June-July 1949 Baja California

June 13, 1949

20 miles N of Ensenada, Baja California

11:30. Left Los Angeles after much packing and last-minute purchases in company with Chuck Lowe and Arlene Lowe. Our trip is to last 38 days and is to take us to Cape San Lucas and back.

The sky has been overcast all day and the air cool. We drove to San Diego by the Coast route, stopping there for a brief chat with Cy Perkins and Chuck Shaw. Dr. K. Canber wanted us to buy specimens for him, but we do not have space to do so.

At the border we drove through with no questions asked at all. As a matter of fact we were the only ones who did any asking. We obtained insurance (Collision, Public Liability, and property damage) for 52 cents per day—\$10,600 coverage total. This was obtained from the America Insurance Co. They gave us a windshield sticker.

We drove on to our camp noting an unusual amount of DOR snakes. The species seen were *Lichanura roseofusca*, *Masticophis piceus*, *Coluber lateralis*, *Pituophis c. annectans*, banded and striped phase of *Lampropeltris g. californae*.

Camped at about 8:00 PM and ate a welcome meal. We are camped in the old spot under oaks and sycamores along a stream in which *Hyla* can be heard calling in a desultory sort of manner. It seems wonderful to be in the field again after all the mental anguish of preparations and dealing with numbers of people who consider Baja California their own.

June 14, 1949

Bahia San Quentin, Baja California

Today everything seemed doomed to complete failure.

7:30. Arose to be greeted by clouded skies and cool weather. The small creek by our camp had a few ponds among the sycamore and oak roots. I saw 6 or 7 Bluegill in one pond, some 4 or 5 inches long. We then drove to Ensenada, changed our money, bought a few items, and took the car into the Dodge garage to have the slight shimmy corrected.

Upon raising the hood we saw oil over everything. The garage attendant (who was the skinniest man I have ever seen, about 1½ inches through the middle) said our 4-wheel drive bushing was leaking and all the oil was coming out of the front differential. This meant we must go back to San Diego and through U.S. Customs with all our plunder. A young fellow named Antonio Escalante looked the car over and said our overflow was shooting out the grease because the differential had been overfilled. We found he was right and everything was O.K. The shimmy was fixed and we were off at about 12:30 PM.

I was feeling better but still mighty low. We ate lunch at the Aneides locality north of San Antonio. By this time the sun had come out. At the end of the pavement we saw our first *S. rufidorsum*, a big fellow that looked exactly like *S. magister*. We did not obtain the animal. We did get two young ones and they are much different than *magister* though obviously closely related.

At San Vicente we obtained specimens of *S. orcutti* on exfoliating granite boulders. The road runs for about 25 miles over a monotonous marine terrace covered with *Agave*, wild roses, a variety of *Ribes*, and sundry other shrubs. This bench is about 5 or 6 miles in width and ends on the sea edge in an abrupt cliff and on the other side at the base of a similar higher terrace. There are four such steps before the main block of the Sierra San Pedro Martir is reached. The first two appear to be of marine origin and probably rise a total of 500 ft. above sea level. Stream beds

dissect this bench at various places in their course to the sea. The road drops down from a rise, crosses the stream bed of the Rio San Antonio and comes to the cultivated plain of the Hamilton Ranch. Corn and beans seem to be the principal crops. The adobe houses here are neat and for the most part, plastered.

We bought gas here (32 cents per gallon). I asked for “diez y cinco litros (5 gallons) de gasolina” (“quinze” would have been better). The Mexican (a pachuco type) said “How many gallons do you want?” I nearly asked him “Hable usted español?” We drove down a dusty dirt road to the Hamilton Ranch, which is a series of adobe buildings set on a small hill. There seems to be considerable water here, judging from the agriculture. I would estimate that 500 acres are under cultivation.

We drove over a rise and dropped down onto the San Quentin plain. It resembles the other part of the coastal terrace closely except that it is fringed on the sea by 4 hills that look volcanic (look like old cinder cones). The road to the Muelle San Quentin (wharf) is a good, fairly high center, sandy road. A three-mile drive brings you to the wharf, a series of pilings going out into the shallow bay. A peninsula, on which the cinder cones lie, forms the other side of this north end of the bay. Some very scraggly pines and eucalyptus stand along the bay, probably planted by the British colony that once occupied the plain.

Salicornia and rushes line the bay in places and in others abrupt cliffs drop to the water's edge. Cliff swallows are nesting in these cliffs. Egrets? were seen roosting in one of the pines. These birds certainly have a Jurassic look when they fly, with their necks crooked and their long legs stretched out behind. The weather is cool and breezy. The stars show through the cloud cover in places. I have had a time trying to rearrange our tremendous load so that we can get at everything where we want it (which is impossible). I look at the load and then Lowe asks me where the folding table is. I quietly crush his skull in the car door and then swim out to the sea as far as I can and sink.

We had a good weiner dinner and a nice eucalyptus fire. I now commence color notes on my specimens.

June 15, 1949

Barranca Rosario, Baja California

We slept late at San Quentin after getting up at 0800 AM. We ate breakfast, packed and started on our way.

The first moment after starting we met a car from ____ that was stuck in the sand. We pulled them out with 4x low.

About a mile further, we stopped in a patch of *Simmondsia* scrub and collected *Cnemidophorus hyperythus beldingi* and *Sceloporus rufidorsum*.

The road degenerates rapidly. It becomes deeply rutted and must be very bad during wet weather. The road is so bad that we made only a little over 4 miles today most of it in second gear at about 10 mph. This road has never felt the sweet caress of a road blade.

The flora is predominantly *Agave*, *Sedum*, and some chaparral elements. Arlene spotted a nice *C. ruber* under an agave. We drove on to Socorro (along the sea coast) where we ate lunch and had a can of warm Tecate beer. I became uncontrollably drunk.

01:30 PM. We drove off over a much dissected coastal plain. The road was very bad and we were only able to travel 10-15 mph. The vegetation is definitely xeric here. Finally the last semblance of a coastal plain is gone and we turned up a large arroyo and then dropped down a canyon to the town of El Rosario.

04:00 PM. It is the first really Mexican village we have seen. The houses are all adobe or mud and wattle and many have thatched roofs. The pueblo is strung along the north side of

an arroyo (about ½ mile in width). There are fig trees, cottonwoods, and some sort of locust tree. It is “muy bonita.” The street is a wide, aimless dirt street with various “perros” lying on it. The arroyo bottom contains a stream of sorts hidden by cottonwoods and willows. Much of the bottom is cultivated and planted with corn, lima beans, and alfalfa.

At the store we met a distinguished gentleman with a brilliant smile which showed 6 or 7 solid gold teeth. He looked to be the Jefe Politico. He immediately took us in hand and told us the names of all sorts of objects and arranged with some niños to have them hunt “culebras y viboras” for us. We offered 1 peso for culebras (muerto) o 1 peso y veinte cinco centavos por culebras (vive). He was most accomodating and spoke slowly. Chuck was trying to say “San Ignacio is far away (muy lejos) and he said muy huevos (eggs), muy vacas (cows), and about 6 other things—all wrong. The fellow thought this was most amusing. We all had a big laugh. He then accosted some small girls and asked them if they would like to hunt snakes.

The little girls acted very shy, giggled, and put their fingers in their mouths. This he took as a huge joke. Chuck asked them to hunt snakes and so it went—big laugh for everyone. We left and promised to return next morning for our snakes.

We drove up the creek, stopping at an old adobe ruin that might have been a mission. It sits up on a bank on the north side of the arroyo. We made camp just east of this ruin (1 mile). 3 small boys came into camp and we accosted them and offered our price for snakes. Shortly a battered *Thamnophis e. hammondi* was brought in. We paid our peso.

This stream is about the most southern stronghold of San Diegan elements, both of fauna and flora. In fact it is an island separated from the north by *Agave-Simmondsia* association. Nelson lists this river as the “Rosario River.”

The first *Pachycereus pringleii* was seen on the north end of the San Quentin Plain.

The weather has been cloudy and cool. At present there is a breeze. A large cloud bank is passing over the sky to the northwest. Collecting has been slow as a result.

June 16, 1949

5.1 miles E. of San Augustin, Baja California

07:50 AM. Arose. A thick fog covered the sky. We left our camp and journeyed into town. There we met our friend with the resplendent smile. He took us to the Escuela and presented us with our sack containing 5 *Thamnophis e. hammondi*, 4 dead and 1 alive. Chuck and Arlene paid him for them while I became involved with a drunken fellow who claimed to be the village surgeon and psychiatrist. Of all the things Rosario needs I think a psychiatrist is the least useful. The place is so peaceful and everything seems to move at such a slow tempo that neurosis would seem to be absent. The gentleman with the gold teeth (I think he is a teacher in the Escuela) showed this attitude by the way he used the dictionary. He took about 10 minutes to look up a word—stopping every once in a while to explain ones that caught his eye. The teacher paid the little girls who caught the snakes, giving them some sort of paternal advice and demanding their records (a piece of paper with each snake listed and its price).

I finally got away from the drunk, who claimed to have been educated at Stanford, Mexico City, and Paris. He was apparently in ill repute with his townsfolk as we had been waived away from his store by a caballero when we came into town the first time.

We left town after giving the teacher some cigarettes.

We drove up a very dusty and rutted road along the Rio Rosario. After 4 or 5 miles of this we turned south in a large, dry arroyo that empties into the Rio Rosario. *Agave*, *Opuntia*, *Pachycereus*, *Idria*, *Viznaga*, and much buckwheat and chaparral elements, formed the vegetation. The first Cirio was seen about 8 miles from Rosario, along the rocky slopes that

bound the Arroyo. About here I shot a leopard lizard that is very different from our California animal. Its blotchings have been replaced by fine punctuations.

Cirios now occupy the whole arroyo bottom in great profusion. The arroyo had been trending southward. It now turned east. At this turn we came upon *Salvia apiana* and *Acacia gregii*. The vegetation is decidedly ecotonal, being a mixture of chaparral elements and Colorado desert forms. In this area we shot *Uta stansburiana stejnegeri*. Many miles east, just past San Fernando we caught a *Phrynosoma cornutum*. This represents an overlap of coastal and desert faunal elements of about 35 miles. It is probably much more in some cases, as we took *Sceloporus rufidorsum* 3 miles east of San Augustin. This is an overlap of about 50 miles.

The road grew worse, becoming rocky. The road traverses rocky hills with a few small valleys interspersed. 34 miles from Rosario the road drops down over a rocky hill to a small valley in which the Rancho de la Arenosa is located. A small field of corn and a puebla that looks like a sub delegacion building make up the ranch.

Just east of the ranch we saw our first *Larrea*, and *Yucca mohavensis* made its appearance. The road became much better, probably due to less rainfall. After a rain the road is churned up and hardens in a very lumpy state. The country becomes less rolling and is dominated by mesas with steep cliffs. Anticlinal folding was noted along one of these faces.

We reached San Fernando, a small puebla in the San Fernando Arroyo. Few people now occupy this once populous site. A mission with elaborate irrigation canals once occupied the area (Nelson).

This puebla is about 15 miles W. of San Augustin. We traveled up this wash and dropped over onto Llano de Buenos Aires, a slowly undulating desert plain encircled by separated mesas. *Larrea* and *Yucca mohavensis* are the chief plants. Arios and Cardon Grandis (*Pachycereus*) occur only on the slopes of the mesas.

We reached San Augustin about 4:20 PM. It is a ranch sporting two windmills, set on the bank of a mesquite covered wash. The houses are adobe and thatch. The fences have been constructed of ocotillo limbs with the spines removed. Here we met two traveling salesmen who had just come from Cabo San Lucas. To them all the roads were "bueno" even though they had had two blow-outs from running over rocks.

They said the Laguna Seca Chapala was good snake territory. We may reach there tomorrow after El Marmol. We were informed we could get plenty of gas at El Arco.

We drove on and camped in a shallow arroyo alongside a mesquite. Arlene cooked a wonderful dinner of roast beef and mashed potatoes (fried onions) with coffee and pineapple for dessert.

June 17, 1949

Camp Aching Duff, 8 or 10 miles north of Laguna Seca Chapala

7:30 AM. Arose and ate breakfast (1 teaspoon of Grapenuts and ½ pint of water) (the Lowes apparently don't normally eat breakfast).

We drove over Llano Buenos Aires to El Marmol. At this mine there are 25 houses (wooden). There is a small airstrip with a tattered windsock to the west of town. The graveyard is beset with the usual Mexican paper flowers and large crosses. Instead of digging graves in the rocky soil, stones have been heaped over the graves.

Onyx (El Marmol) is being mined in open pit workings on a knoll south of the village. 3 large guy poles with block and tackle are standing alongside the pits. Large blocks are cut from the horizontal beds and hauled out of the pit onto a bank where they are numbered and cleaned for shipment. A man with a sledge and another with a chisel and brush clean the blocks. Their

rhythm is amazing. The sledge hits the chisel in a regular rhythm. After each blow the chisel is moved and the block swept with an agave fiber brush. The onyx is yellowish and quite hard.

We drove over a rocky hill and shortly came to a rolling plain covered with huge, exfoliating granite boulders. Cirios were very abundant and large. Cardon Grande was also common as was a small cactus species (*Pachycormus*?)

We collected *Callisaurus* in the washes. *Streptosaurus mearnsi* and *Urosaurus ornatus* were taken on the boulders. *Sceloporus orcutti* was seen but not taken.

The light colored *Callisaurus* with its high temperature requirement seems colored for protection while in the sun, where it spends most of its time.

Streptosaurus mearnsi and *S. orcutti* and *Urosaurus ornatus* are all dark and seem protectively colored for the time they spend in the shade. All have low temperature requirements and spend considerable time in the shade.

We drove on, shortly seeing our first elephant trees. They are unusual trees with knobby obese trunks, few small branches or leaves, and often parasitised by dodder. Their flowers are very small and numerous and are pink in color.

It is impossible to adequately describe this lush desert with much success. It gave me the impression of driving through a surrealistic world. The cirios are straight and tall often branching into 2, 3, or 4 smaller branches at the top and sometimes curving in a wide arc until their tips touch the ground.

The road was very good all the way through this granite area, being of sandy granite gravel.

We ate lunch in a grotto set in a huge granite boulder. We then drove toward Catavina. 2 miles north of Catavina we came upon some Blue Palms in an Arroyo. A single *Rhus laurina* was present. Mesquite, Willow, Idria, Agave, Ocotillo, Juncus, Cordon Grande, and rushes made up the rest of the flora.

I walked up the Arroyo toward some palms I had seen around the bend and shortly came upon a pool filled with rushes.

I set up a call "*Hyla*"—Chuck was up in a moment and we waded in the cool water (22.6 degrees C.) up to our waists. There were many *Hyla regilla* and some *Hyla arenicolor* (a dark little form). The wash was welcome.

This population is apparently the only one in the canyon. It is certainly very small as the pool is about 40 feet long by 10 feet wide and 4 feet deep at the deepest.

We drove on to Catavina—a cluster of 3 or 4 adobes set on the side of a vertical bank. In the Arroyo are several hundred blue palms. Some lush grape vines are growing on a shelf along the Arroyo. Large Mesquites provide shade for the Rancho. It is a picturesque and beautiful place but looks quite unproductive.

From here on the road grew worse and worse until it became one long steep rutted field of boulders and sharp rocks. We passed Rancho Jaraguay, a small adobe. The people were eating on a large table set on the veranda. An old bearded (white) Mexican told us the name. We drove on, now in 4-wheel drive up an excessively steep, rocky road. We drove on, circumnavigating a huge lava flow of some 300-400 feet in height and 10 miles in length.

The road remained very poor with occasional good stretches until camp was reached along the road overlooking Laguna Seca Chapala. A good dinner of tuna, noodles, and mushroom soup, coffee, and peaches was whipped up by Arlene and coughed down by one and all.

The terrain this side of Rancho Caraguay was very poor and sterile. Desert pavement covered with depauperate *Larrea-Franseria* scrub was about all that could be seen.

June 18, 1949

Mouth of Arroyo Escondido, Baja California del Norte

Left Camp Aching Duff at about 9:00 AM. We then drove down towards Laguna Seca Chapala.

About 2 miles north of the playa we passed the house of an indian fellow. He came out and spoke to us. His house was an airy one constructed of ocotillo poles set about 2 inches apart. What means of support this fellow has I could not see. He had a horse and a dog and all the desert he could use.

The road became much rutted and extremely dusty (about 2 feet deep of fine powder) as we approached the playa.

The playa itself is a nearly circular playa of hard mud. It is encircled on the east by granite mountains and on the west by abrupt lava flows. On the southwest edge some sand has accumulated. *Callisaurus* and *Cnemidophorus* were taken here. A Joshua tree made its first appearance.

Arroyo Escondido, at the sea

The road was badly rutted and dusty here also. Many snake tracks were seen, probably made during the night.

Chuck decided that all roads could be defined thus: very good—over 10 mph in high gear; good—high gear. Where he puts pavement I don't know—but it is of little importance to us now as we have the prospect of about 1,000 miles of dirt roads before reaching pavement again.

The road around Laguna Seca Chapala must be completely impassable in wet weather.

We drove on, up and over a rocky ridge on a fairly good road, whereupon we dropped into a basin of granite boulders, Cordon Grande in great numbers, Idria, Joshuas, *Larrea*, and Ocotillo, to mention the most conspicuous plants.

Santa Rosalia Bay

Chuck spotted a *Sauromalus* (Chuckwalla) on a large boulder. We tried every trick we knew to dislodge him, including fire, but we could not force him out. I saw two *Dipsosaurus* and shot another one. He is closely akin to the San Ignacio form with regard to his gular fold coloration. We drove on through a Cordon Grande forest and out onto a barren area of mud hills where we ate lunch in the shade of a lone Mesquite. The road was good here.

Further along the road we came to a concentration of Joshuas where we stopped. After a search I said "No hay *Xantusia* again." Just then Chuck said—"Xantusia!!" at the same instant I caught one and we were off turning boys?? like mad fools. We caught seven. They have yellow venters and show very little dorsal pattern.

Bahia Santa Rosalia, B.C.

I caught a nice *Hypsiglena* under a Joshua log. He may prove very interesting with regard to the so-called *Hypsiglena slevini*.

We pulled the Cactus spines out of our hands and drove on, passing through Cirio forests, Elephant Tree forests, and Joshua forests. At times they were all mixed with Cordon Grandes thrown in for good measure. The Elephant Trees prefer rocky slopes and at times there are real forests of them on these parched rocky desert mountains. They are so thick as to be almost impassable.

The effect of passing through these weird martian forests is indescribable. It is like no desert I have ever imagined.

Shortly we came to Punta Prieta (Black Point), named for a lava ridge that juts out southwest of the Pueblo. The town consists of about a dozen adobes, no cars, many mules and burros, a few “Cerveza Exquisita” signs (Carta Blanca Beer) and many ninos. We drove on and came to the Arroyo Escondido. The walls of this large arroyo become narrowed and form a water gap about 7 or 8 miles above the sea. Water is present through this gap in the form of long pools (50 yards by 30-40 feet wide) and slowly running streams. *Juncus* and *Salicornia* are abundant. We took *Hyla regilla* here.

The road passes over a jumble of metamorphic rocks through the gap; it then leaves Arroyo Escondido and goes close to the sea. Here we turned off and drove to the beach. A beautiful ½ mile long barrier beach lies at the mouth of this arroyo. On either side are cliffs of conglomerate and short reefs of rock.

We put on swimming suits. Chuck and Arlene were wading out into the shallow bay while I was looking at tide pools. Next thing I knew Arlene was looking very sad and wading toward shore. She had a gash on the bottom of her instep and was bleeding rather profusely. Chuck got the first aid kit while I helped her up the beach. The wind was blowing, it was past sunset, and quite cool. The sand was blowing so it was hard to keep Arlene’s foot clean. We made a basket carry and took her to the car.

She was in a good deal of pain. There was no way of telling whether she had stepped on a stingray or not. Arlene was in a semi state of shock. We treated the cut and put her to bed. She must have been in rather intense pain as she is not one to complain.

She was very much despondent about everything—mostly, I suspect, because she thought it might mean an end to the trip which had been going along so well.

Chuck too was despondent because of her pain and secondly for Arlene’s attitude. Both Chuck and I knew that she would be all right and determined to make a permanent camp here until Arlene was well enough for the rough travel that we know is ahead.

We put her in the tent so she could elevate her foot and be out of the wind.

Chuck and I ate a nearly silent supper that I had cooked up. Arlene still did not feel well enough to eat. She was very sick until about 1 AM when she went to sleep.

It was interesting to notice the accentuation of personalities at times like these. Arlene would never have had the attitude she developed had she been one of the scientists (god forbid) on this trip, even though she has already proved to be indispensable in many ways.

Chuck was at once in the depths of despair and wandered around aimlessly seeming not aware of what might be done.

I was also somewhat overroutted but somehow I don’t seem capable of the extremes of emotion reached by Chuck. I kept moving things around, often aimlessly, but did succeed in getting Arlene in the tent and getting dinner cooked and down Chuck.

I fixed only those specimens that demanded it and went to bed.

June 19, 1949

Bahia Santa Rosalia, Baja California

Awoke to find Arlene practically well. Her foot had not swollen to the extent it would have had she stepped on a ray. I think she got a deep cut from a shell.

We put up a shade tarp and I washed clothes and fished. I caught a big surf perch and an 8 or 9 pound spotfin croaker. I am mighty proud of the fish and he is the main course of our dinner.

During the excitement of last evening, I had forgotten to rinse out my air after soaping it in sea water with Fels-Naptha. The salt water turned the soap to scum and cemented my hair

into one solid mass. Arlene came up with a bottle of Halo Shampoo. The effects were amazing on both Chuck and I. What we thought was tan and long beards proved to be plain dirt.

I cooked the fish (in a high wind) and we had cranberry sauce, corn on the cob, fish, coffee, and peaches.

Some Mexican fishermen passed our camp to get water 1 mile up the Arroyo. Chuck told them we would buy snakes and shortly they returned with a much battered *Crotalus ruber*. They told us that La Paz was “muy lejo” and left with suspicious glances at us—no doubt wondering why we should pay two pesos for a dead rattlesnake.

We worked a while on specimens and drove the roads for a while, taking one *Sceloporus rufidorsum* at night and then returned down the road to San Xavier and camped about 2 miles beyond our last night's camp.

June 20, 1949

3.2 mi S. of El Arco, Baja California del Sur, Mexico

7:30. Arose, packed up and commenced driving toward San Xavier. The road skirts the ocean shore for a goodly distance, passing through dense *Salicornia* growth and sand. Many whale vertebrae and one jaw bone were seen. Arlene didn't quite believe the jaw bones to be those of a whale.

The road became somewhat poorer passing over ridges running to the sea cliffs and down into rocky barrancas.

Above San Xavier a fairly high range of mountains come down to the sea (2,000-3,000 feet). The road bypasses these by turning up an arroyo through a sparse forest of *Yucca valida*. All the plants here seem just on the edge of survival. We searched diligently but no *Xantusia* could be found.

Rhus laurina is present here and is about the most lush plant present in the area—*Yucca*, *Pachycereus*, stunted *Veatebia*, and *Idria* (very small) occur. This is apparently an ecotonal situation and it seems evident that most such populations are depauperate for all the forms present. This is probably due to each of the species being present on the fringes of its tolerance. *Rhus* is probably not on the fringe of its range here. Such situations as this one must obtain for the fauna also. *Xantusia* may not be present. The soil is very dry and there is no good cover it seems.

The road continues in a wash and drops down onto the coastal plains again. This plain is again a very much stunted *Yucca valida* forest. We took *Callisaurus* and *Sceloporus rufidorsum* here.

At the cutoff to Miller's Landing the road goes up and over a band of white coastal sand dunes. These dunes are covered with a succulent shrub and a few small *Yucca valida*. *Callisaurus d. crinita* is very abundant here. I took 5 in about 15 minutes.

The first arrival I saw I mistook for *Uma* even though I was very close. This animal certainly has paralleled the evolutionary trends of *Uma* and never seems to be found away from sand. Its body form, stance, locomotion, and pattern all approximate *Uma*.

We drove on, bypassing San Xavier, up and over a granite ridge and down into a flat sandy plain bordered on the south by a 400-500-foot-high lava flow. The plain is densely vegetated with *Larrea*, *Yucca valida*, *Pachycormus*, and *Prosopis*. We took *Xantusia* here under rotting Joshua logs.

They have quite yellowish venters and a pair of dorsal dark lines extending posteriorly from a pair of temporal lines.

We drove on toward the lava mountains and Mesquitiel Rancho. Just before treaching the Rancho we were hailed by a young Caballero who tried every trick known in Mexico to sell us some tanned hides he had tied to his saddle. One, he said, was “El Perro” (Quinze Pesos).

We passed through the main yard of the Rancho. It consists of 6 or 7 burros with pack frames, (kayaks), a rickety stable, and one adobe dwelling. At least 20 people (young and old) swarmed in and out of the house. I could see no other houses in the vicinity and I assume they all lived in this one house of 2 or 3 rooms at most.

We drove through with a “Buenas tardes” to everyone. The road curves down through the river bottom where it is very dusty and up along the edge of the lava mesa. The stream bottom must be quite full of water as the *Yucca* are very lush and large. They look more like our Mojave form when living in such a moist situation.

The road passes out onto the fringes of the Vizcaino desert. The desert is very densely vegetated. Large *Fouqueria peninsularis*, *Pachycereus pringlei*, *Larrea*, *Yucca valida*, and *Opuntia* of one sort and another cover the sandy floor. The road is very fine. Granite dust forms the whole soil and packs to make a smooth dustless road.

We drove up over a rocky ridge, dropped down into a deep barranca, climbed the other side and emerged into El Arco. This small village is composed of about a dozen adobes set at various places over a level dusty shelf about the size of a football field. There is no real street “per se”. The hills around the towns are very arid, rocky, and quite barren. They are dissected here and there by vertical walled barrancas. Some mine colliers and dumps line the closest barranca.

We asked a sober rotund little Mexican where we could get gas. He asked us for our Visitor’s permits. He was the Jefe oficial of the Sub delegacion de gobierno del Baja California del Norte. Since we were not given any at the border even after requesting them we were at a complete loss for a moment. I started to walk out to talk to Chuck when he hailed me back into the office. He had strapped a large web belt and revolver around his waist and was looking much more grave than before, nervously smoking a cigarette. Chuck suggested I get my collection permit, which I did. The little man had an assistant read it aloud while he paced back and forth looking grave. The signature of the General Forestal y Caza raised his eyebrows slightly though he tried to look as if we were all Calabozo-bound.

My picture on the permit showed me in a sport coat and tie with my hair combed. He looked curiously at me and pointed. He said “You” (Ustede). “Si, yo estoy muy sucio ahora,” I said. (I am very dirty now). He didn’t smile but had all the permits read to him, including how many animals I could catch and what to write to Mexico City after each trip. He asked me why we collected snakes and lizards. We told him for scientific purposes. He sneered and we left him to be important in El Arco (it must be hard at times). We drove to the 20 yard line alongside some gas drums and started to get gas.

The adobes here have dirt floors. Baby chicks and half grown turkey wandered in and out among the numerous ninos. Two women and an old man helped get the gas out of the drums by siphoning it with much laughter, spilling of gasoline, and wry looks.

We gave about 6 ninos some peppermint candy. Pancho, a little fellow of about 6, smiled from ear to ear. We learned that “oro” (gold) was mined here. The gas cost us 25 pesos for 10 gallons or about 30 cents per gallon.

We left and made camp south of the line (the del sur line is marked with white stones on a cleared space). We made camp amid Cordon Grandes and Ocotillos. A *Chilomeniscus*—crawled into camp and we caught a *Crotalus ruber* (red rattlesnake) crawling over the road.

Arlene was awakened by a huge centipede racing around her sleeping bag. I killed him. He must have been 8 inches long.

We worked over our specimens until about 12:30 AM and hit the sack amid many insects, one of which bit hell out of me. (Chuck told me to pick it up, which I did—it rammed a fang into my throat about an inch).

Big Joke: Back in El Arco Chuck referred to me as “El Nariz” (The Nose). All the Mexicans, particularly the two women burst into laughter. A boy of about 14 years who was helping me pour gas into the car, looked at me as if to say “You poor guy—I’d hate to be in your shoes now.” Maybe there are connotations to this we don’t understand.

June 21, 1949

San Ignacio, Baja California del Sur, Mexico

Arose and while Chuck pickled *Xantusia* and took color notes, I packed the truck. We drove on a fairly good road toward Los Angeles.

Los Angeles is a corral with a well. A caballero was raising water in the well (pozo) by pulling a rope (with his horse) attached to a leather bucket. The rope was run over a big iron pulley. From the length of the rope the water must have been down 100 feet or so.

Prior to our arrival in Los Angeles we had passed over a portion of the sandy part of the Vizcaino desert. I saw no dunes, the area being one of long low sand hills, vegetated occasionally by *Yucca* and *Opuntia*. *Callisaurus d. crinita* was very common here. I took 9 in about 20 minutes. Their whole demeanor again reminded me strikingly of *Uma*. Chuck saw two adult males who curled their tails before running. None of the some 20 or 30 chirrionera I have seen have done this.

The sand plain probably is quite extensive. The section we passed probably was 10 miles in length. We only crossed a tongue of it.

All day we could see the Sierra Vizcaino out over the plain. It is a most unique range apparently of volcanic origin, the peaks jut up vertically from long level saddles giving the mountains the appearance of a histogram. Joshuas continue to be quite common.

We camped for lunch under a Palo Verde. We stayed here, enjoyig the sparse shade for 2 or 3 hours. During part of this time I slept, being very tired after last night.

We drove on over increasingly rough territory on a rocky road. The terrain became a rocky undulating plain with occasional volcanic necks making conspicuous buttes on the landscape. The plain is dissected by deep vertical walled arroyos.

Copal trees are fairly abundant here. About 10 or 12 miles North of San Ignacio the road seems to have been worked on to a certain extent even though it is still very rocky. It has been cleared of all the larger rocks which have been piled at the sides of the road, thus you travel along in a ditch.

It was dark when Chuck called out and we stopped for our first *Crotalus enyo*, a nasty little fellow with a beautiful color and pattern. He lived among rocks (volcanic). The rocks are dark and the substrate is lighter in color. Ocotillo, poor Cordon Grande, Copal, and *Opuntia* made up his plant cover.

We drove into San Ignacio in the dark and stopped at La Tienda to make contact for snake collectors, which we did, then we drove east of town and camped in a clearing among the boulders. We were very tired but Chuck went off after a call that sounded like a toad but proved to be a bird. Every dog for miles was alerted and barking madly thus keeping us and every person for miles awake. When the neighborhood quieted we discovered a tarantula which may have left some of us a little uneasy about sleeping on the ground.

June 22, 1949

San Ignacio, Baja California del Sur

5:30. We arose early and started collecting. The daylight showed that San Ignacio is an oasis set in a barranca about 500 yards wide, bounded on either side by nearly vertical cliffs composed of jumbled blocks of volcanic rock. The vegetation on top of the banks of the barranca is sparse and arid (Copal trees, Ocotillo, Cordon Grande, and *Cereus* Cacti).

Along the south side of the barranca there is a stretch of water bordered by rushes. It runs for about 1 mile and is about 100-150 feet wide in places. It is variable in depth but must be 8 or 10 feet in some places.

The whole barranca is filled with date palms. Nelson estimated (in 1906) that there were 60,000 then. There are still that many and possibly more today. Broad dirt streets wind under the shade of tall date palms. Many of the houses are of date palm leaf construction and most have thatched roofs. Most of the substantial buildings are adobe though some are brick and the church is constructed of stones.

We crossed the water and drove up a side canyon looking for a way to get to the rock cliffs when we came upon the main section of town that we did not know existed. It was composed of winding and often narrow dirt streets. There is a large shady square in the center of town. The old church stands at one end of the square. It was built under the direction of Spanish missionaries in 1726. It is built of chipped and squared stone blocks about 8 inches on a side.

We entered the church, being guided by a young fellow who spoke English. (He was the village doctor—hired by the government.) The church is a very high domed one of three domes constructed of concentric rings of stone blocks. Candelabra hinge from the center of these domes. A large ornate gilt altar occupies one end of the church clear to the ceiling (40 feet). Several people were kneeling in prayer on wooden benches.

Arlene and I followed our guide up a narrow and steep stone staircase that ascends to the bell tower. It turns up one wall outside the church. There are four bronze bells in the tower. Arlene had attracted quite a retinue of “Lobos” who followed us making sly remarks in Spanish which neither of us understood.

We descended and drove around town. A quick-moving little man walked up to us with his arms waving. “Mira mi huerta”—He took us to his garden and told us how he had grown the grapes (uvas), figs, corn, peanuts, olives, etc. all in two years. I told him he was a good farmer and he told me how much work it was. Arlene and I asked him all sorts of questions. He told us he killed lizards because they ate the flowers off his melon vines. He gave us some peanuts (which we did not eat) and we left.

Arlene and I drove up the hill and picked up Chuck, who had been hunting lizards on the cliff. I got a *Petrosaurus* (see species account) and Chuck picked up 2 or 3 *Urosaurus* on palm trees and rocks.

We were told that San Ignacio has about 3,000 people.

We got water after an Indian had taken us on a long goose chase to the stream. At the stream we met our English-speaking friend. He was in great pain, having dislocated his shoulder while diving into the swimming hole. I drove him back to town and he told me what casa to visit to get agua. This I did. The house was a nice one with large airy rooms and cement floors. The family had a new ice box and several settees and nice chairs. The woman of the house said she had twenty-two children.

We drove down to the water to put up specimens. I drove the car up under a palm tree and we started to work. Children crowded around and Chuck set them to work hunting snakes. When the first one was paid off the rush began and we got six more and some *Hyla*. All the ninos began to gather around to watch us preserve specimens. Their interest in making money is very low, perhaps because they have no place to spend it. We told them they were “my perezozo” (lazy) and they all began to fall on the ground chanting “muy perezozo” to show how

lazy they *really* were. One jumped into the dense reeds that line the stream bank to show that he was *really* lazy. This demonstration went on for some time. We learned that there are tortugas (turtles) in the water but they are muy hondo (deep) during the day. This may be *Clemmys*. We offered 10 pesos for the first turtle. This brought no response at all.

We packed and left, driving over a reasonably good road to Santa Rosalia. We passed over plains and ridges, and mountains. The steep side of these mountains seems to be on the eastern scarp even though they did not seem to be fault-block mountains. We camped just back of the beach in a little draw long after dark.

June 23, 1949

Santa Rosalia, Baja California del Sur, Mexico

Arose and drove into town where I took my shoes in to be fixed, had a haphazard job of greasing done on the car, and sent a telegram home.

The town is set in the most arid of situations along the gulf coast. All the buildings are of wooden frame construction and are closely packed together. There is a sheet metal church and a square with some lush Indian Beech trees shading it and its cement benches and central pool.

Long wharves reach out into the bay, apparently constructed of slag from the processing plant. A 10,000 ton vessel is said to be afforded adequate depth.

A short, narrow gauge railway runs to the copper mines about 7 or 8 kilometers out of town. We saw two engines hauling ore cars. They had tall stacks like the DeWitt Clinton.

North of town near the base of a grade called La Cuesta de la Infierno a new manganese mine is in operation. The ore is said to be a surface deposit with a vein of black ore of considerable thickness. Dr. MacKinnon, a Scotch dentist, who owns a ranch near La Purissima gave us much of this information. He walked up to us while we were waiting for my shoes to be fixed. He was one of those people who have lived all over the world. He gave us the names of several people we would meet along the way. He asked us if we knew what an animal he had seen might be. He then drew a picture of a long lizard-like animal with only two legs, both springing from the sides of the animal's head. The description fits *Bipes* of course. He said they were common under rocks on his ranch near La Purissima. They never come out in the daytime he says but are always buried. The natives call them "Ocolotes" and apparently they are quite common.

He advised us against taking the road to Comondu as it is very bad. Instead he suggested that we go to La Purissima on a level road. This we shall do.

My shoes were fixed and we left, stopping for lunch at a mesquite tree in the middle of a wash. We ate and then I tried to drive out over the sand. The car bogged down on a hummock and before long we were really in the sand. The heavy load did not help so we unloaded it to the shade of the Mesquite tree. The day was terribly hot and humid. I had to stop working very often and every movement became a real effort. Chuck and I let a lot of air out of the tires (down to 15 lbs.) and even this did not work so we slept for a while under a mesquite. I was very much out of it and so was Chuck, though not as bad as I.

Finally a truck came down the road. I un— the block and tackle while Chuck hailed them and he pulled us out with no strain. We gave him some cigarettes and drove very slowly back to town to get air as it was only two miles and we were very tired and would thus save time and energy.

When we arrived at Santa Rosalia the town was fairly humming with activity. All the populace had come out in fresh clothes and were promenading up and down the streets. A cornet band was playing in the schoolhouse. These people are just like the lizards. They get up with

the dawn and work until it gets hot and then disappear from sight. When it becomes cooler they all appear again. Everything stops at dark (most everything).

