on around to others.

I wondered how these whales-on-watch would regard a human dressed in white—a bear? Would they all panic and race for open water?

By August 24, days have just begun their tip toward winter dark. The whales leave the river mouths and at end of August move north to Barrow Strait and east again, either to winter huddled in an opening in the ice, produced by currents, but sometimes kept open by the animals themselves, rising to blow vaporish breaths into the bitter darkness, or perhaps they move south along the Greenland coast—it is not clear—passing village after village that takes from the passing front of animals.

In early spring, somewhere out in the bitter pack ice of upper Baffin, males and females come together and mate, and birthing of the little, dark calves started the year before, takes place.

They seem to feed most in summer, building up thick blubber for the winter, when access to air locks them to these small patches of open water.

The summer feeding seems most dependent on the shoals of Arctic cod, a fish of the Arctic Ocean and its fringes, and one whose range goes clear across the pole under the ice.

When the belugas feed, they may dive clear to the bottom, which is shallow around west of Somerset, save two deep holes of 450 m, and sonar traces show this is no obstacle—the whales may dive to the bottom even there.

So their year is breed and calve, move west to the leads, enter amongst and under the last ice to the bays and river mouths to shed, and all the while dive to feed as they move along building up blubber, wrinkling the old shrunken skin, and go east, to begin the cycle again. At no place along this circle are they safe—bears take their toll, but more rapacious are the hunters atop the rocks of Greenland coves.

Like prey animals everywhere, the beluga seems to taunt its predator when it can. Tom Smith tells of watching a bear walking along the water's edge, seeming to stalk the belugas a bit offshore.

Tom described it: "The bear walked in the water the way they do, and as the water deepened, the belugas began to swim under the bear. The belugas blew big bubbles that rose right under the bear, breaking all around him. He stopped his swim and looked down underwater, and then dove a little on the circling belugas. The bear surfaced and swam on again in a straight-line course."

The tower is all but complete now, out on the bar at the largest tributary of the river, right alongside water now dense with whales. Sometimes, for some reason, they begin thrashing out there and the river surface turns to white.

Dinner's over. I give another talk down at Jess's and will charge him a bottle of Lemon Hart rum for camp. Works out!

I go to my tent and read an article about Max Dunbar. He has a piece in there about parsimony and the impenetrability between levels of organization in nature that I must read.

July 21, 1993

Canada, Somerset Island, Cunningham Inlet

After breakfast I walk down to the edge of the inlet. It is full of whales. Out on the spit at the channel's edge, Tom and crew have erected a tower of aluminum pipes and braces about 15 ft. high. The whales pay no attention to it, now that the cable stakes have been driven and the noise has stopped. The whales line up in the swift outflow of the river, facing upstream. The closest are 15 ft. away. I can see their tightly folded tan skin, I can see their little dark eyes as they throw their heads free of the water. They are arranged like spawning salmon, their smooth, bulbous heads above the roily water, dozens and dozens and dozens of them, their wet melons shining in the low sun. They move and shift and call and flip over and stand up and circle each other.

They whistle, long wavering sounds. They squeak and bleat and especially pour out long, popping snorts like a horse whinnying and punctuating it all are their breaths. Just now a whale emitted a train whistle—the double note—no doubt about it.

[The following two pages are all wet, so bear with the transcriber!]

There is social structure here in these bands of animals. A group of about eight gray whales, the juveniles [?] in and behind a long rank of a dozen of the largest animals, the males in their segregated ranks.

I pick up a long strip of skin $\frac{1}{4}$ inch thick and 12 in. long from the water's edge, a shed fragment of old skin. Doubtless the new white skin will soon enough clothe these animals in pure white. It is limp and floppy, torn loose as a whale rolled and dug in the stony bottom.

Their bulbous heads are lined up like a row of floats in the water, hanging in the current.

Tom says: preferred habitat in winter 4-8/10 ice in winter.

Now and then one rises up until . . .

Perhaps 1/20 of the high Canadian Arctic population of whales comes in this bay at once. It is the wildlife scene of my long career. What words should I use—pageant? No, that speaks too much of banners and caparisoned horses prancing—an event of humans. Above all, this is not an event of humans. We have no real place here.

In fact, I have just walked down the gravel bar and into a scene whose parts were assembled far before humans penetrated here. The players are the turning of the Arctic year, the whales, and the bears, who stalk along the gravel bar on which I stand. They each know the rules of the equilibrium between their two species, a poise that is so delicate that signals quite beyond my ability to detect them, can set off a reaction.

A case in point. The channel is filled with 250 animals lined up, wriggling, tossing heads, jammed in, stationary as best they could in the current. Tom has in his hand a hydrophone. He walks a yard out onto the shingle and places the hydrophone in 10 in. of water. Instantly, there is a thrash from a group of old males a dozen yards away. They turn in haste, pumping hard and are gone, out into the open bay. The other whales farther off start, but do not leave. Was that little splash a bear's footfall?

The barrier between air and water was momentarily breached. What did they hear? Or see? The river was full of noises. River rushing, animals rolling, a blizzard of their sounds. What could they hear? How could they see a dozen yards into that narrow wedge of shallowest water. How little we know. How crudely do we guess at their world!

Yet, this is no pageant of nature. It is, instead, between death and necessity, an equilibrium built between bear and whale, each animal feeling the boundary for an advantage that almost certainly I have no way to sense. It has, I am sure, been this way far back in time.

[rewritten] This is no pageant of nature. That's a thing of humans and caparisoned horses. This was between just the bear and the whales, and it was one of those equilibria we find so hard to understand. Death here is near but the event so normal, so much a part of life that fear may only enter if an attack actually comes, a warning flash, an immediate mobilizing of defensive reaction, the flight. Fear could not otherwise be spent so unwisely. Yet, the two parties probe the edge, one seeking advantage, the other normalcy until one relaxes in unwariness, or the other makes a feint across the invisible line.

July 22, 1993

Canada, Somerset Island, Cunningham Inlet

Flip and Doug walk across the flat to the tower and take their places inside the canvas shelter at the top. They unzip the canvas ports and can look down right on top of the whales. I will take my turn later when the photographers have had their fill. Tom says: "Remember when you come down, zip the ports up or it catches the blast and may damage the shelter."

I walk back down along the channel full of blowing whales, lying still, or moving slowly this way and that. They rise now and then, throw their black-edged flukes, expose a curled pectoral fin, or stand up in the water, sometimes clear to the level of their pectoral fins. I scale the loose rock of the hill to my tent. I crawl in and zip up for a nap. The wind perks up as I read my book (*Man and His Gods*) and then doze off as a cold rain sweeps through. The tent seems dry enough—no drips—though I have little faith in the floor would stay that way, should standing water get under it.

About 4 PM, I put on foul-weather gear and make my way down to Peter Jess's and Judy Jess's Arctic Watch Lodge, where I will speak tonight about dolphins.

A wonderful shower, clean clothes. I take Ted Jess a stromatolite I found and I write up these notes.

Tom may be down there about now trying to catch and instrument a whale for Russ Andrews. I've had a chance to talk to him and he is first-class, I think. He's been around—navy, a saxophonist, very sharp, and very much tempered and balanced. He works hard at his equipment and at various camp chores. I don't think suction cups, which he will use one one test, will work however. The belugas are too used to scratching themselves on the bottom.

So, I left those two guys out in the blast on their tower cubicle, fading in and out of view in the midst, as I walked along inside long johns and flannel shirt, down jacket, and foul-weather gear.

These notes do lose continuity as various visitors stop by to talk.

Quote of the morning: "We've got nine more days of summer," says Tom. It could be spitting snow by August 5th."

Four belugas have stranded on the flat below camp, three big males in a blind channel left by the lowering tide and a blue calf out by the observation stand.

Lisa and Doug were photographing the three big ones and taking "wild sound." When they had finished, I shied a flat stone into the water, ten ft. from them. Their reaction was instant and large, as if a bear's footfall had hit the water. They thrashed and rolled and threw their heads free of the water, peering with their little, dark eyes.

I wanted to see if I could see them deform their melons toward the site of the falling stone, but I could not be sure they did it. Perhaps—the tops of their melons looked flatter, but maybe not. Russ will arrive and do his thing soon. It's a grand opportunity, though handling these big boys, even in this shallow water, is bound to be a handfull. They thrash and throw their heads, sending trains of waves against the bank. They're almost aground now, though there is enough depth that they can still twist around and maneuver stome.

The mosquitos attack even though it is not far above freezing. Boy, am I wrong. 9 degrees C.

I walk across the flat to the tower. There is a gray juvenile there, flapping on the shingle. It cries piteously in fear as I approach, and literally shakes as I walk around it. Its blowhole runs with a sheet of mucus. Blood runs from a dozen shallow scratches. Nonetheless, the shingle under its tail is red with blood.

The big males thrash—"and the ceaseless sea surges against the shore." (I pose for a picture for Flip. It's for the "On Assignment" page in the magazine.)