We found only about 30 pounds pressure in the air hose and had to pump the rest in, surrounded by small boys. We drove out of town and ate dinner on a small playa south of town. We were all somewhat sick from the exertion and heat. We had sauerkraut and spare ribs and potatoes (out of a can) and coffee. It filled the bill but didn't taste like some of the other meals we have eaten. Chuck discovered that he had failed to load the shovel so we had to drive back to where we had been stuck. It seemed like we were unable to pry ourselves loose from the hot clutches of Santa Rosalia.

We drove on, through the night, through a village called San Bruno. It is located 15 miles S. of Santa Rosalia. Some Palms and white houses were all we could see. The ocean (Gulf of California) is close by as attested to by the presence of *Salicornia* marshes.

We drove on through washes, over cobblestones, and finally made camp under Palo Blancos (we saw them first just south of Santa Rosalia) and Palo Verdes. The Palo Blanco is a thin, graceful tree with a pure white bark. They are quite common in washes and near moist situations. The tree belongs to the family Leguminosae, as the bean pods hung from every tree, their yellow color and the white of the bark making a most interesting and beautiful combination.

Only in moist places did the trees show their pinnate leaves. These trees are no exception to the rule that all life retreats from the summer. They simply pull in their leaves and live inside a cool trunk.

June 24, 1949

Santa Rosalia, Baja California del Sur, Mexico

We pulled into camp at about 9:30 PM, all very weary and limp from the sun.

Mulege, Baja California del Sur, Mexico

Arose with spirits somewhat brighter, ate a feeble breakfast (as usual) and took off down the road. We travelled in a sandy valley between precipitous mountains of sandstone. About 5 or 6 miles south of camp we stopped by some boulders, amid Cordon Grandes and Ocotillos. Chuck picked off a small Chuckwalla and I got one shortly thereafter. They are the first to be taken from this part of the Peninsula. They are smaller and not very colorful as compared to our Mojave animals.

We drove on over this good road to Mulege. This town was anything but what we expected. I thought San Ignacio would be the nicest town we would see, but Mulege exceeded it by far. Upon entering town you drop down over a dusty rise onto a main street of adobe buildings, ___? in spots with pinks, blues, and other rather outlandish colors. Many of the windows are grated. The numbers of children are enormous in all of these Mexican towns. They must die off at a huge rate as there are not so many grownups in comparison.

The vegetation is one of the most remarkable things about Mulege. Mangos, Bananas, Grapes, and Palms are everywhere. The place is a veritable jungle of lush vegetation. Both Coconut and Date Palms are very numerous. A stream of fresh water about 60 feet wide flows through the center of the arroyo in which the town sits. (It is dammed to keep it from mixing with the salt water estuary that forms the mouth of the stream). Steep cliffs rise on both sides of the town

We drove through the town and out a little dirt lane shaded from the sweltering sun by Coconut Palms to the edge of an estuary lined on the water's edge with mangroves and on the other side by tall Palms and Grape vines. Fish jumped in the sea water; a group of small children

with bare feet padded down the dusty road carrying swimming suits and 3 or 4 small watermelons.

The road lead to a crescent barrier beach of white sand with the mainland on one limb and a rocky peak on the other, topped by a light house.

We were filthy from several days in the field with no baths, so we put on our suits and swam in the beautiful emerald water. It is quite warm water but not so warm as to be enervating. To be clean was about the best feeling that can be imagined. We rinsed off with fresh water and washed with Vel (a detergent works quite well in salt water where a soap is useless). We saw no sting rays (Manta) in the Gulf though I saw several in the estuary.

Back at the town we picked up water at the town fountain. We made camp along the stream. The ninos came in droves when we offered 25 centavos for a lizard. We got many nice ones this way. Chuck offered 5 pesos for snakes. An old Senora who had been listening perked up and went resolutely down the stream under the palms. About 15 minutes later she returned with a large gopher snake on the end of a stick (even the children will not hold reptiles by the body and come into camp holding lizards by the tips of their tails—why the tails don't break I do not understand). The five pesos had even brought out the old folk. The snake is much different from one form in Southern California. It is quite brilliantly colored with hennas and rich browns

A fellow who said he built houses sat down and talked to us—often too fast to be understood. He tried to bum a ride to Ensenada—what he intended to do about his senora and 5 ninos we never found out.

He told us of snakes (amarillo) in the palm trees and black ones in the palm trees. After this information he told us a snake story about a vibora (viper) and a cameleon (Horned lizard) with many gestures and much laughter. We did not understand it at all, but enjoyed it nevertheless.

After a confab I offered him a cup of coffee. Arlene was worried (along with Chuck and I) that he might carry amoeba on his hands or mouth as many Mexicans do—we decided to offer the coffee and boil the cup later. But the coffee was hot so he walked over and picked up another cup and poured the coffee back and forth—soda jerk style—thus getting two of our cups out of commission. We were all laughing and he thought it was about the hot coffee so we all had a big laugh.

We left this town after getting gas and disappointing dozens of ninos who brought in lizards after we said “No mas chucorones”. The tide had come in and in places covered the road where it passed along the south edge of the estuary. At times we were driving along through the water 50 or 60 yards from the nearest land. The road borders the Bahia de la Concepcion down nearly its whole length. Beautiful beaches of pure white sand and clear green and blue water, bordered by rugged mountains covered with desert vegetation make this bay a most wonderful place. It became dark as we drove along. We stopped and cleaned all our dishes with sand and sea water. A little further, where the tide had covered the road we saw the dreaded trunk fish or Botete swimming on the road. They are chubby, square-headed fish with a pretty brown and white pattern.

The road then goes up a cliff that rises vertically above the bay. It is quite steep but good a good road (4 wheel drive necessary in many places).

Bahia de la Concepcion, Baja California Del Sur, Mexico

We drove on and camped in a little valley. Chuck was very tired and so was Arlene so they went to sleep while I took color notes on a couple of speaniers?? This night we put up our mosquito bars as malaria is present here.

June 25, 1949

La Purissima, Baja California del Sur, Mexico

We arose, considerably refreshed and drove along a good road that follows the bay! (Bahia Concepcion). Frigate birds circled in their weird, disjointed way and numerous flights of white-headed pelicans flapped and glided in single file over the bay. The road shown on the Automobile club map going south along the west end of the bay is now in disuse. The new road does not leave the bay when it reaches the south end of the bay but circles around the base of Bahia on a tidal flat. The road is quite good.

After it has passed clear past the south east corner of the Bahia it turns south past a small Rancho, climbs a rocky grade, and drops down to Rosarito. Rosarito is a rancho built of brick with trellises of morning glories. Mesquites and palms serve to give shade. Beautiful Palo Blancos fill the wash behind the Rancho. The cattle do not look very fat even if the rancho is pretty.

The road always goes through the main dooryard of all these places and everyone comes out to look when you drive through.

A little beyond Rosarito the road passes by a little white Casa set on the bank of our arroyo. There are numerous cattle, many mesquites, and palo blancos and palo verdes in the wash, and a few palms. An Italian lives there with his senora. He speaks English with a mixture of Spanish and Italian accents.

This rancho is called Campoli. From it the road branches. To the left is Loreto along the gulf coast and to the right is Comondu and La Purissima. We followed the latter branch and began to ascend a rough volcanic ridge. About 7 miles south of Campole we came to another fork and took the road to the right that leads to La Purissima.

This road is a winding one but smooth enough. The valley in which it runs is bound by vertical walls, capped by basaltic lava. There is a veritable forest of mesquite and opuntia. Clinging to the vertical walls are large, white-trunked trees of the fig family. The roots and various trunks run into cracks and over rock surfaces like tentacles. On the south Canyon wall, shaded from almost all sun we took 6 of the beautiful *Petrosaurus*. Their demeanor and body form at once places them as close relatives of our *Streptosaurus mearnsi*. Pinks, blues, yellows, olive greens, black and other colors are blended on this animal.

The weather was much, much cooler than it had been on the gulf slope. We felt able to move again and were once more civil to one another—except for Chuck who had gotten dust in his eye and who could not see. A little Murine did wonders for him however.

Before long the walls became higher and the lava cap turns in columnar forms. We saw palms and many lush mesquites. We stopped at a weather station (rain gauge, temperature, and humidity).

The Casa was called Ojo del Agua. A sizeable stream flows over rocks in the stream bottom. Several fords were made. The road runs, at times, over rocky shelves along the river bank. The walls are nearly vertical and perhaps 1,000 feet high, the lower segment being sandstone and the upper 300 feet being lava (Basalt). The stream is a clear, fairly swift-flowing stream backed up in various places to form pools of varying size up to 200 yards in length. Tules, willows, a tall bamboo-like grass, and mesquites border it. Where the canyon widens, groves of Date Palms, Olives, and Grapes are planted. All looked very healthy and green.

We drove up into a small village (50 or so adobes) of San Ysidro. Here we met a jolly truck driver who told us about the MacKinnon ranch we had intended to visit. It is on the southern edge of the Vizcaino Desert and consists of nothing but "Jack Rabbits and sagebrush. He has spent 12 million Pesos on it and now his water is coming salt from the well and all the trees are dying." The driver spoke English very well. He had lived in Los Angeles.

He likes MacKinnon but said he was full of “baloney”. “No matter how thin you slice it, it is still baloney,” he said.

We asked about Ajolotes. He said there were two kinds—a light one with “two hands” and a dark one. He asked all the village populace to hunt them for us.

We drove back upstream and camped near an abandoned shack alongside a sluice that carries drinking water to SanYsidro. We boiled water and filled our cans to the top. Even boiled it is good.

Chuck and I worked and boiled water while Arlene tied tags. We stayed up till 1:30 AM to get our back work out of the way. The air and breeze were like a drink of ice water on a hot day—cool and invigorating. We all felt good for the first time since San Ignacio.

June 26, 1949

Magdalena Plain, Baja California del Sur, Mexico

Arose early and were all sleepy. I washed and hung my clothes out on a mesquite tree as did Arlene and Chuck. The water is quite soft and the detergent worked well even in cold water.

While we worked several Mexicas came up. Some small girls brought in Zapos (toads) (*Bufo punctatus*) and water snakes for which they were paid. A Mexican fellow said he could show us Ajolotes. They were in his garden he said. We followed him down by the stream amid date palms, willows, and mesquites. Chuck and I were ripping apart a cottonwood or willow stump when we spied a beautiful skink with a blackish brown body with light gold stripes and a purple and red tail. He was pounced on before he could move. This, the Mexican said, was the black Ajolote. We had hoped for *Bipes* but apparently that was the other Ajolote.

A little diligent rock turning produced 3 more skinks, a Tuberculate gecko, and a worm snake. Chuck caught a King snake and a racer.

We drove into town and were rewarded with a box full of very battered lizards caught by a small boy. He was apparently the only hunter around. We left formaldehyde and instructions with one fellow in hopes of getting *Bipes*.

La Purissima is about a mile down the canyon from San Ysidro. The town is full of adobe ruins and is in general very dilapidated. Mexican women peer out on the street from behind tattered plaited palm frond mats. A rectangular square encircled with stone benches occupies the center of town. We bought 5 gallons of gas and left.

The road passes up and onto the plain above the Purissima. Instead of lush vegetation and water all is now ocotillo, Cordon Grande, and cactus set among lava boulders. The road is quite good, having bridges of stone here and there. Before long we could see the ocean far out over the undulating plain to the west. To the east nearly hidden, are the tips of the ranges in the Sierra Giganta.

Very occasionally *Yucca valida* clumps are encountered among the *Ocotillo peninsularis* and Cordon Grande. *Larrea* is occasionally common and sometimes lush. Low, rocky hills alternate with wide sandy areas. Epiphytes and Orchilla (a pedulous lichen once used in the dye industry) are very common on Ocotillo, making them appear to have thick trunks and limbs. We took (Chuck did) *Xantusia* and *Phylodactylus* here under *Yucca* logs.

We drove on, long after dark and made camp under a big Mesquite tree. I have a nice fire at my back to ward off the cool night air (18 degrees C.)

Spanish names for lizards:

Callisaurus—Cachimba

Sceloporus—Carnarro

Skink—Ajolote

Bipes—Lolcuatl

Dipsosaurus—Cacharon or Iguana
Cnemidophorus hyperythrus—Guico
Small turtle—Cahuama

June 27, 1949

Magdalena Plain, South of El Refugio about 6 miles, Baja California, Mexico

7:00 AM. Arose after a good night's sleep and worked on specimens until about 1:00 PM, getting everything caught up to date. We started to drive over the monotonous Magdalena Plain. To the east the rugged summits of the Sierra Giganta could be seen. All around us was an undulating sea of scrawny Cordon Grandes, Ocotillo (covered with Orchilla) and epiphytes (Toje in Mexican) that seem to be a xerophytic bromeliad, various opuntias, Cereus cacti, and mesquites. None of the plants are lush.

We came to the Arroyo Santo Domingo where we drove to the most prosperous Casa, belonging to Don Santos Castro. We had been referred to him by Dr. MacKinnon at Santa Rosalia. We asked about roads into the Sierra Giganta. He said there were only mule trails. This was disappointing as we had hoped to collect there. He knew about Ajolotes and said he could get them for us.

He led us to his huerta. It was a fine farm of corn, grapes, figs (*Higuierras* sp?), and beans. He had a deep well with about an eight-inch pipe.

A large engine about the size of a caterpillar tractor pumped beautiful cold clear water out at a great rate. Part of the well shaft had been dug by hand and was shored up with mesquite logs. The engine was set in a dirt cellar about 10 feet below the soil surface, shaded by a thatched roof. The engine was obviously his pride and joy.

We dug for *Bipes* but did not find any (see Species Acct.). We left him a jar to be picked up on our way back.

On down the road we went. The day was beautifully clear and cool. It is amazing to me to find this plain so cool. Palm Springs is probably 120 degrees now. I doubt that it was over 80 degrees F. today here. The nights are so cool that the sleeping bag is most welcome whereas we slept outside at Santa Rosalia and Mulege.

The plain is an alternation of small playas practically devoid of plants and higher areas of poor cordon, ocotillo, and mesquite. We only took 3 lizards. A good dinner was eaten just at dusk and we drove on past El Refugio. We saw only one snake but he made up for the paucity by being a beautiful boa (*Lichanura trivirgata*). Chuck was elated for hours over getting him. He is a beautiful animal with 3 longitudinal dark brown lines alternating with gold tan areas. His venter is flecked with brown.

We made camp under an Orchilla-covered Mesquite and I skinned a vulture (King) (caracara) that I had shot.

Weather stations were seen at San Domingo (in the care of Don Santos Castro) Pozo Grande, Buena Vista Rancho. Instruments include thermometer, pluviometers (rain gauge), and wind gauge.

The vulture turned out quite badly as he proved to be full of lice which crawled all over both Chuck and me before we realized what was tickling us. I tossed the skin (which was nearly done) as far as I could throw it and fell to powdering myself with some rotenone that Chuck had brought along. Chuck did the same. That night my air mattress collapsed and I found myself sleeping on the largest and lumpiest cow pie ever constructed.

Finally, after some shifting, we got situated and slept.

June 28, 1949

I woke early in the morning and the sky was clouded over completely. It was cool enough to have the sleeping bag zipped all the way.

Chuck and I did some collecting in the Cordon Grande-Ocotillo scrub. We shot *Cnemidophorus t. rubidus*, a very distinctive whiptail lizard with a rose colored gular fold, hind legs, and tail.

52.1 mi S. Medano, Magdalena Plain, Baja California del Sur, Mexico

We also picked up a new subspecies of orange-throated race runner and the blotchless *Uta*.

The general aspect of the plain is of stunted vegetation, thickly covered with lichens. All in all it is rather dreary. The road, however, was good for about 30 miles below Medano. In places it is quite sandy and after a while is rutted and washboardy, making for uncomfortable riding. However, nothing can dampen the fact that *we are on the Magdalena Plain*. The names of these places we are seeing were, only a short while ago, only fabled places on a map, to be dreamed about. To be one day north of La Paz makes up for most everything.

We can see Santa Margarita Island poking its summit above the horizon even though the ocean is not visible. It is the highest peak in the area.

The ride was punctuated only occasionally by dips into vegetated arroyos or brief passages through rickety pueblos. The rest of the day was all Ocotillo, lichens, and dust.

At dusk I rode on the front fender while we hunted Poor Wills. Night hawks swooped in every direction in front of us. The abilities of flight shown by this bird are amazing. We got no poor wills but I was tossed off the fender when Chuck stopped quickly for one we did not see until the car was almost upon it. I hit the road running a 9.3 100 yard dash and succeeded in not falling down. Shortly we came to the beach. The road, a very sandy one, running along behind the beach dunes.

8:30 PM. It was several miles before we found a stretch of sand large enough to camp on. I built a rather smoky but warm fire and Chuck brewed a pot of coffee.

Several times today we have seen vultures of the type I shot—sides of head white, ruff of black feathers on back of head, large white beak with pinkish skin around it, body brown, wings brown with white bar at tip, tail is banded at tip with brown, white with brown lines across is on the rest of the tail (Caracara).

Also we have been seeing a bird (Harris Hawk) that looks like a marsh hawk except that he is very dark and has rufous on his back. His rump is white and so is the bar of his tail. The tail is long and thin and the wings broad (Buteonid wings)

June 29, 1949

On Road to Rodriguez, above La Paz, Baja California del Sur, Mexico

8:30 AM. Just away from our camp, about 200 yards, was the beach line. The beach was steep and waves pounded in on the sand. The effect was wild. The sea crashing and spurting up over a headland to the south. Once more underway we continued driving through the same sort of scrub we had seen for two days. At Arroyo Seco the road dips down and passes the abandoned village. From here the road turns inland through the same sort of territory. We collected an additional leopard lizard and picked up several horned lizards. Short walks netted us a good many species.

The road traverses rolling plains country vegetated very heavily by almost pure stands composed of three plants: Cordon Grande, Ocotillo, and Joshua Trees. Joshua trees became more abundant during the day's travel though they never became verdant. The fallen logs were

never large enough to supply adequate shelter for *Xantusia* during the heat of the day. We searched diligently but could turn up none.

The effect of the sea coast was modifying in the extreme as we soon told when the heat closed around us as we drove inland. It felt like Chicago in the summer and before long we were all (all except Chuck) running with perspiration. Chuck never seems to get hot.

The road now passed up and into the southernmost foothills of the Sierra Giganta. These consist of an arroyo dissected bench covered with an arid tropical jungle so thick as to be almost impenetrable.

North side of La Paz Bay, Baja California del Sur, Mexico

Most of the plants are new to me. A new tree with a thick white trunk and dark green palmate leaves has become common. Bromeliads and various Euphorbs have made an appearance. The *Larrea* (creosote) has to stretch its neck to see over the jungle and thus has become tall and spindly. Most of the plants have thorns of some sort and all are adapted to extreme heat in one way or another.

Suddenly, out of this impenetrable sea, we saw ocean and an island. The ocean was La Paz bay and the island Espiritu Santo Island. We soon could see La Paz set at the edge of the bay at the base of tall rocky mountains. About ½ of the bay is cut off into a tidal lagoon by a long spit of land extending from La Paz northward across the bay. We could see that the Giganta ends abruptly at the edge of the La Paz plain as the edge of a mesa. The road cuts down over this steep slope and out onto the Plain. This plain is very low and slightly humpbacked, sloping into the sea on both sides. It is easy to see that very little shift in elevation (either of the sea or land) could inundate it and leave the Cape region an island.

The Sierra Victoria are quite precipitous and remind me of our own Sierra Madres.

The plain is a dense forest of Giant Cactus, mesquite, Ocotillo, and *Larrea*.

We drove up a road leading to Rodriguez and camped by the road. Arlene whipped up a good dinner of tuna and rice and beets and coffee.

I burned my hand rescuing the Coleman lamp from falling and Chuck spilled ink on his journal. A jolly time was had by all.

June 30, 1949

La Paz, Baja California del Sur, Mexico

The road circles the tidal lagoon and before long we came to the outskirts of La Paz. Things look more prosperous here, the buildings are less often of scraps and more often adobe painted various bright calsonine colors.

The road enters town along the waterfront. This is a beautiful place. It is a semi-circular cement walk lined with benches and shaded by coconut palms on the ocean edge. A bandstand occupies the center of the promenade. On the shore side are huge Indian Laurel trees, so dense that no sun penetrates their canopy. Hotel Perla and several impressive government buildings occupy the waterfront. A small steamer dock juts out into the blue bay from the bandstand. A coastal trader was unloading flour and grain from ports along the Sonoran and Sinaloa coast. The bags were labelled "Yaqui". Over cobblestone streets to the center of town we went passing on the way, many houses with the iron-barred windows so typical of the tropics. The central square has the usual benches and the usual bronze bust of some unknown individual in the center.

Chuck and Arlene and I went over to a place called "The Aloha Bar" where we picked up much Carta Blanca (Cerveza Exquisita). We then retired to the waterfront, had ginger snaps, cerveza, roast beef (canned) and brown bread (canned)—a delightful repast. Later we had some

more money changed at Rufo's (the largest department store in town—a whole block) and picked up the car which we were having serviced.

We bought gas and during the heat of the day proceeded out of town on the Todos Santos Rd. to cook dinner. This we did.

Arlene, apparently feeling slighted about our visit to La Paz and no doubt tired gave us more than a few anxious moments by turning on the "female attitude" amid tears and such. Since we had intended to go back into town after dinner and see what we could see neither Chuck nor I knew exactly where to start. At this stage in the trip such goings on left us a little low when we think of the trip back in which there are no new places to see—just jouncing dirt road travel and collecting.

However, Chuck handled things with more diplomacy than I have ever seen him use before—much more than I was able to muster. We went back to town and walked down the waterfront at sunset—a beautiful sight—a shimmering bay, a row of palms silhouetted against a fading orange sky. There is no traffic here and a cool sea breeze moderated the heat of the day leaving everything cool and beautiful.

We walked up town looking for music and found only juke boxes with Spanish _____ music blaring out. "Mi pobre Corazon"—finally, at the Aloha Bar we spotted a neat, rather aristocratic Mexican, with a guitar. He finally came over and sang several songs for us (mostly for Arlene I suspect). Unfortunately he had a rather drunk friend who informed us numerous times that he was a 26 year old First Lieutenant in the Air Force. We left the music as a "hot jazz band" straight from Vera Cruz had begun to play. Mexicans that looked like farmers began to play saxaphones and stand up and give out with various hotnotes. We decided to see Danny Kaye in *The Secret Life of Walter Mitty* (with Mexican subtitles). We bought loges (for 25 cents Ameican) and walked in. It was about 30 minutes beore I realized that there was no roof over us. The moon and stars were not painted on. The loges consisted of wooden benches on the level. The other seats were bleachers. The words were not transmitted very clearly which didn't disturb any one but us. We walked to the car and drove out of town and camped along the Todos Santos Road.

July 1, 1949

Todos Santos, Mexico (Baja California)

I awoke early to see 2 Caballeros driving cattle down the wash in which Arlene was sleeping. The men herded the running cows past her sleeping bag much to close for mine and surely much closer for her comfort.

We drove on toward Todos Santos, collecting many lizards on the way. Chuck noticed a large head jutting from the top of a Gant Cactus (Cordon Grande). The animal proved to be a *Ctenosaura* or Giant Spring-tailed Iguana. The lizard ran down the trunk and disapeared behind it. We found him in a hollowed out nest about 20 feet off the ground. The lizard was about 2 feet long, heavy bodied, and with a large crest of elongate scales along his dorsum. Another was shot in a similar situation later in the day.

The Sierra Laguna loomed on the horizon all day, waiting to be invaded by its first crew of herpetologists. In profile it reminds me of the Sierra San Pedro Martir, with a high peak at its northern end, isolated from the main mass. The scarp is on the west side and is quite precipitous. The mountains appear to slope off to the south.

We rounded these mountains and proceeded down the Pacific side over rolling, ravined foothills until we dropped into a barranca in which some small farms were located. On the south side of this arroyo is the pleasant little town of Todos Santos. It is a quiet little place of dusty streets, bright calsonuned adobes, and shady trees. It gave me the impression of being clean.

A pretty little square (as in all Mexican towns) occupies the center of town. It is encircled with shade trees and benches and has a fountain in the center. Aztec paintings are seen on the walls and benches.

A very old looking church with 3 green bells in its tower for 6 is situated on the south side of the square. A theater and store are on the west and a cantina forms part of the east wall. Just to the west of the church is a bluff. I stood looking over the arroyo below. It is a mass of greenery. Little square farms lined with coconut and date palms make up the greater part of the valley, which is ½ mile across at its mouth. Beyond is a bright blue bay.

We located Manuel Santana, to whom we had sent a telegram asking for burros (mulas) to pack into the Sierra Laguna. He was a fine quiet gentleman and had relayed our message to Tinio Castillo, a packer who guides people into Laguna, a small lake in these mountains. We bought the food recommended by Sr. Santana and proceeded toward La Burrerra. This latter place is the pack station for trips to Laguna.

Somehow we took the wrong turn and ended up near Rancho Santo Domingo, described as “muy lejos” from La Burrerra by a caballero we interrogated. It proved to be about 20 miles by road and 5 as the crow flies. The vegetation in the foothills is remarkable. It is a mixture of all sorts of legumes, bouganvillea, Elephant trees, cacti, all living together forming a forest 20 or 30 feet in height. There is not much shade but so much vegetation as to keep the air still and so it was very hot. We ate dinner at sunset in this beautiful forest, not enjoying it as we should have perhaps, because we were so far from our destination. We drove until about 11:00 PM and camped in a wash on a lonely road over which no one passed during our visit. The three of us were so tired we went to bed without tagging our animals.

We had taken our first Cape Rattlesnake (*Crotalus ruber lucasensis*), a big but skinny fellow.

July 2, 1949

La Burrerra, Baja California del Sur, Mexico

When the dawn broke we were up—not a bit too soon as we worked until 11:00 AM getting our specimens up to date and the car packed. We drove up the road (a fairly good one) through the same foothill forest we had visited yesterday until we came to La Burrerra, a very ramshackle house of sticks and mud with a thatched roof. It is set in a little draw off a larger arroyo. A permanent stream flows down this draw. The girls here brought us several *Bufo punctatus* amid all sorts of screams and giggles.

The price for 3 pack mules, 2 guides, and 3 riding animals was set at 126 pesos or about 15 dollars American for a four day pack trip. We supplied the food for the guides. (Sugar in little brown moulds) 2 kilos, Rice (arroz) (1 Kilogram), Onions (1 Kilo) and Frijoles (2 Kilos), Coffee (2 kilos unroasted). We found that the most important item, harina, had been forgotten. It is the basis of making tortillas which are the staple food for these people. After many rueful looks (we offered him cornmeal and pancake flour) he said he could get it at his house. I took a walk with Chuck, up the little stream that flows back of La Burrerra. It flows in a steep-walled twisting granite canyon. Water snakes are said to occur here. The habitat is such that many chapparal elements might find niches. We saw *Petrosaurus*.

In the evening Chuck and Arlene and I piled up the equipment we wanted to take to Laguna. For three pack mules it wasn't very much.

July 3, 1949

La Burrerra, Baja California, Mexico

Chuck told Senor Castillo we would see him “muy temprano” (very early). We worked until quite late on specimens and notes and then hit the sack in the stream bed where the car was parked, which proved to be a gathering spot for all the stock.

La Laguna, Baja California, Mexico

With the first greying of the dawn (about 5:00 AM) I awoke to the sound of women's voices. It was the Mexican girls getting water. I got up and walked up to the Casa where I met Senor Castillo. After showing him the gear I walked down to the creek bed and found Chuck and Arlene dressing. We had all had 5 hours sleep that night.

We walked to the car and Senor Castillo brought the mules down. They are small animals compared to the mules I have seen in E.V.A. As all packers do he sort of sneered at the items we wished to pack. Though the pile was small he objected to our water cans. We ignored his protests as well as possible, but still he had the upper hand and we were merely a crew of ignorant turistas carrying a lot of frivolous equipment. I have received the same treatment in our own Sierra Nevadas. I guess it is to be expected.

The pack mules each have what looks like a leather saddle bag packed with straw as a pad. These are called aparejas. They are all handstitched with leather. Very little manilla or hemp rope was in evidence. In place of these were horsehair ropes and braided and twisted rawhide ropes. The cinches were of horsehair.

We had two packers: Senor Tino Castillo and Antonio Salvatierra (22 years old). Sr. Castillo is a man about 45 years old and as lean and tough as his mules. On our trip he wore a felt hat (much battered), dungarees (much battered and patched), and sandals over his horny feet. These sandals are an ingenious contribution of the machine age. They are pieces of truck tires attached to his feet by leather thongs.

When all was lashed down we were given three saddle mules. Antonio rode a horse without a saddle using only a halter rope and sitting on a pad of blankets. Sr. Castillo was on foot.

La Laguna, Sierra Victoria, Baja California del Sur, Mexico

7:00 AM. Off we went, down the trail leading up the Arroyo. I purposely slipped into last place and had the supreme satisfaction of watching the pack train wind along the trail in front of me. The sun was not yet hot. Many 30 foot trees lined the trail.

Even though my packing experiences are few it brought back a pleasant feeling to see the dust rising from the mule hooves, gleaming like mica in the morning sun. Trees, unidentifiable by me, of all sorts made the trail very interesting and beautiful. A large tree with yellow papery bark was common. Castillo called it “Heilo”. I think it is a close relative of the elephant tree. Many trees were hung with pendulous pods. Mimosaceous trees of various types were common. A tree with abundant large white flowers and leaves like those of the tulip tree were scattered among the others (tree morning glory). Several different crawling vines, including wild begonias (bougainvillea) with masses of bright magenta flowers wound among the trees. With the sun pouring down in twisting lanes? and tattered shade mottling the dusty trail I found it a most beautiful place.

We climbed rapidly, passing out of this forest into a sparser vegetation. At 4,500 ft. we came to our first deciduous oak tree. Though it is closely related to the Sonoran Mainland species it has much in common with the California Kellogg oak. The sun had set in, and by the time we stopped under a large oak, unpacked and ate lunch the day had grown torrid.

The mules weremuch refreshed by the rest and climbed a very steep hogback with little effort. Chuck (6'4½") was quite a load for his little mule. At 6,000 ft. the oaks were common

and we encountered our first pinon pine (*Pinus cembroides*), which is the same species as that on the Mexican mainland.

The trail followed a ridge from which we could see the ocean near Todos Santos and the precipitous western rise of the Sierra Laguna, up which we had climbed. The vegetation was now an oak-pine forest. Altitude had modified the heat and we became more comfortable. I gave Sr. Castillo my horse while I took a turn walking, as Chuck had done earlier.

At length we dropped down into a winding draw heavily vegetated with Pinons and Oaks. Our first Madrono was seen here, a great spreading giant with typical reddish peeling bark. Shortly a little grassy meadow was reached in which were several clear pools of water. The mules were watered and we rode on a short distance to La Laguna.

A sandy winding wash meanders out into a grassy valley of perhaps 500 acres extent. At one corner two stick and mud, thatched shacks are located and a rain gauge and thermometer shelter stand. These are operated by a man living at Rancho ____.

Rocky hills rim the valley on all sides and many large granite boulders are scattered around the edge of the meadow. 6 or 7 small streams flow over granite sand beds out into the meadow where they are clogged with water cress. There is no lake as such.

A band of horses ran off across the valley as we rode up. We camped under a huge spreading Madrono at the edge of the meadow. We were all weary (except the guides who had done all of the work and who had hiked most of the way) and so Chuck and Arlene went to sleep while I took a short hike. *Petrosaurus* is very common and very large—the size of a small Chuckwalla.

The tinkling of the bells on our hobbled mules was the only sound that was not strictly wild, and it is not a foreign sound in a place like this. I felt very peaceful, mostly because we were so far from the nearest big town or the nearest automobile. Here we are in Laguna, a fabled place visited by many famous naturalists and yearned for by many others. The impact of Loye Miller, Joseph Slevin, Dr. Eisen and E. Nelson and the rest is here and can be felt. I was impressed. It is something Chuck feels but Arlene cannot.

We wolfed down a dinner of meatballs, gravy and potatoes and coffee and took a walk on which we picked up *Xantusia*.

A note about the vegetation is in order. The pines here attain very large size—up to 70-80 feet high. The oaks, likewise, are sometimes huge. The pines seem to be taking the place of yellow pines could the latter species have invaded.

In the ecologic niche (equivalent niche) of poison oak is a mimosaceous plant with a red feather duster flower. Lower on the mountain many chaparral species have their equivalents—*Adenostema* for example is replaced by another mimosaceous plant with lavender flowers. *Rhus* has its equivalent.

July 4, 1949

La Laguna, Baja California del Sur, Mexico

We awoke about 6:00 AM after a very refreshing sleep. I took off on a hike after a pancake breakfast. I walked along the edge of the Laguna. Several *Petrosaurus* were seen and taken from the granite boulders.

The outlet of the laguna gathers all the water from the valley and forms a nice clear stream, tumbling down a narrow walled boulder choked canyon. Much vegetation fills the canyon. Grape vines, berry vines, and poison oak (a very much altered form recognisable only where lush). The Mexicans call the plant “Hiedra” which translated means Ivy. Water striders are present in tremendous numbers.

I stopped at a little water fall and a granite gravel pool full of clear bubbling water. I washed my clothes and myself. I needed it.

I returned to camp by crossing over a ridge, taking several more *Petrosaurus*. Cold pancakes and jam and coffee made a most acceptable lunch.

Chuck returned from a hike with Tino and Antonio with a rattlesnake, a spotted night snake, a *Xantusia*, and a pair of skinks, and several *Urosaurus*.

I left on another hike with the pinch bar. Much flaking and log rolling uncovered nothing. I was far out of sight of La Laguna. The direction I was hiking should have taken me to the outlet stream I figured, but it had turned so I was hiking away from the little valley. Finally I became a little worried and checked the sun. After a considerable walk up and down steep-walled canyons I saw a little section of La Laguna through the trees. It was a welcome sight as I was tired and in no mood for an extended hike around these precipitous mountains.

Back at camp Arlene cooked a good meal of chile con carne, coffee, and apricots.

I decided to whip up some biscuits and accordingly built a little fire, walled on three sides and set our big kettle on it. A small upside-down frying pan, inside greased, served as a pan. Everyone had suggestions, comments etcetera including Tino who said I was “Uno Nuevo Cocinero”. The biscuits were O.K. so I was spared any additional ribbing.

I noticed Anotnio building a fire for his cofffee con panoche (they boil the little moulds of panoche with coffee). He used little sticks and placed each one carefully so there would be plenty of draft. The training the Boy Scouts give tells you to build fires this way and I was pleased to see it done by a woodsman who had never seen a boy scout.

The rest of the night was spent with the specimens. Note: During the day Chuck, Tino, and Antonio were out hunting animals. Chuck rolled a pine log. He saw a skink. He grabbed for it and just before he put his hand down he saw a coiled rattlesnake under his hand. He kept on going and pinned the snake’s head with his hand. Of course Tino and Antonio were amazed (so was Chuck). I think they believe it is the way he normally catches rattlesnakes.

Today was Independence Day but we didn’t notice it.

July 5, 1949

La Laguna, Baja California del Sur, Mexico

While I was buttoning up my shirt during dressing, Tino and Antonio walked into camp carrying a deer.

The dog was fed (and he needed it). Antonio butchered the deer. He was very deft about it, first slicing off the backstrap and then the front saddle and legs. Then the ribs were removed. The hind legs were split at the pelvis and hung by a tendon. This maneuver was completed in about 15 minutes by using a long machete. Both Antonio and Tino carry sharp machetes which they use for all sorts of purposes—for clearing trails, gathering wood, butchering deer, and eating.

Chuck, Arlene, and I took a hike down the outlet stream. Though we searched long and hard flaking boulders and rolling logs we turned up nothing. I walked back to camp alone, shooting a pair of Juncos for Loye Miller on the way. These little birds have a tomato red eye and a pale grey head. Their underparts are buffy and they have a normal Junco tail with its 2 white feathers. It is classified as *Junco bairdi* at present, I believe.

I shot a Mexican white winged dove, and roasted him in the coals of a little fire, first oiling and salting his skin and then wrapping him in moist paper and then mud. He was steamed rather than baked. I left him in for about 50 minutes. A little more time would have improved the cooking job. Of course I was laughed at from all sides for my attempt—but that is to be expected.

Another long hike with much flaking and log rolling produced only 2 animals, an alligator lizard, and *Xantusia gibberti*. I returned to camp very much tired out. Chuck's luck had been no better, though earlier he had located several specimens. Each specimen obtained here in this season requires a large amount of work. We are not collecting *Petrosaurus* as we have a fine series already—32 individuals.

Tino presented us with one backstrap from the deer and we cooked it kabob style with slices of onion between the meat. It was delicious. Chuck and I were both starved after our day's work and ate as much as was given us.

These Mexicans are the most generous people I have ever had the pleasure of meeting. We ate a backstrap (the filets) while they roasted a rack of ribs. Probably they will take the other filet home. Pears and coffee completed the meal.

The weather here has been as beautiful as one could ask for. It is cool all day, though warm in the sun. In the afternoon there are cumulus clouds and once we had a few drops of rain though even then, most of the sky was blue. The nights are cool but not cold. All in all it is a welcome change from the heat of the desert. The drawbacks are insects: noseems in huge quantities under oak trees though there are few in camp, and poison ivy. All of us are breaking out a little but not badly as yet. I hope all will go well when we return to the heat below, tomorrow.

Tino says there is some snow here in December though not much because of the low altitude (6,800 ft.).

Specimens are piling up and so the rest of the evening will be spent with them.

July 6, 1949

La Burrerra, Baja California del Sur, Mexico

It is a shame to write notes at a time like this—I am in my sleeping bag on the floor of a sandy wash—all fagged out.

First thing this morning I took a walk around the west end of Laguna, rolling logs and rocks. My luck turned a little better and I returned to camp with 5 alligator lizards and 1 spotted night snake. We pickled specimens and packed. Chuck and I nearly had a tiff. He was cross from having worked till 1:00 AM the night before and I was tired from my hike. Sometimes I think it will be a small miracle if we ever get the paper on Lower California in print.

Chuck is strictly unidirectional. He is not interested in camping as such. He does not care what he eats or if he sleeps. He is apt to look askance at anyone else who is interested in other things. These things combined with a complete preoccupation make him hard to get along with as he is also moody and apt to turn to anger when tired. But when he is happy there is no better companion or field man.

We watched while Antonio and Tino put on the aparejos (stuffed pads for the mules) and then lashed on our gear. We could do nothing to help as every move during this operation is routine with them. I tried to help once but was obviously in the way.

I was sorry to leave Laguna. It is only a pretty meadow like many others in our Sierra Nevada but unlike them it is on the tip of Lower California, surrounded by a desert. It was such a change and relief to camp in its cool confines after almost 3 weeks in the desert. Our guides were congenial. They spent most of their day hunting specimens for us and returned to camp quite tired out (which means a tremendous lot of work for a Mexican guide).

We rode off down the trail, the little mule bells clinking as we passed through a forest of Madrono and pine. The understory in this forest is not dense. Under oaks, among rocks, and lining streams there are often dense thickets of shrubby plants, chiefly mimosaceous forms. In the stream canyons there is much poison ivy. It has leaves that are much more pointed than

poison oak and not so glossy. Also it seems to require much more moisture than poison oak, being replaced in the drier situations with a mimosa that has the same life form as poison oak, including red leaves.

The pack train plodded along under the forest canopy, passing up and out of the bowl-like valley of La Laguna. Once out of the valley we swung to a new trail and commenced to go down the scarp. This trail was much steeper and dustier than the other one. Much of the time I had to lead my little mule (Christmas Rosamond II). I asked Tino the mule's name. He said it had none. Antonio shouted back from his horse "El Diablo"—so that was its name from then on—the gentlest mule in the train—El Diablo indeed. He closed his eyes in contentment as I scratched his ears. Arlene's mule—also a gentle beast—had previously been named "El Malcreado". We all had a big laugh about these names.

Quickly the trail lost altitude as we wound down a 35 degree hogback. The pines were left and then the Encino Negros (a broad-leafed black oak not seen in the valley proper). For a time we passed through an area of little vegetation. The air became hotter and more humid. Before long we entered the strange foothill forest with its Mantos (a thin, graceful legume), Elephant Trees, begonias, and twisting lianas. Vines were everywhere as was a little bright green plant with vicious stinging hairs. I had learned of its venomous properties earlier—the hard way.

We saw brilliant red cardinals flying in this weird jungle. Chuck picked up a *Trimorphodon* (Lyre snake) that had recently been killed by a cow or mule. It was a fine rare specimen. Imagine a DOR on this little used road (trail)!

Chuck fired a shot at a *Cnemidophorus maximus* (whip-tailed lizard) and two of the mules bolted from the trail, deranging their packs somewhat. We stopped for a short while repairs were made.

Mule riding is just like horse riding as far as I can see. I have been told that proper riding is accomplished by using your legs to take up the shock as the animal jounces along. Also that your legs must be close to the animal's sides. With this information in mind I tested these notions and found that my legs became much more tired than my bottom had the other way.

Shortly we dropped down a steep slope and emerged at the upper ranch—run by Antonio's father, Sr. Salvatierra, a deep-voiced, rather rough fellow.

Tino left him some deer meat and we continued to the lower ranch where we took the bits from our mules and unpacked. La Burrera seemed (and was) hot and dirty after La Laguna. Somewhat against our feelings we camped in the arroyo and boiled water as our supply was nil. It took us 8 hours to La Laguna from La Burrera including 1 hour for lunch and 4 hours to return, including 20 minutes for lunch.

July 7, 1949

19.2 miles S. of Todos Santos, Baja California del Sur, Mexico

The night was spent warding off mosquitos and thinking about my various itches (not serious). Peace settled only after I walked to the car and got my mosquito bar.

We got up about 7:00 AM, all much the worse for wear and I began packing while Chuck hunted lizards.

Note: Just as we awoke Arlene came running down the wash shouting that some ninos had a vibora (rattlesnake) cornered. This was the only time I have ever seen Chuck not leap into action at the word "snake". He lay there debating whether to get up or not. He must have been really tired. Finally we arrived at the ranch house to find the ninos with a nice specimen of *Crotalus ruber lucasensis* noosed and alive.

While I was packing the children and Antonio brought in many good specimens including a *Salvadora* (patch-nosed snake). Chuck, Antonio, Tino, and I caught a 6 foot racer in a stone wall. He is a yellow animal with a black head. The snake is obviously one of the flegelb— group and appears to be a washed out pic--.

11:30 AM. We left La Burrera with many friendly good byes, adios's, and return some times.

Both Chuck and I had grown to like Tino and Antonio a great deal—for what they are—simple, generous, sometimes a little blunt, always gentlemanly people. They live so close to the plants and trees and animals, and soil that everything they do is tempered by it. Their generosity is a function of this—it might often be hard for any man to survive here by himself. These people make you stop and think about we Americans. Most of us are so self centered and smug—and for what reason? We don't have many of the things these poor Mexicans possess.

We work so fast that often we don't have time to stop and laugh. Tino caught a grasshopper and his whole large family was having a wonderful time watching him catch it. How many times have you seen a 45 year old American do something like this?

The tension here is survival. There is no uncertainty. Americans live in a world of uncertainty, tempered by events in Russia, Indochina, and all other places on the globe. I have not seen a newspaper in a month and have not missed them in the least. If one of these backwoods Mexicans has heard of San Diego or San Francisco he is unusual.

Which way is better? Probably neither one is better as each person is individual and would see things through the same set of emotions in either society.

We drove to Todos Santos and talked to Manuel Santana. He is a wonderful person. He offered to do anything for us if we come to Todos Santos again. We are going to send him a present from San Lucas.

We drove on south of Todos Santos through the little Mexican village of Pescadero. It is a real Mexica village of adobes, thatched roofs, and dogs, ninos, and carretas in the dirt street. The road becomes a two rut dirt road again and has several unmarked junctions south of Pescadero. We went a total of 17 miles on wrong roads. The San Lucas road is very little used and continues along the sea coast, sometimes just back of the sand.

The Sierra Lagunas rise abruptly to the east from a rolling, hill studded plain covered by a forest of thorny bushes and elephant trees so thick that a man on foot would have trouble passing through and it would be impossible for a man on horseback.

We camped alongside a little salt sump bordered by a few tall palms. I baked a bucket of biscuits for lunch and worked on specimens.

July 8, 1949

Cape San Lucas, Baja California del Sur, Mexico

We arose early, awakened by the passing of some Caballeros and the cows they were driving. They were the first people we had seen on the road south of Todos Santos. In fact we met no one on the road all the way to San Lucas.

Chuck and I began work on our specimens. Arlene did not feel too well so she slept. We worked steadily until 2:15 PM, preserving, cataloguing, tagging, and taking color notes. Each specimen shot requires a considerable amount of time before it is stowed away and forgotten for the time being. I put up the tarp for shade as we were near none. We ran out of water for preserving so Chuck and I walked down the road about 300 yards to a ranch I had spotted during an early morning walk. We found it abandoned. However it had a large (10 ft. in diam.) brick cistern, designed to trap rain water from the arroyo. 40 feet below we could see water. I found a

bucket and a palm fibre rope. After one lowering this broke and we constructed a majestic affair of rawhide strips, bits of rope, twine, etc. and then got our water.

2:30 PM. We broke camp and drove toward Migrino, a small village 27.5 miles north of San Lucas. The road was very poor being eroded and gulleyed in many places. Often we had to drive in 4 wheel low gear because of grades or ruts. Some stretches we made only 8 mph average.

The vegetation continued as a scrubby dense forest of Elephant trees and Cordon Grandes.

Often we passed beautiful white beaches that stretched along the seashore—completely untouched. Finally, the road cut inland leaving the seashore behind. It seemed unfortunate to leave the cool seashore but the new direction was not a disappointment as we passed up (on a very steep, poor road) and over the southern foothills of the Sierra Victorias. The scrub forest grew taller as we gained altitude. At 2,000 ft. the graceful Manto became common. Various vines and flowers made their appearance. Rocky hills of granite boulders stud the landscape here.

Shortly the road reached the summit and dropped down in an arroyo past the little village of Sandecito??. The road follows the arroyo here. It is good but sandy. Palo Blanco trees are numerous here and here they have their leaves, whereas at Santa Rosalia, the extreme heat of the gulf had left them bare.

On a long straight stretch of descending road we saw a cape of land jutting out into the sea. According to the map here was Cabo Falso—the false cape. We took some pictures and continued on our way. A villager informed us that it was Cape San Lucas. *We had traversed the length of Baja California.* I guess we should feel elated but somehow I didn't. The knowledge that we had reached the end hasn't sunk in yet.

A crescentic bay, lined by a white sand beach swings to the east of the rocky point of Cape San Lucas. The point itself is composed of 4 more or less disjunct rock peaks rising vertically from the water.

Alongside this rocky ridge back of the sand lies the town of San Lucas. It rises in tiers on the dry hillside. Oleanders and natal plums are everywhere. The houses are neat adobes and brick buildings. As usual, the best building, a large brick structure, is abandoned and roofless.

Along the sand, at the bases of the rocks is a cannery of some proportions, said by John Steinbeck to generate electricity for the San Lucas light, but since it operates only during the day the light is never lit at night.

We drove out east of town and camped back of the beach. I built a little stone fireplace and cooked coffee while Arlene prepared a dinner fit for a king of chicken and gravy, mashed potatoes, green beans, and cranberry sauce. We all ate until we were stuffed. All this was accomplished because the chicken, cranberry, and beans were canned, and the mashed potatoes were powdered.

After dinner we took a walk down to the beach. I wore my bathing suit. The air was just pleasantly warm. A full moon shone over the bay, glittering on the wavelets producing little flashes of light all along its path. The cape was pure black, outlined at the tip by moonlighted water and a backdrop of moonlit sky. A fishing boat rode at anchor, lighted brilliantly, apparently at work with cargo.

I took a timed exposure and then dove in the water. Often tropical water is so warm as to be enervating, but this was not, even though we are below both the Tropic of Cancer and the 23rd latitude.

All this was tremendously refreshing. We walked back to camp, each involved in his own thoughts.

The rest of the trip is toward home.

July 9, 1949

San Jose del Cabo, Baja California del Sur, Mexico

I woke up about 8 times last night because of mosquitoes, once I took a walk to the seashore. At sunrise the light brought hordes of noseems. I walked down to the beach again and lay down on the sand and slept until 8:00 AM when Chuck woke me. We packed and drove up to San Lucas. We went through the tuna cannery (planta). No canning was in progress. Out on their landing wharf we saw a group of fishermen. Upon looking into the water we saw a tremendous school of fish so dense the bottom was occluded in places. There were Sergeant Majors, Morena (trumpet fish—*Fistularia*), a sea eel, Botete (trunk fish), and red fish of some kind, and thousands of another grey species about ½ lb. in weight.

Back of the plant we stopped to do some collecting on the rocks. *Dispsosaurus* were very numerous. I saw one eating Bouganvillea blossoms.

On the rocks I took *Petrosaurus* and *Sceloporus orcutti*.

We continued on driving toward San Jose del Cabo. The road was fairly good though full of dips as it cuts across all the arroyos as they enter the sea. Weather was hot, clear, and sultry. Along the way we stopped alongside a gentleman and his son in a jeep. They had driven down to go fishing. He told about catching a 182 lb. Marlin off La Paz. They were from Long Beach, California. They seemed to be having trouble with their Spanish.

The road cuts along sea cliffs and through a small varicolored badland and through forests of Elephant trees, Mantos, Ocotillos, and various vines.

We ate lunch under a Palo Verde and I took a dip in the green ocean where it crashes on a small white beach at an arroyo mouth.

A short drive brought us up over a range of hills to a promontory where we could see a large river valley set among hills, leading up to the rugged sharp granite peaks of the Sierra Victoria to the north. In this Palm-filled valley lies San Jose del Cabo. From the start we did not like the place even though it is situated in such a beautiful location. The people seemed crude and the ninos were full of smart cracks.

The town is fairly large. It is not neat and shade is sparse even though in the fields, a few hundred yards away are beautiful mangoes, bananas, palms, sugar cane, corn, and along the roads tremendous cottonwoods.

The windows of the town are grated, either with iron or wood. Calsonines of various colors tint the doorways of all the houses. The town square is quite uninviting as squares go as its shade is limited to a few poor trees.

We located a cantina and billiards hall from which loud quartet music was pouring. Chuck and I bought six bottles of cold Carta Blanca Cerveza Exquisita and we retired to a large *Erythrina* tree and spent our most enjoyable moments in San Jose del Cabo.

While searching for a campsite near water we saw the large estero or lagoon where the river enters the ocean. Finally we were guided down back alleys by a nino to a spot, much bedecked by burro pies, adjacent to a stream of fresh water.

Here we activated by the local hoard of ninos by setting up various prices for different animals—1 peso for Brown Water Snakes (*Thamnophis*), 1 peso cinquenta centavos para Culebra del Agua Negro (*Natrix*), 15 centavos for Bejori (*Sceloporus*), 15 centavos for Camelones (horned lizards), 2 pesos for Coralillo (racer), 10 pesos for the first Ajolote (*Bipes*), 1 centavo for pesca (fish) and so on.

We lowered or raised our prices as animals came in or failed to. We got so many brown water snakes we had to say “no mas” for them. No *Bipes* were obtained (a two legged lizard).

The little kids flocked around, particularly when someone was getting paid. We had fresh kids (who caught few snakes), a few silent hard working ones who were our mainstays, and hoards of silent ones, including little girls and grown men who merely sat on their haunches and watched our every move.

We never got quite used to working on and ignoring these people (they needed no other amusement than watching us). If an empty tin can was dropped it was snatched up as they are valuable prizes here. There are no beer cans on the roads of Mexico. Arlene, in particular, did not like to have them around at dinner time. They had to be shooed. They would go off about 50 yards and close in again when we turned to other work. We told them to go home to dinner. “Adios” we said—and they repeated “Adios” but did not go home. All day they came up and said “Adios” until we would have gladly choked a few.

I washed clothes and boiled water. The water flows in three streams. A woman told Arlene the middle stream was “mejor” (better) and promptly showed us how good it was by washing her feet in it.

In the evening great grey and white thunderheads filled the sky. We could see lightning and heard occasional thunder. I ditched the leanto and Chuck and I set up the tent for Arlene. The smell of rain was around us. The air was sultry and passed by us in fitful gusts. Rain fell a few drops and then all fell dead calm. It became hot. I sweated as I lay on my cot under the mosquito bar. I could see the moon behind still palms through gaps in the clouds. All in all a very tropical picture.

July 10, 1949

North of Buena Vista, Baja California del Sur, Mexico

We arose early and worked on specimens till 3:00 PM amid fluctuating Sunday hoards of idle Mexicans down to see the crazy Americans who paid pesos for water snakes. The heat and humidity were terrific and our locale was far from scenic as we were adjacent to a main footpath and watering station.

We were all glad to leave and get on the road again. The road took us north toward black clouds and rain. Before long (driving on a very good dirt road) we came to Miraflores, a small town set on the bank of an Arroyo.

Miraflores is a quiet place of palms, mangoes, bananas, and vines, of adobes with thatched roofs or stick and mud dwellings. The thatch is trimmed on the edge like bangs and often allowed to hang down a foot or so from the roof giving the impression of hair that has grown too long.

Many people were gathered under trees by the community bake oven talking quietly and laughing.

One house, in particular, in Miraflores, was attractive. A veritable jungle of potted plants, bouganvillea, grapes, and small shrubs grew in front of the house—which was a whitewashed adobe with a thatched roof. Through the foliage and a diagonal lattice we could see wide hard packed floors and simple wooden furniture. A stone olla hung from a beam and several bird cages could be seen. Large beams, supported here and there by smooth poles with a forked end formed the roof. Everything was immaculate which is more amazing when you consider that the floors were dirt.

All the Mexicans appear after siesta (12-3 PM) in clean starched clothes—usually a white jacket and pants, a straw sombrero, and sandals (or none). Many of the little ninos (about 5 years old or under) appear “au naturel” and look much the cooler for it.

Out of Miraflores we passed through another forest and saw several iguanas (*Ctenosaurus*) in the trees and on Cordon Grandes.

Santiago was the next town. It is old. Old stone work lines its bluffs. The town is on an island in the center of a large arroyo and is hot and dusty and shadeless. The town square is exposed and little used. All around the town in the bottomland of the arroyo are fields of tall sugar cane and corn. Many cocoanut palms line foot paths. It is a beautiful green place. Back of the town rises the Sierra Victoria, which at our visit was covered with clouds and rain. It was nearly sunset and shafts of light pierced through making a most beautiful scene.

Shortly after we drove into the rain. The smell of wet ground and the paddling of the jeep through the puddles were highly pleasing. We followed the shoreline and then cut inland and camped along the road. It is still cloudy but I do not think it will rain again.

July 11, 1949

La Paz Plain (S. of La Paz), Baja California del Sur, Mexico

Up with the sun (and the noseums). One must adjust his schedule to these animals as they do not adjust.

We drove up a wide arroyo toward San Bartolo and the Sierra Victoria. The canyon narrowed and became steep walled. Clinging to the granite cliffs were many huge, white trunked fig trees. Their roots are thick and high ribbed like a banyan tree at the trunk and crawl like snakes over the surface of the cliffs for long distances.

Chuck and I had a field day here, collecting many animals. We took the beautiful blue, green, orange, and tan *Petrosaurus* in numbers from the cliffs. We collected *Cnemidophorus maximus*, a huge race of whip-tailed lizard that races up cliffs like a rocket. We took *Ctenosaurus*, the spiny tailed iguana, a big fellow with a large dew lap and spines along his neck.

The road cut sharply up out of the Arroyo under palms and mangoes and drops into the town of San Bartolo. A small dam holds water for irrigation. Groves of citrus fruits (citrons, limes, and lemons), mangoes, and sapotes line the arroyo bank on both sides. There are many palms and the huge fig tree is common, reaching well over 100 ft.

We ate sapotes and mangoes. Both were delicious fare.

While hunting for Elaphe in the trees I was accosted by a woman dressed in black. She gave forth with a constant flow of fast Spanish—all unintelligible to me. Finally I realized she was trying to sell me a pig. She was not a little disappointed that her sales talk had fallen through. I suppose I had said “si” enough times to make her think she was winning me over.

The road wound out of town through a forest of sclerophyll trees. These trees, with their thin leaves give rather scanty shade (except mesquite or Palo Verde) and the hillsides give the impression of being thinly vegetated. They are far from it as it is difficult to find a way through and every species has its own thorn or sting (except the dumpy Elephant trees).

The road is excellent as compared to other Baja California roads. We made 30 mph at times.

In the midst of a forest of Palo Blancos just before we arrive at Santonio, Chuck saw a mine shaft going back into the hill on the north side of the road. We walked back in it a long way. The air was a cool 22 degrees C., quite a change from the heat outside. Back about 150 feet we came upon a group of 14 bats (*Myotis* I suspect) clustered together on the ceiling. Farther back we came to a shaft leading up. We stopped and shortly we heard a noise that I took to be thunder, but it turned out to be hoards of bats flying in the shaft. Our flashlight beam turned them and they flew back and forth. Some flew past us but would not go out into the sunlight so we had milling bats on both sides of us.

Over the hill is the little town of Santonio. We bought rice and gasoline. The latter came from a *pump*! Most of our other gas had come from big barrels by the mouth siphon method of El Arco, or from 5 gallon tins. The town is quite shady and supports several brick buildings and

a church of some beauty and antiquity. A little further we dropped into a tree-filled valley from which juts a huge brick stack of 150 ft. height. Under the trees we located Triunfo.

5:00. It may have been the time of day but the place seems all but deserted. Many of the buildings on the main street are boarded up or locked. The square is barren and shadeless. I suspect that 500 people might live here.

We passed through a low rocky canyon and out onto the La Paz plain. Shortly the junction with the Todos Santos Road was reached and the new scenery of our trip was over. We are really homeward bound though we still have 12-14 days travel ahead. It will not be leisurely travel as we will probably try to make 100 miles per day. Driving 100 miles on these roads is a good day's work in itself.

We are camped under a big mesquite about 5 miles out of La Paz to the south. 2 wistful looking cows are nosing around camp. We had rice and meat balls and canned peaches for dinner. I was about starved so we broke out some ginger snaps and ate them too. Specimens are next and then the sack.

July 12, 1949

El Medano, Baja California del Sur, Mexico

The ants got us up and we proceeded towards La Paz. On the way Chuck spotted a Chuckwalla and we spent a half hour getting the animal out of a crevasse. A hike produced 3 other animals. We drove into town and had the car greased, bought groceries at Rufo's, and stopped by the Aloha Bar for some "Cerveza Exquisita". Chuck and I had a few while Arlene went shopping for a purse. The bartender is a jolly young fellow named Jesus Ortega Ojeda. He is the son of the Jefe Secretario of La Paz. He told us there are 16,000 people in La Paz.

After about 4 rounds ("Dos Mas") Arlene returned with two bags and had a beer with us (they are small and cost 1 peso or about 12 cents). We took out 3 bottles and ate lunch under palms along the waterfront.

We drove rapidly out of town (the pressure of time is really on us now) and over the foothills of the Sierra Giganta and Magdalena Plain to El Medano. 8:30 PM. Near El Medano we picked up a *Chilomenisaurus* (Bearded burrowing snake). Camp was made about 9:00 PM on a playa. We had few specimens so we hit the sack at 11:30.

July 13, 1949

San Ysidro, Baja California del Sur, Mexico

When I woke up, everyone else was wandering around, dressed, eating "Tostados de Mais"—(Kellogg's Corn Flakes). No bags were about, which was a welcome change.

We drove, picking up several horned lizards and scaly lizards on the way. The Magdalena Plain is quite monotonous driving and these animals livened our way.

Once I saw a black racer disappear into a bush. We leaped out and cornered him (or so we thought). Instead of staying on the ground he raced aloft 4 or 5 ft. Since the bush was a Mesquite we could not grab him though Chuck tried and got punctured in the attempt. The snake slid down and out of the bush and under the car before we knew what had happened. Finally we did catch him but he gave us a real chase.

At Santo Domingo we pulled in alongside Don Santos Castro's little casa. He came out and said he had "Ajolotes" for us at his garden. We drove down to his fine farm and he pulled some brush away from a hole in the moist earth. In the bottom was our coffee jar, buried in the cool damp soil. Excitedly we dumped out 2 of the strange pink *Bipes*, the lizard with two hands coming out of its neck and no hind limbs. In the jar were 7 specimens in all.

These animals have a small head with two sightless eyespots, two mole-like hands with which they pull themselves along, and a large flaccid worm-like body and blunt tail. A large specimen may be 12 inches long. It is easy to see why the natives often fear this animal (though Sr. Santos Castro knew they were harmless). The creature must be entirely subterranean except when rains drive them to the surface. We paid Sr. Castro two pesos for each animal (catorce pesos) and left.

Just before sunset we stopped for dinner in a fine arroyo filled with Cordon Grandes. A little food made me feel better as I had been a bit low for the first time since the heat of Santa Rosalia had touched me when the car had been stuck in the sand. We drove on to La Purissima and found it 15 miles closer than the map shows. Camp was made at our old spot alongside the sluice. Water boiling operations were begun at once. I picked up a *Leptotyphlops* while going a la little boy's room.

Specimens occupied the night. We made about 160 miles today.

July 15, 1949 [no July 14]

Mulege, Baja California del Sur, Mexico

Arose and had a small cup of oatmeal and commenced driving up Purissima Canyon towards the gulf coast. We collected a good series of animals including *Sceloporus orcutti* and *Dipsosaurus*. The hot sultry gulf climate became apparent as we moved eastward. Very little air stirs and you begin to feel like a wet, hot dishrag. As we approached the Bahia de la Concepcion it became hotter and sultrier. It was easy to envy the Tropic birds that were circling slowly in the cool upper air.

We traversed the forest of Cordon Grandes that line the southern edge of the Bahia. We crossed the road where it clings to the cliffs above the water. And finally we came again to the white sand beaches and islands where we had washed our dishes about a month before. I took a short walk and picked up some of the beautiful shells that are scattered over the sand. A bright rose colored *Murex* is fairly common here. The sand on which we hunted was in a beautiful location. A small island is connected to the shore by a thin strand of sand about 200 yards long. The center of this strand is covered at high tide, by 'knee deep' water. A single Mangrove grows on the sand.

We drove on, catching 6 specimens of the Collared Lizard—an animal never before taken in this area.

The sun's heat was abating and we were nearing Mulege when I tried to shift into low gear while climbing a small hill. The car would not shift and stopped dead still on the hill. We were blocking the road completely and could do nothing about it. The trouble is still unknown though it is probably a broken axle or drive shaft.

Chuck and Arlene and I sat down on the rocky slope while we tried to puzzle out what to do next. I wanted to look at the gear box and 4 wheel drive mechanism to see if something was jammed there and to see if the gear forks might have been displaced. Chuck thought it might be in the shifting mechanism near the base of the steering post. A little fiddling produced no results. At this time we heard the whine of a truck climbing the hill below. Shortly they came up behind us. In it were three young Mexicans, an older fellow, and a load of Queso (cheese). The driver came up and fooled with the gear box. Finally we decided to have Chuck ride into town with the truck. To get it around us we cleared away a group of 400-500 lb. boulders from a small wash. They tried to drive the truck through but could not. More playing around with the gear box in neutral and it rolled down hill. After a little work we revised positions and the truck began towing us to Mulege, which they said was "muy cerquita" (very close by).

We found that we had been stuck on the south slope of “Cuesta Tiburon”. The north slope is a series of hairpin turns descending a volcanic slope. One of these turns is very sharp—in fact we had to back up to get around it on our way south.

The big truck (a 49 Ford) backed up and made it but I had no power and could not back. After a few very anxious moments I cleared the turn by about 3 inches—no more. Another turn was nearly as close.

One young fellow rode with me. We had quite a conversation—from the price of shirts (40 pesos) to how to drink Tequila. He deplored conditions in Mexico saying that nearly everyone was poor and that there was little water. He agreed that the language was better than English and the people in Baja California more honest (we have had nothing stolen though many times our equipment has been all spread out with dozens of Mexican men, women, and children milling around watching us). I learned of the red snake that is as bad as a viper but does not bite—instead it lashes you with its poisonous tail. In Mexico nearby everyone falls prey to these stories and believes them implicitly—even many of the educated people. Tino Castillo—our guide at Laguna—would help bag a rattlesnake but would not touch the small harmless Gecko, *Phyllodactylus*. To him and to all other Mexicans I talked to the “Salaneanquesa” is deadly poisonous. It may be that this superstition has arisen because scorpions and geckos occupy the same habitat. A careless hand placed under the loose bark of a Manto tree might be objected to by a scorpion and when the bark was removed little malevolent *Phyllodactylus* would be sitting there leering out of his slit pupils.

We were pulled toward Mulege just at sunset and it was quite dark when we arrived. The trip had consumed 1 hour. I bought soda pop for all hands (they did not want beer) and we were taken to a triangular dirt square formed in the angle of two diagonal streets. On the side was a thatched-roofed garage and on the other was the Power Plant. Behind us, abutting the triangle of the square was a thatch and stick dwelling containing numerous Mexicans. The driver introduced us to Mr. Ruiz, the mechanic of Mulege who was “igual a Santa Rosalia” (equal to those of Santa Rosalia).

Mr. Ruiz was a small portly gentleman, with a stubble beard, round dime store glasses, and some very dirty clothes (we were far dirtier however). He was a fine fellow. He talked slowly and made sure we understood him before he went on. He said that he would see us “la primera hora en la madrugada” (the first hour in the morning).

There is a telegraph office here which we may have to use to send for parts as there are none here for jeeps I am sure.

We had a cold dinner of spam, crackers, peanut butter, and canned fruit. As we are all very tired and a good deal dismayed we are going to bed now. The place is very public but it is the best we can do with the car broken down. The air is still, probably because we are in the center of town, very hot and muggy. We three are as dirty as we have ever been and are all saturated with perspiration. I feel like a hot, damp, and dirty dishrag—the kind you would rather throw away than wash.

July 16, 1949

San Ignacio, Baja California del Sur, Mexico

It is hard to realize how vocal and noisy a Spanish town is until you have slept in the Plaza of one. Myriads of dogs yapped all night in dozens of different voices. Several burros and mules wandered aimlessly about the streets, giving vent to the most pained sorts of retching “heehaws”. Young men walked along the broken sidewalks until late at night, whistling loudly, so as to be heard above the dogs. In the house abutting the square women laughed and chattered in high pitched penetrating Spanish voices.

We didn't take off our clothes to sleep as it was too hot to get in the bags and there were too many people around to undress. In this uncomfortable, sweaty, noisy state I went to sleep only to be awakened shortly by rain. In a sleepy exhausted daze I stowed cartons and books away and then lay down on my sleeping bag waiting for it to stop—which it did shortly. Later we had another—more violent shower which I ignored completely.

I awoke to find Sr. Ruiz waiting for us to awake. He tinkered with the gears for a moment and asked us some questions. We had difficulty in explaining to him what had happened as we had no vocabulary of automotive terms at our command. He left us and returned shortly with a dapper indian type fellow who spoke English. This gentleman was named Jose Louis Kelly Dorantes. He was part Cherokee Indian, having been born in Chickasaw, Oklahoma. It turned out that he was a convict serving 9 years for murdering a man in Mazatlan. He was apparently quite popular in town and wandered around at will, doing as he pleased and stopping by the Calabozo for meals. With his aid we explained all to Sr. Ruiz and forthwith he fixed the trouble in less than ten minutes. Gears had jammed in the gear box due to bad shifting. Sr. Dorantes said Sr. Ruiz was a mechanic of all things from watches to the generators in the light plant where he was the Engineer, hired by the Mexican Government. He would accept no money until we gave him 10 pesos (he wouldn't take 20 through Sr. Dorantes).

Arlene was carrying on a spirited conversation with our benign murderer while we thanked Sr. Ruiz. Sr. Dorantes asked us to send him reading material and post cards. This we shall do.

We drove (I couldn't believe it) out of town and on to Santa Rosalia. Here we got gas and some food and a few bottles of beer (Pacifica—which cannot hold a candle to Carta Blanca). We drove on, up the Cuesta de La Infierno, past the new (8 years old) Manganese mine where dump trucks hauled out coal black ore from a horizontal bed.

The trip to San Ignacio was quite uneventful except the weather became cool once we left the gulf coast. Camp was made above town at a small clearing in the rocks. Small dry *Larrea* stems were the only fuel as the local lenadores (woodgatherers) had cleaned the area to the last stick.

July 17, 1949

Del Sur—Del Norte Line, Baja California, Mexico

The morning was spent writing notes and hunting turtles in the large posa (pond). The reed covered banks made hunting very difficult and though we saw many (*Pseudemmys ornata*) sitting with their heads raised above the sargassum we could catch none. This was very tantalizing, as the animal has never been taken here and it is about 300 miles from the nearest recorded locality.

About noon a little nino volunteered to take us to the "Poza grande" where he said there were many turtles. This pond is a long shallow one with clean rocky banks lying in an arroyo southeast of the main canyon. We saw only two turtles because the heat of the day had arrived and the turtles had sounded. If we had known about the Posa Grande . . .

July 18, 1949

Del Norte-Del Sur line, Baja California, Mexico

We packed up and said adios to all our nino friends. We liked San Ignacio. It is pretty and breezy and has cool nights, but most of all the people were nice and the children were well behaved.

The road leaving San Ignacio is rough and rocky for about 20 miles and then it drops onto the Vizcaino desert and becomes sandy. In most places it is good here but occasional dunes would seem all but impassable to 2 wheel drive cars.

We had talked to Mr. Meadows and Son (from Long Beach) at San Ignacio and we ran in his tracks all afternoon.

We drove on into the night.

Making camp on the line that separates Del sur and Del Norte.

4 mi. N. Punta Prieta, Baja California del Norte, Mexico

This morning we drove into El Arco and asked our government official directions to Calmulle [Calamajue?]. He told us and asked us if we had gotten all our snakes. We said we had caught enough. He then sneered at us as if we were crazy and retreated to his office.

We drove up a rocky dirt road 3 miles to Pozo Aleman. This small village is apparently centered around a large windmill. Some mining is done in the vicinity. 5 miles more brought us to the hot, dusty, and dilapidated town of Camilli. A government building occupies the center of a group of adobes. In front of it is a flag pole with a copper ore base. Ore dumps from the refinery are piled on the hillsides. Very little machinery is in evidence and most of the work must be accomplished by hand. We drove northward and out a narrow canyon with lava walls. Here we potted some slips of a sage for Dr. Epling and took Collared Lizards. Also the southernmost Cirio was noted. We ate a pancake lunch and pushed on—driving till late at night. At 11:00 PM I saw a stick that shone, lying under a bush alongside this road. We backed up and it proved to be a California Boa (*Lichanura roseofusca gracia*). This is the southernmost record for this animal by about 100+ miles. They are very docile creatures and never move quickly except when striking prey.

We camped under a big Cordon Grande on a shelf above the arroyo in which Punta Prieta sits.

July 19, 1949

13.1 mi N. Catavina, Baja California del Norte, Mexico

Today we drove to the locality (6.2 miles S. Laguna Seca Chapala) where we had previously tried to smoke out a Chuckwalla. We caught two adult males and 1 female. The males are a sooty black with a yellow tail and Chuck thinks they represent a new race. Certainly the animal is unique among the Chuckwallas I have seen.

After collecting at this locality we drove the terrible road to Catavina. It is one of the worst stretches on the whole road and there is thirty miles of it—sharp rocks, ruts, and steep grades.

Chuck was driving along about 5 miles per hour when we heard a tremendous thud under the car. I looked under and found that we had hit a rock (which none of us saw or could find) and had bent a flange on a crossmember of the frame. No damage was done but it shows what sort of road we were traversing.

Past Catavina the road is a good granite dust road and we had little trouble making it to a camp in a sandy arroyo where we had collected on our first leg. I was very tired and sleepy and so went to sleep for half an hour under a mesquite with no trouble. My air mattress has long since departed in this land of Cacti so now I can sleep on nearly any substrate with no pains the morning after—gravel, sticks, or sand all feel like a Simmon's Inner Spring after a hard day's work. I tagged my specimens and went to bed.

July 20, 1949

Rosario, Baja California del Norte, Mexico

Immediately after getting up and eating some of Arlene's rice pancakes Chuck and I hike to a distant rocky hill on a collecting walk. We didn't get many animals. Upon returning about about 11:00 AM we packed and drove on, out of the Cirio-Cardon forest to El Marmol and then to a Windmill where we all took showers and washed off some of the fine dust of Laguna Seca Chapala that is ½ inch thick over everything in the back of the truck and which had formed a considerable coating over us also.

We drove on up and over a section of road as bad as that south of Catavina and made camp 5 miles East of Rosario. Arlene is baking twist bread over a fire I built to keep us warm. Fog is hanging over the hills and the night is very cool—just like it was when we were here before.

July 21, 1949

San Telmo Rd. near Main Hwy, Baja California T. N.

We slept late and finally got up because of the sun and the flies. At Rosario we bought a little food and gasoline. There we met some fellows who had driven down in a new Ford sedan. They were cursing all the Mexicans for the high center highways.

A little way north of Rosario we noted snake tracks crossing the roads. I followed the trail and shortly came upon a red rattlesnake sitting coiled in a burrow. A little later we saw another track and this time Arlene spotted the snake coiled in the mouth of a burrow. It proved to be *Crotalus enyo*, the Lower Calif. Rattlesnake. Chuck and I were very excited as this is the first time this snake has been taken north of Punta Prieta, 200 miles to the south. A little farther on we saw another track. After some difficulty Chuck found the snake coiled under an *Opuntia*. It was a female Red Rattlesnake. Chuck took pictures and we drove on—following several blind tracks.