I climb the tower gingerly—I don't much like ladders these days. I didn't go through the hatch but sat on the platform beneath and watched the scene. The view is one

of the most remarkable in my experience as a field biologist—1,500-1,700 whales were lined up cheek by jowl into the river mouth and 200 yards or more along the beach, most propped on pectorals with round melons in air, others rolling and throwing flukes, a few stand up to the flippers, heads erect. The sound is continuous snorts, long, long whines, belches, tubas, bubbles, clicks, squeaks. The spawning salmon image occurs. Only these are whales. Tom calls them the “Salmons of the Arctic.” Very fitting. Big, white, docile, give food for the asking.

Russ catches another and Tom puts on the tail noose. The big, white animal settles down.

Tom has been given permission to work here but no money, so we [?] his camp and pay the freight. I feel for him. His work is excellent, groundbreaking, solid stuff, and he gets little credit from his bureaucrats. So he does this, and we break his peace. Tough, almost poignant situation, but one I'm very familiar with.

Later Tom and crew made a flight to site north of Wadworth Island on Peel Sound. We will strike this whole camp—taking a day—and fly SW by Twin Otter and helicopter. The strip is so short, it can land but not take off with a full load. It's a place where belugas come in a very small bay at the edge of the ice. The whales come in in numbers and can be seen in fairly deep, clear water.

While they were flying, I walked over to Jess's camp, and talked to the visitors. The Jess's have been very gracious indeed and fed us a steak meal with drinks. We later walked back to camp and slipped in our tents.

July 24, 1993

Canada, Somerset Island, Cunningham Inlet

This morning we rise, have a pot of coffee, oatmeal, bacon—Lisa and crew are wrapping up their filming. They've been getting a lot. Doug Allen has been up the tower filming. He dropped a lens in the water, but the only glitch so far in a very complicated operation.

Russ Andrews tested his heart monitor, and then a suction cup attachment device—and things work.

Today we will listen to the whales and record them. For me a few minutes of listening will do. I need to compare the underwater to what I could hear in air. Then I will be ready to move. I must say my inactivity is a bit of a drag. It's the bears that restrict. Here at Cunningham they may be avoiding the place because of all the people. But at Wadworth maybe not.

So the day starts. The day clears.

I climb the tower and make my way clumsily into the shelter at the top (Tom mother-hens me up). We sit on boxes and barrels, surrounded by a tangle of cameras and recorders.

Below us are ranks of white and gray belugas. Tom points out the age classes to me. Neonates are gray and about 40% the length of mom, to whom they stick like glue, almost always in contact, sliding back over her body. The yearlings may be darker gray than neonates.

A nursing bout by a yearling takes place right below us—a brief butting of mom's mammary area, who rests quietly.

I put on the ear phones. Immediately I realize that many of the sounds I heard in air aren't what I am now hearing. The underwater sounds are click trains, low, desultory, and chirps, warbles and whistles—in other words, most of these sounds are made by the

MLDB complex and coupled to water, whereas the stuff I described in air is burst-pulsed stuff, probably significantly made at the blowhole lips—airborne and hardly coupled to water.

The whales are visibly turning whiter—the yellow glaze disappearing. Insistent click trains and long, wavering whistles. Not an inordinate amount really considering that there are some hundreds of animals within earshot of my hydrophone, which is buoyed out from the tower base 40 ft. or so in 1-2 ft. of water, or so. In front are animals lined up in the current stationing, not all quiet, some pump slowly with their flukes and then where the water is quieter the formation is less obvious and animals turn and swim across the ranks, babies and yearlings circle and rub on mom, and big, bulky old males with neck ruffs of fat move slowly. They are essentially all in the river outwash—in low, salty or fresh water and their skins are hydrating, I'm sure.

In shallow water the whales may roll on their sides or even onto their backs. They show their pectorals often and in older animals one sees the rolled-up pectorals at the tip as if around a newspaper. I'm impressed with the time here the whales spend resting on their peccs. Does this cause the flippers to roll?

I clambered down gingerly, kissed the shingle, and walked back across the flat.

July 25, 1993

Cunningham Inlet

Camp breakdown day.

Everybody helps to do all the needed things we have to do to make our camp into a cache that remains here and other sling loads for the stuff that will go over to our new camp at Wadworth.

My major tasks were setting a permanent cache to leave here and getting all the kitchen supplies boxed and labeled, and then Lisa and I emptied the ice hole up the hill of all the cheese, salami, bacon, milk, etc.

Then I cooked dinner—a stew—no pot had the proper lid, but I prevailed, I think.

Tomorrow we will have an Otter and a helicopter.

The stew was good. My meat could have used a little more time, but everybody ate up hearty, and then we took down the Park-All. It takes about half an hour, and then everything is rolled and placed inside the big, wooden floor sections, which fold over on themselves to make a long box.

I'm sitting out against the wall of Tom's wooden cabin, which is snug, two bunks, a Coleman stove, a worktable, a diesel heater. The tide is mid high. Belugas are scattered along the shore below me—perhaps 30 of them, milling and moving slowly. The biggest group is nine and it has four young and a sub-adult gray. Over in the river mouth there is the continued roar of animals rolling, thrashing, swimming against the quite swift current. When the belugas leave, the river makes very little sound.

Earlier I watched similarly scattered animals to those below me and repeatedly I could see them blow underwater, producing a ring-like boil. It was common. Now for some reason, even though the animals swim in about the same places, I have yet to see it in this observation session.

There is head slapping between a dark little young and a white adult facing each other. Maybe she's mom.

An Arctic hare lippety-lopped through camp—a gawky, long-legged juvenile.

[Drawing of area.]

July 26, 1993

Canada, Somerset Island, Cunningham Inlet

There is a very dense group of 12 belugas moving slowly together. They are in three ranks, almost touching side to side, and with head over flukes of the rank ahead. Since the heads are up and they don't throw their flukes, they can move this way, one to two knots at most.

There are lots of blowhole sounds—a whine with the interruption of bubbles. I still see no underwater blows. Chip tells me his team is doing a time-lapse of the tide coming in—nine frames a minute.

The others have gone down to the Jess Lodge, but I'll stay here and read and then, doubtless drift off. I'm tired.

Later, I lie in the tent with my book listening to the river. I'm about 300 yards away from the main channel—up a couple of benches to a shingly bench where our camp sits. The whales in the channel make a sound like the rapids in a river—white noise. One can sometimes hear the thrash and beat of animals, but usually it just roars like water. Whale voices rise clear above it. The deep tuba sounds, the long, wavering sounds like someone learning to play a trumpet, now and then higher sounds and blows, the hollow sibilant rush of exhaled air, now and then a tail slap, a blat, a snore . . . rain taps ever so lightly on my tent. I hear footsteps outside, the readjustment of tarps over our gear, the rip of tent zippers. Tomorrow at about 9, we load for Wadworth Island.

The hope is to move camp to the coast of Somerset Island near Wadworth Island on Peel Sound. So a Twin Otter flight was taken after we broke camp. Flip, Doug, Lisa went. I was to go on the next flight, but the weather turned, and we could not get out. Clouds and fog here and the three isolated down the coast with rather little gear and not a great deal of food. We get another load of gear in so they are OK.

I walked up to Jess's camp and stayed on for dinner and they set me up with a nice bunk, sharing a room (canvas) with Pete's dad, Edmond. We shared WWII experiences. He was a navigator on Wellington bombers.

July 27, 1993

Canada, Somerset Island, Cunningham Inlet

All day we wait for the weather to break. It doesn't. On and off low clouds obscure the headlands and a very light rain spatters. A bearded seal comes upon the beach—it's twice as big as a ring seal. A lone musk ox grazes on the vast beach of the inlet. Ted Jess catches a lemming—a feisty little ball of gray-brown fur, trimmed with sienna around the belly. He bites Chip who tried to pick him up. The little fellow shows his displeasure by emitting a rapid train of sharp clicks.

I give a nearly extemporaneous talk on Arctic paleontology—geology, which seems well received.

We are hustled out to the riverbottom strip for an attempt at Wadworth. We swoop down over Flip and Doug standing by a pile of gear. They wave as we make a pass and pilot Monty decides the crosswinds are too high for a landing. The spot is on a shingle beach. They like a field at least 600 ft. long, and a bit better, 1,000 ft. long, for a loaded Otter. Unloaded, 350 ft. is minimum.

It's a vastly lonely spot. Bleak, treeless hills, gravel benches, and a great, winding river with not a bush on the banks, just shingle, and nearly offshore is ice, and far off the

dark land of Prince of Wales Island. The flight took us over the Somerset landscape—first sedimentary terrain, on the SW end of the island. It doesn't erode so clearly or plane down so nicely. It's rocky and rough.

A dozen musk ox graze in the river bottom of one big canyon—yellow-green with plants and looking rich . . . black shapes against the yellowish green. Our pilot, Monty, a blocky, quiet-spoken, perhaps Irishman[?], makes the decision. Too dangerous to land. The crosswind is pushing 20 kts., and the runway at the lower margin of capability. Two passes and we leave, heading back fairly low over the island—the undulating, vacant, ice-scarred land. There is so little vegetation that the soil decides color.

No belugas, though I saw some farther north. Tom says they'll soon be there.

The metamorphic rock—dark gray, the sedimentary tans, reddish rose, the streams flashing like winding mirrors. We cross Barrow Strait and into Resolute and hole up at the Polar Shelf facility—a fine, clean place to stay—dining room, reading alcove, with a lot of scientific papers from all the people who have worked out of Resolute—a pool table shuffleboard, a TV room. I watch the Blue Jays take the Orioles. Tom finds me a sleeping bag from the gear storehouse, and I'm set. Mine is at Wadworth with most of the rest of my gear.

July 28, 1993

Resolute Bay

We wait and the wind picks up. Tom makes a couple of anchors for narwhal capture. They are caught in a nine-inch mesh gillnet, set net. I write postcards, snooze, wash my little bit of laundry, visit the store, eat, BS.

We don't get out today. Good book on Canadian Arctic—*Canadian North of Sixty*.

July 29, 1993

Yesterday we didn't get out, but this morning in the middle of breakfast the word comes. Borek has shoe-horned us into a full schedule so we push aside the last pancake and pull our boots on and run for the planes.

Lisa, Russ, and I squeeze in behind the kayak and we are off.

Out over Barrow (it's become old hat when I leave off "Channel").

Ice seems solid off to the west. Past the island off Resolute (Griffith Island). Tan land striped with snow in clefts and canyons. The water is still and reflections of the land are snow striped and perfect.

Out in the main channel, rotten ice covers maybe half the channel. There are pale slicks between the fragmented ice—like paths of haze.

I can still see pale-green pools on the rotten ice, and the long fracture lines of earlier splitting.

The wind, at least this wind, seems not determinative. The splitting must come from upwelling or currents or ice pressure from the west—the circling of the ice on the great ocean. You could find your way through it now with a small boat.

Out northwest, toward the poles, first the magnetic pole off Melville Island and then a few hundred km farther on the rotational pole itself out on the bleak ice plane.

Clear, dark water below us now, then the northwest corner of Somerset. I can see Prince of Wales Island on the horizon now—a dark, flat band like the rest, planed down

flat by the ice cap, which is now gone. Tom tells me Prince of Wales is a rich place—bird flocks, musk oxen, bears, seals, walruses, and the rest.

I talked last night to Tom about an early spring skiddoo trek he took—4,200 miles of transects with Jimmie, his Inuit friend.

Tom got money to do a mammal survey for where a gas pipeline was projected—back and forth on a grid over the ice. Ring seals were scarce to the west and picked up as they moved east toward Cornwallis and Somerset islands.

He describes two encounters with polar bears. In one case one stuck its head in his tent with him inside. He killed it with his pistol—a photo shows the bear lying slumped outside the tent—a huge, white mound.

Then he tells of Jimmie in pressure ice sensing a bear behind him. He whirled and stuck a gun barrel in its face and it too began to die. Jimmie then shot off its feet in his anger and he left it dead. Another of these unsung odysseys.

We circle and land on the totally inadequate beach (to my untutored eyes, anyway). Russ and I could see nothing useful to land on out of either side of the plane and not much more once we were down. The Twin Otter can jump into the air. The runway was 350 ft. long—600 ft. is considered adequate.

Flat calm as we come in. Who knows what weather we will have to get out four days hence.

Are Doug and Flip chewing us out for our food and TV and beds? I'll bet not.

We begin our stall, flaps go down. The water below us like glass, the low sun reflecting. The beach rushes under us. The tires clatter on the shingle. The engine roars as we brake, and in moments, rock to a stop near the fuel barrel cache. The heavily clothed figures of Doug and Flip come up and open our door. We are down.

We unload and stand aside as Monty taxis down almost into the water and roars by, dancing and faintly bouncing into the air. He is off over the gravelly riverbank. He turns and comes over, low lights blazing, and is gone to the south.

Tom says: "This is a bear highway. We have to make camp out of the way. Up on that bluff looks good," pointing to a bench about 50 ft. above sea level and a ¼ mile back into a barren river canyon. A beautiful 75-yard-wide stream of cold meltwater sluices by over rushing rapids and into deep pools before sliding into Peel Sound. Later, I'm sure I saw the dark forms of, to my California eyes, huge Arctic char, switching and stationing in the swift, clear water. They reach 30 lbs. or so, reports have it.

Everything for the camp is loaded in the ATV trailers and they arrive at the bench where I await to help unload. It's an impressive pile—two big double-walled field tents, 10 x 14 or so—one for gear and one for cooking.

Tom asks us to concentrate our tents together so if a bear enters camp he will not get lost among the tents.

Everyone falls to with a will and soon enough camp is in place. I put up my dome tent and arrange my gear inside. Very cozy! I have a bag for gear related to appendages—socks, hats, gloves, bootliners, and another of the mid-body—it splits out about half and half.

The TV crew have their work cut out for them. They set up a big tent alongside the river and deal with bugs in their equipment.

The camp consists of two, double-walled long houses 10 x 14, everybody in their personal tents, an elegant john-in-a-tent, and a long, triple tent for the TV people down by the river. Tom prepares apple crisp and a big baking pan full of hamburger mix.

Now we wait for the arrival of the belugas to come down from Cunningham.

I spent a bit of time today photographing, using my new 70-200 zoom telephoto and other lenses. The plants came first—the drabas are in seed now. There is a plant that has a paired ovary like a *Primula*—or is that a characteristic of a saxifrage, I seem to recall.

Then there is a low, spreading plant with scaly leafed stems that are erect. In these, many had turned scarlet. It had a nodding bell [drawing].

The Arctic willow is with cottony seeds now. The little water seeps and pools are rich with moss, and a yellow-green alga streams along the slow streams.

I walked down to the sea edge (Polar Bear Highway). Flip was there with the rifle getting his beautiful Easy Rider outrigger kayak together. Tom says we are to go to the beach together and to have a gun at hand. He emphasizes that two guns in camp are enough. The greatest danger is for people to shoot each other, rather than to worry about bears. I'm sure he's right.

Tom also told us of an old Inuit lady who whirled on a bear and hit it square in the forehead with her hatchet. She then announced, "I'm not strong enough to pull it out—somebody else do it."

So dinner comes along. It is calm and warm, dinner is cooking, we have a shot of Peter Jess's rum, and all is well.

Tom is a helluva cook—very tasty hamburgers, apple crisp, scalloped potatoes, a shot of rum. He slices himself off a piece of the muktuk he has brought along. I take some.

The dishes done, Tom wanders off down to the beach. The sun still rides high; it will be a while before it touches the horizon as it goes round and round. The breeze picks up a little and it chills down, after a balmy day with us wandering in shirt sleeves.

Tom comes in with a big safety pin in his wool sweater—the sign of an Arctic man, he says. To pin his parka to his shell. I guess I understand.

"You know," Tom says, "that sense you have that a bear's behind you?" as if I did. I didn't but I could imagine it . . .

July 30, 1993

Canada, Somerset island, near Wadworth Point

It's after midnight now. I rise to go to the bathroom, a little tent and inside a bucket topped with a seat. Fall's on its way. The sun is low in the north and my shadow falls long against the gravelly rise of land behind camp. The light is rose-colored, tinting the ice fields offshore, making the dark hills up canyon lit with orange light on their promontories. It's still out, so the wind off the ice does not chill us unduly. I roll a stove to shore up a tent stake and find two tiny black spiders underneath.

I think, "If I were to travel north, and not too far as travels go, I could level out the path of the sun and when it would no longer dip, I would stand on the North Pole, out there to the north on the bleak ice sheet, which I can see from the mouth of my tent. I know such a trip is across wrinkled ice, from the spinning of the Arctic Ocean itself, which piles hard against the shores of the Canadian high Arctic islands, NE Ellesmere, Axel Heiberg, and others.

Much later I get up again and head for the cooking tent where I hear voices. Coffee's on and strong. A hot cup stirs me awake.

No whales yet. Pack ice, fissures and cracked ice offshore of 100 yards of open water, clear blue. I look both ways, carefully scanning the beach for bears—bear highway, Tom calls it. Flip is there already rigging his elegant kayak and Lisa, Doug, and Chip are at their big instrument tent, struggling with their gear. They are having one problem after another—the monitor is the wrong color. Later, their camera housing leaks and nearly gets their camera. Lisa hauls it out just short of disaster and then Doug tries to locate the leak—O-rings? stuffing glands? I left them still at it.

It was a lazy day for me, though the others kept busy getting their gear in order. Flip and Doug put on wetsuits and swam in the crystal clear river. Flip says it is full of char—most 15 inches or so, but two big ones twice that. So me seeing dark shapes switching is on the mark.

Flip and Doug both talked of the halocline—where the freshwater slid over salt—wavering, hazy. Below Flip talks of comb jellies and isopods.