At San Quentin plain we stopped and were introduced by our friend Mr. Meadows, to Frank Frymier, a rancher on the plain. His ranch is owned jointly by three men—Mr. Ingles, Mr. Castillo, and Mr. Frymier.

They have a nice warehouse, a group of dwellings for the workers, and a C shaped ranch house of stuccoed adobe—one wing for each owner.

Over a couple of cans of Tecate Cerveza we learned of all sorts of roads—one from Ensenada to San Felipe that takes about 11 hours to traverse—of roads into the pine forest of the Sierra Juarez. He said Laguna Hansen was once full of big bass and supported a large duck population.

While he fixed one of his pumps we learned about other roads.

His wells hit water at 40 feet but have been put down 120 ft. No bottom is hit—only mud, which restricts flow a good deal. With more water this plain has unlimited possibilities. We drove on and made camp after dark in a wash along the San Telmo ??. Arlene cooked up a “last supper” of mashed potatoes, meat balls, peas, peaches, and coffee.

July 22, 1949

Los Angeles, California

We all slept rather late and were driven out of the sack by the sun. A cup of “Café Peninsular” and we were off.

We collected a few animals as we passed out of the coastal agave covered plain. Then we passed into the familiar rolling plain studded with granite hills and mountains near San Vicente. The aspect had changed in a month—all the wheat fields had ripened and some had been mowed.

Already Chuck and I were planning our next trip to Baja California (a short trip to San Felipe and south to Los Angeles Bay by fishing boat). The feeling of wanting to get home was present but not because any of us wanted to catch up with the news or enter the old swim at UCLA again. All those things had been forgotten nearly and I, for one, was not anxious to start in again with the old grind. Of course, we both have the prospect of a trip to New Mexico (4 days after we return). I look forward to this as it should prove to be relaxation of a sort as we will have a permanent camp among the Pinon pines on the Chupadora Mesa.

We arrived in Ensenada, hungry as wolves, whereupon we descended on the “Panaderia” (Bake shop). The numerous kinds of cookies and pastries are on trays arranged on racks that line the walls. With a tray and a pair of tongs you go around and pick out what you want. A huge sackfull came to 35 cents Ameican. We each picked out our own and with a quart of milk we stuffed ourselves so full of goodies we never want to go in a Panaderia again.

We then drove the beautiful coast road to Tijuana.

We were worried about our specimens and the plants for Dr. Epling—particularly about the live turtles and rattlesnakes. To have them taken away at the border would be a calamity as we had the types of a new race of Chuckwalla and a probable new race of rattlesnake.

We drove through the border with no trouble—being asked only to declare Arlene’s purchases that she had picked up in La Paz. It was with great relief that we drove off with our loot.

A steak dinner merely added to the uncomfortable feeling brought on by the Panaderia.

I arrived home at 1:00 AM temporarily somewhat the worse for wear.

Our trip is over but the work on “The Herpetology of Baja California” has hardly begun. Chuck and I figure 4 years work will see all our data worked up into a comprehensive report.

Jan 29, 1949

7:15 AM. Left Lowe's house with University jeep and my jeep truck. Weather at Los Angeles was above freezing (slightly) at this time.

12:00 Noon. Stopped at Reptile House at San Diego and had a talk with C. B. Perkins.

11:15 PM. Crossed into Mexico. The Agent was too lazy either to write us passports or charge us the usual \$2. Along the coast to the south of Tijuana the flora consisted of dense *Agave* (a species new to me), some of which were in bloom, a *Cereus* cactus, and coastal sage. *Rhus* also noted.

In Santa Monica Mts. temperatures were cold enough to freeze *Rhus*. These plants along the Mexican coast are apparently unaffected. Snow was present on the north side of mountains forming the south rim of Bahia Todos Santos—about 5 miles south of Ensenada. It extended from the peaks down the mountainside 200 or 300 feet.

Along the coast exceptionally flat beaches were noted. At high tide this sand is apparently completely covered, the water at this time abutting against a layer of volcanic rock. This sand is apparently prevented from assuming any of the typical dune shapes by this water coverage.

Camped in oak woodland 23 miles south of Ensenada. The air is cool, soil damp, skies clear. A stream with a few calling *Hyla* was below our camp

Water temperature at 7:00 PM—9.9 degrees C. Air 1 inch over water—4.1 degrees C. 5 cm above ground—2.9 degrees C.

The *Hyla* are apparently still out by virtue of the warmth of the water. The ground is covered with newly sprouted grass. The camp is situated in a rather wide (1/4 mile) canyon, apparently the result of rather rapid erosion—I suspect the mountains on either side have not yet reached maturity. The Sierra Juarez could be seen from Ensenada and were covered with snow. 7.5 pesos=1 dollar.

January 30, 1949

Arose around 8:00 AM. It had frozen during the night and my sleeping bag was covered with frost. We drove down to Santo Tomas, a small village on the south side of a fault rift valley. The feet of the spurs on the south side of the valley showed evidence of two uplifts, one of 30 or 40 feet and the last one of 10 feet approx.

The fault ran in a WNW direction approximately. Santo Tomas was built directly on top of the fault line. The rift valley was cultivated and large fields of grapes were being raised.

The road leads over the fault ridge and down into a valley in which a considerable stream of water was running. At the lower end of this valley the water was standing in considerable pools. *Carex* was in abundance. The north slope of this valley was covered with *Agave*, some of which were in bloom and others nearly so. These buds look like swollen clubs. The flora on the south slope more closely resembled chapparal.

We then dropped down onto the coastal plain, a broad plain approximately 7-10 miles from the ocean to the foothills. It is extremely flat, apparently a wave cut terrace. Here and there it is dissected by arroyos, most containing streams at this time. The flora of the plain is a rather poor one consisting of agave, a cactus looking like a *Cereus*, and coastal sage? The soil is leached and red.

We drove down a gravel road (since 12 miles south of San Vincente) to Hamilton Ranch. Actually we did not quite reach the ranch but stopped at Colonia Guerrara about 1 mile south of the Rio Santo Domingo.

There we met Charles Lamb, author of *Enchanted Vagabonds*. He had a jeep equipped with a boat, a 110V generator, all sorts of cabinets, and a sound scribe, with which he recorded conversations with natives and travellers.

We decided to go to San Jose, a cattle camp at the foot of the Sierra San Pedro Martir. We turned around and proceeded back 20 miles to the San Telmo-San Jose Road. It was a reasonably good road, requiring low gear in some places. In spite of the fact that it runs in stream bottoms part of the way and that it had rained in the last three days, erosion was not sufficient to cause trouble. After leaving San Telmo, a town of about 40 people, adobes surrounded by 4 or 5 *Washingtonia* palms and 1 date palm, and considerable lush fields of beavertail cactus, we crossed a high narrow spur and dropped down into a segment of the Rio San Telmo river valley, a prosperous looking ranch raising sorghum and cotton. The soil was quite sandy. In its unplowed portions this valley was a nearly pure stand of *Lycium* sp. After leaving this river valley we entered a forest of various chapparal plants and desert plants including *Yucca mohavensis*, *Adenostema*, *Eriogonum fasciculatum*, *Eriodictyon*, lemonade berry, *Artemisia tridentata*. *Agave* had dropped out. In addition *Encelia farinosa* and possibly *E. californica*, *Ephedra californica*, *Simmondsia*, *Arcotstaphylos* sp. Ribbonwood was present with the *Lycium*.

This weird agglomeration gradually gives way to a more typical chapparal as we went into San Jose, a prosperous cattle ranch, situated in a cottonwood-willow riverbottom. There are several houses—2 are frame buildings, the rest adobe. There is an air strip just east of the house. One large Swainson's? hawk was seen near the ranch. The hills to the east of the ranch are covered with granite outcroppings and look like good territory for *Xantusia* and *Trimorphodon*.

We drove up an old mining road from the ranch. It was a lulu and required 4 wheel drive in several places. We camped in a little swale just at dusk. There was considerable snow-ice on north facing slopes under the chapparal.

By 7:00 PM the temperature was down to freezing. After a good meal of canned meat balls, I constructed 4 loaves of pan bread presumably to be eaten tomorrow on our hike to the oasis. They look a little heavy. The night is clear and now the road is covered

with frost. The Sierra San Pedro Martirs are completely snow covered. The escarpment can be seen and is apparently rather steep. Off to the frozen sack. (Altitude approximately 3,200 ft.)

January 31, 1949

Proceeded up the mine road to a point about 10 miles from San Jose. We passed considerable snow and were finally stoped by a snow bank. The ground was too slippery to pass over even after ruts had been dug with shovels. Just behind us, at this time, were the ruins of two old adobe houses and a stone chimney. Other stone foundations were evident. This was the Socorro mine of worked placer deposits. One [Ore?] cont-graphite or molybdenite was found.

We hiked about ½ mile farther down the road to a point where it descended into a steep north-south canyon. Here we noted *Pinus quadrifolia*. At this point we were at about 4,500 ft. and 1 or 2 ridges away from the main western escarpment of the Sierra San Pedro Martir.

The sky looked ominous and as the road was a bad one at best (4 wheel drive in several places) we decided to return to San Jose.

3 species of *Manzanita* were noted and 2 of *Rhus*—*laurina* and *guala*? [?] The *Encelia farinosa* of yesterday proved to be a similar form but not identical. *Yucca whipplei* was noted. Back at the ranch we met the owners:

Mr. & Mrs. Salvador Meling

Rancho San Jose

San Telmo, B.C., Mexico

She invited us in and we had a considerable talk. She informed us that we could reach the top of the scarp on horseback in one day. She said there were 7 meadows on top and an old mission built for the Indians (now absent), a belt of oaks is traversed before reaching the pine covered plateau on top. This table is highest (approximately 10,000 ft.) on its northeastern edge. Separate from the table are the high peaks (11,000 ft.)—Rio San Antonio (containing *Salmo nelsoni*), she said, drains about ¾ of the western scarp. The trout are found in the river below the falls. She said a Mr. Utt had planted these trout in all the streams of the Sierra S. P. Martir.

In addition he had introduced pheasants and red fox squirrels to the Sierra S.P.M. He had done it so that he might leave something when he died. He operated an orange juice plant at Tustin, Cal. and owns a house and grove near Oxnard, Calif.

Mrs. Meling tells of mounds of oyster? Shells—one 6 miles or so west of her ranch and another at the south end of a sandy valley (desert) to the east of Sierra. She also says that great quantities of Indian relics including obsidian arrowheads and pottery were found in the sandy areas to the west of the gulf (near San Felipe) behind the row sand dunes that skirt the coast. She mentioned great quantities of shell fish in the sand south of San Felipe.

She mentioned that the vaqueros burned the brush to drive the cattle out as there was no other way of getting them out. She said the whole area had been burned over at one time or another. Apparently none of the ranch hands had seen salamanders though they were familiar with waterdogs. Coral kings (on top of the scarp), garter snakes, and turtles (probably *Clemmys*) were reported. A *Clemmys* was caught on a hook and line in Rio San Antonio. Black rattlesnakes and one black and white one was mentioned.

We purchased 5 gallons of gas (2\$) and drove off.

San Jose is on Rio San Telmo rather than Rio Santo Domingo as shown on the map. 2 miles west of San Telmo we stopped to investigate a chorus of *Hyla*. Some were captured. They were all of the brown phase. We heard what sounded like *Scaphiopus hammondi*. The water was slowly moving. Water temp—10.4 degrees C., air temp—6.2 degrees C.

We camped about 4 miles west of San Telmo. Slightly cloudy. Moon in quarter. The night is not as cold as last night. We are also much lower (approximately 800 ft.).

Feb 1, 1949

Broke camp at about 10:00 AM after a rather illuminating conversation with a vaquero. He informed us that vibora de cascabel was quite scarce (poquito) in this area but was common upstream at the base of the Sierra San Pedro Martir. We drove out to the main road and up toward Ensenada.

At the old camp site we stopped (the first night's camp among the oaks)—23 miles south of Ensenada. We ate lunch here and commenced collecting. A skink (*Eumeces skeltonianus* probably) was caught. 2 *Gerrhonotus multicarinatus* were caught under stones, 1 adult and 1 juvenile, 15-25 *Batrachoseps attenuatus* were captured, 1 *Sceloporus occidentalis*, 1 *Uta stansburiana*, 9 *Aneides lugubris* were captured.

The ecologic situation was as follows: the Sanfransisquito Canyon? flowing in a WNW direction bisects mountains about 2,000 feet high. The flora on the upper portions of these mountains is very sparse and xeric. A band of oaks and associated chaparral elements extends along the mountains on the south side of the canyon. They are intermittent, being eliminated where spurs extend the exposed surfaces down into the canyon bottom. This oak band occurs on the stream's edge in some places and in others it extends up the slope 100-200 yards. In general it is not more than 50 yards wide. The stream bottom proper is a sandy wash and covered with scattered *Baccharis* and willow plants. An occasional *Sambucus* and *Lycium* also occur. The north bank has a band along its bottom edge of *Rhus laurina*, *Sambucus glauca*, an occasional scrub oak, and *Photinia arbutifolia*. The upper slopes have agaves, *Rhus*, *Lupinus*, *Artemisia sparsifolia*, *A. californica*, and a mallow.

In the oaks the following plants were noted: *Ribes*, *Rhus trilobata*, *Quercus agrifolia* and *Q. dumosa*, and *Photinia*.

The *Batrachoseps* and all the lizards were found in the moister habitats under rocks lying on the ground under the cover of large oak trees. The *Batrachoseps* seemed more common on fairly level ground. *Aneides*, on the other hand, was found in the more xeric portion in scrub oaks and *Photinia* among rock rubble at the base of a road cut where rocks had been used to make a fill. The soil was moist but not wet at point of capture.

The oak grove in which these animals were taken was about 200 yards long by 40-50 yards wide. The ends were much more xeric than the central area of large oaks.

We drove on up to Ensenada and found we could rent a skiff for both ways to Todos Santos Island for 15 dollars.

Birds seen: brown thrushes, *Pipilo fuscus*, San Diego towhee, juncos, myrtle warblers?, flickers, Cal. jays, wrentits, sparrows of some sort, band tailed pigeon. One *Neotoma fuscipes*? was almost caught.

Camped about 5 miles out of Ensenada on the Ojos Negros road. It is raining now and these notes are being written while lying prone in the back of the pick up by flashlight—Adios.

February 2, 1949

It rained all night intermittently. Broke camp about 10:00 AM and drove up the Ojos Negros road in an attempt to reach Laguna Hansen. The road was quite slippery with mud and 4 wheel drive was used most of the time

About 5 miles east of camp we drove to an isolated patch of oaks amidst chapparal. We rolled what rocks (piedras) were present and searched a little while but no luck. A Mexican said he did not think there were any there (no hay)

We drove on up and over a range of high hills and stopped approximately 16 mles east of Ensenada at Mina de Felicidad. A narrow band of oaks (*agrifolia*) followed the north-south stream bottom. The hills (palos) on either side are clothed with chapparal. Under rock rubble and in woodrat nests approximately 10 *Batrachoseps* were captured. The soil was moist and water was running in the creek.

We drove on (a cold and bitter day with some rain) to Ojos Negros, a cattle and farming camp on a flat valley edged with juniper. We met our first Automobile Club sign—one of the old blue variety. The valley is transected in many places by different unmarked roads that make navigation confsing. Once the proper road was determined (by questioning natives) we drove up a long low bajada through belts of joshua, ribbonwood, and *Rhus* to the small village of La Huerta (2 houses). The first patches of snow were just above La Huerta. We reached oaks about 5 miles beyond La Huerta. It began to snow while we were coming out. We drove back to Ensenada.

At La Huerta the surrounding mountains are rock covered (boulders of exfoliating granite) and look very good for spring lizard collecting. We camped about 15 (20 miles) or so north of Ensenada in a canyon of beautiful large oaks and sycamores.

It has commenced to rain again so Dick and I will have to sleep in the truck bed again—god help us. Chuck and Arlene are using the arctic tent. *Hyla* are calling in the creek. Soil Temp—5.5, Air—4.5, 7PM.

February 3, 1949

The situation here (20 miles north of Ensenada looks ideal for *Aneides* but none were found. A series of 15-20 *Batrachoseps* was taken. The canyon is a rather wide one—approximately 150 yards, with a narrow gulley in the center in which the stream flows. Large oaks and sycamores cover the canyon bottom. The sides of the canyon are covered with chaparral. The oaks extend up into the tributary canyons and here the trees become smaller and smaller as exposure is increased, gradually merging into chaparral. A skink and 2 *Sceloporus* were taken under rocks. Soil temp—8 degrees C. The skink was just barely capable of movement. The weather is cloudy with occasional showers.

March 4-5-6, 1949

Panamint Mountains Trip

At about 5:00 PM on Friday, Chuck and Arlene Lowe and I left Los Angeles in my Willys Pick-up. We drove up through San Fernando and the Newhall gap and had dinner at Solemint. It had been raining over all the area covered by our trip the day before. Stratus clouds covered the area to the edge of the desert.

We drove up Soledad Canyon and captured a *Hyla regilla* (gravid), a *Bufo boreas halophilus*, and an *Ensatina eschscholtzi*, all on the road. The pavement was wet. Beyond the detention camp the new bridge has just been completed and now eliminates the only ford left on the road.

At Harold (aprox) the skies were clear overhead. We drove on to Mojave. No animals were seen on the road. We bought gas at Mojave and talked to a man named Brewer in the Associated station who knew George Pipkin at Wildrose Station. He had previously lived in Trona.

At Inyo Kern the Michelson laboratories and ordinance depot now cover a tremendous area (I would estimate 1,000 acres), and even at this time of night (10:00 PM approx) the lights were everywhere. What a tribute to man's overall sanity! The Trona Plant to the north has expanded considerably and now two huge units are operating—both were in operation when we passed.

A new road has nearly been completed over the Slate Range. We took a considerable detour over the old gravel two rut road. The new road is a good two lane macadam strip. Pavement has also been extended down Wildrose Canyon about 1 mile below George Pipkin's place and probably will be extended to meet the other new road.

We drove past Pipkin's past the park service summer quarters and up across a considerable sloping valley (about 1,000 acres) to the lower edge of the junipers, on the Mahogany Flats Road. Here we found snow. We turned around, just as it commenced to snow lightly and camped in the Summer Quarters Garage on the cement floor.

March 5, 1949

Arose 7:30 AM. We drove to George Pipkin's. He had a Panamint red rattlesnake that he had caught about 2 years before. We had left alcohol at that time. George said there had been 14 inches of snow in January at Wildrose Station. He had a pet pair of ravens and a burro.

We tried to drive to the kilns and were stopped about 1 mile below by snow that covered the road about 1 foot deep. We then drove down to Stovepipe Wells and to the duns. A short search revealed *Uta stansburiana* and *Callisaurus orc*[?]. Temperatures were taken and found to show that the animals were operating at the lowest part of their optimum range.

A *Cnemidophorus t. tessellatus* was taken (sub adult).

At the Park headquarters we saw Sam Huston and wife. He offered to guide us up Johnson Canyon to look for skinks in the willow thickets and cottonwoods that are said to occur there.

Following Sam and Chuck who were in a park pick-up, we drove down the west side to the valley past Trail Canyon (has a road up it), Hanapan Canyon (also a road), Bennets Well, and Shorty Harris' grave (Sam says they made Shorty's grave the length of Shorty (5 ft.) and neglected the fact that he was buried in a long coffin, thus he was buried on a slant head up). Just past Eagle Borax Works we turned up an unmarked and faint, two rutted road, over the sharp stones of the alluvial fan of Johnson Canyon. We

drove for about 5 or 6 miles up the fan on a ridge between two steep walled barrancas. We saw 4 burros in one group and 3 in another and one single animal walking on the almost completely barren bajada.

A few *Eriogonum inflatum* stalks were the only noticeable vegetation. Sam showed us where these animals had eaten a viznaya (*Echinocactus*). He said they kick the spines off the top and eat out the inside of the shell. Just at the base of the first foothills we dropped over the bank into the stream bed, went around a corner and reached the end of the road—some 5 or 6 miles below the springs and trees.

Here we met a Mr. Lucian Willard Gaskins, 1414 ¼ (about 30-40 years old), Mariposa, Los Angeles (6) and a long lanky gentleman known as “Mississippi.” The latter fellow was seemingly not too bright but very pleasant. Gaskins, however, was quite intelligent and seemingly a rather accurate observer.

We quizzed Mr. Gaskins about the country and fauna. He had a mill up the left fork of the canyon and was working silver and free gold with an amalgam shaker. The mill was still uncompleted according to him. He had hired Tom, a Piute indian who lived during the summer at the water in the right fork of Johnston Canyon, to haul his materials to the mill. This mill is on the lower edge of the juniper and at an estimated 7,200 ft. elevation. Gaskins showed us a copper deposit he was working (a fissure vein). He said it had assayed 19% copper, 12% zinc, and the deposit was ½ way up a spur directly across the canyon from the road’s end. The vein was about 18 inches across and extended about 100 yards in strike. The surrounding rocks were metamorphics.

Gaskins described finding “small, brown, spotted animals in the rotting pine logs high up on the ridge above the head of the canyon (Johnston Canyon). He showed us a picture of a salamander in Prisson and Schuckeits *Historical Geology* text, which he had in his mobile cabin. I asked him if the animal was under pinon logs—he said “No, these were green pines and I was using the rotting logs for firewood.” This probably means limber pines or foxtail pines, which occur above 8,000 ft. on the mountain. He had found them near a half completed log cabin built years before. It will be May before we will be able to reach these pines. Tom, the Piute, mentioned finding them while picking up pinon nuts as a child, at Mahogany Flats.

Gaskins mentioned picking up “little gem crystals” in the tuff mounds back of the regular Park headquarters near Furnace Creek. He said they had to be washed out of the matrix. We left Gaskins our names and addresses and some alcohol.

We drove out and left Sam at the junction. Sam told us that snow had fallen at Badwater and considerable had fallen at Furnace Creek. The snow had not stayed on the ground at Badwater. A 600 acre lake now covered the Badwater area.

We drove to Saratoga Springs being forced to use 4 wheel drive to cross the Amargosa River. On the old road into the springs we used 4x again for a long stretch. A new road greeted us as we swam up through the mire. It hits the road about two miles south of the old one. It was built in conjunction with a mine that is in operation in the hills behind the spring.

We caught 2 *Cyprinodon* in a potato sack net from the spring. They apparently rest at night by sitting on the bottom, scattered about—no groups were observed. They were much less wary than during the day.

Hyla regilla were calling everywhere—we caught several though they were hard to locate because of the dense papyrus-like rush, and pinnate leaved salt grass that looks like devil grass. Coyotes were heard—yapping out among the creosotes.

We ate a sumptuous meal of “instant potatoes”—a dehydrated potato mix that makes very tasty mashed potatoes and T Bone steaks.

We drove on to Baker and there asked about the road to Kelso through the devil’s playground. Most people don’t know. Those who claimed to said we couldn’t make it because of deep sand.

We decided to take the Windmill station road to Cima. This we did. We camped just south of the station about 11:00 PM. A Screech owl was heard cawling.

March 6

Arose about 7:30 AM. Proceeded to Cima. The New Yorks and Providence Mts. had scattered snow on their northern slopes. We then drove to Kelso—all on fine desert roads. At Kelso—from the General Store owner—we learned that 18 in. of snow had fallen during January. They were snowed in for about 2 weeks. The Devil’s Playground road could be seen cutting over a saddle to the north.

Kelso is a town of about 85 people supported by the railroad and a mine now in operation, in the Providence Range.

A large range of sand dunes probably 15 miles in length and 2 miles wide extends from the base of the north foot of the Granite Mts. up into the Devil’s Playground to the north. Peaks of sand (pure) probably 400 ft. high are prominent at the southern end of this sand.

A new paved road cuts out from the western end of Kelso and extends up into the foot of the Providence Range to the mine. A pile of gray ore about 100 yards long and 30 ft. high awaited shipment by the railroad. We drove the road to the powerline where we cut off the pavement to the right on a two rut road. This road was quite good and not sandy as reported on the map. It passes through the saddle between the Granite and Providence Mountains, over a bajada and around the northern end of the Marble Mountains to the west and hits the highway just east of the southern end of the Bristol Mts., about 2 miles east of Amboy.

We could see where hay had been dropped to the cattle during the snows of January. At Amboy the station attendant told us the horned lizards and grid iron lizards were out behind the town to the north. He said a sidewinder had been brought in by a Mexican 2 weeks earlier. It had been found under a pile of railroad ties.

We took the 29 Palms road. It crosses Bristol Lake on its northern end. The lake is being exploited for its salts. Many green settling basins lined the road, which is raised above the lake bed by a dirt fill.

The Coxcomb Mountains, to the east, are covered with blown sand and may harbor *Uma*. A small patch of sand was noted on the north end of the Marble Mountains.

The road (a good wide dirt road) leads over a gap in the Sheep Hole Mts. and down to Brush Lake (a salt lake with an extraction plant on its north side). About 1.7 or 1.8 miles after the road makes a right angle turn on the flat north west of the lake we cut off by an old ranch house through reddish dunes toward Old Dale. Several people including a lady (Schmidt) greeted us at the ranch. The dunes are much restricted and small. We saw 7 *Uma* and caught 4. They were all sluggish to a certain extent.

Using 4 wheel drive we drove through and hit a good road in about 1 mile. We drove on over to the Pinto Basin, catching 3 chuckwallas on the black rocks just this side of the basin.

In the basin there are no real dunes in the west end though the east end looks very good from a distance.

We ate dinner at Cottonwood Springs where we saw woodpeckers working the cottonwoods.

We drove out and down to the Blythe road and thence over to the All American Canal where we took the road bordering the canal and then cut off on the Powerline Road (paved after a fashion) to Pushawalla Canyon. This canyon is just opposite a ranch with a airplane beacon on it. It is about 2 ½ miles south of the 1,000 Palms Oasis Road. We cut up Pushawalla Canyon and observed bats, *Bufo punctatus* not calling very often), and *Hyla regilla* (calling constantly in great chorus)—1 pair of the latter was in amplexus. *Myotis* and *Pipistrellus* appear to be the bats seen. We drove out and home by way of Redlands.

The Coachella was literally purple on the slopes east of Indio with *Abronia*. Various *Oenothera*, chia, *Lupinus*, *Coreopsis*, and *Dalea* were in vigorous bloom. The fouquieras were in leaf and just about ready to bloom in this area. One mallow was seen in bloom.

March 12, 1949

Left Van Nuys at about 7:30 AM. Drove on to Covina Knolls (the hills on eastern edge of West Covina). I stopped to investigate a rather open oak woodland (about 25% cover). The oaks were quite large and were intermixed with a few California walnuts. This latter tree is quite abundant in some locations on these hills.

The hills are rounded hills of sandstone—most of ground surface is covered with soil. The understory is almost entirely grass with an occasional poison oak plant.

Batrachoseps and *Aneides* were found under logs (see species account)

Drove on uneventfully. The sky was overcast the whole way changing from stratus to cumulus as I neared Banning. At Banning the skies were clear. On the desert the skies were clear and in some places (particularly the lower San Gorgonio wash) a brisk breeze was blowing.

1 mile NW of the Riverside County line on Hwy. 99 I stopped to inspect some oaks. These were more depauperate than the last though probably no younger.

They lined the steep south western bank of a stream from the foothills of San Gorgonio Peak. The oaks clung to this north-facing slope only. The more exposed locations were chaparral covered. It is a marginal situation for oaks as they are no longer in evidence 1 mile south on Hwy 99. *Batrachoseps pacificus* were taken.

Drove on through Beaumont and Banning and stopped at eastern edge of Snow Creek alluvial fan where it touches the Palm Springs Road. A considerable wind was moving some sand. The wind was from the direction of Banning. One juvenile *Uma*? was seen. *Isomeris* and *Abronia* were in bloom.

Drove though Palm Springs. It is at the height of its season and then took the Palm Springs-1,000 Palms Road. At my study area no animals were seen. Sidewinder

tracks (medium sized) were noted on one dune. *Dipsosaurus* and *Canis* tracks were abundant. A juvenile *Callisaurus d. gabbi* was noted on the road.

Dune temperatures were taken at various intervals. I drove up Pushawalla oasis between my 2 PM and 4 PM readings. Lambda Sigma was en absentia. Instead a delegation of medical students from Loma Linda were in occupation. *Hyla* were calling.

Several tracks were noted on Microclimate Dune (2 miles west of 1,000 Palms on Palm Springs Road). They were probably juvenile *Uma* or *Uta graciosa*.

At the study area two oenotheras, a lupine, *Abronia*, and an unidentified white flowering plant were in bloom. Also a yellow composite was out. Plant samples were taken.

March 13, 1949

Arose about 7:30 AM. I had heard a clatter of hooves during the night. I looked around from my sleeping bag but didn't see anything at the time. I had pulled the pick-up in a little wash out that formed a cirque-like hollow about 5 feet high. There were hoof prints about 15 feet from the car. They were sheep tracks (in all probability those of the desert big horn sheep). I could see where the sheep had been frightened and had leapt. He apparently had come over the edge of the washout on a trail without noticing the car until he was right upon it. Up on top of the alluvium there were many tracks of all sizes and a fairly definite trail. All this took place about ½ mile below Paul Wilhelm's place in 1,000 Palms Canyon. The animals probably come down to drink in the stream that flows there. *Hyla* were calling.

I drove down and completed my microclimate work

In a wash about 1 mile west of the study area I noted 3 *Uma*, all juveniles and sub adults and 2 *Callisaurus* juveniles. All these animals were on dunes accumulated around the base of large *Chilopsis* bushes. In these dunes were many burrows that look like *Dipodomys deserti*. On the flats around these hillocks were burrows of gophers. These are the only gopher burrows I have seen in the area.

2:00 PM. I drove toward Indio Hills on the Chuckwalla Ranch Road (about 4-5 miles south of 1,000 Palms). There are some very fine mesquite dunes here (2 miles off of Hwy 99). Many tracks were scattered over the sand. They were either *Cnemidophorus* or *Dipsosaurus*. One *Uta* was seen. Mammal tracks were especially abundant. *Dipodomys*, *Lepus*, what might be badger, coyote, and paisano (road runner) tracks were all common. Desert fox is probably here. *Abronia* is in bloom and makes the dunes purple.

I drove back to 1,000 Palms-Palm Springs Road. I drove the pick up out over the sand dunes. It works like a charm. An adult *Uma* or subadult *Dipsosaurus* was seen but disappeared.

2:30 PM. Two sidewinders were captured in the center of *Larrea* (see species account). I then drove up through San Gorgonio Pass (see botanical notes) taking notes and botanical samples every mile, starting at north side of Chino Canyon alluvial fan. Sunday evening wildflower traffic was so thick that it took over ½ hour to get through Banning.

Arrived home about 10:30 PM.

March 28, 1949

Trip to San Francisco-Reno-Death Valley

Crossed over to Scotty's Castle from Goldfield-Beatty Road on a good desert road that crosses a playa at one place. Grapevine canyon, in which Scotty's Castle is located, has considerable flowing water at two places. One location is about 2 miles upstream from the castle, the other is at Scotty's. Mesquite is common at both localities. The upstream patch has been badly burned. No frogs were heard calling.

I drove up to Ubehebe Crater at the north end of the monument. It is a crater about 100 feet deep in a series of lava hills that run north and south. The hills are covered with a black lava gravel. Few large pieces are in evidence. In the crater, sedimentary strata are evident and show the reddish color produced by heating.

On the east side of the valley, across from Ubehebe crater is Grapevine Springs, a series of seeps and trickles running down and over a sloping bluff of whitish soil (tuff?) for a distance of $\frac{1}{4}$ mile. Some cottonwoods are present and much mesquite and saltgrass is evident. I did not get close enough to look for frogs but the locality looks good. These springs are about $\frac{1}{4}$ mile east of the road

Just south of Scotty's cut off on the main road running the length of Death Valley the Mesquite Springs road cuts off. It runs down, 2 miles, to the central drainage of the valley. The spring is located in a group of huge mesquites (25 ft.) just above and to the east of the main wash. The small flow makes a stream about 1-2 ft. wide and 1-2 in. deep. The water is good. No frogs were seen or heard.

In one of the mesquites a pair of interesting birds was seen. The male was slightly larger than a blackbird, had a heavy grossbeak-like bill and a lemon yellow head and nape. The rest of his plumage was black except for two staggered longitudinal white bars on his wing. The female was smaller (slightly smaller than a blackbird) and had a streaked gray, brown, and white coloration overall.

Leaving the spring I dropped down the steep alluvial fan from a height of 2,000 ft. approximately to sea level at the Stovepipe Wells Rd. I drove on down to Furnace Creek where I ate dinner. The water is flowing swiftly in a rush-bordered ditch. There are 1 or 2 basins but no amphibia were seen. After dark I drove to Shoshone and camped about 15 miles south of this town. It was very windy and slightly overcast.

March 29, 1949

I arose at about 7:30 AM—still very windy. I drove over Ibex Pass and turned east on an oiled road that led up the Amargosa River at its southern bend. After crossing an extensive bajada the road turns down into the canyon of the Amargosa. The steep bands of the wash are lined with a string[?] of blown sand that extends for a considerable distance down the stream. Desert lilies were in bloom on these sand slopes. Their long crinkled leaves look very similar to the amole or soap plant of the chaparral.

They sported large white blossoms about 2 in. across. One lizard was seen. It was either *Uma* or *Callisaurus*, probably the latter. At any rate it escaped down a rodent burrow in the sand.

Borax mining is taking place up the canyon. An ore truck passed and many pieces of white ore could be seen along the roadside.

The bed of the Tonapah-Tidewater railway crosses the canyon about $1\frac{1}{2}$ miles up from the bajada. On a bench (40 ft. above the stream) of very sandy gravel about 300-

400 yards south of the stream bed lie a series of large sand dunes. They are nearly 400 ft. high in this spot. The dunes lie in a crescent around the northern end of a large valley with the remnants of a playa in its center. This crescent is perhaps 10 miles in extent. It is approximately $\frac{1}{4}$ mile wide. On its western end lie the 400 ft. dunes, piled up on a black volcanic hill.

I drove up across the bench to these dunes, having much trouble with changing the 4x drive in the midst of a sand storm.

I climbed one face of the dunes. At various levels, one only 10 feet from the top, the sand is quite hard and compact and does not give when you walk on it. Its crossbedding is evident. In between these hard bands the sand is quite soft.

On the north slope in some places, there are scattered *Franseria* bushes with an occasional *Larrea*. In this sort of locale I spotted and caught an adult and a juvenile *Uma scoparia*.

In a sandy wash near the main road below these dunes I shot a male *Callisaurus*.

No sand dunes were seen between the aforementioned locality and Baker, though sand is present on the hills on the west side of Silver Lake.

At Baker I drove toward Kelso on the Devil's Playground Rd. It leaves Baker just to the west of the Union 76 Station. The road was good as far as I took it. I drove home from Baker by way of Barstow. At the south edge of the Cronise Dry Lakes are some fine large mesquite-*Chilopsis* covered dunes. One *Uta* was seen.

All along the Mojave River sand dunes can be seen. They are particularly good 22 miles east of Barstow and at Dagget. The rest of the trip was driven in darkness. No incidents.

April 5, 1949

Departed for the Colorado Desert at about 11 AM. Drove through Redlands. Skies were completely overcast though the day was warm (75 degrees F.) Over the desert the clouds were thinner but still blocking sunlight. The sun was sometimes visible.

Keith Powell and I drove out east of Palm Springs about $1\frac{1}{2}$ miles and then down a wash.

3:30 PM. *Uma inornata* was seen in a *Chilopsis* that had accumulated a fairly large barchane[?] around its base.

4:00 PM. *Uma inornata* (adult female) taken in *Larrea*. The animal was not as active as I have seen them in July. *Dipsosaurus* tracks were much in evidence though no individuals were seen. They may have been out in the morning.

Dipodomys tracks were everywhere. Fresh burrowing of *Thomomys* were observed in the wash on the lee (downstream) side of *Chilopsis* plants. *Abronia*, *Encelia*, *Oenothera*, a yellowish composite, a legume (*Astragalus* or *Lupinus*) with inflated pods—were all in bloom. I dead adult *Dipsosaurus* was seen $\frac{1}{4}$ mile east of 1,000 Palms Junction.

At about this point and for $1\frac{1}{2}$ miles farther east along the road (1,000 Palms Oasis Rd.) a species of black caterpillar was seen crawling all over the road. They were about $2\frac{1}{2}$ in. long with a single spine on the tail. The animal was black with reddish dottings along its lateral edge. The spine was orange. They were feeding exclusively on a white flowering plant.

We drove up to the Powerline Road and east to Pushawalla Canyon and up the wash to the oasis. *Hyla* was calling. A few *Bufo punctatus* could be heard (see species acct.). The water was quite low.

6:15 PM. A *Sceloporus magister* juvenile was running among the roots of a palm—even though the sun had set below the canyon walls for some time. Hrs B.T. 22.4 degrees C.

Bats were noted flying down for water at the main pool shortly after darkness came.