I did a little birding today—out looking at eyestripes and wingbars and similar identification marks. Three semipalmated sandpipers walked the edges of a sea pond—probing, probing, and pretty fearless of me. I walked within a dozen feet.

A glaucous gull circled—large, nearly white, heavy bill, pale gray cape . . . predaceous, I'm told.

Tom says there are ravens here—imagine that. He says dumps draw them. How does that bird manage such a range and such thermal difference. Tom says they will kill seal pups, and peck holes in condensed milk cans. What a bird!

Chip had been south of the creek looking for musk ox, and I took the chance of going in the freight canoe when we had to pick him and his ATV up on the opposite beach, to get him across the river.

The canoe is big—it will hold four 45-gallon drums of fuel. He uses it for caribou hunting and much else.

I hopped in and we cut off along the shore and out along the edge of pack ice. I could see from the side, instead of from air, the patterned ice. The ice is divided in low, flattened hummocks, undercut by wave action into low, broad, mushroom shapes—in between are melted pans filled with fresh water and greenish.

Below one can see a haze of ice below the surface—I suppose about to rot and break.

Later I walked the cobble beach and heard a rushing splash behind me and offshore a bit. I turned and it was a little berg 12 ft. across and perhaps 6 ft. above water that had been undercut and finally turned turtle—in just a second or two—no warning. A canoe near it might well have been swamped or dashed to pieces.

I forgot to mention that we brought back an ATV in the freight canoe—rolled in sideways on planks, to rest at an angle, front wheels on the [?]. It was rolled out on the same planks at our beach.

Some guess tomorrow the beluga will come down from Cunningham.

I'm reading *Man and His Gods* by Homer Smith. What a human saga our religions have been, and what remarkable things we have believed in and run our lives by.

A good curry dinner. The sky is clear but hazy and the air nearly calm—restless—and the sun warm so long as the breeze does not come off of the ice-filled channel.

The sun is on its circle—now from the WNW, 20 degrees elevation, more or less. Yellow amber . . . at early morning when I first arose to relieve myself it was over our palatial outhouse. ESE and somewhere near the same elevation, except the bluffed hills made it seem lower.

July 31, 1993

Wadworth

No whales today. A nice clear day at the start with the light breeze off the island behind—and so it was shirt sleeve weather—maybe 58 degrees F. or so at times. Toward afternoon—it's now 9:30 PM—it clouded over—a deck at 2-3 thousand, stratocumulus, but still rather warm.

Russ dug the considerable hole and I built the box for a frost hole. He dug down to permafrost—2-3 ft. in the cobble and gravel of an ice edge channel. Then Tom came up to instruct us and we packed it in lichens (reindeer moss?) and then dirt. It has a double door and will hold a lot.

[Drawing with caption: Inner door out of driftwood and some old sheets of plywood]

Tom located a place where he can route a 550-ft. runway. Tomorrow we clean it of stones and fill the snow channels.

A great pork dinner tonight with three kinds of chocolate frosted cake and the last of the rum.

I wanted to describe our scene but first Lisa and Doug wrassled with a leak problem on their underwater video housing. Every once in a while it leaks. No real solution yet, though the last two times they tried it, it didn't leak. They're calling in parts.

I'm reading *Man and His Gods* and they've just arrested Galileo for proposing the heliocentric universe. The church did not like it. They then had seven equal planets instead of the earth in the center—one Jesus, one true god, etc.

August 1, 1993

Canada, N. of Wadworth, Somerset Island

It's turned bleak, though relatively calm. All the light wind has to do is come off the ice-choked sea instead of the hills. Up above, if the sun is out, it may reach 70 degrees F. I look down from our gravel bench and the sea is mostly ice—the pack goes as far as I can see, though shot through with channels.

We've seen ring seals out there but so far, not bears. Tom reports a sleeping pit of a bear, up above us in the hills. He says he thinks these let the bear get comfortable—provide a place for its hips.

Today was airfield day. Tom had located a fairly rock-free bench back in the canyon behind us, perhaps $\frac{3}{4}$ mile from camp—a long, undulating bench of fairly fine-grained material, only a scattering of boulders, about 500-600 ft. long from a dropoff in a bend of the river to a curve in the next bench up. [Drawing]

The airfield had a series of shallow channels across it that we filled. Russ brought the ATV, a trailer, and some shovels up, and we found a place up at the beginning of the upper slope where we found elegant loamy soil—it cut like cake. Filling the trailer we then upended it over the ditch, and then we spread it and Tom flattened by driving back and forth with the ATV. Voila, an elegant patch. It didn't take too long with all of us shoveling, including Lisa, to fill everything. We pried up the big rocks and filled the holes and Tom put a series of white plastic bags to mark the course and there was our

airfield. A lot better than the beach, which the pilot, Monty, would not use for takeoffs, loaded.

We hope he will like this one because if a Twin Otter can come in and take off loaded it will save a lot of money—moving the fuel in to make caches is the expensive part. The helicopter can convey very little compared to the Twin.

So we're now ready for a flight test, which will come in when we pull out, the 5th or the 7th.

So now we wait for the belugas. I look at that ice-choked sea—at 4-5 degrees C—and realize the environment these big animals inhabit.

Tom says that in a couple of weeks, there will be a freeze—a light one that will come and go on the sea. And then comes the fall—to the first week in February—everyone goes to sleep—travel by moonlight in December through January—the most immobile time of year. Most babies are conceived.

Hockey has become big. TV arrived in 1978. Tom came back in 1980 in Holman, and he was met by full dress hockey players.

So, we wait for the belugas. Tom and Flip will go off by helicopter do a survey of beluga and narwhal abundance—around Somerset. Then to Devon, work locally. He will work at the S. end of Peel Sound. Then we head off to Creswell Bay to catch and tag narwhals and belugas (5 narwhal and 3 belugas).

Our camp sits on a gravel bench perhaps ½ mile from the water and up perhaps 50 ft. above sea level. Behind us the rounded hills and bluffs of Somerset rise. A fine rushing river curves by a bluff just south of camp, where an alluvial bluff slides into the riverbed. Our camp has two Parkalls—or the smaller version, a tented john, and our separate tents set so a bear, if one wanders into camp will not get lost among them. Tom fears that someone opening a zipper will attract a bear—so stay inside while he deals with the animal.

The rain patters very lightly. I've ditched my light summer tent and feel grateful for my double down bag and two layers of foam mattress.

The river arcs around in a big bend and thence into the sea. It seems to keep the ice out a little. That's where we expect to see belugas arrive.

The sky is lined with gray clouds, Prince of Wales gray and low, the ice a rough jagged sheet. Does Peel Sound ever become open water? 4/10 ice at end of August sometimes.

Out in those bleak precincts somewhere are the belugas picking their way south in the leads between the ice. When the wind here [?] our hill shifts from off the sea, a deep chill settles over our lovely camp, the exported climate of the beluga's world. When winter comes the air the belugas must breathe will dip to 40 or even 50 below zero. Then the to me icy water must be protective to these whales.

We wait, we wait for them to appear out there. In their world but surely not mine. My wrap of two layers of down works where I do not thin it too much, or extend my arms outside into the cold, or write without my fingers being encased in double gloves. What does the beluga feel? He seems so at home where I have watched it.

August 2, 1993

Camp, N. Wadworth Island

Tom and Flip were to go off today by helicopter for a circuit around Somerset and on up to Devon Island with the goal of making counts of various marine mammals—especially belugas and narwhals.

But after they'd called in for the helicopter the weather began to close in around our camp. On the radio we heard it was snowing at Resolute. At our camp the clouds descended, long gray banks offshore and it began to rain—not heavy but continuously enough that I worried for tent leaks. A wet sleeping bag is not a good idea up here. The wind came in cold off the sea and then shifted from the canyon. It picked up and up, pressing tents down, including mine. I checked the stakes (inadequate at best) and piled on additional rocks and did my best to keep rain from running under on top of my ground cloth.

We congregated in the big long house where Lisa whipped up pizza for us all. I read my *Man and His Gods* book and the wind grew worse, pummeling the camp in a constant slat and thump of canvas and a flutter of thin nylon. I checked again. A pool in one corner but no damage and cold, cold, bleak, the sea gray under the cloud deck and no belugas. Needless to say Tom and Flip were grounded.

Both have now retreated to read in their tents. I sit in the long house hoping I hear the wind slowing a little. My old tent is hanging in there and the rain has stopped, but it is possible I may have to move inside the equipment long house if something goes. I go out and replace all my ridiculous small tent stakes and retrench everything and hope for the best. So far I'm hanging in there. The rain sheets horizontally across the face of the hills now and will soon be on us I expect.

Tom makes date squares and we listen to the wind. Lisa reads *Wonderful Life*. I'm finishing *Man and His Gods*. Russ has something about pioneers, and Flip and Doug are in their tents. I wish my feet were a little warmer but basically I'm OK, and this stuff will in time abate. Maybe our wonderful Arctic sun will shine through the fog and it will clear and calm. I'd like that. Damp gloves and cold feet are not my favorite things.

Finally, as the pummeling continued and the rain became near horizontal, I decided to move into the long house. Fine drops were going up under the tent fly and through the mesh windows. Mine is a summer backpack tent and not designed for this stuff. I found a place on the tent floor where the stones weren't too close together. The two foam mats helped, but not for the worst of them. So, I was ensconced in a perfectly dry tent and could listen to it bang away without concern for my duffel and bag.

A great game of hearts and then to bed. Tom had cooked up smoked meat and cabbage. Now if a whale would show up.

The last happening of the night. Doug decided to make death masks with aluminum foil. We pressed squares to our faces and left a note to Tom to guess who it was (he got everyone wrong).

Calm and hazy this morning. The sea is glassy flat and no belugas yet.

I flake out after breakfast, not having had my full ration of sleep—and try to fix the tingling in my fingers. Cold? Carpel tunnel syndrome?

August 3, 1993

Canada, Somerset Islsand, Wadsworth

I have a theory for how these big subrectangular cracks developed. There are big beach berms—high, wandering—a topographic line down an old beach. Then more or less at right angles to them are eskers—sub-ice streams dumping out, that are long, sinuous mounds of badly sorted but often quite well-rounded rocks. The land rose under elastic rebound making the families of beach berms.

The eskers tumbled and rounded rocks and were quite swift so they carried fairly heavy rocks and rolled them. Then as ice melted the eskers came to mark paces where the

ice thinned, dividing the ice over these extensive flats into blocks, squares, rectangles, and sometimes the continuing melt stream cut into the eskers so they left a berm on each side. [Drawing] (This can be explained differently as an ice wedge—a freezing phenomenon.)

(I've observed these berms and they aren't always on both sides.)

The eskers do not always go down grade but will swoop into hollows and up over low hills.

Finally, outwash rivers cut into the landscape gathering melt water and taking it to the sea as the ice retreated. [Drawing]

The rocks in the esker tracks can grade downward in the V-shaped water courses—as if the small stuff had washed away leaving larger rocks. These big ones are often pretty well rounded, tumbled, I figure in the sub-ice esker streams [Drawing] (It's probably a two-step process—first running water from melt then freezes to push up the berms.)

So we settle in and wait. Waiting's not always easy, but the wind and the rain give us much to do. Flip and Tom wait for the weather to break so they can take their flight.

Doug's out on a walk up the beach, carrying the 30'06 for protection. (He wasn't.)

The river roars on. The hearts game roars on. Oops. Dirty Dora falls, but Flip is gunning for Shooting the Moon—he did it! Everyone else gets 26 points.

We snooze in our tents, I in my big one, thankful for the protection, Tom in his homemade wall tent with tarps piled on top—dark inside but warm—he has a heater and a lamp on his chest to read by.

Elegant roast beef dinner, carrots, tomatoes with spices, coffee and cake at the end. Lisa has been our baker with Tom doing most main courses. An Antarctic card game courtesy of Doug—called _____. I come in second.

It blows lightly and coldly, the overcast is too low for a helicopter to go out. Tom and Flip want to do their survey. The film crew waits for belugas to show. They don't. Doug found a polar bear sleeping depression ½ a mile away. We have seen none. Fall's coming. I am writing lying on the floor of the big tent writing in thick gloves and still my fingers are cold, cold, cold. No place for bad circulation, I fear.

August 4, 1993

Wadworth

I had a cup of coffee (dope that I was) before going to bed, but it left me wakeful much of the night. I lay there listening to the wind whip the canvas. The night now consists of the light dimming down so that inside the double tent there's hardly enough light to read and my fingers soon chilled down so I would have to warm them inside the bag to go on. Finally, I warmed my hands and put on double gloves and then I could turn pages and hold my place with a big paper clip. I finished *Man and His Gods*.

This morning the overcast had lifted enough that helicopters were stirring. We heard only 15 minutes before its arrival that Walt [?] came in the Bell helicopter, and set down just N. of camp, and as he did so the light mist turned to snow. Flip and Tom readied their gear aboard, with Tom in front, photographing, and Flip in the back. They'll go down around Creswell Bay and up the east shore of Somerset and across to Devon and back to Resolute Bay, counting marine mammals, belugas, narwhals, bowheads, seals? Anyway, they'll be gone two days and just after that we slip camp and I move to

Creswell to a camp where the Inuit are taking a quota of narwhals mostly for tusks, which they sell for \$100 a foot for good ones. A Japanese was buying most of it for apothecary purposes.

It's cleared some now. This pack is a little farther offshore and quite a bit of open water edges the shore—but beyond is the jumbled and bleak pack. No beluga heads bob in the open water. They should come in the river where the underwater team can film them.

Some prints of the footage thus far came in and it's pretty spectacular stuff at Cunningham, as is the bear kill.

Doug is making an elegant beef stew. Chip and Lisa are out looking at nesting birds up creek and I write. It's a long poke, Matilda, with more inactivity than I like. I want to not be a trouble and a worry to Tom and I also am uncertain about my limits here. I understand the desert better.

The stew fills a whole roasting pan.

We play Blob. I lose ignominiously.

Lisa hauls out, miraculously, a pre-birthday present, a bottle of scotch. Considering my state of *deja vu*, it was the finest, finest of gifts, and its 48% alcohol lifted my spirits markedly, if not my blob game.

August 5, 1993

Canada, N. Wadsworth Island, Somerset

We sit in the warm cook tent with about two full days of rations. The wind pours by, slatting the tent—too hard for me to take down my little dome tent, which I want to do before it self destructs. So far it's holding up well.

It's bleak out, the sea cold and gray and the bay choked with pack ice. This offshore wind could blow it out into the channel. The wind is 25 kts. or so.

We talk to Flip and Tom—they're locked at Resolute DOING LAUNDRY, the devils, while we rot in our long johns. Lisa lightens our load by cooking a lemon cake. It's an adventure out here, just going to the john.

Thoughts on predators: The great white bear, an animal that eats people, is near to the surface of everybody's mind up here. We learn to look both ways emerging from our tent. We discuss where the rifle will be put in the tent, butt or barrel first, so it can be reached both by someone in or outside.

We discuss how to shoot and dissuade a bear—off just to the side into the rocks. Don't try to kill it unless in danger of actual attack. Place tents so there is a lot of space between the long house tents and them, so a bear won't get in between them and get spooked, and so gunshots won't hit someone.

Don't zip tent zippers if one comes in camp. It's an attractant. Stay inside. Then we see the practiced and awesome dispatch with which a bear deals with a 3,000-lb. white whale. Economy of action, no limit but the available number of whales to how many are killed. So much for economy of nature. A myth.

By the way in the rushes of video about the beluga kill, I could clearly see apparently uninjured whales standing by the wounded—at what risk to themselves. Some of these clearly could have escaped.

I'll go out into the blast now and retrieve my tickets so we can radio instructions to Resolute.

We read, have a game of Blob. I come out last. Lisa cooks spaghetti, Doug sleeps, we look at the sea for belugas—there are none—but the ice pack has been pushed quite a ways offshore.

The wind continues off the mountains and the temperature near freezing, with mist, at times rain, slush, snow, but not much. Doug and I sing songs loudy—H.M.S. Pinafore, Lydia the Tattooed Lady, etc.

Dinner is spags and Lisa has cooked a lemon cake with orange-almond glaze. The cake mixes and the digestives are in good repair—not sure about main meals. We plan to take stock.

We talk to Resolute. They talk piously of hot showers and laundry runs, though they too have been kept from finishing their flight series.

A guess is that the ice pack may have turned the belugas and perhaps they are on the other side of the island. It's probably like every other human prediction of what animals do—in our minds and maybe not theirs.

I solve how to deal with these bears—wear my reading glasses at all times and you can't see them or anything past 2½ ft. with any clarity. It relieves the mind.

How long will it blow? Will the whales arrive? Will we be reduced to eating muktuk from the frost hole? It's the Arctic fall and who can predict. Glad I'm not scheduled for Isabella Bay, over on Baffin, where Doug and Flip will go for bowheads. There are an identified 87 individuals, or thereabouts.

I marvel at the gulls, dipping and planing in this wind. Insulation of these little bits of protoplasm is truly remarkable. I saw what may have been a longspur and a glaucous gull or two. Tom says there are ravens up here. Amazing bird. We stand in the cook tent and laundry, shoes and the like [?] Doug sends in the weather—25 kts. wind, ½ mile visibility, 3 degrees C., drizzle.

We have a fine dinner with the weather howling and buffeting and raining and snowing outside. It's getting cold, now that fall has arrived.

I make my presentation of the Idaho tuber festival selecting its queen for 1993. A smash hit. We sing songs, play Blob (I win after three successive defeats). My confidence is restored.

Tomorrow we break camp preparatory to a flight the following morning (9 AM) to Creswell. I may stay three days or so, depending upon transportation. My flight is out on the 14th.