11:15 PM. 2 *Pipistrellus hesperis* were shot BT 34.8 (fallen in H20) and 36.0 degrees air at 5 ft. 23.18 degrees C. Retired after observing *Bufo punctatus*.

April 6, 1949

8:00 AM. Arose to a cloudy sky. Cooked breakfast (bacon and eggs) and drove down the canyon and out onto Powerline Road where we turned south. We drove up on embankment of All American Canal. Just before we reached the Desert Center-Indio Road (9:00 AM) we stopped to investigate some large dunes covered with mesquite and *Larrea*. Sand verbena was in bloom everywhere as was *Larrea* and *Oenothera* (the large white one). Tracks of *Dipsosaurus* and *Dipodomys* were numerous. The sun was covered. One *Callisaurus* female was shot in the mesquite.

10:50 AM. The sun came out and so did the *Dipsosaurus*. Keith began to see them all over. They were mostly in partial sun under *Larrea*. One juvenile (subadult) was seen but he escaped down a hole. All specimens were in the near vicinity of holes and 3 or 4 escaped in this manner.

There are many large burrows, probably of the kit fox or badger in these mesquite dunes.

Dipodomys burrows are everywhere. Other specimens of *Callisaurus* were shot. Both Keith and I were panting for something to drink so we picked up a quart of Pabst (33 brews in one) beer at Coachella (12:00 Noon) and had beer and peanut butter sandwiches under a cottonwood tree.

After lunch we drove to Truckhaven (the car had begun to heat up), stopping at Travertine Pt. Where we caught 2 *Dipsosaurus* and saw *Callisaurus* and *Cnemidophorus*. Both of the latter were so alert that I couldn't even shoot them.

2:30 PM. 12 miles south of Truckhaven we stopped because the car was at 212 degrees F. It was fortunate as the area was one of sandstone hills (numerous large concretions) covered in many places by drifting sand. *Larrea* was dominant though quite sparse. The sand has a pink tint to it.

2 umas were caught, both having three internasals and the ventro-lateral blotch—both were male and showed the ventro-lateral red color. *Dipsosaurus* was seen here.

We drove on south and up Hwy. 78 to Borrego Cutoff. The ocotillos were in leaf and many were in brilliant red bloom.

5:00 PM. At Borrego Springs we filled up with water (very good) and drove up to Borrego Palms Canyon. It is a mile hike to the palms from the end of the road—we did not hike it but turned around and drove east on a paved road, past the schoolhouse, turned north about 2 miles east of it and drove to the base of a small group of mountains.

6:00 PM. Here there is a sign saying "Peg Leg Monument and Clark Lake Airport 3 miles". We took the latter road (now dirt) over a saddle of alluvial material

(apparently burying a low ridge). This saddle is *Larrea* and *Franseria* covered. It is rather gravelly and seems to be of such a type of soil that *Uma* could not occupy it

The road drops down onto a playa (much mud cracked and not good driving in most places). This playa is about 3 miles wide. On its northeastern edge the road divides—we went straight ahead and then turned east a little later—bringing us into an abandoned ranch composed of a 3 room house (fair condition), a storehouse, and a very small bunkhouse, not to mention coals and 3 old auto bodies. A pump is in the center of the houses. After a few gallons of rusty water it gave forth with some very fine, reasonably cool water. The water is close to the surface as 1 or 2 pumps brought it up.

Mesquites are all around the ranch as are some rather large sand dunes. These dunes form a semi circle around the northern side of the playa. The lake is in a drainage-less basin of quite limited extent being about 10 miles long by 5 miles wide. The foothills of the Santa Rosa Mts. form the northern enclosing range.

6:45 PM. We ate some Vienna sausage and bread and started to drive the roads. Almost at once we came upon a large sidewinder (15 rattles) that was travelling toward us. Keith was properly amazed at the motion of his first sidewinder and realized why I was unable to explain how they moved before. We drove to Borrego Palm Canyon and back, catching 6 sidewinders, an *Uta*, and 1 *Coleorynx*. I was fooled twice by the same “Klauber Snake” which turned out to be a tea bag.

It seems a little cool yet for most species to be out. Back at the ranch we coked some clam chowder and coffee (the most concentrated stuff I ever tried to drink—even including that Lowe makes at times)—diluted 5 to 1 it was still strong.

11:00 PM. Ceased activities in favor of the sack. Mockingbirds are calling in the mesquite. A nighthawk flew low over our camp.

April 7, 1949

Clark Dry Lake, San Diego Co., California

8:00 AM. Arose. Skies cloudy and considerable breeze blowing. We cooked breakfast and started out to hunt animals in the dunes nearby. At 10:00 AM the sun came out and so did the animals—*Dipsosaurus*, *Uma* (looks like good *notata*), *Cnemidophorus tessellatus*, *Uta*, and *Callisaurus* were noted.

The dunes are very heavily overgrown and make hunting exceedingly difficult.

This ranch is the “Rock Ranch” and was a homestead. Mr. Rock is now in Missouri.

The dunes stretch out and go up the eastern bajada for a considerable distance and may reach the top of the intervening saddle on its eastern curve. This may represent the route by which *Uma* reached the valley.

12:00 Noon. We drove toward the western end of the lake (about 3 miles from the ranch). The dunes are here also and thus form a letter C around the north, east, and west sides of the lake with a sandy gravel bajada on the south side. There are signs of an old abandoned ranch under a few large *Casuarina* trees on this west end. *Uma* was taken here. A Cooper’s hawk was seen flying with a small mammal (probably an antelope ground squirrel or gopher) in its talons. The bird was unable to fly very far and progressed in flights of 75 yards or so in front of the car.

2:00 PM. Drove out over bajada and stopped at some sand dunes in eastern part of Borrego Valley. I saw an *Uma* but did not obtain him. Caterpillars of the variety

mentioned before were seen eating *Abronia* and *Oenothera* (the large white one). In places they had devastated large patches of these plants. Individuals were seen burrowing in the sand. They formed a low domed burrow by bending themselves around and pushing the sand out with the side of their body.

These animals are black with three yellow lines—a continuous central one and two lateral disrupted ones. About 6 fine yellow punctuations appear on each side of the central line on each segment. The first three segments have pairs of horny feet. Then there are 4 blank segments and then 4 segments with soft sucker-like feet. Then a blank and a terminal pair.

2:00 PM. *Ocotillo, San Diego Co., California*

At Scotty's Café we had a talk with Scotty. He spoke of a road running from Squeaky Springs or Truckhaven that goes over the low ridge into Clark Dry Lake. Also he said it was in fine shape in places but required 4x drive in others.

The elephant trees, he said, may be reached by driving up Split Mts. Wash past the Strontium Loading Dock and going over a saddle to the north and dropping down into a sandy valley.

The well at Rock's is about 10 feet deep he says. Other places in Clark Valley, water may be reached at 30 feet or so.

We drove on to Westmorland and just south of Alamorio we saw a DOR *Pituophis catenifer affinis*. Fields were on both sides.

We camped just west of the Yuma dunes with lightning showing in the sky to the east of us but stars overhead.

Yuma Dunes, Imperial Co., California

Keith cooked hash and eggs and peas and coffee and coffee cake. Mighty soul satisfying around a fire of *Larrea* roots.

April 8, 1949

Yuma Dunes, Imperial Co., California

6:30 AM. Arose and cooked bacon and eggs. We then drove past Gray's Well about 2 miles from here.

8:00 AM. I stopped to photograph the old corduroy road where it crosses the main highway. The sand has shifted and heaved the planks up and torn up the metal strips that were bolted to these.

8:30 AM. A little farther down the road we saw a juvenile *Uma*. We stopped and caught 15 or 16 mostly juveniles.

We drove on to the east side of the All-American Canal and down a very sandy road on its east bank. Several umas were caught including some good sized adults.

We went swimming. The water is colored like weak tea but is nice and cool. The banks here are covered with reeds. The water becomes deep very rapidly and is quite swift in the center, it being about all I could do to make progress swimming against it.

We turned around and drove back but became very much stuck in a little rise of soft sand about 100 yards off the road. Keith and I tried everything—digging, jacking the car up and putting *Larrea* branches under the wheels, digging ruts, wetting the sand, and finally we crossed the road and found a section of the old plank road. We ripped off two

planks and hauled them about 200 yards to the car. At this juncture another jeep pickup came along.

2:00 PM. He pointed out that driving in sand is easier if the tires are soft. Both Keith and I felt like complete fools as we knew this but neither of us had thought of it. With the planks and soft tires the jeep went out easily. We were so hot and sweaty and hungry that we ate lunch and took another dip under the bridge.

We shot a Mexican free tailed bat that was hanging on a mud dauber's nest under the edge of the bridge. BT 29 degrees C. Air Temp 28.9 at 5 ft.

We drove to Winterhaven stopping by for a beer and some groceries. We drove up to the gravel pit on the Picacho Rd. We were going to camp but left shortly after Keith returned from an unsuccessful fishing venture in the All American Canal . . .

Winterhaven, Imperial Co., California

. . . because of mosquitos. Quail were noted in lush mesquite and palo verde. Nighthawks were seen winging down from the hills toward the Colorado River.

We drove on toward Picacho on a good dirt road for about 10 miles and camped in a wash under a large ironwood tree. Skies have been clear all day and the weather warm.

We cooked a dinner of coffee, meat cakes, corn, milk, raisin bread and jam, and peaches. This we ate alongside a nice fire of ironwood logs.

8:00 PM. We are both tired as dogs and should sleep well as there are few if any mosquitoes here.

April 9, 1949

Picacho, Imperial Co., California

6:30 AM. Arose and cooked breakfast. We drove up the Picacho Mts. over a very rocky road. Just at the summit of these mountains along the road is a rock shrine to E-vee-taw-ash. She was an evil old indian of the Yuma tribe who changed herself into a mountain and demanded gifts from all travellers passing by or she would wreak havoc with their party.

The mountains are very rugged, being composed mostly of lava and much dissected by erosion. The surface of these hills is a sea of rocks about the size of a soft-ball. A little farther we passed the Picacho Gold Mine which is still operating. It is located on a fairly level area at the eastern foot of Picacho Pk. This peak is knife-edged and has vertical cliffs on both east and west sides—near the top it is very thin, being pierced in one spot by a hole about 40 feet below the summit.

Picacho is a settlement of 5 or 6 buildings including the ranger's headquarers. He is in charge of the game refuge there. Mesquites and palo verdes are very lush as the town is situated at the edge of the Colorado River on a flat.

Two lakes are formed by waters backing up behind Laguna Dam—the northern one is Taylor Lake. There seems little possibility that the Colorado could have followed a sandy course through this area.

I hiked back in the hills behind Taylor Lake and secured *Cnemidophorus* and *Dipsosaurus*.

2:00 PM. Having had no luck fishing but a strike on a juvenile *Uma*, Keith and left for Winterhaven where we found that the generator had broken loose and thus

loosened the fan belt thus accounting for the heating of the car. This was fixed and we drove to Ogilby and Midway Well.

Midway Well, Imperial Co., California

6:30 PM. The water at Midway Well has been piped to a faucet. It is fine water. The Ogilby road rises from Ogilby over a low saddle in the Chocolate Mts. and drops down into a broad mesquite, ironwood, and *Larrea* covered wash in which Midway Well is situated. We camped about 1 mile north of the well.

April 10, 1949

Midway Well, Imperial Co., California

8:00 AM. Arose and cooked breakfast. We drove down across the wash and down to Davis Lake. It is a small area of backwater along the Colorado. The gentleman who runs "George's Camp" there was very helpful (he smoked a large meersbaum pipe that was so heavy he had to hold it with one hand all the time).

He showed us *Dipsosaurus* and *Cnemidophorus* along the river bank. His dog "Princess" was a good lizard hound.

We could not navigate the road direct to Palo Verde as it was swampy so we went back to the Midway Well Rd. and over the Barren Mts. Grade—a very rough road and down into the Palo Verde Valley. A bluff runs along the west side of the valley. It is of 2 levels. The lower level is faced with sand. The upper level in 2 or 3 miles further west. They apparently are old river banks.

Palo Verde Valley, Riverside Co., California

A good pinkish sand deposit lines the slope in places.

We had a swim in an irrigation canal and started home (6:00 PM). On the south side of the road about 20 miles west of Blythe is a deposit of sand. Palen Dry Lake is circled with sand on its southwestern border. We reached Desert Center at dusk and ate dinner.

A drive along the aqueduct road proved fruitless except for a single *Coleonyx*.

The day had been clear and hot and the moon was nearly full. We reached home at 1:00 AM.

April 16, 1949

11:30 PM. Arcadia—in front of "Arcadia Tots to Teens Shop."

An idea has been growing in me since I heard a Sigma Xi lecture on "Life on other Planets" by a distinguished English astronomer.

I am privileged to wonder. This is a great privilege. Of all the billions of stars in our galaxy a few certainly have solar systems. In our own solar system Mars and the earth alone are capable of supporting life. On Mars it is a mere rudiment. The conditions for life are very special—the proper size of the planet so noxious gasses may escape the force of gravity, proper moisture contact, proper distance from sun to allow heat, even the tilt of the earth must be considered.

Life as we know it must be ephemeral at best as it is fostered only on planets of gravity that is such that the atmosphere is gradually being lost. Thus life on any planet has a life of its own.

Of all the vast quantity of stars and planets in the universe only a few could satisfy these conditions. Of these few life need not have emerged on all. Since life itself has a span it could not exist on many of those so particularly situated that they are susceptible to the condition of life. Thus of all the vast and unknowable “quantity” (the word seems to have no meaning here) of material in the universe only a completely miniscule portion of it could take part in life.

In life there are infinite arbitrary divisions. Its variability is prodigious. At one end of this spectrum, forming a very minor part, even on our earth—is man. A creature such as man certainly must have been conceived on many of the planets ripe for life. Within the species man the group is rife with gradations.

The great masses are lead by faiths that are not of their own construction but heresay instilled by repetition and fear. A few of the leaders have conceived a faith that is their own but few have passed on a faith. Among the led life is taken for granted as in all lower animals from protozoans upward. A few minds have wondered at life but how few? Even of the group of humans working with life—biologists, botanists, zoologists, philosophers—only a few do not take life for granted.

Therefore—the few who wonder represent the most special class imaginable—even among living things. The number is growing. Humans such as myself must have facts before we can wonder and the facts are being viewed by more and more people. However, before science the men who wondered must have been remarkable indeed.

A painter and a Mexican laborer just walked past on the side walk. I doubt that they wonder at thought or at feelings, or sight. Do they ever wonder what it is that they see?

My own privileged position was purely a matter of chance. There are a thousand courses I might have taken where I never would have wondered.

A sugar molecule, taken into the body is assimilated, burned, and excreted. It never changes into a living thing. A perfectly homologous reaction can be reproduced in a test tube. Where then is life—the thread about which we wonder? It lies in the use of the energy produced from the molecule. In the tube the energy is expended into the air. In the organism it is controlled and used in the organisation that is life.

The mystery lies in this organisation that is the exact antithesis of physical phenomena. The observation of the devious paths this thread or organisation follows to maintain itself against the completely inert but all consuming suction of things physical, is a most remarkable pastime.

Life is at times new, then vigorous, and then senescent as the organisation leaves and the matter is once again physical. To think that I, in the face of all these before-listed special categories, find myself in a position where I may wonder and be amazed at the remarkable physical universe and the even more remarkable manifestations of that universe makes me say that “I am privileged to wonder.”

April 17, 1949
Pushawalla Palms, Riverside County, California

Last night I left Van Nuys at about 10:30 PM. Arrived at my study area at about 2:00 AM. A misty fog covered most of the skies between Glendale and Beaumont. A cold wind was whipping up San Gorgonio Pass and was most evident to me as I was driving an open University jeep. At about Cabezon the moon started to light through the clouds. By the time I reached Snow Creek wash there were clear skies overhead though the air was cold—blowing down off of Mt. San Gorgonio. Bushes were whipping until Chino Canyon was reached. By the time I reached the study area (3 miles east of Palm Springs on 1,000 Palms Road). The air was warmer and only fitfull gusts of wind came by. “Hit the sack” at once.

Pushawalla Oasis, Riverside County, California

8:00 AM. Arose in a much dazed state, dragged over to the microclimate barchane and took my first readings. After this I set out the lead trap in my study area and drove to Whelan’s Drug Store and ate breakfast.

During the day I marked 3 *Dipsosaurus* burrows and excavated another (an old *Dipodomys deserti* burrow). An *Uma* was seen perched on a rock for the first time.

I drove to Indio and bought a pair of khaki pants as my pair had just given out.

At Thousand Palms I bought some chow and said hello to Mary Hicky then I drove up to Hidden Springs to Mr. Doyle (Charles). He was in Los Angeles.

I then drove up to Pushawalla. The entrance is even more obscure than last time I came up. You drive south along the Powerline Road—from the Thousand Palms Road until you just past a ranch surrounded by *Tamarix* about ¼ mile to your right. There is a large aircraft beacon on the southwest corner of this ranch. The Pushawalla Road is the third dirt road going up into the Indio Hills. The first is an extension, across the Powerline Road, of the ranch road leading to the beacon. The second road leads to two houses set on the base of the Indio Hills. The third, the Pushawalla Road, turns back at greater than a 90 degree angle and goes up the canyon. It is very sandy as are the other two.

While driving up the wash I could see a sea of clouds in San Gorgonio Pass, filling it completely about 1/3 the way up Mt. San Jacinto. The end of these clouds was so abrupt that it looked exactly like an enormous snow bank.

April 18, 1949

17 Palms Oasis, Imperial County, California

8:15 AM. Pushawalla. Arose after a much needed good sleep. The wind has abated since last night but the skies are clouded over and the air is cool. I packed all the 15 *Bufo punctatus* and 12 *Hyla regilla* that I took last night and prepared them for express. Then I ate breakfast and drove down the wash. To the west of Thousand Palms I stopped to mark the *Dipsosaurus* burrows I had noted yesterday including that of the marked animal that was released 70 yards east of his home. I used 3 1 gallon square cans as markers. 2 burrows are on the south side of the road about 100 yards and 150 yards east of the railroad tracks. The other is on the north side and right near the metal railroad sign.

9:15 AM. At my study area I retrieved the trap that had been set. It contained 4 caterpillars. The wind had blown my lead fences all around. Then I drove to Indio

through all the date gardens (Cathedral City-Indio Road). The package was expressed at about 11 AM. The express man asked no questions about water and I told him nothing.

Stopped for gas at Union Station. The attendant is a rock hound and was interested in all my plunder.

I drove south on Hwy. 99. 5.3 miles south of Coachella I turned right and headed toward a line of white sand I could see lying over against the hills. On one road I drove while trying to reach the sand, the dust was so thick that I had to stop the car in order to breathe or see.

11:20 AM. Needless to say, everything in the jeep was covered with dust and all day long, as soon as a wind would come up, clouds would arise from inside the ???. This must have produced a curious effect on some of the paved roads I drove.

Finally, I drove over an irrigation ditch on a rickety little bridge and past an abandoned adobe ranch and up a wash to the sand which proved to be an ancient beach of unsorted (by wind) sand. The sand abutted right on the rocky foot of the mountains and no *Uma* were found nor were any expected as the sand was wrong, it was isolated, and during inundation offered no habitat above water level for *Uma*.

This is apparently the case all the way from La Quinta to the southern base of the Santa Rosa Mountains.

12:30 PM. Sun came out. The beach line is clearly evident along the base of the mountains here because the rocks that have been covered by water have travertine over them and are rounded. The ones above water level are fresh, clean, and angular. The rocks below the line are brown while those above are gray.

Recession of the waters must have been rapid as the main beach line is well demarked and beach formation and wave action is evident. The recession levels are marked by very much fainter lines made most evident by plants growing in parallel rows along them.

While inspecting these marks I found a dirt road following the foot of the mountains. I drove southward along it and found that it lead to "Ancient Fish Traps" which must have been near my beach as that is where the road leads.

1:00 PM. I did not see any traps. This road leads out to the road connecting Hwy 99 with Mecca. I crossed it and continued on south along the base of the mountains, ending at last in the mouth of a rocky canyon. Seems that there was no possibility of sand dunes, even though I was above sea level. I turned and drove down a sandy wash and came out on the west side of a row of *Tamarix* trees lining the west fence of a ranch. Once more on the Mecca Road, I turned on 99 and drove to Travertine Pt. stopping on the way for lunch and a brief[?] turn off on Dr. Forbes Ranch road. The beach line is evident here too but there is not much sand and none above sea level. I caught a big male *Dipsosaurus* here. The area is a bajada covered with a most[?] lush growth of ocotillo. All in bloom or leaf or both.

2:00 PM. I drove up a wash for a distance but the sand hummocks soon gave out and turned to gravel and rocks. *Callisaurus* were common.

At Travertine Pt. I drove up a sandy road on its north side (200 yards north) over to a patch of blown sand lying just at sea level on a foot of the mountain made of travertine covered boulders. This sand is about ½ mile west of Travertine Pt. proper. *Dipsosaurus* and *Cnemidophorus* were seen but no *Uma*. I doubt that any of the sand at

Travertine Pt. supports *Uma*. I drove over the barrier beach behind the point and down to the old road and on it till Hwy 99 was reached.

At Truckhaven I took a road to the right marked "Closed to Public Travel" (Road Dept. sign). That leads to the Caucote Mine. For about 8 miles it was a good gravel road following stringers of the old surface of a now dissected alluvial fan. Then it dipped down very steeply into a baranca (about 80-100 ft. deep) and went up the other side (north side).

3:30 PM. I could see a shack sitting on the side of a yellow hill in a very rugged situation in the Santa Rosa foothills but the road was so badly washed I turned around and went back to Truckhaven.

Going south on Hwy. 99 Arroyo Salada is crossed just before you reach Squeaky Springs Station. I drove down the arroyo and headed west. Following the main wash left, I followed the main stream bed all the way. Only once did a bed of equal size enter the one in which I was driving. I kept left at this juncture. The wash is generally wide but sometimes narrows to 40 feet or so. On either side are banks, usually vertical, of old muds and alluvial material. All seem to have a pinkish cast. These banks are no higher than 20 feet. ___ miles from Hwy. 99 I passed a little surface water and a lone palm tree growing on a little shelf.

4:00 PM. Some blown sand lines the edge of this wash in various places. The sand of the stream bed gets increasingly whiter as you go upstream. At ___ miles from Hwy. 99 I passed a 100 ft. hill with a cross on its top. Passing south of this I could see palms ahead. It was 17 Palms Oasis.

The oasis lies in a bend in the wash. A nearly level shelf occupies the south bank. At its edge it slopes downward about 5 ft. into the wash. The other bank is a vertical one of water cut mud stones and alluvium. At the edge of the shelf stand in a broad arc 28 palm trees, 18 of them of good size (including 1 dead one). The larger trees show burned trunks though some good skirts are in evidence.

Water seepage is evident along the edge of the shelf by a stand of salt grass. A few bushes of sedge are present. *Lycium* is growing in various places.

4:40 PM. The ground is covered with salt. A hole has been dug in the shelf and is filled with potable though highly mineral water. The seepage is very slow as the flow only extends 4 or 5 ft. from the hole. A benchmark at the SE end of the grove says 410 ft. elevation.

The wind has come up and is blowing my pots and pans around. I ate a whole can of spam—god rest my soul.

April 19, 1949

5:30 AM. Arose before daybreak—ate breakfast and was off. Backtracked down the wash 200 yards and drove up the main wash. It started to get quite rocky. 2.8 miles beyond 17 Palms a road entered the wash on its left bank. It was a good dirt road! After about .3 miles it dropped into another wash. I drove up the wash about .5 miles and cut up a west bank and drove down hill. I ran into the road again—apparently the approach to the stream bed has been washed away.

6:00 AM. Once again on the road, it lead over the divide and down into Clark Lake Valley. The road is the Old Doc "KahRah" road. An *Uta* was seen out at 6:30 AM.

It seems impossible that *Uma* could have entered Clark Valley from the east as it is rocky, much dissected and eroded mud hills and badlands. There is no sand along the base of the Santa Rosa Mts. in this area except in the lake proper.

I hunted for a while at the Rock ranch, reaffirming my observation that *Uma* (at least juveniles) does not match its background but is pinker. I washed up at the pump and left.

The barrier to Borrego Valley could have been easily crossed and is probably the source of *Uma* in the Clark Valley.

Callisaurus, *Dipsosaurus*, *Uma*, and *Cnemidophorus* (*Phrynosoma*) were cavorting on the road in Borrego (see species acct.).

Borrego Valley, San Diego, California

10:00 AM. I bought gas at Borrego and drove out to Ocotillo and Kane Springs. I then went to Westmoreland and Calipatria and Niland.

1:00 PM. A large red racer was seen crossing the road at Calipatria.

I drove up the Blythe road from Niland in search of the All American Canal Road, on which I hoped to reach the north end of the sand hills. No canal could be found. It must be underground. I backtracked and followed south a road on the east side of an irrigation canal. About 2 or 3 miles down this road it crosses the canal. Another road cuts out to the east instead of crossing. I took the east road which presently began to follow the railroad. After a bit the All American Canal appeared and the road followed the west side of it. At the dunes I was able to cross over to the east side and hike around the dunes.

Sand Hills, Imperial Co., California

3:00 PM. *Callisaurus*, *Dipsosaurus*, *Phrynosoma m'allii*, and *Uma* were taken—all matched their background. The lateral spot on *Uma* is somewhat washed out. A peculiar pincushion shaped plant was noted. It is completely buried except for the top. It has a circle of purple flowers and a long foliaceous stem. I think it is parasitic. Maybe Orobanchaceae? (It is *Ammobroma*, a member of the family Lennoaceae, and is cooked like a potato (tuber and stem) by the Indians.)

I then drove up to Mecca. The east side of the Salton Sea looks like the invasion route for *Uma inornata* because of its low relief above sea level.

Drove to Morongo Valley and over to Old Woman Springs and camped at Cottonwood Springs. Everything is filthy and incredibly dusty.

April 20, 1949

8:00 AM. Arose and drove in towards Palmdale. I took the Lucern Valley road going to Sidewinder well. There is considerable alfalfa farming on the borders of Lucern Dry Lake. On the NW edge of the lake there is very limited area of poorly sorted gravelly sand. No lizards of any kind were seen though tracks (probably *Cnemidophorus*) were observed.

The road goes straight up a thin wedge shaped valley. At its northern end I picked a *Crotalus scutulatus* off the road. He was sunning. At the apex a road goes to Barstow and one to Sidewinder Well. I took the later and found no sand deposits of any sort on the rest of the road to Victorville.

9:00 AM. At Victorville I bought gas, drove 2 miles north to the Adelanto Rd.—took it toward El Mirage Dry Lake.

El Mirage Dry Lake

9:30 AM. El Mirage Lake is a playa rather distantly rimmed by low buttes. It is circled on its west, southwest, and northwestern sides by much vegetated hummocks of sand. No *Uma* were seen though they may well occur here. *Callisaurus* was taken.

I drove on past Black Butte and Three Sisters Butte to the Llano cut off, which I took. At the Cottonwood Store I bought 6 bottles of Schlitz and went down to the powerline and met Dr. Epling and his Linanthus crew (Dale Steffanson, Paul Levine, Chuck Lowe).

We finished the transect by noon, drank the beer, drove to Pearland, and ran his (Dr. E.) circles for him. Then we ate lunch (quarts of milk and pie), drove west of Palmdale, and ran another series of circles. A new [?]1,000,000 well has been drilled here. Water was hit at 300 ft., and drilling continued to 600 ft.

Palmdale

2:30 PM. Chuck and I left Dr. Epling, Dale, and Paul and drove to Peck's Butte. The butte is poking from sand deposits, on all sides except the east. On the south east considerable sand has been blown up near the top of the butte.

5:00 PM. *Uma* occurs here but none were seen. We drove over a small butte lying south west of Pecks. There is considerable sand on its south and western faces but no *Uma* were seen.

Chuck and I drove to Llano for gas and then drove to Lovejoy Lake. It is a nice pond about 15 acres in extent damned at its NW end by a cement dam [drawing].

Lovejoy Lake, Los Angeles Co., California

6:30 PM. Large cottonwoods rim the lake. *Bufo boreas halophilis* and *Hyla regilla* are very common. Approximately 70 *Bufo* were marked and released. They were introduced and no natural predators are present (*Thamnophis*), which must account for their great numbers. Some *Hyla* were huge.

Chuck and I took a swim. The water is quite cold. The Becks were not at home.

April 21, 1949

Awoke and drove to Pecks Butte—no *Uma* were seen. None were seen at Wilsona. Only 2 or 3 *Cnemidophorus* were seen. We drove to Victorville and up the Harper Lake Road. We drove across Harpers Lake to some sand blown against an old lava flow. *Uma* was found. They were sitting under small *Franseria* bushes controlling temperature.

Harpers Dry Lake, San Bernardino Co., California

4:00 PM. 5 animals were caught. On the way back across the lake I remarked to Chuck—"There is nothing I fear in driving a jeep but mud." Just then we began to bog down. I stopped and tried to back up—no luck. Some hardware cloth strips from my trap laid in the ruts got us right out.

Breathing a sigh of relief I drove toward the edge of the lake where the bushes grew up so as to get off the lake surface. I drove toward a salt-covered space and just as I tried to get the jeep up over the rise onto the hard bank she bogged down. We had our front wheels about 2 inches from hard soil, but the car was in saturated mud that quivered like jelly. In no time we were resting on both wheel housings.

7:00 PM. We walked 1/3 mile to an old fence from which we ripped 8 2x4s in 2 trips. Darkness set in and the Coleman wouldn't work. There were only low (6 in.) bushes for about 1 mile. The mud was so sticky that we could dig better by hand than by shovel. After innumerable jackups of wheels and frame we finally put 2 2x4s under each hind wheel. I pushed and out she came. Both of us were exhausted from our 7 hours work in the dark. That towards the last (Soledad) we were driving 20 miles/hr. to keep from running off the road.

At Boron we stopped for coffee and phoned home. The waitress was flabbergasted as we were unshaven and covered from head to toe with Harpers Lake mud. Reached home at 4:30 AM and went to sleep on the living room floor.

Harpers Dry Lake—6-7 miles across the dry lake lying in shallow basin draining south east to Mojave. River at Hinkley. Some cottonwoods and other trees all SE corner. Wind has blown sand NE against a lava flow about 300-400 ft. high. *Uma* occurs with *Callisaurus* on this limited sand area of about 4-5 miles in extent around the base and on the sides of the flow. Lava boulders poke through sand here and there. A circlet of hummocks of sand lie about 1/4-1/2 mile below base of lava ridge. They conform approximately with elevation of SE saddle.

May, 1949

West Fork of Mojave River, San Bernardino Co., California

10:30 AM. Left Van Nuys, speedometer 11272.7. End 12189.6 (917 miles).

Drove out to Solemint Store (got white gas at the station there). The weather was quite cloudy but fairly warm.

11:30 AM. 2 miles west of Ravenna I seined the Santa Clara River and caught about 100 fish in 2 tries. Working a 10-foot seine single handed isn't easy but results of this sort are gratifying. About this time I began thinking of Ichthyology as a career. The fish are suckers of some sort I think as their mouth is directed downwards and consists of a sucker like affair.

Mileage from Solemint Store to Acton Junction by way of Mint Canyon 19.2 miles, by way of Soledad 19.8 miles.

I drove out to the small butte west of Lovejoy Butte where considerable sand has blown up against the south face of this granite mountain.

12:00 Noon. The stream bed draining the Picks Butte-Lovejoy regions goes to the west of Lovejoy—swings east along the south face of Lovejoy Butte [drawing].

The sand in the stream is white while that on the buttes is pinkish. Could the Butte sand be a degradation product of the feldspar in the granite without the aid of water sorting?

Callisaurus and *Uta* were the only lizards seen on the butte.

3:00 PM. The north side of Peck's Butte produced nothing. I started to hike up the SE face of this butte but was stopped by the owner of the Golden Mesa Guest Ranch. He was all set for a beef but I didn't give him the chance. I think he was upset because I was so cooperative and polite. He appeared disappointed but introduced me to his wife. I told them what I was doing and all about the animals that live on "their" butte. I am sure he really wanted to boot me out but ended up by being sorry he did.

What I didn't tell them was that as far as I am concerned it is just as much my butte as it is theirs.

I asked him how long he had been there. He said "1 year". Then I told him about the McCalebs who live over on the NW side and about all the other owners and the museum. Maybe he realised he didn't own it any more than I do.

3:45 PM. At Wilsona I hiked over the Butte with no results.

4:00 PM. At Mirage Dry Lake I watched the gliders take off. Two men steady the wings and run along beside while the tow plane picks up speed. They fly quite high before releasing the tow line. They land at 30-40 mph on one nose wheel and skid to a stop on runners that extend clear up to the nose of the ship.

There are some "blow ups" of sand (limited) on the west hills around the lake bed.

5:00 PM. I drove up Horsethief Canyon to West Fork-Crest Line Road junction (Mojave River). A little seining in the strong current netted 3 small fish (*Gila* I think) and water up to my waist. Ichthyology is out—the river is much higher than it was at my last visit and I was constantly picking up boulders and swearing at Boyd Walker for lending me his damned seine.

7:00 PM. Cooked chow and built a small fire. *Bufo californicus*, *Hyla regilla*, and *Hyla arenicolor* could be heard calling.

Bufo californicus has a call much like *punctatus* only softer. This species preferred the edges of the swift cold water and would swim to the bottom when disturbed. In this situation it matches its background perfectly.

Hyla arenicolor liked this same situation. One pair was found in amplexus at WT 15.1 degrees C. Their call is similar to *regilla* except that it is a single note and harsher.

Hyla regilla and *Rana aurora draytonii* preferred the stagnant backwater areas. 1 specimen of *Bufo boreas halophilis* was taken in the stream.

May 8, 1949

Base of Mountains at SE corner of Coyote Dry Lake, San Bernardino Co., California

7:00 AM. Arose and cooked breakfast. Drove along Mojave River. Crossed it to Apple Valley Road, crossed bridge at narrows. Bought gas at Victorville. I seined the narrows and drove past Hodge to the Hinkley Cutoff. Took it and drove past Hinkley to SE corner of Harpers Dry Lake, turned around, drove on a dirt road to sand dunes near Hodge along the river. Drove upstream on riverbed and finally crossed over. I then drove through Barstow, over the Mojave River again and out past Calico Lake, turned south to Daggett, drove up the north stream bank on a dirt road in sand dunes. I returned to Barstow-Baker Road and drove past Yermo to Coyote Well Road. Then I cut off and drove to the lake, cutting across the bed and after 2 attempts I drove up to the sand dunes at the base of the mountains at SE corner of Coyote Lake.

10:30 AM. Mojave River at Victorville: I seined the stream here. It is a cussed job alone. The current is surprisingly swift. *Gambusia* was most common fish. Boyd Walker sinks lower in my estimation each time my seine comes up empty after breaking my back pulling it through the water.

Finally I learned to seine among the reeds and moss at the edge of the creek and at once came up with enough fish to renew my interest in ichthyology. I caught many *Gambusia*, a number of *Gasterosteus*, 1 perch, 3 or 4 *Gila* (?), and about 1 dozen large tadpoles of *Rana catesbiana*. They have a spiracle on one side only. They are not bilaterally symmetrical.

12:00 PM. Hinkley: As far as I can see there is no sand in the near vicinity of Hinkley that might support *Uma*. The animals recorded from Hinkley may have come from Harper Lake or Hodge. I saw 2 *Crotaphytus wislizenii*. Females both were in nuptial color and both were shedding.

The sand deposit at Harper Lake is bigger than I had supposed. It completely encircles the lava flow on the NE corner of the lake, thus there may be 50 acres of sand available to *Uma* there.

12:30 PM. Hodge: There are some good deposits of sand here, maintained by the Mojave River. I saw no animals. They run for about 2 miles and on the north bank get to be ¼ mile wide in places. Some of the most well developed dunes are right on the river bank.

1:30 PM. Daggett: Ate lunch here. I saw my first *Dipsosaurus* of the trip—5 in all—I only got 1. They are very wary. The sand is in a nice long deposit both NW and NE of Daggett on the north bank of the river. The sand is very white and somewhat compact. It is definitely derived from the river as it rests on a reddish volcanic range of hills. The stream beds are pink with the volcanic material.

Daggett: No *Uma* were seen. The wind was quite strong (from upstream) and this may have been the cause.

Calico Dry Lake: Apparently there is no deposit of sand of any consequence from this lake.

3:00 PM. Coyote Lake Road: It is a dirt road that winds over a saddle of volcanic material (also agate like rock is common). I observed territoriality in *Callisaurus*.

A male *Callisaurus* was startled on the road by my car. He ran across a little flat of desert pavement. Another male at once took up the chase and drove the intruder about 50 yards away—up a bank. The aggressor ran with his tail curled and his black bars showing. A female was resting right in the center of this territory. I shot her and she proved to be in full breeding color (gular spot) and full of developed ova.

4:00 PM. Coyote Lake: The road leads along the west slope of the lake. There is no sandy soil here. The east side is very sandy. On the south east corner of the basin is a ridge of mountains with a subsidiary ridge in front. Both have sand filling their canyons over a considerable area. Large patches occur clean to the top of the larger ridge. The rock is brown and the sand is white.

A fork in the road of SW corner of lakebed is reached and at that fork is a 20 in. pipe (tile) with a metal cover which projects about 12 in. out of the ground. It is a well and water can be seen at about 20 ft. The water was good (I dipped a can into it on a cord.)

5:00 PM. I crossed the lake (not wet thank god) and drove up one road leading to a mine on the north west end of the sandy mountains. No sand here of any consequence.

5:15 PM. I came upon a *Chionactis* lying in the sun (see species acct.). He was lying, stretched out, on the south side of a small hummock. The snake, thus, was not receiving all of the effect of the sun, but nonetheless—he was out! Sunset was at 6:30 PM.

6:00 PM. An *Uma* was definitely identified. I made a grab for him and missed and the rest of the story is as sad as this—he ran down a burrow. Camped at the base of the larger ridge with a good *Larrea* fire and some corned beef hash.

It has been very windy, fairly warm, and clear today. Collecting has been punk[?].

May 9, 1949

Newberry Road, near Yermo, San Bernardino Co., California

Itinerary. I have gone an amazingly short distance today.

6:00 AM. Arose, not of my own volition but of the sun's. I drove around these dunes for a considerable time and then picked my way down the alluvial fan to the "East road to Coyote Lake." I then returned to the Barstow-Baker Highway, crossing a small playa on the way. I then crossed the railway at Harvard and cut down into the Mojave River Bottom. There are some nice farms here and a little running water teeming with *Hyla regilla*. Crossing over, I followed the south bank eastward toward the Cody Mts. There is a small "blow up" of sand from the river here. I hiked up a wash and returned to the car. After driving a short distance west from the slope, I stopped and ate lunch next to a low circular tank (31/2 ft. high.)

There are 2 or 3 fish in this tank. The water is very good. It belongs to the Cady Ranch. Next I drove south to Troy Dry Lake and then up to the sandy ridge to the east of the lake. After some hiking I returned to the lake again and out a new dirt road to the south west leading to a railroad siding. I found that it leads to a silica mine where sand-blasting material for the navy is mined. Their road is very dusty and very windy. The pickup top was bent and 2 of the stays (metal) were snapped by the wind. I took the top down at Newberry. I am now on the Newberry-Harvard Rd. waiting for darkness.

Alvord Mts. *Uma* was found here and seems fairly common. I shot a *Cnemidophorus t. tessellatus* and didn't kill him at once. I sw a piece of his tail wriggling on a low twig of the bush (*Dalea*). When I retrieved the whiptail I was surprised to see that a little investigation revealed *Urosaurus graciosus* hanging head-down in the bush. He was untouched except for his broken tail. What a way to discover this animal so far north of his known range!

I caught another specimen after shooting a *Callisaurus* which ran into a *Dalea* bush. In the bush was *Urosaurus*. I never did find the *Callisaurus*.

Cady Mts. extend from the Mojave River on the north to the SE corner of Troy Dry Lake. On the north end some sand has blown into canyons and up on the face of peaks. It was derived from the Mojave River.

A hike up a canyon netted no *Uma* though it is reasonably certain that one was seen. The area habitable for *Uma* is very small here (5 acres).

Cnemidophorus were seen twice following each other "indian fashion"—the larger individual behind.

Blow ups on the south end of the Cady Mts. are considerable and have been derived from Troy Lake. This deposit is one of the coarsest ones seen. On the slope directly exposed to Troy Lake I do not think *Uma* will occur. The sand is compact and blown into windrows that made the car bounce like on a washboard.

Cady Mts., San Bernardino Co., California

Behind this ridge when the force of the wind is lessened the sand is finer but is still quite coarse. I think I saw 2 *Uma* but neither identification was positive. The tracks look like those of *Uma*.

I drove till 9:00 PM and picked up 2 geckos and a *Chionactis*.

The car is parked in a wash near Afton Canyon. Water must be close as palo verdes(?), *Chilopsis*, and mesquite are thick.

With my notes out of the way and no one to talk to I feel that I should write something—preferably something sage with the smell of the desert about it—old prospector stuff. After my experiences with a 10 ft. seine alone I could write something acid about that—but that is far removed from the desert.

Afton Canyon, San Bernardino Co., California

The Coleman appliances have been, as usual, putting me through my paces. A change has been wrought, though. It might make happy prose to tell how I mastered the lantern. One night, at a very critical time (while Chuck Lowe and I were stuck in the jeep up to both wheel housings, in Harpers “Dry” Lake) it refused to work and we were forced to slave for 7 hours in the darkness. Twice on this trip it has failed me—but I’m on to its tricks now (maybe). Right now it is grumbling and groaning but giving off light. This is only because I cleaned its generator out with a needle. The stove is still another story which I am not going to tell.

How about talking about camp fires? Every outdoorsman writes about campfires.

May 10, 1949

Cronise Dry Lake, San Bernardino Co., California

There is considerable sand in this area [drawing]. Sand has blown over the ridge and has formed an area of limited sand in Afton Canyon.

Along the west edge of the playa just north of the blow up called the “Cronise Cat” is another blow up. At the base of this sand is an old beach—probably reworked with numerous shells imbedded in it. There are 3 species. (They look like fresh water forms.) The sand itself contains quite a few fragments of shells. Afton Canyon supports a few fresh water snails and is only about 5 miles away.

Silver Lake, San Bernardino Co., California

[drawing] 2:30 PM. A large male *Callisaurus* was shot on a rock protruding up from the lake bed proper. He was wounded so that he could not run away but instead gave me a threat display. His dewlap is amazing [drawing].

He tilted up on one side and presented all his bright colors to me. He could be frightening to another *Callisaurus*.

The *Uma* here occur on a very restricted habitat. They are beautiful animals having red color on eyelids and along lateral fringe from axilla to groin and along middle

portion of tail (on its edge). Medial to pink color on lateral fringe is the yellow green typical of *scoparius*—this is on hind legs and tail also. This color is on ventral surface of tail. A *Callisaurus* was caught (female) with an orange red gular patch, the same colors in axillae, bright yellow along lateral edge of abdomen and prox. portion of tail. She had developed eggs.

Uma for the first time was seen to climb rocks and go in crevasses. The habitat is so limited (1 acre) that they may be forced to occupy marginal habitats.

Over the hill from Silver Lake (to the west)

Large male *Uma* taken that does not show the red color.

3:30PM. There is an area of perhaps 20 acres of poor sand and brush here. A very small playa (1/2 acre) is present. A powerline road and the road to Gailie Springs pass through this valley. It drains to the north in Silurian Lake.

May 10, 1940

Saratoga Springs, Inyo Co., California

Itinerary:

6:30 AM. Arose and ate breakfast. Drove to Afton Canyon. The road to this canyon is as follows—pass Cronise Station going east, cross the bidge over wash that drains the lake—on the east side, up against a hill is a dirt road going south. Keep right for 2 turns and keep to the left of a black hill with several mines in it. This hill is about 3 or 4 miles from Highway. Drive up small canyon and over the top by making left turn just before summit is reached. (I think left and right are reversed in these directions—K.N.) You then drop down on a road built over a narrow gauge railway (dirt filled in between the tracks). Cross the Mojave River east of railway bridge and turn right before you go up on a fill. You pass around an old shack and then up the canyon.

I drove out of Afton Canyon—a very beautiful canyon of precipitous walls of fluted sandstones of reds, grays, and browns. The Mojave had risen to the surface here as a small stream full of mosquito fish (*Gambusia*). Mesquite and *Tamarix* are common.

Then I proceeded to Cronise Lakes where many specimens were secured, including a new locality for *Uma*. I then drove on to Baker. On the way I saw a raven eating a *Callisaurus* (probably a DOR) and what looked like *Dipodomys deserti* sitting up in a bush! I then drove up to Silver Lake and then over the hill on a very dubious road and then out on Powerline Road to Shoshone Hwy.

At Salt Springs I cut in to the Sperry Canyon (Ibex Pass) Dunes. There is no road and the going is very rough. I advise getting to these dunes by going up Sperry.

I obtained a *Urosaurus graciosus* here and a couple of *Uma*. I think this sand [labeled 1 in drawing following] is a composite of sand from Silurian Lake and from the Amargosa River—probably mostly the latter. The sand at 2 [in drawing] is probably mostly from the lake.

A similar deposit (smaller) occurs just south of Saratoga Springs (along the Amargosa River).

At the springs I met 2 men—one middle aged and the other 89 years old. They are both here for the health giving properties of the spring water. They are staying in the little rock shack. The old man has put in a screen porch (to keep out mosquitos). I wish I had one as there are lots of the beastly creatures.

The old fellow was a prospector of sorts in this area for 25 years or so on and off. He says an old Dutchman established Cave Springs. A man named Runey (Jack) who works in some capacity for the state in connection with mapping built the shack at Saratoga Springs. A two story store and house once stood here. He also built a bath house and a small house for bottling the water. Apparently the Government stopped this latter endeavor.

I took a very fine swim in the pond and got cleaned up a good deal—now I am going to take another one just for the enjoyment. The water is 72 degrees F.

May 11, 1949 and, 3 miles N. of Saratoga Springs, Inyo Co., California

It is apparently produced by the Amargosa River [drawing].

2 miles S. of Saratoga Springs, Inyo Co., California

This sand has been accumulated by Amargosa River. There are peaks 150 ft. high of pure sand [drawing].

Kelso, San Bernardino Co., California

7:45 AM. I arose after a nearly sleepless night (due to mosquitoes). I devised all sorts of clever systems (none of which worked) to ward off the beasts. I made a mosquito bar out of the seine—this kept them out but I could not move or I would upset it. Finally I went up on top of the hill where there was a good breeze. This kept them away for a while but the wind died down so I got up.

I drove up the So. Cal. Mineral Company road (a talc outfit) to the sand 3 miles north of the spring. I saw no *Uma*. They are probably there however. I was very sleepy and not very diligent.

Back at the spring I said goodbye to the old man (Fen Winans) and to Frank Barman (?). I then drove up another mine road from the springs that circles south around the mountains to the deposit of sand there.

I took *Uma*, 2 of which showed the lateral red color I had seen in the Silver Lake population. I clocked an *Uma* (male adult) at 15 mph. He was running full speed over open sand.

Then I drove to the Sperry Canyon Dunes. I took several *Uma* and other beasts.

Down in the canyon I seined out 2 species of fish, a pale *Cyprinodon* and a little silvery fish (*Rhyniethys*?). I ate lunch here and then drove on into Baker. I was mighty sleepy and had to stop for a snooze.

At Baker I began the “much fabled” Kelso-Baker Road. I had been told it was solid sand and had big washouts 10 ft. deep, etc. etc. It leaves from the west side of the station. For the first 10 miles it is a fine road. About here I cut off to the west to a black volcanic peak north of Old Dad Peak/Devil’s Playground.

Before I turned I told myself I would go over and get a new locality record if I found a road. I found the road and *Uma*. The main road became quite sandy and I picked up *Uma* (in a wash where sand has been blown up) about 3 miles beyond the cut off I had taken to Old Dad Peak.

The road then becomes rough because it crosses an alluvial fan at right angles. None were impassable however. A few miles further I came to a powerline road—one way lead to Sands and the other to Kelso.

Sands must harbor *Uma*. It is a large area of black hills with long ridges of sand leading up to them. The flat places support real barchanes.

I went toward Kelso. The last Kelso sign I saw read 16 miles. Apparently I went wrong as I followed the powerline road for miles and finally cut down a road along a phone line that brought me out east of Kelso. Indigo bush, mallow, penstemon, and lupine were in bloom on the ridge north of Kelso. I have camped in some sort of excavation pit.

A while ago I heard a weird noise. It sounded like something big was choking or rabid. Then I saw the white muzzle and belly of a burro. I guess I never heard one “hee haw” before. To the sack.

May 12, 1949

Kelso Dunes

7:00 AM. Arose and drove to Kelso. I dropped in the general store to buy some milk. A real “farmer type” was reading the paper with comments—with regard to workers who had dug a little girl out of a 90 ft. water pipe. He said donations totalling \$40,000 have come in for the 4 men who dug the hole. Someone had suggested that the money go to establish a scholarship to Claremont College.

The farmer (whose face was twisted off to one side) said “Why that god damned _____. What the hell does he think he’s trying to do? Send some rich man’s son to college to learn to be a goddamned astronomer or something?” Then he shot a bolt of tobacco juice into a No. 10 can (this explained his twisted face) and turned to a new tack—“I ain’t see a no husband killins for a month. Some old lady was always knocking her husband off a fire plug. I reckon the city ain’t what it used to be.”

I drove out to the dunes but had little luck as it was already so hot (8:30 AM) that most animals were controlling their temperature. A good road goes just south of the dunes. To get to it you cut across the tracks just west of town and turn up the paved mine road (a Kaiser Mine) till you come to the phone line—turn right out the road along the line. After a couple of miles it makes a bend and then goes straight over the saddle between the Providence and the Granite Mts. About ½ mile south of the bend is a “good” (2 rut) dirt road cutting off to the right—take it and you will skirt the south face of the sand mountains.

May 23, 1949

McCoy Mts., Riverside Co., California

Dad & I left Van Nuys. Speedometer reading 12382.9. Drove through deserted streets and had breakfast at Azusa. We drove to Beaumont and Banning. Next canyon west of Snow Creek I made a short reconnaissance of some sand that has blown up on the west slope of a spur in a semi-circle on the south bank of San Gorgonio Creek. *Callisaurus* & *Cnemidophorus* were taken and *Uma* was seen. This extends *Uma*’s range upstream.

Drove through Palm Springs to 1,000 Palms.

10:20 AM. We caught *Uma* and *Dipsosaurus*. *Dipso* was controlling temp for first time I have seen it this year. One *Dipso* was seen in Chino Canyon perched on a

huge boulder. The females are definitely under cover. The *Uma inornata* show a slight spot on the lateral fold.

10:40 AM. Had lunch at Indio and drove to All American Canal on Aqueduct Rd. There I saw *Uma* probably. I caught 2 *Dipsosaurus* controlling temperature.

1:30 PM. Drove to Desert Center. Then we cut down a road 10 miles past Desert Center to a shack and corral at the edge of Palm Dry Lake. There we met a gentleman with a large cud of tobacco in his cheek. He apparently had some stock—dogs, sheep, cattle, and plugs (as he put it). He well was 150 ft. deep but drawing “good” water from 90 ft. Desert Center gets their drinking water at a well north of town. The wells in “town” were salty. We drove past his house and over a nearly absent road to the playa (last rain in 1939). The playa is very soft and sandy.

At the SE corner of Pinto Basin there is a low group of rocky hills. These hills are covered with sand blow-ups of some extent [drawing].

Sand surrounds the south side of Palm Dry Lake in a semi circle, there being two concentrations of well developed dunes. These are on the SE and SW corner of the lake. The SW concentration is the largest and is constituted of barchanes and nondescript dunes of very fine sand resting on a hardpan base. 3 *Uma* were seen for sure [drawing]. None were taken as the animals were extremely wary (very hot) and there was lots of cover.

3:00 PM. We left Palm Lake and drove about 10 miles to the Hopkins Well Road (which proved to be to the south of center of Ford Lake rather than on its western edge as the Auto Club Map said). This road apparently leads to the west base of the Palm Mts. (good road). Hopkins tank and well are abandoned. We retreated and returned to the road. About 3 or 4 mile further east I saw an area of about 50 acres of low dunes at the SE corner of Ford Lake. *Uma* was taken here.

5:00 PM. Left Ford Lake and drove east of McCoy Springs Road which we followed northward. It is a very devious but good desert road. We did not find the springs because we were hungry, tired, and General Patton had left so many roads we didn't have a chance. We camped in a wash. Pa cooked ham and potatoes and coffee over some palo verde and mesquite branches. Dinner was delicious (thank you Theodore Roosevelt). The bacon was literally wringing with grease—our butter was liquid and the jar top was loose. It leaked out—it may not butter our bread but it did lubricate the rear springs. I called up a screech owl. I also heard a poor will and saw a great horned owl. To the sack.

May 24, 1949

3 miles S. of Sonoita, Sonora, Mexico

5:30 AM. Arose and cooked breakfast. We drove back to Blythe Highway. Enroute it was noted that Ford Dry Lake has a considerable area of hummock sand at its south east end in addition to the small dunes mentioned yesterday. Drove to Blythe and out on the scarp to the west of town. I took a considerable hike over an area of very excellent *Uma* habitat. I saw 1 *Uma*.

I shot a female leopard lizard in the most brilliant post nuptial coloring I have ever seen. This coloring must serve different purposes in different lizards. Probably in the leopard lizard and *Callisaurus* it might serve to frighten away males. Male and

female *Uma* (the female in brilliant color) were seen together at Ford Lake. The function here is not at all clear.

We drove to Quartzite and down to near Yuma where we cut over to the highway at Ligturta. About 6 or 7 miles up this road from the highway some blown sand is located. It apparently has come from a stream bed nearby. The day was exceptionally hot (108-109 degrees F.). We drank water, beer, water, orange ade, water, ice cream, water, coke, and water.

The country is most uninteresting and barren till Gila Bend is reached. The road south to Ajo is quite vegetated with mesquite, palo verde, and cacti. We did night drawing[?] till camp was reached. 2 *Hypsiglena* and 1 *Phyllorhynchus decurtatus* were taken. A *Bufo punctatus* was taken at Sonoita checking station. The stream houses a very loud chorus of these animals. Bugs are everywhere and I can hear cows mooing. Pa is objecting to the bugs so I must stop.

May 25, 1949

48 miles SW of Sonoita

Good sand—*Uma* seen. Rolling sandy plain. Sample taken. This sand extends for 7 miles, nearly to Punta Penasco.

Cholla Bay, 6 3/4 miles NW of Punta Penasco, Sonora, Mexico

Left camp 3 miles south of Sonoita. Our camp was located among a lot of saguaro cacti and ironwoods, palo verdes, and mesquites. Many of the palo verdes are in bloom. White-winged doves cooed at each other in contest fashion from the tops of these cacti.

7:00 AM. We drove toward Punta Penasco through a series of rocky mountains on which grew dense forests of the vegetation we had seen at camp. Organ pipe cacti became common. Shortly we began to lose altitude and all the cacti disappeared giving way to *Larrea* scrub. This scrub clothed a more open plain.

At El Papolote we stopped to investigate a sandy area. *Uma notata cowlesi* is common. They were not very wary.

At Punta Penasco (about 3 miles west of the end of the dunes) an area of stark white sand dotted with low scrub occupies the edge of the bay to the north of the town (1/2 mile long).

Punta Penasco is a busy little place of possibly 2,000 people. The town is built on a rocky hill (Rocky Point) that juts out into the sea. It has felt the American influence as some signs are in English and most persons speak a little English also. A railroad (Ferro Carril) with a very small, though modern engine comes into town.

The graveyard is typical of all Mexican graveyards, being full of paper wreaths and gaudy tombstones. It is perched precariously on the side of Rocky Point.

At El Papelote we were converged upon by 3 ninos of about 10 years. Pop gave them some candy. They looked very pleased. I had a great time exercising my spanish on them. They asked as if we were going to eat the umas. They were also convinced that my *Hypsiglena* was a "vibora". I showed them that it had no "cascabel" on its tail. They conceded that it was just a "culebra pequena".

We left P. Penasco and drove to Cholla Bay. The road goes along the east side of the railroad for a while and then cuts over the tracks and winds to the Bay.

A Mexican named Nacho runs a fishing camp at the bay. When we arrived he had a 12 change record player going in his 9x12 store (abarrotes y cerveza). It was so loud that I had to yell to him to get 2 beers. The little shack fairly pulsated with spanish quartet music. It is a series of choppy words said in harmony and then a word such as “corazon” strung out and sung on a decreasing pitch—then more choppy words. I can hear the music now.

We fished and I swam, seined, and hiked.

May 26[?], 1949

Mileage 13044.7, 661.2 miles from Los Angeles.

I saw 3 great horned owls up in a small rocky hill that lies on the south west corner of Cholla Bay. The bay was a crescentic bay about 1 mile across when we arrived. By 4:30 it was completely empty. Mud flats run out about ½ mile. The tide must exceed 15 ft. in range.

A large range of peach-colored sand mountains can be seen to the north of Cholla Bay. They reach the sea's edge about 5 or 6 miles up the coast from Cholla Bay. They run southeast from there. I have no idea of their extent to the north. They appear to be 100 ft. high or so. I suspect the sand at El Papalote is the southern remnant of this range. Both Pop and I are tired. I am quite sunburned. I suspect we will not stick around here three days as the heat is quite uncomfortable and we only have a tarp for shade.

It is now about 9:00 PM and the tide is not yet in. I think I will hit the sack.

May 27, 1949

34 miles SW of Sonoita, Sonora, Mexico

There appears to be a stretch of peach-colored sand going along the base of a small range of mountains. It appears to cover a series of low hills NW of this range. On its eastern end it is blown up on what might be a volcanic peak.

1:20 PM. Sonoita River—seined a series of *Cyprinodon*. Water temp 34.3, 6 in. to 2 ft. deep. Filamentous green algae. Water clear, 2 mph current and still pools 7-10 ft. wide.

Quitobaquito, Organ Pipe Cactus National Monument, Pima Co., Arizona

[?]:30 AM. Arose and started to eat breakfast when a spanish gentleman came walking down the beach. He began talking (in spanish) about a “liebre” he had seen. We talked for about an hour. I was constantly looking up words. He told me about Apache pictographs on a “cerro” near Hermosillo showing the moon, arrows (fletcha). He said snakes (vibora y culebra) come out about May at Hermosillo. He also said there are all kinds of salamanders in the area. He was much impressed with our cots. They would cost 35 pesos in Hermosillo and still rip to pieces as soon as you used them, he said. The truck, I told him, belonged mostly to the finance company (hacienda publica). He didn't seem amused about this. What probably impressed him most was the fact that we buried all our rubbish. He said he was a good friend of Nacho's. He asked if we were “amigos o padre y hijo”—apparently you can't be both. He said to be sure and visit him when we come to Hermosillo. He seems to be chief clerk there. His address is Ramon E. Corral, Jefe Archivo Gral. Gobierno de Estado, Palacio Gobierno or Ramon E. Corral, Calle Morelia No. 18 Pte., Hermosillo, Sonora.

I gave him my address with similar instructions.

7:00 AM. We left and drove to Punta Penasco. There I made a trip over the white sands back of the bay. I saw a lizard thrashing in a bush so I shot at it. It ran off but I found I had hit a red racer (that had captured the lizard). I caught *Uma* here. We drove to El Papolote and I shot 9 *Uma* here. The little ninos reappeared bearing a dead *Uma* on a string. Pa gave them 2 sacks of candy and some water, both of which they accepted with wide grins. I still wonder how they caught the *Uma*.

We drove up the road to the Sonoita River where I seined a series of *Cyprinodon* for Boyd Walker. We then crossed the border and had our Los Angeles potatoes taken away. The guards were interested in my snake (except 1 guard). This latter fellow seemed very much impressed with his own importance and glad to take our potatoes away. He tried to make us feel like criminals who were smuggling potatoes. About this, we didn't feel guilty. If there was any such feeling it was about the gun hidden under the seat.

One of the guard's friends told of running over a 4 ft. snake about as thick as a lead pencil. He said it was quite pale. Also it disappeared before he returned. This location was about 3 miles north of Sonoita. He was the sort who is full of hot air but nevertheless the description fits *Oxybelis* and I doubt that he would have heard of the snake.

We drove to Quitobaquito (15.2 miles west of the Ajo road). You take the road just north of the border marked "10 mile scenic loop". A short distance west the loop goes north. Go straight ahead at this junction. Later on another crossroads is reached. Take the one marked "Patrol Road". Quitobaquito is a good spring of clear water running into a shallow pond surrounded by rushes and mesquite and cottonwood. Some willows occupy the south end.

We saw Mexican ground doves, white-winged doves, mourning doves, cowbirds, vermillion flycatchers (a beautiful beast), English sparrows, nighthawks, verdins, turkey vultures, killdeer, and Gambel's quail. The border patrol has a station here. We talked to Mr. Cleveland and wife who rides the fence. He was at Triajas Altas last year.

Back at Monument headquarters we talked to a Mr. Bean (ranger) and W. Max Hensley of Univ. Illinois who is working for his Ph.D. on a population study of birds in the monument. He is working under S. Charles Kendrigh of Univ. Illinois. He had collected a lot of snakes including *Trimorphodon*. We drove the road getting 1 *Chionactis* and a gecko. We camped near Ajo.

May 28, 1949

West side of Mohawk Mts., Yuma Co., Arizona

11:30 AM. Peach-colored sand deposit. The sand is not very extensive.

Mouth of Pushawalla Canyon, Riverside Co., California

6:30 AM. Left camp south of Ajo and drove to Gila Bend where we had breakfast and picked up ice in our precious water jug. Pa got his hair cut and nearly ruined the barber's clippers with the sand and gravel trapped in it. We drove on to 6 miles east of Yuma where some small sand dunes are located. They are concentrated along a river bank but I think derived from across the Colorado and not from the wash.

No *Uma* were seen and I do not think they occur here. *Dipsosaurus* was seen. It was very hot and clear.

11:30 AM. We ate lunch in a lousy café served by 2 platinum blond (H202) painted waitresses. We then crossed the Colorado and drove up to Laguna Dam. Just over the sluice gate there is a sand spit extending northward back up the lake about 250 yards from the dam. There is a row of palms and a good many cottonwoods on the land. It is quite rocky. Who should we meet sitting in the shade drinking from a canteen but Joseph Slevin of California Academy of Sciences. With him was Wallace Wood. They had just returned from the Huachucas Mts. They didn't find *Bipes*. [Drawing]

We went out on the spit and by turning over rocks shaded by dense willows we got 4 *Leptolyphlops* and 3 *Sonora miniata linearis*. It was very hot and humid. The snakes were found in somewhat moist soil. J. Slevin was on his way to El Doctor on the head of the Gulf of Calif.

We left the Yuma valley and drove to the All American Canal at the Sandy Hills. Here I observed *Uma*. They show the red ventral coloration. It seems to be definitely not post nuptial with this form. We then drove to Holtville and had dinner at a nice café. The waitress sneered at me (I hadn't shaved for 5 days). She served us however. Then we drove through Nilaud and Mecca, picking up several snakes on the way. Geckos were quite common.

We drove through Indio and up the Powerline Rd. to Pushawalla Canyon. I could not find the road in and we were both very tired and sleepy so we camped on the alluvial fan. The wind was blowing down the fan about 20 mph in gusts. Under these uncomfortable circumstances we hit the sacks.

The day had been clear and warm. The only wind we encountered was at Coachella Valley.

May 29, 1949

Van Nuys, California

5:30 PM. We arose and drove to Garnet, had breakfast, and drove home. The wind was near 30 mph in San Geronio Pass. A thin drizzle hovered over us from Beaumont to Glendale.

11:30 AM. Arrived home. I have been looking at *Leptolyphlops*. They would make a fine experimental animal for temperatures as they are translucent. Peristalsis and heart beat could be directly observed by shining a light through them. Different environmental conditions could give some interesting answers.

July 30, 1949

6.5 miles N. of Old Bingham, Socorro Co., New Mexico

After much packing and waiting around, Chuck Lowe and I, driving a 4xWD weapons carrier and Dave Dunn and Sid Gordon in another similar vehicle left Socorro. We drove south of town to San Antonio, crossed the Rio Grande and proceeded towards Bingham on the Carizzo Road. The weather was clear and warm with thunderheads forming in the afternoon.

We left the highway at Bingham, driving to Old Bingham and then towards the Wry Ranch over rolling juniper-dotted plains. We ate lunch at the Wry ranch (an "Alamo")

type adobe and a wooden shack). A rain (very recent) had filled a catch basin with opaque red water.

12:30 PM. Several pairs of *Scaphiopus hammondi* were seen in amplexus, floating in the center of the pond. The females were often completely submerged and out of sight. The males were clasping with their front legs only.

We drove on and made camp alongside a large juniper. Tarps were strung as a thunderhead began to spatter us with rain. Later we set out traps (135) for wood rats. Later I cooked a cake (successful). We discussed this and that and ate the cake.

July 31, 1949

Same camp. Shot a porcupine and cooked him. He was very tough and we are parboiling him. Dissected rats and set out traps.

August 1, 1949

Kept cooking the porcupine. He still repels our gastronomic advances. Trapped and dissected more rats. This is a tedious process (1½ hours per rat) and I do not especially care for it.

August 2, 1949

Same camp. Made chili con carne out of parts of the porcupine. Dissected more rats. Trapping was poor (5 rats for 135 traps plus several *Peromyscus* and *Perognathus*). We drove up to Chupadera Mesa about Cok—[?] Ranch and met a crew of visiting dignitaries including Dr. Bellamy of UCLA, Dr. Peirson, incipient assistant director of Medical Biology of Atomic Energy Commission, and Dr. Jenson, the present Assistant Director under Dr. Shields Warren.

Dr. Jenson was quite sympathetic with our ideas concerning population structures and reinvasion at the crater. This support was pleasing when from so high a official of the Commission. The Dr. is a remarkable person, most incisive and logical. He has one of the best commands of the scientific method I have yet seen.

We left and drove into Socorro.

August 3, 1949

Socorro

Packing for our trip north.

August 4, 1949

Sandia Peak, Bernalillo[?] Co., New Mexico

We left Socorro about 11:00 AM and drove northward. Chuck Lowe and Dave Dunn in 1 weapons carrier and Sid Gordon and I in the other. After a flat tire at Jarales we proceeded to Albuquerque while Chuck and Dave went to Mountain Air.

While our tire was being fixed Sid and I shopped for a few items. Then we drove up a long alluvial fan to the base of Sandia scarp. These mountains have a gentle east slope and drop off precipitously on the west. The mountains reach approximately 9,000 feet and are forest covered in their higher reaches by yellow pines and white firs. Lower down the forest changes to pinon-juniper.

We drove up the Sandia loop road and camped at about 7,500 ft. under oaks and yellow pines alongside a small grassy meadow.

After a while the wet wood finally gave us a fine blaze. We had T bone steaks, fresh fried potatoes, mushrooms, peas, and a chocolate cake. Later we worked on plants and lizards and hit the sack at 11:20 PM under a clear moonlit sky.

August 5, 1949

Santa Fe Airport, Santa Fe Co., New Mexico

I awoke about 8:15 and took a short hike. When I returned Sid was still asleep. He got up just before 9 and we collected a large series of plants from the meadow. Pressing is a long tedious job and took till 2PM. We then drove up the road toward Sandia Crest (10,678 ft. elev.) We collected many more plants on the summit. The diversity was great. We took mariposa lilies, Indian paint brush, larkspur, columbine, buttercups, and many less spectacular plants.

On the way down we stopped to press plants. This we did until dark without getting done. Then followed a long cold ride in the open weapons carrier to Santa Fe. We had planned to stop at a motel but they were all filled. We drove around town looking and finally got lost. Finally we found our way after driving through several backyards and drove out to the airport.

At 11:30 PM we camped, tying our tarp to a farmer's fence with lightning storms on all sides of us. We immediately hit the sack and I slept through our only shower.

August 6, 1949

Truchas Peak, Santa Fe Co., New Mexico

We pressed the remainder of our plants and proceeded into Santa Fe for breakfast. Then we drove north toward Taos, cutting off on a backroad to Truchas. Truchas is a lumber town set on a pinon-juniper covered bluff bordered by stands of yellow pines. The streets are dirt and since it was raining they had turned to a sticky red mud. We bought a pie and 2 quarts of milk at Martinez General Store. This is a fine store and carries everything from pabulum to garbage cans to peevies. We left and drove up a road (called one out of politeness) which was really a sea of mud, past farms set in a long meadow between forests of yellow pine. We met 2 log wagons which were pulled by horses. At this rate logging will make no real inroads into the forest.

Presently we cut into the forest, passing through park like meadows and dense stands—always following a little mountain stream.

As we gained altitude white fir became dominant and aspen became quite common. Some of these aspens grew in groves so dense that each tree was forced to vie with its neighbors for sunlight. Thus the trees were 80-90 ft. tall and straight and limbless for 60 ft. or so.

After crossing several doubtful log bridges we came to a grassy hill on which were 4 log buildings. We camped here and set up our equipment in a mud and aspen log building about 15 ft. square. 5 large pine beams support a sod roof about 1½ ft. thick. We took several species of plants from the dense growth on the roof.

To the northeast we can see the boulder fields of Truchas Peak above the timberline. The stream forks on either side of one hill, flowing through grassy meadows. The elevation here is 9,750 ft.

The altitude is affecting me and I have lost much of my energy. Sid is just recovering from an attack of indigestion. In spite of this I cooked up creamed tuna and rice, hot corn bread, and coffee.

The wood stove in our cabin has warmed us and we are both ready for the sack.

August 7, 1949

Rio Hondo, near Taos, Taos Co., New Mexico

I woke up about 7 and got up. Sid was still sleeping. I went down to the creek and washed myself. All traces of the altitude sickness of yesterday were gone. I found a trail that looked like our best bet for Truchas Peak. All the birds and beasts were out in their usual morning numbers. Both a chipmunk and a golden mantled ground squirrel were on the meadow cavorting around. Also a tree squirrel, dark gray in color with slight ear-tufts was seen. I could hear them cussing at one another as they leapt from branch to branch.

Finally Sid arose, we ate breakfast (his indigestion was gone) and left for the peak. Thunderheads were scattered over the sky occasionally rumbling at us. I carried a pack sack containing lunch, my camera, and a pistol, and equipment for our radiological samples. Sid carried binoculars and a vasculum.

We hiked up a well marked trail through dense fir and aspen stands. We were well over 10,000 ft. when the trail ended in an area of felled trees. After considerable reconnoitering we located an old logging road where it crossed a water-filled meadow and followed it up onto a ridge. It gave away to a good trail which rose rapidly through the forest.

Once I stopped to look at a tomato-red fungus about the size of a softball. Among the red areas was a reticulum of orange. This forest is full of fungi of all sorts, many very large.

The trail entered a pine stand of tall aspen at about 10,000 ft. It was like walking into a greenhouse. The light was filtered by the leaves giving everything a green look. In addition the forest floor was covered with all sorts of moist-lush plants. Pinky logs covered with many kinds of mosses and lichens lay here and there.

As we continued to climb the trees grew smaller and more contorted. In some places many of the aspens were bent to the ground by winter snows. The clouds now covered the sky and thunder could be heard nearly constantly. Finally we dropped down into a beautiful meadow, hanging on the side of Truchas Peak. The altimeter stood at 10,700 ft. This meadow, about 100 acres in extent, was the source of one of the streams that flow from the mountains. Among the fields of skunk cabbage, ice cold water flowed from the black soil. In this icy water were matings of a small white *Ranunculus*. Here and there in the meadow were islands of firs and aspens. To the north we could see the barren rocky and sparse, snow-clad slopes of the peak itself.

The storm closed in and the peak became hazy through rain. We saw rain at the upper end of the meadow and watched it advance towards us about as fast as a man could run. It came down in huge drops intermixed with hail. We took our grass and bark sample and turned back somewhat reluctantly. We managed to keep ahead of the rain and reached camp quite dry.

We packed and left the "Hotel Truchas" and drove down the canyon to Truchas. Then we drove north through the fine pine forests of Carson National Forest to Taos.

There we obtained directions and a topo sheet from a gas station attendant and proceeded to the Rio Hondo.

This river forms a narrow v-shaped gap in the massive mountains that culminate in Wheeler Peak (13,100 ft.). We made camp alongside the stream (a swift stream 40-50 ft. wide). Sid chopped a couple of sections off a huge dead pine. We used these as back[?] logs to produce a most pleasant campfire.

While walking along the banks looking for salamanders and I saw several small (4-5 in.) trout. They were all white in the flashlight beam. It is interesting that they should change color phases from day to night. I see no ready explanation.

Notes and specimens took the rest of the time until the cot.

August 8, 1949

Rio Hondo, below Twining, Taos Co., New Mexico

We got up fairly late. I did so because a spring wagon and team started sloshing across the stream. Sid woke up when I started stirring around.

While we were packing to leave, a fisherman walked up (Frank Schultz) and we got into a discussion of radioactivity. He was an oil field foreman. He asked if a small radioactive element might not be fixed to "go devils" (a finned device that fits inside oil pipes and is pushed along by the oil pressure and cleans out accumulated paraffin with its cutting fins). He said sometimes ¼ mile of pipe is ripped up trying to locate a go-devil that has stuck on some inequality of the pipe. With the element and a Geiger the go devil could be located precisely by walking over the pipe line. Probably a single application would save enough labor to pay for the equipment—why not?

We drove 8 or 9 miles up the stream to Twining, a pack station at 9,950 ft. elev. It is situated alongside a green grassy meadow surrounded by groves of tall aspen.