No whales here. Looks like they went the other way.

Greetings, everybody. Welcome to the Idaho Tuber Festival. I'm Billy Bob Scruggs, your host, and in real life a corrupt alderman from Bugaloo County, Idaho.

Tonight we have a real treat for all you lecherous ole rednecks. A contest to select and crown the Tuber Festival Queen for 1993.

Our first contestant is a real favorite of mine, Bobbie Sue Hardesty. Bobbie Sue has been selected by the Bugaloo County chemical industry as Miss Persistent Pesticide of 1993. Let's hear it for Bobbie.

(I change hats, take off my foul weather jacket and emerge in black long johns with bright yellow hair—polypropylene)

Bobbie, what performance are you going to give for us?

Bobbie says: The DDT in this costume has saturated my fat and it's all I can do to remember the first four lines of my song:

Bobbie sings "Up Against the Wall, Redneck Mother"

“Up against the wall redneck mother,
who has raised a son so well, 34 and drinking in a honkey tonk, kicking hippies’ asses
and raisin’ hell.”

Thank yuh, thank yuh, Bobbie.

The Wedding Song (Actually I sing this to uproarious applause while the chill
wind whips the tent.)

The Oceana Roll.

August 6, 1993

Pack up day. It took us all day and more to break this place down into little piles
to go here (Creswell) and little piles that go there (Resolute), or there (Fury Pt.). After a
long and agonized discussion, Lisa and crew are headed for Fury Point, where Lisa and
Doug will go in an attempt to get some underwater footage of belugas.

Lisa Truitt, a handsome, slim gal of 31, Nordic in appearance, began to reveal to
me her fears and I mine to her. She is a producer, and runs a magnificent program in my
view, weighing everything. The stuff she is doing here is very difficult in my view. The
weather can and does turn, fall comes like a rock, things break, people haven’t sent the
right stuff, the electronics makes a red picture instead of a colored one, and on and on.
And every move is boxes and boxes and boxes of stuff. Above all is a budget, large yes,
but up there looming over them, and beyond that whether or not they can fill an hour of
prime time. Tough stuff. For instance, Lisa wants to cut from the belugas at the surface of
Cunningham to an underwater shot of the animals that you can see—where? They fly
over ¼ of the Canadian Arctic looking for a place to shoot in clear water, underwater.
Finally they find one, Fury Point, but it has a steep dropoff and she won’t fake it, since
[?] doesn’t.

Anyway, she confided her fears of the bears, of going off in a camp with one guy
(Doug). She ended by singing a song that must have been running through her mind, “I’m
Not Afraid,” from Anna and the King of Siam. None of the others, she said, showed any
signs of fear. Doug just sings and laughs. Chip just smiles and does anything (he’s a
perfect silent cowboy type—from Montana, too). Russ just plans.

I told her I moved into the long house last night instead of sleeping, defenseless in
my tent, a larva waiting to be plucked out of the termite mound with a straw. I could at
least tie the door closed and prop a heavy box against it. All capable of being pushed
aside with one swat of a paw.

I slept in the vacant long house, my little tent flapping outside and the cold wind
sluicing down the canyon.

Russ cooked breaded porkchops and we ate up, sitting on this and that and
contemplating the morrow. We decide to leave the empty long house up (where I slept)
and the cook tent, and get up early (6:30). The chopper arrives at 9:00 AM and then the
Twin Otter. I got out in the first load to Creswell and Doug and Lisa next to Fury Point,
around the outside of Creswell.

This place, with its drifting pack ice and winds and loneliness begins to erode
one’s spirits after a while. So all will be glad to go. Tom flies in tomorrow and we make
the big camp move. It’s logistics, logistics, logistics. And it’s expensive, expensive,
expensive, done by air.

August 7, 1993

Creswell Bay, Somerset Island

I go out on the first load to Creswell in the Twin Otter. We had to helicopter everything 5 miles N on the coast because our field was deemed too short for take off (Twin Otter) loaded. I was very tired after a morning of helping sling and move the camp, so in spite of myself I dozed off after we had bumped into the air. These Otters can be backed up, a maneuver our pilot used to spin the plane around on the gravel beach line runway—a runway created by elastic rebound.

Down along the west coast we go and finally in over labyrinthine Creswell Bay and then over a narwhal-beluga camp of an Inuit family who have a season and quota for narwhals and who fish beluga for muktuk, a few miles away. The take will be the tusks of narwhal males and will be sold to a Japanese who is in the Chinese medicine supply business.

We land adjacent to a full-blown camp—plywood building and tents and vehicles alongside an absolutely flat, mirror-like bay, an island offshore and a long arm of steep-cliffed land off to the north—one can see the Pre-Cambrian basement of rocks, and a shield of Paleozoic (Upper Silurian) sediments that go out to a long point in the distance.

One Long House is up, and Tony Martin and Jack Ames greet me as I step off. We unload and haul stuff down adjacent to the long house. Really good to see them again. We are right next to the Inuit camp, leaving space for one another's tents. Thoughtfully stacked piles of rocks are around to anchor tents, in an otherwise gravelly landscape.

We contemplate what to eat, where to put the john, and Tony picks at his new transmitters as usual. He is epoxying them now.

His recent results from belugas tagged at Tuktoyaktuk are very exciting stuff. They once again show how we try to impose preconceived ideas on wild animals and they do as they damn please.

Four were tagged, three males and one female at Tuk three weeks ago, 10-16 July. Males all went north on same track then lost one after 11 days. All went into pack. Other two kept going to 76 degrees. One turned east, past Prince Patrick Island, Melville Island. He is now 200 km west. The other turned west and north and is now at 77 degrees N, 145 degrees W, but way up into pack where it is more than 9/10 ice coverage.

The female went east, to Victoria Island and then circled around to within a few hundred meters of where she was tagged. Then she made another loop of the same sort.

Amazing stuff. It completely upsets preconceived notions about stock separations and movements.

Tony still thinks the east stocks and west are separate. A Dr. Jim Clayton, Fisheries and Oceans at Winnipeg, has been using mitochondrial DNA and he thinks the stocks are different.

When we landed at Creswell at the Inuit Camp, the kids were out. Little boys and girls playing tag. The rule was you had to kick the oil drum and spin around, then jump the creek. Off they go, four of them up the rocky hill and back down the beach. Fulmars swoop by over the glassy water, converging on some food source. Over the hills storm trails twist in the upper wind, turned rose in the low light. Skiddoos, drums—lots of drums—clothes lines, an ice hole up the hill for muktuk and meat.

Andrew is 25-45, well-spoken in English, direct, and his extended family sluices around him. As Tom says, they teach their kids by observation—not by direct questioning or direct instruction.

We get the camp up in stages. Tony has arrived without a sleeping bag—imagine that in the Arctic. He is in full fiddle. All of his transmitters are lined up and he had doped them with some kind of goop. He then stuck on some duct tape and then mixed up a bunch of epoxy and then lined all of his precious creations in a box and gave us instructions not to touch them upon pain of death. He has a new wrinkle. His transmitters now have a duty cycle—they transmit in bursts and shut off for a matter of days and then come back on. Not much is missed by leaving such data out and his batteries are predicted to last ____ months. The records come out without long data spaces, but they hitch together in a long track that misses very little. Elegant.

Malcolm Ramsay, a polar bear expert from U. Saskatoon, hopped out of the plane, big mop of curly gray hair, decked out for cold in true winter boots with little valves on their sides. He told me a little of his work at Churchill when the ice pack comes in—the bears have been out on the ice subsisting on ring seals. He is working on narwhal stuff here.

I will try to talk to Andrew about the renaming of Somerset Island for his father. Nunavut—our land, Nuna—terra firma, Taleok—out there on the salt water, Immark—salt water, Innerk—fresh water.

My reading of *Man and His Gods* says that we humans have an almost infinite capacity to organize our lives around any concatenation of myths, so the situation of the Inuit is made vastly more difficult because the myths about nature begin to be operative in the USA and are spreading. The disjunction shows in hundreds of big and little ways—forcing us apart.

On the mythologia, or southern side—the perception that the human race is screwing up nature and that this has begun to affect the carrying capacity of the earth is operative.

Up here the Inuit are being forced away from their bearings, their social structure is attacked. Both are right, but both attack the other and the contest.

I call it mythology. What I mean is that a mythological remove has occurred between services of food and connections with nature in the support of the larger perceptions and goals that are necessary to save the earth.

Yet, the precious structure of Inuit society. The extended family, the observational learning of the children, the taking of their own food, as is opposed to concern for the less immediate surround, for the direct things of life.

There is a snowy owl in the Inuit camp, and I hear snow buntings outside. Tom says they are picking up insects.

Suddenly a call goes up. Flip is trapped in the john and about to fly away over the bay, really. The fly of the tent has become a spinnaker and with only two decent tent stakes on this fall nylon leisure tent, it threatens at firsts, in spite of the several large rocks I had piled inside it. We went out to find Flip lying on the floor, the tent zipper zipped up tight, with a real threat of ascension. After restaking we finally decided to take the fly off, and the pressure abated.