We drove a little farther and then began to hike up an old road, too much in disuse to be driven. We found all sorts of plants in this moist habitat—a huge blue and white columbine, a big blue gentian, skunk cabbage, canterbury bells, all sorts of daisies, thistles, Indian paintbrush, delphiniums, and dozens of less conspicuous forms.

The trail went quite directly up the stream course through fir stands and groves of aspen and grassy meadows. It began to rain and some hail fell. We put on rain coats and continued hiking through the rain. Shortly we saw a black-hatted young fellow carrying a plant press swinging down the trail. He was a botanist from East New Mexico State College. He had attended a summer session at UCLA and taken a course from Chuck Bogart.

He said the hail had gotten him up above timberline and he had turned back. We walked on, reaching a sign saying "Wheeler Peak 6 miles"—the sign at the base of the trail said "Wheeler Peak—5 miles". This was something of a letdown but we continued up turning westward along a good trail that rose rapidly in a series of switchbacks.

We could see the effects of altitude. Plants that were through blooming at 10,000 ft. were in full bloom at 11,000 ft. Of course many plants do not span this change in altitude and many new elements have come in.

Finally timberline was reached just as we hiked past an old copper mine dug into a contact fault. Sid had been feeling the effects of altitude like I had 2 days before (only less) so we took our sample here and climbed to the top of a nearby peak (Bull of the Woods Peak 11,610 ft.). The diversity of small clinging plants at this altitude is amazing.

Composites, lilies, various succulents, and many grasses made up part of the interesting flora. Low, almost reclining closed cone(?) pines clung to the borders of timberline.

The top of "Bull of the Woods Peak" is one jumbled pile of cracked rocks. Sid (Syd.) asked how this came to be. My explanation of cracking due to cold and heat doesn't seem to supply all that is needed by the question. Why is it nothing but a boulder pile with nothing of the matrix exposed?

I enjoyed singing a few old ballads to myself as I hiked down ahead of Syd who was collecting grasses. Syd spotted a weasel and a grouse (which I also saw). Probably I saw nothing because of my singing. The hike down was quite wearing on my legs and took more out of me than the uphill jaunt.

We reached the car and drove to a nice meadow surrounded by aspen alongside the stream. I made camp while Syd pressed our tremendous plant collection (already there are 3 1/2-4 ft. of plants and blotters in the press). I cooked dinner (codfish cakes, potatoes, peas and carrots, and coffee). Note writing and plant pressing occupied the rest of the evening in front of a fine campfire.

At present the skies are quite cloudy but I don't think it will rain on us.

August 9, 1949

Agua Fria Peak, Taos Co., [next page says Colfax Co.] New Mexico

This morning I was the one who slept late. Syd had been up pressing plants for an hour and a half when I got up. Packing and plant pressing were consummated just in time as it began to rain before we had strapped the tarp down. We drove down out of the canyon with gathering clouds behind us. On the flat we ran through a hail storm. Behind us we could see dense storm clouds filling the canyon and hovering over the peaks.

The road lead us to Questa and up the Red River Valley. This valley is a tree filled streamcourse limited on each side by steep cliffs. The Molybdenum Co. of America runs a large mine about 1/2 way up the canyon. Just before leaving the canyon we came to the resort town of Red River to be noted for its high priced food (40 cents for a hamburger) and female tourists.

We left the canyon by ascending a series of 6 or 7 switchbacks up the canyon face and over the ridge at a height of 9,852 ft. We drove down a beautiful wide grassy valley enclosed by pine clad peaks to Eagle's Nest. This town apparently deals in tourists and lumber and sits on the edge of a shallow looking lake that nearly fills the bottom of the valley at this point. A short distance below Eagle's Nest we turned onto a dirt road to "Black Lakes". Rain was falling and the mud was thick and slippery. Even though we went slowly the car slid broadside several times. Some anxious moments were had when we crossed narrow railless bridges.

By use of a contour map we located an old logging road that ascends Agua Fria Peak a considerable distance. Compound low wheel drive was used nearly all the way. We camped in a small meadow at 9,300 ft. Tomorrow we shall try for the top (10,960 ft.) to get radiologic samples. It is suspected that since the bomb cloud passed this way in 1946 that radioactive particles may have been precipitated by rains and dew that fall on these high peaks. Therefore we are climbing the highest ones in the cloud path.

Syd cooked the dinner and went all-out by making french fried potatoes to go with the steak.

I wrote these notes and Syd enjoyed doing nothing in front of a nice hot camp fire.

August 10, 1949

Las Vegas, Mora Co. [next page says San Miguel Co.], New Mexico

We got up fairly early and ate breakfast. Syd was slow about getting ready for the hike and I was urging him along so we could get back before the rains when a pair of horsemen rode into camp. They told us of a logging road (Roy Cartwright's Null??) that went up Agua Fria Peak. Syd sighed with relief and we drove off and up the mountain to about 10,000 ft. I hiked on up to 10,500 ft. while Syd dried blotters.

12:00 PM. We drove down, taking samples as we went and continued on down to Black Lake. After 2 false starts we found State Hwy. 120 leading to Ocate. It was a rocky and bad road but passing through beautiful aspen and yellow pine groves and some wonderful limestone rimmed meadows. Ocate is an interesting town set alongside a high bluff. A mass of green fields cover the long narrow valley floor. It was dusk as we drove along this valley. Finally we came to Las Vegas where we engaged a motel and enjoyed a good long shower.

August 11, 1949

Santa Rosa, Guadalupe Co., New Mexico

We rose late and drove toward Santa Rosa. The road leads through rolling grassland with occasional limestone bluffs covered with pinons and juniper.

We tried to cross La Pintada but a rain the day before had filled it and the road was blocked. We turned back and went to Santa Rosa, took a room and slept.

August 12, 1949

Hope, Eddy County, New Mexico

We left Santa Rosa early and drove south taking several samples and readings at Pastura. I collected a good number of reptiles here. On we drove, across grassy plains toward Vaughn. We had lunch at Vaughn and drove south, steadily losing altitude. ____ miles above Roswell we saw our first *Larrea*.

Roswell is a nice town surrounded by farming districts. Much cotton is grown here. Apparently there is a good supply of water. We drove past farms to Artesia—turned up the Cloudcroft road and camped alongside the Rio Penasco outside of Hope.

August 13, 1949

Sacramento Mts., above Tularosa, Otero Co., New Mexico

We drove up into the foothills of the Sacramento into a gathering storm. Pines begin to replace juniper at about 6,000 ft. and by 7,000 ft. we had driven into a good forest of pines and deciduous oaks. Here just above Mayhill I picked up a specimen of the rare *Eumeces gaigei*, a skink of which 8 or 9 are in collections at present. This was quite a thrill.

At about 8,600 or 8,700 ft. we stopped to inspect some downed Doug-fir logs. Shortly Syd called me over to investigate a strange noise he heard under a large log. The noise was a meadow mouse but under the bark of the log was my first *Plethodon hardyi*.

We took a nice series of 42 animals with little trouble. I was quite surprised at the striking resemblance to *Aneides ferreus*. Chuck keyed them out later and every character fits *Aneides*. Of course he was very excited as he is working on the group for his Ph.D.

Syd and I drove on, after much plant pressing and camped in a wash under a nice cottonwood. I called a poorwill into camp and collected him (with data) for Joe Banner.

August 14, 1949

Socorro, Socorro Co., New Mexico

After breakfast we drove to White Sands National Monument. This is a considerable accumulation of gypsum sand lying in the bottom of the Tularosa basin along its western edge. The basin is a graben[?] and the sand is supposedly wind sorted from erosional products of the surrounding mountains.

The dunes rest on a red sandy soil and are probably 20 miles in length by 10 miles (at the widest) in width. Grain size is about that of granulated sugar. The largest dunes are 30 or 40 ft. high. All the sand is pure white and very hard on the eyes in the bright sun. The gypsum holds moisture readily and an inch or so below the surface the sand is very moist.

I collected a very pale (unnamed) form of *Cnemidophorus perplexus* and a similarly pale form of *Sceloporus undulatus*. Also the pure white *Holbrookia maculata ruthveni*. After a long tedious siege of blotter drying we left and proceeded homeward by way of Carrizozo. We stopped off at the lava beds west of Carrizozo where I collected a very dark *Sceloporus undulatus*. The rest was driving with no events.

August 21, 1949

White Sands New Mexico, Otero Co., New Mexico

Chuck and I left (sub rosa) from the Chupadera Mesa driving directly to the sands. Before we reached the dunes we passed through a large thunder shower which produced torrents of red muddy water among the mesquites and creosote bushes.

It had not rained at the sands but cloud cover and gusts of wind kept the animals in hiding.

We visited the museum and talked with the rangers there. Mr. Johnwell C. H[?].jaris, the superintendant, and a Mr. Ray Schaffner were most helpful to us. Mr. Schaffner has written a thesis on the botany of the sands. A copy is on file at the monument. For geologic information on the sands we were referred to 2 USGS papers: Water Supply Paper 343 "Geology and Water Resources of Tularosa Basin, New Mexico, 1915. O. E. Meinzer and R. F. Hare and Dept. of Int. U.S. Geologic Survey Bull. 794, 1928 "Red Beds and Associated Formations of New Mexico", N. H. Darton (includes a summary of the geology of the state).

From the museum I learned that the Tularosa Basin was formed as a graben valley dropped down along two faults that cut along what are now the scarps of the San Andreas Mts. to the west and the Sacramento Mts. to the east. The gypsum, of which the sands are composed, was deposited by evaporation and concentration of an arm of the sea during Permian times. It was a red bed deposit.

Erosion has exposed lenses of gysum and they have been broken down by wind and water. Some sand (which is denser than ordinary sand) has been produced directly by this means and the rest has been produced by solution and evaporation in a lake (Lake

Lucero) at the base of the San Andreas Mts. abutting the sands. Since gypsum is heavy, wind has deposited it and swept the impurities on out into the basin.

7 species of plants are reputed to grow on the sands themselves. Even these plants do not draw nutriment from the sterile sands but send roots (sometimes 50 ft. long) into the red soil below.

A list of publications consulted in the preparation of the museum is available as: "A Bibliography of National Parks and Monuments West of Mississippi River, Vol. II, 1941, U.S. Dept. of Interior, National Park Service."

We left the headquarters and camped out among the dunes. It is a remarkable place at sunset; the black and rugged San Andreas Mts. silhouetted against the sun. Red and gold clouds and white sand lined with black shadows. At night the white sand reflects all the available light and makes an eerie white effect even under starlight.

August 22, 1949

Foothills of Guadalupe Mts., Eddy Co., New Mexico

We arose, being driven out of the sack by the heat. After a quick breakfast we commenced collecting and shortly took several of the very faded *Sceloporus undulatus* and 3 *Holbrookia m. ruthveni*. It was some time before the *Cnemidophorus perplexus* were in evidence.

Oct. 7, 1949

Palen Dry Lake, Riverside Co., California

Left Westwood about 1:00 PM, and picked up Dick Zweifel and Bill Reeder in our UCLA jeep. We drove out of Los Angeles under a heavy cloud cover. This cover extended to the eastern edge of San Geronio pass. A strong wind blew in the pass and low clouds hung over San Geronio and San Jacinto peaks. It was cold.

We were relieved to find it clear in the Coachella Valley. At dusk we passed through Indio and up toward Desert Center. We drove down a dirt road 8.8 miles past Desert Center and made camp on the flat of Palen Dry Lake, among sand dunes.

[Drawing] In the wash, water is quite close to the surface. Moisture can be reached by digging a very few feet in inches in some places. *Tamarix* and *Salicornia* and *Atriplex* are scattered up and down the wash.

Near Chuckwalla Springs

Imperial Co., California

We arose after a good sleep broken only by two mosquitoes and an inquisitive owl. We ate a hasty breakfast and began searching for gopher burrows. The sky was clouded over and rain appeared to be falling to the west on the Chuckwallas and Eagle mountains. I didn't expect to find *Uma* in this sort of weather but Dick kicked a big male out and saw him run down a burrow. We caught him and drove some more, locating some green *Tamarix* in moist soil at the south edge of the lake—still no gophers (Bill Reeder is interested in them).

We drove up to the highway and up a good desert road southward up the bajada of the Little Chuckwalla Mts. into a deep canyon with a sandy bottom. *Olneya*, catsclaw (*Acacia*), *Larrea*, mesquite, *Chilopsis*, etc. were lush in the canyon bottom. Shortly

(about 10 miles from the highway) we came to Corn Springs. It is a palm oasis of some 60 trees (mostly with their skirts burnt) situated in almost the center of the canyo. A concrete pipe about 3 ft. across is run into the ground about 5 ft. to a seepage. This was dry. Mesquites are numerous and a quail guzzler has been built.

We drove on up the creek past several shacks 3 miles to Aztec Well where we met John Garza, an old miner who has lived in this canyon since 1927. He is a very pleasant rotund gentleman and was listening to the World Series at he time (Yanks over Brooklyn 3-0). We quizzed him about *Bufo punctatus*. He told us they were common in the area (not at Aztec Well) and could be found in a steep-walled canyon near the Morningstar Mine about 1 mile away.

We drove down the road and cut off on what we took to be the right road. We ended up at a little shack. Bill called and presently out came a most disheveled being who ignored Bill and commenced to urinate—oblivious to us. When he finished he started to go back in the house—only then did he see us. He seemed relatively unconcerned. He was a remarkable fellow for his outfit. You could see his feet through his shoes in several places. A red face and a large nose, dime store glasses so dirty I could hardly see his eyes. He was hard of hearing but finally directed us to the mine. Dick drove us up a horrible rocky road to a steep canyon cut into the granite. High boulders formed the walls. We hiked up over the falls but found no water. *Bufo* could occur here under the same circumstances as it occurs in the Granite Mts. We took a couple of mummified *Bufo* from Corn Springs. They had been trapped in 2 shallow tanks and had desiccated.

Lunch was eaten at Corn Springs and we drove on down to the highway and Hopkins Well. This place is now abandoned and the beaten old tank and some *Tamarix* trees are all that remain.

We took a road out onto the north end of the lake. The soil is moist here and filled with gopher burrows. *Tamarix* trees form about the only vegetation in most places. These are small and shrubby. We drove on to the area of sand dunes and located 6 *Uma scoparia* by tracking. Clouds had come up and a dust storm was brewing over the south end of Palen Lake. As a consequence no *Uma* were out. We left and bought gas and started up toward Wiley Well. The south side of the road supports a good area of sand dunes habitable to *Uma*. The jeep had some trouble but we made it to Wiley Well. The well is a tank of good water (considerable algae) running from a windmill. The water was down about 40 ft. Ironwoods filled the wash around the well. We drove on and tried to find Chuckwalla Well but the road gave way to a mess of vague General Patton roads. We ate dinner and are now sitting around a nice ironwood fire.

January/February 1950
March 1950
April 1950
August 1950

Sonora, Mexico
Baja California, Mexico, Arizona
San Bernardino Co, Panamint Mts. ...
Guracoba trip (Sonora, Mexico), Arizona

January 17, 1950

Gila Bend, Arizona

Packed and left Los Angeles about 12:30 PM. We drove to West Covina and had lunch. Two trucks, a Dodge power wagon, and a Dodge pick-up were taken. We have a full rig for fish collecting including dip-nets, seines (including a 160 ft. one), 80+ 5 gallon cans, 2 30 gallon drums (for large specimens), 6 cans of derris root (for poisoning tide pools) and numerous other items.

In the party are Dr. Boyd Walker, Dave Joseph, Art Flechsig, Andy Rechnitzer, and myself.

We drove on across the Coachella Valley having dinner at El Centro and continued on to just east of Gila Bend where we camped (hastily) at 2:30 AM.

January 18, 1950

South of Nogales, about 20 miles, Sonora, Mexico

We were awakened about 7AM by an irate real estate man who complained that we were decreasing the value of his property. We packed up and left (how we could decrease the value of his creosote and saguaro land I cannot see). We drove on toward Casa Grande through farming country—many cotton fields, with just the stalks standing. After a good breakfast we drove south toward Tucson through a broad valley surrounded by disjunct volcanic ranges, some of which (Desert Peak and Santa Rita Mts.) had a little snow on their north summits. Alternate stretches of desert and farm land cover the valley.

Tucson is flanked on all approaches by numerous motels of all sorts, some very elaborate.

We left after much fooling around (buying dynamite and tire tools and fan belts (one had broken out of Yuma).

Crossing the border was surprisingly easy—a few pesos or promises of same apparently greased the way.

We drove through a peculiar area of rolling hills and spare oaks (look somewhat like valley oaks) and overgrazed grass. We camped in a thicket of some sort of mesquite, ate a quick dinner, and wrote these vital words.

January 19, 1950

Guaymas, Sonora, Mexico (Miramar Beach)

The temperature had dropped considerably during the night and we got up in a cold wind. We ate a fine breakfast of pancakes and bacon. Shortly we got the show on the road and started off driving through a valley filled with a forest of mesquites and palo verdes.

The big truck stopped along a big cottonwood lined wash at Muris, where we could see 2 women washing clothes along the small stream that wound across the

streambed. We seined the stream, at some expense to our dry clothing and caught 2 *Cyprinid* fish and a *Cyprinodont* fish (Poeciliid). The males of the latter have a long intermittent anal fin. They look like mosquito fish but are slimmer and more colorful. One of the cyprinids had heeding[?] tubercles on the top of the head and on pectoral and anal fins. These tubercles (on head) looked pale blue in color. The other fish had dark longitudinal lines down the side and reddish pectoral bases.

The creek was full of burro "end products" but we perservered and collected a fine series.

The country was covered with a dense forest of mesquite and palo verde. A jagged north-south ridge of volcanic origin rose on either side of the alluvium filled valley. Tree morning glories (in bloom) began to appear in increasing numbers.

Shortly we came to Magdalena. This town is a sprawling village lying in a broad river bottom. We could see the dome of a cathedral above the palms and street trees.

After leaving Magdalena I saw my first palo blanco growing on a boulder strewn volcanic slope.

After crossing a section of dusty dirt road we dropped over a low ridge and down into the town of Hermosillo. At first it looked very hot and dusty but shortly we began passing clean modern buildings. There is a nice park and at least 2 beautiful cathedrals. Also several clean modern motor courts were seen.

A new hotel covering an entire block has just been completed. We bought insurance for the cars and mailed post cards. We were all amazed at the number of pretty girls wandering around and we haven't been out long enough for it to be an artifact.

We drove on, passing over the Sonora River just out of town. It is quite a stream of water for a desert region such as this. In the city of Hermosillo the stream is restricted to a channel about 40 ft. across.

Out of Hermosillo the road passes again through volcanic terrain clothed with mesquite, palo verde, and numerous wispy palo blancos up on the slopes.

We have been losing altitude continually from Nogales (3,950 ft.), Hermosillo (690+ ft.), and Guaymas (+2 ft.). A dense, symmetrically rounded tree (30-40 ft. high) began to appear in washes. It has a thick trunk and dark green leaves which are spirally arranged around the stem. The leaves are thick, glabrous above, and ribbed below. The stems are whitish [drawing]. For some reason I suspect it is an Asclepiadaceous plant.

As sunset approached we drove up and around a precipitous volcanic range. We crossed through a low divide and dropped down into the alluvial fan at the head of Miramar Bay. The sky was yellow and silhouetted against black, jagged peaks with a blue tidal lagoon visible down the valley. A long sand spit cuts this lagoon off from the Ensenada Bocoibampo except for a narrow channel at the north. A row of beach cottages stood black against the sky with yellow lights shining from their windows. This scene combined with a warm night created a most pleasant welcome to the gulf.

We drove out to the end of the spit and with the permission of a fine fellow named Jesse we made camp in his parking lot. He is a bartender and lays claim to being an ordained minister, a medical student who quit to get married, and an interior decorator.

We ate a rather hasty dinner and went seining. All sorts of interesting fish were taken. Bonefish larvae were taken on the first haul. They are transparent (like glass) with a small head and a long body. No internal organs other than eyes can be seen. They shrink when they metamorphose. [Drawing] We took several large-sealed flat fish

(*Etropus*). Sand lances were taken. These are peculiar fish with the mouth opening on the top of their head [drawing].

We took a grunion (*Hubbsiella*) in quantity and of course Boyd was excited. He observed them coming up on the beach to spawn (the first such observation on this fish).

We seined in the lagoon inlet and on the sandy beach. Several new species were added to the list before we hit the sack at about 11 PM. Booyd stayed up for the grunion run, which took place at 1:30 AM.

Before we went to bed, Boyd, Dave, and I cooked up a mess of mullet, which was excellent, particularly considering our starved condition. With a cup of coffee we had a real meal.

January 20, 1950

Guaymas (Miramar Beach), Sonora, Mexico

I got kicked out of my sack at some early hour. Boyd went in town to see the Fisheries Commission people. The rest of us stayed and seined. We took the boat over to a rather secluded beach and set the 100 ft. seine. Before long we had a crowd of school children watching us. Our seine brought in three baby botete (puffers) and that is all.

We also had an audience of people who were staying at the Coronado ____ Hotel and who proclaimed the food there "simply vile". The woman had buck teeth and a British accent. She would have looked well on a shooting stick.

Another haul succeeded only in getting our net tangled among the rocks.

After stowing the seine we took the boat to the beach along the sand spit where we are camped and made 3 hauls. Great quantities of thread herring, several very large mullet, and 7 or 8 other species. We took several stingrays, 2 good sized butterfly rays, and a guitar fish.

We were all a bit "pooped" when we got back to camp. Shortly Boyd returned and we ate dinner. Boyd, Dave, and I went out in the lagoon and caught several new (to us) forms. I saw my first eel. We caught a most peculiar attenuated goby among the roots of mangroves where they were covered with moss.

Gillichthys (a goby) was taken. It seems to be strictly nocturnal as I saw none during the day. Apparently they hide in holes in the mud during low tide.

So far we have seined several *Uranosopus*?, a star gazer. They are worthy of a note. These little fish (6 inches or so) live in the sand. When placed on the beach they make peculiar undulating movements with their pectoral fins. The anterior edge of each fin is dipped down in a scooping motion. The median anal fin is equipped with hooks on its anterior spines (ray?) and is moved back and forth in such a manner as to dig the fish into the sand [drawing].

It has filamentous processes? which cover its mouth with a sort of meshwork—this must be a specific adaptation to its particular food supply. After our goby hunting expedition we hit the sack (most willingly).

January 21, 1950

Guaymas (Miramar Beach), Sonora, Mexico

I was again unceremoniously disturbed at some unmentionable hour. Boyd and Art were going in town to see the fisheries people as Art is going out on their boat for 5 days while they are doing experimental trawling for shrimp.

Dave and Andy and I took the boat and some dynamite and went out in the bay collecting. Three tries netted us 1 fish—a *Haemulid* (grunt). We ran the boat all around the bay and landed on one island but saw very few fish. Finally Dave tossed a stick into a pool near some rocks and we picked up a gunny sack full of 4 or 5 lb. fish including a trigger fish.

We came back for gas but a pin sheared in the outboard so we have ceased operations for the time being. I think I'll knock this off and go have a cerveza (Carta Blanca).

We had a fine dinner of the croakers—fried quickly in very hot fat. The fish was cut into small pieces (about 2 bites) and dipped in pancake flour first.

Boyd and Art arrive, after having done some poisoning in a rocky area south of camp.

We dropped over to Jesse's bar for a few beers. Jesse's helper, Manuel, asked us our names. Art's was Arturo, Andy's was Andreas, Dave was Dah-veed, and I was Kenuto—but nothing could be done with Boyd. There isn't any way of making a spanish name out of "Boyd."

Dave asked me the name for bird. I told him "pajaro"—so he flapped his arms and said "pajaro". Jesse, who speaks very good english, said "Brooklyn" and laughed. Then Jesse told Manuel. Manuel was shocked to think that students would think of taking such liberties with their professors. Apparently spanish professors are placed on pedestals and revered by their students.

Art purchased a "submarino", which is a concoction composed of a shot glass full of tequila inside a glass of beer. We all were glowing like neon sighs when we left for night seining.

We worked the sandy beach by camp with a 100 ft. seine. The seine is piled carefully in the stern of the rowboat and the oarsman rows out to the limit of the seine rope. He then cuts at right angles and parallels the shore while a net man pays the net out throwing the bag to seaward. When all the seine is out the boat is turned inshore and the ropes are pulled in, 2 men on each rope.

A set looks like this: [drawing]

Seining is hard work but the sight of mullet jumping over the net or of the excitement when the bag is laid open more than compensates. We took a good many large jacks or "el toro" as the Mexicans call it. They look something like this [drawing].

We collected a number of interesting fish including a bat ray (*Holorhina*) and a salt water catfish (Andy picked it up in the surf).

Dave and I rowed the boat back which was another pleasant task. When we got to the truck it was about 12:45 AM. All of us were hungry after our work so we cleaned and cooked 3 big jacks and they were really fine. Each fish tastes better than the last and all taste far better than anything you can buy in stores or restaurants.

January 23, 1950

Rio Muerto, near the sea, Sonora, Mexico

Andy and Dave and I got to sleep late as Boyd and Art had gone to Guaymas to start Art on his sea trip.

We cleaned up camp and fixed fish (I am getting sensitive to formaldehyde as my hands are all cut up). While washing the boat I noticed that something was wriggling in the sand. It was an amphioxus (*Branchiostoma*) or lancelet. They are primitive chordates but have no true backbone. Andy collected about 8 more by digging in the sand near the water's edge.

Boyd returned and we left for Guaymas.

Guaymas has some nice houses on its northern outskirts and some terribly poor cardboard, mud, and stick dwellings on its south side. There seems to be little in the way of a middle class in Mexico. Either a Mexican has lots of money or none.

Guaymas is a dusty, dirt-streeted place with the typical iron grilles over the windows and the calsonined adobes. The main street sports a center section of nice shade trees and a couple of statues of unknown (to me) but dignified looking Mexicans and an obelisk dedicated to some other unknown person too horrible to remember by a statue.

Guaymas Bay is a beautiful harbor surrounded by a rather intricate series of islands and peninsulae. Several sport fishing craft were at anchor and one small (about 5,000 ton) steamer was tied up in the bay.

We tried to get a Mexican calendar (which are real works of art—for example one has a scantily clad female in a transparent dress with a rose clenched prettily in her teeth).

Boyd had decided to try to reach the mouth of the Rio Yaqui to do some estuary work so we drove southward, becoming quite entangled in the town of Empalme. I did not like Empalme. It has nothing charming about it. It is a dirty squalid mess and even the people didn't seem very friendly. Finally we got out of Empalme and drove southward. Another stretch of the paved road is being built here. It will be a fine road when it is done.

Shortly we had to revert to the old dirt road but it isn't a bad road by Mexican standards.

At Pitahaya we inquired of some young Indians about a road to Rio Muerto. They showed us a road and then hitched a ride on our trucks. We rode off through the mesquite to a little pueblo of wattle and bamboo shacks centered around a large brick church with an impressive dome. Our riders left us here and we were given directions. We drove off over a flat plain, alternately covered with dense mesquite thickets and open mud flood plains. In the darkness the effect was rather weird. Before long we came to an old ruined adobe along the river bank. Here the river is subject to the tides and is salty. Broad gooey mud flats border a stream about 100 ft. across.

The ground was damp and crusty with salt all around so we drove on. It became apparent that we were on a oyster fisherman's road. After about 5 or 6 miles we came to some large mangrove trees alongside the Rio Muerto and stopped to make camp.

The place was set on the bend of the river and was a camp spot for oyster fishermen judging by the piles of shells and the boat tied to a mangrove.

After a quick dinner of meatballs and rice and asparagus soup everybody went to bed except me. I went fishing and caught nothing, had no bites but got neatly covered with mud. I wrote notes and hit the sack.

January 24, 1950

Rio Yaqui near Vicam, Sonora, Mexico

We got up fairly early, had our pancakes and began collecting. Andy, Dave, and I went out in the boat and dropped ½ a stick of dynamite. When it went off the fish leapt out of the water all over the stream. Another blast killed a good many fish, mostly anchovies and herring. A 3-stick blast brought in other species.

We seined up and down the river, using a 50 ft. and 100 ft. seine. The river is about 200 ft. wide at this point and has a very mucky, muddy bottom. The banks are lined in places with dense growths of mangroves. *Salicornia* (pickleweed) is a common plant in the area. Back of the river the flood plain is as flat as a pool table.

There are many species of shore birds along the banks. We saw great blue herons, long billed curlews, terns (a small white species with a black bar through its eye), a willet-like bird, and some small sandpipers?

I saw a small kinglet-like bird with a yellow breast, olive wings, and a rusty red cap on its head.

Wading in the muck while pulling the seine was hard work so we all ate a good lunch and went back to work. We made a fine collection and returned to camp, packed up, and left by 4:00 PM.

Back on the highway (graded gravel) we drove southward over the alluvial plain. Many pitahaya cacti covered the terrain, among mesquites. Volcanic mountains form the eastern limit of this plain. Apparently much of the lowland area is covered in times of flood by the Rio Yaqui. Floods occur mostly during August—so we were told.

Black vultures and caracaras were common, most often perched on large cacti.

At Vicam we drove westward toward the Rio Yaqui. We passed a small village and drove into a dense forest of mesquites, cacti, vines, *Baccharis*, and numerous unknown plants.

In one place we had to chop away a limb to allow the boat to pass under. After passing many mud houses with cooking fires flickering through the doorways, we cut off toward the river on a cart road through dense stands of bamboo?

Shortly we came to a grove of huge cottonwoods close to the river. We stopped, made camp, and cooked dinner. A pleasant campfire made this spot into a perfect camp. Note writing and work on the fish completed the day's work.

The river is a fast flowing river of large size (about 100 ft.). Steep banks rise from the river in places. Boyd and Dave saw a flight of parrots go over.

Enough for tonight.

January 25, 1950

Near Mapoli, Sonora, Mexico

About 5 AM we all awoke reluctantly because of a drizzling rain. I was the most reluctant of all because the dinner of the night before was not sitting too well and I was feeling low. Because of the poor road, which crosses lowlands, we thought it best to get to the main road before our cart-road got muddy.

On the way out we were better able to see the forest we had passed through the evening before. It is a dense forest of huge mesquites (some 30 ft. or so high), bamboo thickets, and patches of solid *Opuntia*. Also there are many cordons and pitahaya cacti

scattered among the other plants. In very few places, other than on roads could a horse be ridden through this jungle. Scattered through this forest are the shacks of Yaqui Indians. The houses are constructed of sticks and mud wattling with thatched roofs. Apparently, these Indians live chiefly from goat herding.

The rain did not materialise. We drove on toward Cocorit. At the Rio Yaqui we were ferried across. The ferry was a barge of about 4 passenger car capacity. It was suspended on a big cable and was propelled by a Mexican pushing a long pole in the river bottom. We paid them 7 pesos for both trucks.

Just over the river a little way is the town of Cocorit. It is a typical spanish town with its adobe houses and town square. A big man in a plaid shirt rode by on horseback. We asked him where we should go to get fish from the Rio Yaqui. He replied in English—it turned out that he had lived on Western Avenue in Los Angeles for a number of years.

Two other fellows were with him, one the town “pill doctor” did not speak English and the other a boat builder named Leonardo spoke very well. The horseman’s name was Nat. Both he and Leonardo volunteered directions and offered to go as guides. Leonardo said he knew where there were all sorts of fish. Since he talked louder and more often than Nat we followed his advice (a bad move) and set off, after getting gas, for Buena Vista.

Andy, Leonardo, and I drove in the Power Wagon. We crossed the ferry again and cut off toward the hills on a beat up dirt road. We drove 10½ miles on this road. Leonardo told us he had lived in El Paso for a few years until 1930. He pointed out a cactus whose spines were used for ladies dress combs. He also showed us the pitahaya cactus which is used for food (the cactus apples) in early summer. He also showed us the palo santo (tree morning glory). Leonardo told us a number of tales of his importance. He claimed to own several shrimp boats and to make 78 cents a pound on shrimp.

From the looks of his house at Buena Vista, the stories must have been stretched somewhat. After our drive we drove up to the little town of Buena Vista. The bell tower of an old Spanish church stands on the crest of the highest hill in town. Leonardo told us a Spanish bishop had been buried in the foundation with all his wealth (doubloons). Leonardo said he dug in the foundations at night sometimes looking for the treasure.

Below this central hill are the remains of an old fort. Several Mexican families live in the various parts of the fort. We drove down to the river’s edge and did a little seining. It was not one bit better than the river at the ferry. We realized, as we had suspected, that we had brought Leonardo home. He informed us that we could get back on a much better road if we got a permit from the engineers constructing the Yaqui River dam.

Nat (a rugged handsome fellow) went along with us. He was quite a guy. He had a couple of bullet wounds from fighting Yaquis. He owned 4,228 hectares along the Rio Yaqui (about 2¼ acres to a hectare).

At the dam we met an engineer who spoke perfect english. In spite of our filthy condition he treated us very well and gave us our permit. He said the Yaqui dam was the largest dam in Latin America. It goes down 128 ft. to bedrock and contains about 1/12 the material of Boulder Dam. With the dam the lower Yaqui Valley will be irrigated and the flood danger during August and September will be minimised. He showed us a wall

map of Sonora—Secretaria Agricultura y Fomento, Dirrection de Geografia, Metreologia and Hydrographia—1941. It is a fine map in some respects.

We drove off past the dam (nearing completion) and over a bridge and out on a much better road. Nat directed us to a place where the river was dammed and partly diverted into a drainage channel. Here we found some back water areas and sloughs. Dave and I dragged a common sense seine through some muddy pools. We were up to our knees at times but we caught some new forms—one is a goby like fish with jaws like a eleatrid pike. Also we caught 3 turtles (*Pseudomemmys*), 2 of which got away.

Back in Cocorit we bought a tequila for Nat and had one for ourselves. We said goodbye and drove to the ferry, paid our 3rd 7 pesos for the day. We drove on until we came to Mapoli and camped on a flat a little ways off the road. The sack felt mighty good.

January 26, 1950

Estero San Carlos, Sonora, Mexico

We woke up early and started off up the road toward Guaymas. At 1 roadside pool we tried a stick of dynamite with no results other than a tall spout of water. Up the road a little farther we stopped to seine the pool where we had taken *Elops* in on the way down.

The pool was the result of drying of a tributary of the Rio Muerto with consequent concentration of the fish fauna. A long (150 yards) shallow pool lined with reeds leads down to a 4 ft. deep rocky pool under a railroad culvert. A shallow pool goes to the edge of the main road. On the other side of the road a channel goes west for an unknown distance.

Boyd dipped a common sense seine in the pool by the culvert. He brought up about 5 *Dormitator* (a goby) weighing ½ lb. Or so. I walked across the pool and could feel fish swimming under my feet at nearly every step. Dave and Andy and I seined the pools and brought up a tremendous amount of fish. With a common sense (10 ft. seine) we could bring up 25 lbs. of gobys at a try. We caught a good many sunfish (*Lepomis megalotis*), a fine series of *Ictaluris* (a catfish), a big series of *Elops*, and some big carp among other things.

For 1 small pool it was tremendously productive.

Empalme didn't look so bad on the way back. There are some huge shade trees in town that make up somewhat for its other defects.

At Guaymas I got bread while the others gassed the trucks. It was siesta time and so we couldn't get any vino.

We drove on north of Guaymas, past the Miramar Beach Rd., past the airport, to a dirt road that cuts off to the left over a low saddle. Before long we came to a rancho where a boy was pulling water up from a shallow well. He was on horseback pulling a rope over a pulley. For a bucket a hide was strung on a hoop about 1 ½ ft. across. An older fellow was dumping the water into a trough. They told us directions to Estero Soldado and to Estero San Carlos [drawing].

We drove on past a big sandy beach to the edge of Estero San Carlos. It is a most beautiful place. The Estero is a fairly large bay walled by steep volcanic peaks. North west of the bay a rugged peak rises from the edge of the gulf. It is topped by a big pinnacle of considerable height. This mountain can be seen for some distance in some

directions. We could see it at Miramar Beach. After taking a small side road we camped back of the beach by a little crescentic bay near the mouth of Estero San Carlos.

Dave and I tried poisoning a poor tide pool while Boyd and Andy went out in the boat to try their hand at dynamiting. Neither of our groups did very well. However, the dynamite produced fish for dinner.

After dinner we took the boat and some dynamite and tried some night blasts. We got our first *Apogomid*, a beautiful little red fish. Around the point Andy dropped a line and shortly came up with a beautiful red snapper (*Lutjonidae*). A little later he brought up another. All the rest of us could do was get a few bites. We returned and hit the sack.

June 27, 1950

Estero San Carlos, Sonora, Mexico

After our usual tasty breakfast of fruit juice, bacon, and pancakes we took the boat up and around the Estero. Later Andy and I located a beautiful big tide pool at the mouth of the bay. A shelf runs out about 50 ft. from the base of a big cliff. On this shelf is a big pool that is 6 ft. deep in places. We poisoned the whole pool and made a really fine collection including such things as a grouper with electric blue outline ocelli (*Cirrhites*), more cardinal fish, a big moray eel, a butterfly fish (*Centropyge passeri*) with an orange tail, a blue bar back of his pectoral fin, and neon blue fringes on his fins, and a parrot fish decorated with stripes of magenta, blue and green.