Flip describes it as follows:

I felt an extra layer of clothing on my back and then an explosive event took place. The tent was going to fly away. I lay down on the floor, the bucket between my feet spread-eagled, I lay down to anchor it. I was a little reluctant to call for help too loud. I yelled for help gradually increasing volume. Tony came first and then Russ. People then

flooded out, restaked the tent, with Micklin's body evident through the windward tent wall. He managed through it all to keep the shit bucket from upsetting.

"Hello, anyone there? I seem to have a little problem here," was the alert that called Tony, according to him.

August 8, 1993

The snow came while I was sleeping in my tent and then, since the snow was being driven laterally, it began to collect on the tent itself, under the fly and then it began to leak right over my sleeping bag. So, for the second time this trip, I had to move to the long house before things got soaked.

It snows and snows in the wind.

I stopped by the cook tent and Andrew had dropped by. We had a long, rambling conversation. He and Malcolm and Jim and Tom talked about everybody across the Arctic.

I asked Andrew where his father had come from before he came here—Pond Inlet.

Andrew had gone to school at Inuvik. The government gathered up all the children across the Arctic and then to school for eight months away from family. "Very hard," he allowed, for a child who had never been away from house or family, or had seen a building of more than one story. No bitterness in his handsome, open, direct looks. He smiles readily, revealing a gap tooth smile and talks about everything in his world. He's very interested in knowing how to prevent narwhal tusks from checking as they dry. He is thinking about a tourist operation. I liked him a lot.

The snow continues falling. We sit in the cook tent. Flip feeds us a good chicken and spags, Tang. I collapse another chair. I'm just too heavy for these K-mart specials.

If it clears, we'll try for a narwhal here and belugas off out farther in the bay.

We discuss crazy trips to the pole—mountain bikes, water skis (magnetic pole), motorcycles, ultralites.

The snow abates. I go out of the tent to an Arctic scene—all white domatiks[?] and four-wheelers, and oil drums topped with snow. The two boys are down by the calm bay, hatless, shooting slingshots at passing fulmars. Andrew emerges to wait for narwhals in the channel just off his tent. His day seems to start about midnight.

Tom, Tony, and others will go across to the island to attempt net a narwhal tomorrow. I may pack it in next time a flight from Resolute arrives.

But right now the wind blows and snow spits.

August 9, 1993

Canada, Somerset Island, Creswell Bay

I spent a nice dry night in the long house. The snow has all but stopped but not the wind. Outside the clouds cling over the Precambrian mountain across the sound and low over the alluvial island across from us. It's there that we expect narwhals to come skulking by. Andrew and crew will wait and shoot the males that come near. I wonder if there will be competition between our two camps. My guess is that Tom will handle it well.

One thing about this Arctic work—it comes in spurts followed by long sessions of inactivity where dishwashing and stories is the norm. Then comes the massive logistics of a camp move. Everything is taken down, boxed, put in slings, the helicopter comes in and

up it goes, dangling below the craft. You can see the craft respond in the wind—dangerous I am told, and then another load. Or the weather gets you, as it is doing now.

As for me, I'm a super cargo of sorts and so they defer to my supposed fragility. The inactivity gets me. So, the story is mostly in the case, and I'll talk to Tom about flights and costs, etc. It looks like the 12th.

My last aim here is to talk to Andrew, get the new spelling of Somerset Island, and the names of his kids.

I ask his children's names and he lists them all. Andrew speaks very well in perfect English. A bright, engaging man. I tell him I want to use the new name for the island of his father, but Andrew tells me to wait, intimating it hasn't been decided yet within the family.

The Stanwill Fletcher from whom the nearby lake is named is a man who parachuted in here when they first flew in, laying out a landing strip.

Today our camp was split into two camps, to catch a narwhal. Tony, Tom, Jack, and Russ have set up across on the alluvial island across from us and have put out a narwhal net—9-in. mesh, anchored out at right angles to the shore, in Zodiac and also one of Andrew's boats.

Flip and Jim Savelle and I stay here. We will cook dinner for their return at about 10 PM. They'll call at 7 PM. There's not much time (not many days) to get Tony's new transmitters on an animal, but in spite of wind and the temperature around zero they are trying.

I try to prepare a pork roast but the oven refuses to light. The stove is on a bit of a slant—on the gravelly beach on which the cook tent is erected. Maybe that's the problem. Anyway, I abandon the idea and at Flip's suggestion, cook pork chops instead. So, a meal for eight—boiled potatoes, melted butter and salt and pepper, the chops, flavored and spiced with tarragon, garlic, and rosemary (nobody objected). The garlic had been inserted while it was still a roast. Then I fried a whole pile of onions in the chop pans and scraped off the brown into them. Carrots in some sort of sweet sauce, prepared by Flip—and in they came from the bleak, cheerless island camp, into our warm tent.

Jim Savelle was assigned the task of peeling potatoes—and we soon learned that to Jim, nutrition is a chemical event—he had never, he confessed, peeled a potato before. I could see it was true as he whittled away, producing something like potato sawdust. Time was getting short so I had to relieve him and his eyes opened wide as the peelings flew. Jim says his mother had to instruct him that eggs should be removed from their shells before frying. He subsists on food packaged in boiler bags. Such a contrast with Tom's camp, which is elegant food, albeit with an emphasis on red meat that was a bit much for Lisa.

Jim is one of constant goodwill and spirit—full of fine trivialities. He's a history and aircraft buff, uncovering eclectically the stuff of Inuit history, Dorset tunes, or the Franklin voyage.

Flip doesn't miss much. He tells us of his time on the Exxon Valdez, and other assignments—of going under the hull to photograph the black water where the welders were cutting away.

Most time, Inuit camp included, is spent indoors, with brief forays outside to the bleak, snow-dusted world and the cold bay where fulmars flock and dabble for plankton and quarrel. I hear a red-throated loon through the tent wall.

It seems to be arranged. On the 12th an Otter comes in to take Jim Savelle south to Boothia peninsula and on its return it picks me up for the trip to Resolute Bay. Whether I stay at the Narwhal or Polar Shelf is not yet clear.

August 10, 1993

Canada, Somerset Island, Creswell Bay

I'll try to settle with Tom before I go and straighten it out later.

He's having trouble with Fisheries and Oceans, who seem unable to deal with a person of independent mind—I think, demanding such conformance is the death of science. No real scientist can flourish if not allowed to “say it as it is.” Universities are devices designed to provide a good garden bed for such curmudgeons as him and me. So science in governmental agencies is always watered down in the process. The only places it works are where a scientist sacrifices himself to act as a buffer, usually to be director—between the requirements of the political structure and the scientists—there being two mutually exclusive social systems involved. Tom is caught in the warp and wonders if he can take four years to retirement and the agency loses its best, true Arctic biologist—a serious loss for both sides and difficult for both Tom and the agency. There has to be a better way.

Have I described our camp? Not very well, I think.

We are camped on a gravel strand—a ribboned feature—50 yards above an often glassy bay. Just offshore, ¼ of a mile, are two alluvial islands, on the N. of which is the new camp. Between the two islands runs a channel and to the west of the camp island a deep, two-mile-wide channel bends around under steep dark gneissic cliffs to run east as a series of much softer-contoured hills of Paleozoic sediments and out to sea through the Sarvak Channel to Creswell Bay and Prince Regent Inlet. [Drawing]

The channel in front of us can be glassy or the wind can sluice down off the land and turn it gray and flecked with white wavelets. The land is dusted with snow now—the rocks still showing through, even where later it will be a blanket of snow. We have two long houses, the ridiculous john tent now anchored with big rocks and spare dunnage, and personal tents. The Inuit camp is more established—wall tents, a couple of wooden buildings—temporary knockdown looking—vehicles, drums.

It's very communal, very social in that we are driven into tents much of the time, the pace is slowed down to its essentials, even now. The communal society of Inuit folk is certainly derivative from this in part, their attitude toward sharing. One is very much aware of the intimate texture of others' lives. We are too. Much you don't expect emerges—Jim's jokes and trivia and cooking, Flip's wisdoms and jokes, Tom's skills, predilections, enthusiasms, and trials. We rush to the support of this man whom we have grown to admire.

Flip lent me his big, heavy Eddie Bauer down coat (immediately I have a new dimension of freedom. I can stand out in the wind, and, as I did, I can curl up under it and sleep—warm like a curled up sled dog. Next come feet which have always been chilled. The heavy, incredibly bulky boots the wise ones wear, buy freedom from cold feet. The best have an air lining and a valve to regulate pressure on aircraft.

I may read a little—Cheney and Seyfarttes “How Monkeys See the World.” In summary, they see many things the way we do, with allowances for the differences in size and mental development between the two of us.

I have radio duty. At 12:00 Noon, I call the island camp, just to check in. Flip is reading in his tent and Jim is probably sleeping in his tent.

We seem to have called past each other. Jack on the island, me on the shore.

Word comes through that I'm on the next Otter flight out. So, I get packed. It's no big deal as I've kept everything together and ready. So I stack up the bags inside the tent and go out to say goodbye to Andrew and the kids. He's fixing an ATV engine. He has his tools all laid out on an upside-down comatik (a freight sled) and the parts are laid out in orderly fashion. He comments: "In 12 years you learn to fix these things." He says: "Would you like to meet my wife?"

"Yes," I reply, "I would."

We walk down the beach to the canvas wall tent, open the flap, the tent is half taken up with a raised bed larger than king size by twice, about knee height. On it is wife Mary sewing, and grandmother whose name is Inuit and which I do not catch. Mary is sewing a parka out of caribou hide. She's matched colors and makes little puckers for the parka, for little, three-year-old Palacia. The stitches are neat and small, of thread not sinew. Grandma, old and a little immobile, speaking only Inuit, sits on the other end of the bed, or rather reclines, amongst the covers.

I admire the sewing, and then make my way out over the plywood floor and into the cold day.

The kids are following a snowy owl chick—18-in. tall, downy gray, big yellow eyes, and whitish feet. It waddles across the tundra and the cotton grass (the "cotton" of the seed heads is used for seal oil lamp wicks—laid out across the burning place, alight along its whole length). I took a suite of photos. Then my plane came in, jouncing on the gravel runway, turned, and came in near my gear. I climbed aboard via the inadequate ladder and there was Lisa, glad to leave her cheerless Fury Pt. camp to Doug and now Chip.

August 11, 1993

Canada, Cornwallis Island, Resolute Bay

We took rooms at the Polar Shelf facility. The dining room was closed so I did without dinner. It didn't seem to matter much. I took my delicious shower (my towel hangs in the tent at Creswell, so I used a T-shirt).

Tomorrow I may head for Edmonton if I can transfer.

I call Phylly—all's well at home. Pam and Mike are there. Shall I transfer my ticket, or shall I stay here and write? The extra expense would be Tom's and there's always the threat of a weather cancellation so I opt to go, even though the unfettered writing time is attractive. I'll try to get a reservation at Edmonton. I did. They'll meet me. Now laundry.

Oh, I wanted to describe how Andrew hunts. He gets belugas a ways down the coast from here—but fishes at camp for narwhals (he calls them "nar whales") with a rifle. He lets them pass by his camp nearly to the mouth of the Union River and then shoots them. They sink in the glass-clear water and when they lie on the bottom he can see their white bellies and then he retrieves them with a grappling hook.

Muktuk was being used as food but none was drying on the lines. But caribou meat was out on a table—heads, legs, hooves, and piled skins.

While waiting for a phone I met Michael Kingsby in the rec room of the Polar Shelf. He commented on the beluga situation at St. Lawrence about as follows:

1) Hunting caused the decline and even continued locally after it was officially stopped.

2) His bitch with Beland is that stranded animals and the figures for disease derived from them cannot be extrapolated to the population as a whole. The rest could be healthy.

3) The figures for the present population are a little shaky—though he seems to agree the population is rather stable at around 500.

4) He says there is no question that cleaning up the St. Lawrence is a good idea.

5) He smiled wryly when I said Pierre had an image problem and mention his use of TV a couple of times. All agree that cleaning up the estuary is a good idea, whatever the biology.

I try to leave but the place is socked in and they send everybody back to either the Polar Shelf or the Narwhal.

Hey! The kitchen staff—Jennifer, Helen, and Karen—come out with a cake and four candles, for my birthday. I give them hugs.

We have a brief flurry of hope as Air Canada is coming in, but the fog just gets thicker, and after hustling us all over to the terminal hope dies as the word comes in that they've turned . . .

I room with Mike Waskiewicz, who tends remote sensing weather stations scattered around the Arctic and Russia. He is a sculptor and naturalist who spends his time on the mountains. He speaks lyrically about the land, its ancient connection to him.

Mike has found some serpentine and comes back with two great boulders for his luggage.

The landmarks here are: meals, Star Trek, pool, sleep, a lack of exercise and something organized to do. Writing helped a little today.

August 13, 1993

Canada, Cornwallis Island, Resolute Bay

Breakfast with Helen, who tells me about cooking on Ice Island, a station that floated on an ice island in the Arctic Ocean and finally ran aground up near Ellesmere Island. A good many people (scientists) were on it, especially geophysicists doing seismic work for oil structures. She, a wonderful, buoyant spirit, loved it.

The weather is calm and clearing. I think Lisa will get out to Montreal today and if it holds, I will make it to Edmonton tomorrow and then home.

What do we know about the shrinkage of ice as temperature rises? Does it expand on a curve with lowering temperature? [Graph]

If there is such a curve there should be cracking at 90 degrees at the ice wedge edge (I was told this term by a young geomorphologist) as things thaw. Thus the 90 degree L's at initiation of cracks along ice wedge lines should occur, as it clearly does from the measurements I made (I eyeballed several dozen cracks). [Drawing] Thus, maps of Iowa are produced.

Apparently freezing and thawing of water in the ice wedge are thought to produce the berms one sees along major cracks.

When the sheet of ice melts, the runoff must be very striking in terms of volume because of the size of the cobbles one finds in the bottom of the ice wedges.

Lisa leaves today. We'll have a goodbye lunch with her, and then I'll make my way down to Buster Welch Aquarium, a couple of miles down the road. I want to see what the invertebrates and fish up here look like. He's a great shaggy bear of a man in suspenders. A beard tinged with white. He retires this year and apparently he and his wife will leave for the south. One wonders about a fixture such as he, and retirement. I wonder if he has my resources to meet retirement?

I put on my jackets, long johns, and knitted cap and walked the two miles down the gravel road to his aquarium. I passed a couple of lakes on the way, after bending around the south end of the airfield. [Map]

One lake is blocked off by fencing, I suspect as a water supply (Resolute Lake). Then I took the road toward Resolute Bay, which is choked with pack ice. The Aquarium sits on a long stone jetty, and is a long, rectangular building, mostly crammed with research tanks, experiments with urchins, a protist lab on the very tip, but with a few exhibit tanks on one side. They contained Arctic cod, sculpins, lumpfish, what look like *Cerianthus*, and *Tilia* anemones, a big, broad *Laminaria groenlandica* kelp, a curious isopod that looks a little like a caprellid, a *Strongylocentrotus* urchin, and a few other things.

I walked up to Buster's house—flying the Canadian flag—and knocked. Wife Cathy answered and invited me in. There was Mary Valentine, knitting a sweater for a Welch child. We had a piece of cake and a dram of Mary's scotch. I got Buster going on whale management. He feels as I do that no real management will come until the Inuit guide their own courses in the north.

Right now he says it is murder here at times, but much worse in Greenland, where everyone may shoot, whether they can retrieve the animals or not, and he too believes the population is drying up, as it has done in southern Baffin, Ungava, and E. Hudson's Bay.

He feels the Inuit, once relieved of our southern control will come to national management policies and may utilize existing caucasian biologists until they can develop their own. He thinks it may be a rough transition.

He agrees that density measure only mask the problem. He gave me a ride back. He said that Michael Kingsley headed a DFO lab in Quebec that was in charge of the beluga studies for St. Lawrence. Kingsley evinced lack of understanding about why his group and Beland were at odds, but then noted that Beland was using TV. I sensed the animosity of a scientist using the media. Common.

They drove me back to Polar Shelf where we had a great steak dinner, and a dessert called "Murder," which is a slab of double chocolate ice cream and literally a splash of strawberry sauce.

Now notes.

Welch talked of a recent Spanish expedition to Greenland, which he regarded as strange. I'll bet the sign at Rodebay came from this source—the one proclaiming the Embajada de Espana.

Thoughts for Story:
Start atop the tower.

Tony's new transmitters send signals like a line of dashes on a typed page—a track across the Arctic Ocean. A battery can last twice as long or more.

The management equation.

Into the hands of the Inuit and Greenlanders.

Sadness and boredom is all that's left once hunting and all that goes with it (the completeness of life) is gone—the hide preparation, the clothes, the six-hour waits over a breathing hole. It was not dull. Now, without the animals, that are the source of life, it threatens their very place on the land.

They must know that these non-Inuit scientists have cared very much for the welfare of Arctic animals and have given every bit of expertise and training they have. They are ready to help until the Inuit forge their own scientists.

It is no different in the St. Lawrence, really. the different scientists may argue about methods; such discourse may be spirited, even bitter, but the aim is the same—to right the wrongs of the earth. And this is also true of industries on the land, such as the great aluminum industry at Jouquiére. They too seek to learn and in their terms to right the wrongs of the earth.

Thrust in the Inuits hands, their fate, and what they will do with their land and the living things in their domain, become crucial parts of their own cultural survival. That is where it would seem to belong. They, the Inuit, know better than anyone, that to avoid the long sadness the beluga must thrive.