Since tide pools of this sort are hard to find in the gulf, Boyd and the rest of us were very pleased.

We returned cold and tired to camp. Dave who had gone to town to pick up supplies (food and porto and tequila), met us on the beach. We drank a slug of tequila. It is really fine at times like this. It warms you and makes everything seem better. Dave brought letters and news that he had passed his Ph.D. qualifying but no news about Andy's fate or mine. We had more tequila and then dinner and then went fishing.

Everyone was a little rosy by this time, particularly me (as I remember it). Before long I was really out of it and never even bothered to disentangle my fish line. In spite of a vicious looking mess of line and hook I managed to land 2 bass. Boyd caught a great freak of a fish with a huge mouth which I insisted (with no one disagreeing) was a *Neoclinus* (*Opisthognathus*). Apparently I had quite an argument with myself. Back in camp we all hit the sack at once.

January 28, 1950

Estero San Carlos, Sonora, Mexico

In the morning I found that one can drink too much tequila, even if it does cost only 70 cents a bottle. Leaving my sleeping bag became a major issue and staying out was one for the rest of the day. If the others were as bad off as I was they didn't show it, though Boyd said he felt a little crummy.

I slit fish and cleaned up camp in the morning with Boyd while Dave and Andy took the boat over to the pool and picked up fish. In the afternoon we all poisoned and collected some smaller tide pools close to camp. Boyd drove to town to pick up Art.

At dusk Dave and Andy and I returned to camp and built a fire. We were all tired and so we did nothing for about an hour, enjoying the leisure. None of us thought we wanted to go fishing this night.

Boyd returned just after we had finished dinner and told us Art was still at sea trawling for shrimp. Boyd wanted to go fishing so we all weakened and went along.

In the water we could see thousands of ctenophores (conch jellies) glowing with their cold light. A flashlight beam in the water revealed tremendous quantities of decapods (little shrimps—possibly Euphasids). In one place they were so thick they looked like rain as they leapt out of the water. Some of them glowed with a bright greenish light. We caught no fish—returned to camp and went quickly to sleep.

January 29, 1950

Estero San Carlos, Sonora, Mexico

This morning dawned brighter and better than yesterday's for me. With breakfast over we piled the seine in the boat and drove the boat to a sand beach east of camp. The first haul was through beds of sea lettuce. We netted a large quantity of fish but had so much algae too that we had to throw it up on the beach before we could land the net. Sorting it all took about ½ an hour.

Our next haul was over sand. Dave and I saw a big school of anchovy before setting the net. We thought we had missed them but when the bag came in it was bulging with flapping fish—nearly all anchovies. We released about ¾'s of them. We took some of the rest of them for collection, took a gunny sack full for chum, and still left the beach covered with them for the gulls who promptly came swarming around.

As we rowed down the beach a big pelican swooped in and began scopping fish off the beach with sidewise swipes of his bill. He then raised his head and gulped the contents of his pouch as they slid down his gullet.

After lunch we poisoned a big rocky shelf adjacent to the beach. A beautiful little red headed goby proved quite common. Their heads are bright red with blue lines, one through the eye. These little fish frequent the holes in the rock occupied by sea urchins.

Boyd took a *Lythripus*, a little red fish previously reported from Southern California.

Back at camp I tried to cook a sea cucumber. They have a considerable quantity of white meat that looks like abalone. I diced him and tried to fry the meat. It shrivelled and rolled up in a ball. I tried it and found it the most resistant meat I ever tried—it was just like a tough rubber band. They might be good if beaten thoroughly.

After dinner Dave, Andy, Boyd, and I went fishing again. We had hardly lowered our lines to the bottom when the fish began hitting. We hauled them in and they proved to be red snappers. Poor Dave was all fouled up. Either he was hooked to the bottom or tangled in the fish sack. The 3 of us caught about 18 fish before he got a bite. It proved to be an irate octopus. Finally he brought in a fish and joined us. We caught about 25 snappers and some bass (*Paralabrax*). We came in about 1:30 AM. Boyd and I fried up some fish (snapper). It was really delicious. We hit the sack a little later.

January 30, 1950

Estero San Carlos, Sonora, Mexico

We got up quite late and I filleted a lot of the snappers. Some fellows from UCLA are camped on the beach. We gave them snappers. They said they would get us some lobsters.

We poisoned a big pool and collected a good series of fishes. It began to rain a little and by evening a drizzle was coming down quite regularly. We hit the hay under a big tarp.

Boyd and I had been wiping our fishy hands on the legs of our pants and before long we began to smell them. Andy, in particular, did a lot of groaning about the stench.

January 31, 1950

Estero San Carlos, Sonora, Mexico

Boyd went to Guaymas to go trawling on the Instituto de Pesca's boat. The rest of us took the boat and the 100 ft. seine and went to the Estero Soldado.

It is a long trip by boat. We passed about 3 or 4 miles of beach before coming to the narrow shallow entrance to the lagoon. The tide was going out and a current of about 3 mph flowed against us as we entered. Just back of the entrance the lagoon splits into 2 channels both of which wind in various directions and open into a broad shallow flat north of the entrance.

In many places the lagoon is edged with mangroves. These trees harbor a sparse population of oysters on their roots.

We seined the channel in 4 places obtaining several rays (*Dasyatis*) and a fair series of very large *Colpichthyys*, a smelt-like fish. Also we took lancelets and a few other forms.

After leaving the lagoon, we made 1 beach seine haul and headed for home. A wind had come up making the sea very choppy and the air cold.

Art warmed our frozen feet by pouring warm water from the outboard exhaust over us. It felt wonderful but we had to bail out the boat at intervals.

After dinner we went fishing (Art, Boyd, and I) and caught some interesting fish. I caught a fairly large shark (3 ½ ft.). Art brought in 3 big (1 ½ lbs.) blenny like fish with a mouth so large he could grasp a fish as big as himself. We returned to camp and hit the sack.

February 1, 1950

Estero San Carlos, Sonora, Mexico

We got up fairly late. Boyd went to Guaymas again to go trawling.

None of us was feeling like a tiger and Andy was lowest of all but we loaded the boat and left for San Carlos Bay. After a couple of seine hauls we stopped to eat lunch—but Dave had left the lunch bag on the beach at camp. Not only that but the seine had rolled in the eel grass and become very tangled.

Our patience was getting tried more than we appreciated. Andy walked back to camp over the hills while Art and Dave and I took the boat around. When we arrived at camp I discovered we had left a seine braile back in the bay.

After lunch (the chocolate had melted in the sun) Andy went back for the braile while the 3 of us set out to poison a tide pool.

While climbing over some rocks Dave slipped and fell, cutting his chin open about 4 stitches worth. Art left me on some rocks with the poison and took Dave back to camp.

I found some deep semi open pools and poisoned them liberally. Before long a great many brilliant little red cardinal fish (*Apogonids*) began rising. Then numbers of

brilliant red squirrel fish (*Myrispristis*) came to the surface. Art returned and we made a fine collection including 5 forms we had not taken before.

After dinner we went fishing without much success except that I hauled up an octopus and while it was hanging on my line it squirted its sepia. The stream hit Andy square in the mouth and got all over his face and coat.

Back at camp I learned that I was going out on the Instituto boat in the morning.

February 2, 1950

Miramar Beach, Near Guaymas, Sonora, Mexico

Boyd and I left camp early, leaving the others to pack up. We drove to town, unloaded the truck, and boarded the boat. It is a converted yacht built in San Diego. Rene Nunez, the biologist for the Instituto was in charge. He is a young fellow, who speaks English well. He had studied at Stanford under Rolf Bolin.

The Boat has a large central boom equipped with lights and 2 smaller booms (like davits). 2 masts are forward of the deck house which is placed aft. A winch and cable are used to tow the shrimp trawl (30 ft. across wings) used on the boat. The stern is quite pointed and makes little wake as it passes through the water. A gray marine diesel powers the ship. Rene said it was purchased for 15,000 pesos (about 2,000 dollars) by the Instituto.

We passed out of the bay and picked up a shark line that had been set the day before. 2 floats marked its ends. The line is composed of half inch hemp rope with very large hooks tied on with the same material. Anchors hold the ends of the line in place. We hauled it in and found 3 sharks and a batray. 2 of the sharks had been eaten by hagfish (*Polistotrema*). This fish burrows in the side of the fish and eats out the viscera. About 32 hooks were set which must have had a 3 inch gap. Large thread herring were used or bat.

The try net was then set. This is a small (10 ft. across the wing) net used by shrimp fishermen to sample the bottom before lowering the big nets [drawing].

2 boards are hooked, 1 on either wing to spread the net. This is the same design as the bigger nets.

We collected a lot of flat fish and grunts (*Haemulidae*).

Rene had some work to do at the office, so we started in. He has 3 crew members, 2 seamen, and a cook. All were fine fellows. The seamen were young kids. 1 went up steel guy lines, hand over hand with no apparent effort.

After reloading we left for Miramar Beach. The power wagon appeared in town and we went out to Miramar together. Camp was made alongside the bar again and we immediately dropped in for a couple of Carta Blancas. Manuel was there but Jesse was on his day off.

After dinner Boyd announced we would leave for Kino Bay tomorrow if it was O.K. with everybody. It was O.K. with everybody. Andy started moving things like a mad man. Dave and Art also looked like new men. Obviously we had been in 1 place too long.

With our preparations finished we went to bed—all except Boyd who went out to watch grunion.

February 3, 1950

Bahia Kino, Sonora, Mexico

After going to Guaymas, mailing cards, and getting gas we drove northward toward Hermosillo. After lunch along the road I piled in the back of the power wagon and slept until we reached town.

Numerous directions finally got us on the Kino Bay road. Yaz St. is taken north almost out of town to Calle Mesa Grande? This is taken west toward the gulf. The road is a dusty dirt road that is sometimes quite good and sometimes poor with high centers. It passes down the Sonora River wash. There is no channel near the road but there is a flood plain covered with a forest of palo verdes and mesquites. Some rather large fields of wheat edge the road just west of Hermosillo.

Several miles west of town we passed a pair of wagons pulled by burros. A whole family of Mexicans and all their belongings were in the wagons.

Where they could be migrating in this desert is hard to see. The truck scraped bottom in a few places but we got through all right.

After many miles in the dust we emerged onto an undulating plain which became increasingly sandy as we approached the bay. About 6 miles from the bay the accumulations became deep enough to support *Uma*, should it occur here.

We could see a series of jagged peaks to the north and a few scattered peaks to the south jutting up over the plain. Amangrove-like plant with thick ovate leaves [drawing] .

..

Suddenly we saw the gulf and a long crescentic bay lined by a long sand beach. 5 minutes more and we drove into Kino Bay.

Kino is a real fishing camp. The poor road has eliminated most of the turista influence. A number of adobe shacks, in various stages of decay compose the town. There are no areas which are really the streets but the dirt is packed around all the adobes and one may drive where he pleases.

A large portion of the population came out to see us enter. We had a man open the tavern and give us a beer. This building is one of the few frame buildings.

Several interesting Mexican calendars are tacked on the walls. 3 pool tables are blocked up on the dirt floor. We drove a little north of town out among the sand hills. These dunes occupy the edge of the beach back a variable distance—50 yards to 200 yards approximately—in a crescent around Kino Bay from a rocky promontory on the north about 3 or 4 miles above town, to a southern rocky point southward and seaward from the Laguna de la Cruz. The sand is quite fine and monderately densely vegetated, chiefly by a succulent plant resembling a small elephant tree.

Dunes reach their greatest heights right along the beach where some are 50 ft. high. In some places there is considerable shell material mixed in the sand. *Callisaurus*, *Uta*, and *Urosaurus* were seen but no *Uma*. There were no large lizards out and it is highly possible that *Uma* occurs here but has not yet emerged from winter hibernation. The habitat seems wholly suitable for *Uma*.

We made camp, ate dinner, and commenced seining the shallow water off the beach. Our first haul brought in a flapping mess of very larg rays (*Holorhinus*). In no time they had their stingers entangled in the net and it took about 20 minutes before they were worked loose. Several hauls brought in more of these big fish. Some were easily a yard in width with a stinger 3 in. long. These stingers have a serrate edge whose spines are recurved. It acts like a compound fish hook and is very hard to disengage.

We also caught a nice series of corbina, enough so we had 7 left for food fish. I saved a couple dozen squids also. We got back to camp about 12 midnight. Art and Andy went to bed at once. I cleaned the fish and Boyd filleted them. While he fried them I cleaned squids [drawing]. This should leave a piece of meat shaped like this [drawing]. Turn it over and pull off outer skin and fins. Then wash this, flour it, and cook in very hot fat (deep) for about 30 or 40 seconds—just until brown.

The corbina was the most delicious fish I have ever eaten. Boyd cuts the fish into pieces about 2 inches square, flours them, and fries them in hot deep fat until well brown but not dry. With salt it is really wonderful and made moreso because the fish had been out of water only about an hour or so.

The 3 of us ate 6 fish (good sized) and several squid. The squid had a delicate flavor all its own and is really wonderful.

When we finished it was about 2 AM and we went out to watch the gulf grunion on the beach (*Hubbsiella*). We saw a few flipping on the sand. At about 3 AM we hit the sack.

February 4, 1950

Bahia Kino, Sonora, Mexico

When we woke the camp was swarming with small Mexicans.* (*I set about buying turtle skulls for Chuck Shaw at he San Diego Zoo, who is studying the beasts. While I wrote notes on the running board—skulls kept coming in. I gave each smiling kid 25 centavos or 50 good ones. One kid kept appearing with a particularly good type of skull. Finally after 2 such returns I realized he was bringing me a skull so I paid him and put it in the bucket on the opposite side of the truck. I went around, sat in the sun and wrote notes, and the kid picked up the skull out of the bucket and brough it to me after an appropriate period of waiting. This profitless (for me) barter was stopped at once.) A pair were engaged in a hot ball game over Dave's still inert form.

He woke when a sizzling grounder buzzed by his ear. It is Sabado and there is no school today so we had company all day. They were nice kids well versed in the arts of begging. They extracted considerable food from us during the day. One, Manuel, a little kid of 9, was Dave's buddy. He had on the usual baggy kneed jeans, a denim shirt and a ragged coat (and of course, no shoes).

He could smile from ear to ear—showing teeth in all stages of growth and disappearance. He jumped in the boat at the last minute, leaving his amazed friends behind, when Dave, Art, and Andy went to seine the Estero south of town.

I remained in camp and later hiked about 5 miles over the dunes looking for *Uma*.

Later in the afternoon Art and Dave and I took the boat, through a choppy sea, to a rugged rocky island about ½ mile off shore. We collected a tide pool there—driving off a whole fleet of pelicans from the rocks as we landed.

At sunset we were treated to a real spectacle. Clouds turned brilliant rose red and the sky a dark blue—over the shimmering water it was a really beautiful sight.

Tomorrow we leave to go to La Libertad north of here. Preparations and dinner and notes occupied the evening.

February 5, 1950

24 miles W. of Santa Ana, Sonora, Mexico

Andy got us all up at some horrible cold hour (7:30 AM). We ate breakfast, packed, and said adios to our nino friends.

The drive back seemed shorter and was much less dusty (in the big truck). At Hermosillo we bought gas and drove out to a tributary of the Rio Sonora in an attempt to sample the fish fauna. We rode through some fields where Mexicans were plowing with a crude plow drawn by 2 motley horses. Shortly we came to a damp river bottom with a few shallow muddy pools. Boyd didn't like the looks of it so we left for Santa Ana. A couple of beers later after lunch we arrived at Santa Ana.

I would judge it is a town of 5,000 people. Boyd wanted to leave our collections somewhere in town so they would not be bounced around on the dirt road. Finally, after a short aimless drive Dave pulled up in front of a big white building with the Mexican flag flying in front. Art went over to ask directions and the first person he met spoke English and the second was the town mayor. He opened the building and told us to stack our cans in an office. Quite a stroke of luck. The building was the city hall.

We drove off towards Altai on a fairly good dirt road passing through hills covered with *Larrea* and mesquite. Just after sunset we crossed a muddy little creek. Andy turned off on a small dirt road along the creek. Camp was made on a flat dirt bank by the stream. The water flows in an arroyo about 8-10 ft. deep.

Willows, *Baccharis*, mesquite, and cottonwoods fill the river bottom. The banks are vertical and in some places eroded into small badland formation.

I was voted Ranch foreman because of my sterling accumulation of dirt and other sorts of grime. All my clothes are filthy and I have a dirty 3 week's old beard—so I guess I deserve the honor. The others are not far behind.

The day has been warm and partly cloudy with the air becoming quite cool in the evening. We all enjoyed a fine campfire and a good pot of stew. We will get up early and drive on to La Libertad, 125 miles away.

February 6, 1950

La Libertad, Sonora, Mexico

Andy got us all up before dawn (indigestion we decided). I am very unhappy about leaving my sleeping bag at such an hour and did so only under protest. It was cold and I was nine tenths asleep.

We pulled out and drove on down the main road to Altai. The road follows a phone line and shows vague signs of once having been graded.

Shortly Andy and I pulled into Altai. The town is a fairly small one with a big brick church, a square (plaza), and lots of palm trees. Some farming is done in the valley and water flowed in an irrigation ditch going through town.

After a rough drive through a mesquite-palo verde-ocotillo covered semi-desert the road crossed the railway, went up over a hill and dropped down into the cultivated little valley in which Pitiquito lies. The town is somewhat sloping. We all liked the town. It is rather neat for a Mexican town and the people were helpful and pleasant.

While trying to buy gas we met a ma named Diego Salceda. He took us over to a gas station he is constructing and got us 40 gallons of gas from a drum. He is an interesting person. His english was quite good and we learned a good many hngs from him. He plows for people with his big Fordson—50 pesos per hectare (2 ¼ acres). Diego

drove a yellow jeep (given to him by Pres. Aleman). He was a lover of engines and had 2 power plants and 2 or 3 tractors.

His wife cooked us 40 tortillas. She used wheat harina, lard, and salt. They were cooked on a butane range. We all enjoyed them.

At the local cantina we stopped in and bought a couple of rounds of beer. Diego got a half dozen Mexican calendars for Dave. These calendars are real works of art. One, we got from Guaymas, shows a scantily-clad girl clutching a long-stemmed sweet william in her teeth. Diego knew Van Rossen and had carried on some correspondence with him. Of course he was unhappy to hear of his death.

Diego bought some beer and cigarettes for 2 of his friends at La Libertad. Also he gave us a note to Bill Boswell asking this fellow to come up and try out an airfield he had just cleared.

We crossed a cottonwood lined wash, drove past some large cottonfields and entered a cholla desert. Some of these cacti were 7 feet tall. The road was dissected in many places by washes and the going was quite slow. The 2-rut road wound through small valleys and over low rocky ridges. Large saguaro cacti became more and more common as did the organ pipe cacti.

Just past Rancho Primavera we took a road cutting off to the right that cut north over a low ridge clothed with tall dense palo verde and mesquite. This road continued northwestward for several miles, past a small area of *Yucca mohavensis*.

Andy and I looked for *Xantusia* but found none. It seemed too dry. I believe *Xantusia* may occur here.

A little further on we came to a junction—one road leading to Caborca and the other to La Libertad. This road lead southwestward past Ravelo[?] Americano, through a gap between saw-tooth barren mountains and out onto a huge bajada back of La Libertad.

Just at sunset we saw the little village. Shortly we came to an airfield (with a small plane parked alongside). A small hotel (7 or 8 rooms) built on the land just back of the beach is situated at the end of the airfield. It is not in use now but is in good repair. A little ways back from the beach are 4 or 5 adobes, a well and some tents. We met Bill Boswell here. He is a young fellow from California. He was quite close-lipped but helpful. He is farming some sort of grass for seed. Supposedly he owns 38,000 acres (or some other fellow—I am not sure) here at La Libertad. He has 560 acres cleared and is working on 500 more. There is a 400 foot well said to pump 4 2 inch pumps at once. This information comes from an unreliable source. This same source tells of a new big hotel that will be built here. He (an ex navy man of some sort) tells of big deer taken out of this area—(straight stuff) a game preserve which extends from La Libertad to the north end Tiburon and back inland a considerable distance. Pres. Aleman, is however, allowed to hunt. (He told us moose and elk were common in the area.)

Bill showed us a camp spot where we could launch the boat. We ate dinner and seined the beach. The bay is a fine crescentic one limited by rocky headlands both on north and south.

In one of the seine hauls we brought in a fish which Art said was a numb fish. He said it would give a shock if picked up. I thought it was an angel shark and so I told Art he was nuts or words to that effect. I picked it up and played around with it to prove my point—whereupon I got a good shock—about like 110V. The fish was about 2 feet long.

February 7, 1950

La Libertad, Sonora, Mexico

Before I had time to dress Andy and Boyd shoved off for some rocks to look for tide pools. I went along minus my shoes—in my sweat pants. These pants are a bit disreputable now due to 3 weeks of dirt. We found some beautiful reefs but few pools. We could see the big groupers swimming away among the kelp.

By the time we returned with poison the wind had come up and we had a lot of trouble locating fish but a good collection was made including several *Lythripus* (a red a blue goby).

After lunch Boyd and Andy and I went out fishing. We caught a lot of fish—mostly small bass and grunts. Andy caught a nice pinta (grouper). At dark we returned and we went out again in the dark. There was no moon and we were given a beautiful show of phosphorescence.

The wash from the boat glowed with a bluish white light so bright that the entire boat was illuminated. The stern waves glowed for a long distance behind us.

2 fish and 3 hours later we returned. It had been so dark we couldn't find our rocky point. I tried a little surf fishing (there is virtually no surf) and hit the sack.

Note: Today Art was probing around in a tidepool and his pen dropped out into the water. A long snaky arm with suckers on it grabbed the pen and pulled it back under the rock. We think the octopus was out of ink and needed a refill. Art didn't get his pen back.

Later I was filleting a trigger fish. I had one fillet off and the other one nearly off when he bit me on the leg. They have quite a mouthful of teeth. This one raised quite a welt. The fish is not very tasty, however.

February 8, 1950

La Libertad, Sonora, Mexico

Just after our usual pancake breakfast we all went out to the rocks and poisoned along a reef. Andy caught the octopus that took Art's pen. He didn't have it. We kept him to cook.

A lot of the poison drifted out to sea and we picked up a good many fishEs from the boat using the outboard motor. Some tidepool poisoning!

Back at camp I cleaned and tried to skin the octopus. He was the slimiest beast I have run into yet. Finally I cooked just part of him. The flavor was O.K. but he was rather tough.

After this fiasco I went south to the edge of the bay. This deposit is roughly triangular. One side is a series of steep dunes along the seashore. These dunes reach a maximum of about 75 ft. The dunes drop sharply behind this line of beach dunes to a series of hummocks lying along the north bajada of a range of mountains that extend out into the gulf forming the southern headland of La Libertad Bay.

The dunes line the beach for about $\frac{3}{4}$ of a mile. In extent they probably cover 200+ acres.

I saw no *Uma* but did see tracks quite typical of the species. The sand is fine well sorted sand of a light peach color. Just north of this deposit is a small line of beach dunes that are obviously beach-derived. They are pure white and are separated from the main mass only by a small wash.

It seems probable that *Uma* is not yet out. I suspect that they occur here but have no real indication to back this view. After a very dusty drive I returned to camp and ate dinner, seined the bay, and hit the hay. We netted a big halibut (about 25 lbs.). I filleted him for Andy to cook in the morning. Boyd showed me how to cut out the cheek meat from a halibut. It is a little semi-circle of meat lying just anterior to the pre-opercle. The meat is esteemed by the fishermen who save it from their catches.

February 9, 1950

24 miles SW of Santa Ana, Sonora, Mexico

Another trip to the sand dunes showed that *Callisaurus* was making my *Uma* tracks.

Art and Dave and I returned, getting well powdered with dust. All of us quickly packed and left for Caborea. Before long we passed Americano Rancho. A little later we reached the junction and took the branch to Caborca. It proved to be highly dusty. Art, Dave, and I came out looking like we had dipped our heads in a talc barrel. The 2 in the power wagon (Boyd and Andy) didn't even get dusty. They had a big laugh at my expense.

The road was much faster travelling, even with the dust, than the other route. Shortly we passed a cotton field and then a couple of wheat fields. Then we could see the old ruined cathedral. "Cathedral Nuestra Senora de la Concepcion de Caborca" and the palm trees of the town. This cathedral is an ornate one with a fancy belltower and a big crumbling dome. It was built in 1694 by Spanish missionaries.

Caborca is a typical sprawling pueblo. Mexican music was being played in the plaza as we passed. We bought gas and drove toward Pitiquito. Just out of town we seined the Rio Magdalena.

We caught a lot of Poeciliids and minnows and a turtle that is probably *Kinosternon sonoriense*. The water was highly mineralized. The banks were white with salt. Water temperature was 24 degrees C.

After dark we drove through Pitiquito. Thewen as bigger than we thought. It was interesting at night with its unshaded 25 watt bulbs and dozens of straw-hatted Mexicans crouched on the curbs in the half light. A neon sign advertising Carta Blanca beer looked highly incongruous.

After a long drive and much singing we made camp in the same spot we had occupied on February 5.

February 10, 1950

Ogilby, California

Arose early and drove to Santa Ana (pronounced Sant-Ana). We picked up our fish cans and drove to the border. The inspectors gave us very little trouble—principally because of the immense amount of dust on everything. We drove till about 1:00 AM and camped on the bajada near Ogilby.

February 11, 1950

Van Nuys, Los Angeles County, California

We were all up before dawn with the mosquitoes. At Riverside Art and I seined the stream. We had the help of a couple of small boys. Dave phoned his wife and found that I had passed my Ph.D. qualifying exam.

I arrived home in the late afternoon, shocking my mom with my filth and newly cultured moustache.

The trip had covered about 2,100 miles and had been most successful.

March 12, 1950

Pushawalla Oasis, Riverside County, California

This morning I cleaned off the truck top, killing 4 black widows. A liberal spray of kerosene was used over the parts I couldn't inspect. Then I packed up the truck and left about 9:30 AM.

At Sunland I stopped and bought \$12 worth of food and then continued on my way. The day was quite overcast. By the time I reached Redlands the clouds had descended and a few drops of rain spattered the windshield.

The San Gorgonio pass was its usual windy self with wind whipping up clouds of dust and sand in the wash. At Cabezon I reached the edge of the clouds. Often I have seen them plugging the pass and stopping abruptly in the region of Cabezon or Snow Creek, with clear skies over the Coachella Valley.

In Palm Springs I stopped at the Standard station and changed the front wheel flanges so that the 4 wheel drive would be operative. It is always quite a job and I cursed and swore for half an hour before I succeeded.

Out along Ramon Rd. things are building up rapidly. The "desert outpost", a series of closely packed houses in the middle of the sand dunes, advertise "Enjoy real sport to the most at the desert outpost" and "Your friends will drool when they see your new pool". I'm glad I don't live there—the idea of having a lot of drooling friends around, messing up the [?], is too much for me.

3:30 PM. The wind had abated somewhat but the air was far too cool for lizards to be active. I drove on past Hidden Springs Ranchos, Golden Dawn Acres, Moon View Guest Ranch, past Shangri-la Palms, to the dirt road to 1,000 Palms

Driving south along the Powerline Road I passed 9 big power poles and drove about 100 yards further, to the road leading into Pushawalla. This road is somewhat south of a right angle line from the road to an airplane beacon out in the valley next to a ranch.

I drove slowly up the wash. Among the palms of the oasis I startled a bobcat. He loped off into the *Tamarix*. At the oasis I stopped and walked around looking for signs of Lamda Sigma, who was supposed to be at the oasis. A big covey of quail (gambels) shot from a nearby mesquite, startling me no little bit. No one was around so I made camp, cooked dinner and observed the toads (*Bufo punctatus*) and *Hyla regilla* in the small stream. The *Hyla* chorus has been deafening all evening (see species acct.). This oasis is a wonderful spot. It has no particular view as it is in a steep-walled canyon and is not quiet. The frogs, the palm fronds, and the birds see to that. But it is really a gem in this desolate area (and nowadays—built up area) where you are seldom bothered. The road in requires 4 wheel drive and is very hard to find. The wind is never bad in this oasis though it does blow in gusts—but compared to the valley it is calm.

March 13, 1950

Travertine Point, Imperial Co., California

A dull roaring noise pushed into my mind and roared for a while until I decided to wake up. I sat up, blinked, and saw a jeep, whose motor was racing, pulled up in back of mine. [Drawings] I got up and let them drive through. This is the first time I have had traffic problems in Pushawalla at 6:00 AM. After breakfast I drove slowly down the wash and out toward Indio. At the La Quinta cutoff from Hwy. 99 I turned left toward the Chuck-a-walla ranch. In the dunes there I caught an *Uma* by noting where the sand had slid down a dune face. He was just above the mark. This animal shows the trace of a side blotch I have noted before in *inornata*. The day is clear and calm but not very warm.

I drove on to Mecca, past the "beautiful Hotel Caravansery" to the All American Canal. Taking a road just to the west of the canal I drove to Dos Palmas Spring (see description) . . .

(Dos Palmas Springs, Riverside County, California)

The spring is situated on an alluvial fan that reaches down toward the Salton Sea but is blocked by a low range of hills resembling old lake beds. There are several seeps scattered over the fan and just back of these hills is a rather extensive area of reeds. There is a playa near these reeds. Some sand has accumulated along the slopes of the hills away from the Salton Sea.

The spring proper runs from 3 main places. The southern is a muddy area grown up with reeds and supporting 15 palms (*Washingtonia*). The water flows in a small stream and coalesces with spring no. 2. No. 2 has been cemented. A good flow rises from a deep hole and flows into a channel running to the ranch below. 2 palms grow here. The third is about 100 yards away and is in the midst of a dense mesquite-rush thicket. One palm grows there.

Poeciliids and *Cyprinodon* are in the first 2 springs. The third was not inspected. Water temp. 31.1 degrees C. vicinity)

. . . where I took a few individuals of a Poeciliid (*Gambusia*) and a Cyprinodontid fish. The water is much like that at Saratoga Springs. It is warm and highly mineralized. The whole alluvial fan of Salton Creek is dotted with various groups of palms and rushes, which mark the seeps and springs. A small flowing stream runs from 3 of these that constitute Dos Palmas Spring.

I drove on up the alluvial fan of Salton Creek, past a Navy Firing Range "No Trespassing Sign" to Clemen's Well. This well has plenty of evil looking water about 15 feet down which may be dipped up with a bucket (1 bullet hole) and a rope.

The road to the well cuts off the canal road a little north of the center of the Salton wash (the pass which leads to Chuckwalla Mts., Baumunk Mine, etc.). It is quite rocky for a while but becomes better as you near the large fill of Henry Kaiser's Railway. After passing around a rocky point and going under a big railroad bridge, the well is reached. There is no habitat suitable for *Uma* in this vicinity.

I drove back to Dos Palmas Spring and to a couple of other palm groups—on my way back to the Canal Road the car cut out and stopped dead.

I had no idea what was wrong at first—after ½ hour of resultless labor I walked up the road to a car parked along the canal. 2 men were fishing. They told me they would take me to Mecca when they finished fishing.

I walked back to the car and traced the trouble to the distributor. After scraping a few items the car started and I was on my way again. I thanked the fishermen and drove back to Mecca via a cutoff which hits the Niland Rd. 200 miles south of Desert beach resort, where it passes out under a railroad bridge.

I gassed the car and drove to Travertine Pt., made camp in a wash, built a fire, cooked dinner, and wrote letters and notes.

March 14, 1950

Coyote Well District, Imperial County, California

To the northeast of Coyote Well, in the “Nattie[?]” Navy Air Base is a range of hills covered with sand, probably derived from Carrizo Wash. These hills may be part of Superstition Mt.

The valley floor (wash bottom) west of Seely is dotted with sand hummocks topped by *Larrea* and mesquite. The wind direction, judging from sand grain size, is generally toward the east.

At Coyote Wells there is some sand, apparently accumulated by water seeps. It is heavily vegetated and of coarse size.

½ mi. S of Seely, Imperial Co., California

I got up fairly early, cooked a breakfast of pancakes and bacon and took off down the road. At Sandy Beach I drove east of the road and investigated a series of disjunct barchane dunes. A variable wind direction has apparently caused the barchanes to flatten out on the points [drawing]. I caught a big male by digging in the drop face of the dunes. I could see the bury mark where the animal went in. He was just above the surface mark.

After getting slightly stuck I drove on down to El Centro and out toward Superstition Mts. On their west and south slope considerable sand has accumulated. I was unable to reach this locality because it is a navy firing and bombing range being used by jet planes. I drove on up to Coyote Well and down to Mount Signal. The road is a good graded affair that reaches pavement at Mt. Signal.

I met Art at El Centro after getting all dressed up and shaved. To my surprise Art was shaved too. We ate dinner and played a few games of pool—then drove out to Seeley and hit the sack.

March 15, 1950

North End of Laguna Salada, Baja California, Mexico

Art and I arose somewhat the worse for wear (we both have colds) and drank a little orange juice and drove into Calexico to meet Dr. Hubbs et al.

We met a Mr. Walter Bowker, who is nominally in charge of the Mexican division and is actually in charge of the Calexico Office of the Imperial Irrigation District. He knew the country very well and has many contacts. He referred us to Johnny Alvaraz of the “Leon de Ono” in Mexicali. This gentleman runs a guide service along with his restaurant and bar. We did not meet him.

We left Mr. Bowker. I took Dr. Hubbs to the airport where he flew off to go over the Laguna and the lower Colorado on reconnaissance. Art, Al Allanson, and I drove out took for Pozo Tule at the north end of Laguna Salada. We drove the roads until night and never did find the spring. We made camp among some tamarisks at the north end of the playa. The wind was blowing like mad and Art and I both have dismal colds. I was glad to hit the sack. Doc Hubbs and Bob Miller (Michigan) and Howard Winn (grad student Michigan) came in just in time for dinner.

March 15[16?], 1950

Guadalupe Canyon, Baja California, Mexico

Things look brighter this morning though I still have the cold. The laguna is really an amazing valley. The Sierra Juarez drops from a high crest to the valley floor in a steep scarp. The crest is extremely rugged and lined with pinnacles. A ring of dunes lines the huge playa (40 miles or so in length) on the west. The Sierra Cocopah is a desolate range rising to the east of the playa in an equally steep scarp. The playa has been dry for several (16) years now. It has filled up many times in the past by a combination of high tides in the gulf and high water in the Colorado.

I drove into town to get gas while the others went to Pozo Tule (which we had found directions to from a woodcutter). When I returned the cars were driving off across the playa. I caught them a few miles out and we drove about 25 miles down the playa to Pozo Demara. This Pozo is a well dug in the edge of the playa among big mesquites. There is a small dilapidated casa, a corral, and a pump, and the water is cold and clear. I estimate it at about 10 ft. deep.

We drove up through the dunes about or 4 miles to a junction of the road. The road to the canyon goes up this road for a while and then branches off to the left along the base of a spur among palo verdes and ironwoods. It rapidly becomes worse and worse and finally becomes a jumble of boulders.

We stopped and hiked up to the palms in the canyon above. The canyon is a beautiful one filled with palms and cottonwoods with a nice small clear cool stream flowing down the boulder choked canyon.

A pinnacle called Virgin de Guadalupe was the butt of many jokes, particularly by Dr. Hubbs, who seems to be fascinated by the rock.

We all walked up to a big falls. The water flows over a cliff into a nice deep pool (8-9 ft.). Since the day was quite hot the water was too much of a temptation so we all went in swimming.

I collected lizards and returned to the car at dusk. The others had done likewise and we drove to a place lower in canyon and made camp. Dr. Hubbs regaled us all with stories of his fabulous doings, chiefly various airplane rides he has taken. He also told us about Dr. David Starr Jordan when Hubbs was one of his students. We hit the sack shortly and just as shortly thereafter my air mattress collapsed—so I slept on stones all night and I didn't mind it much.

March 16, 1950

Pozo Tule (synonymous with Pozo Loreto), Laguna Salada, Baja California, Mexico

The good doctor was up wheezing on the fire just as the first streaks of dawn could be seen over the Cocopahs. Of course he bellowed until all of us were irrevocably awake—so I got up at dawn, which is not my custom. On this day Dr. Hubbs planned to explore Tajo Canyon, a deep gorge just north of Guadalupe Canyon. There is a small group of palms in between known as Carrizo Palms but there is no extensive canyon.

Since I wished to collect some *umas* for my forthcoming epic I did not go with them but drove toward Demara's well and along the west side of Laguna Salada Playa. 3 times I hiked back into the dunes, hunting *Uma*. I saw them, but they were extremely wary. I was able to shoot only 1 small juvenile (see notes).

The day had grown quite warm and the hiking had worn me down some so I drove to the north end of the playa and backtracked to Pozo Tule. The road to this well cuts off to the right (west) about 100 yards out on the playa from the north end and swings over to the west edge of the playa to a group of *Tamarisk* trees surrounding the various springs of the pozo. I guess the springs are about 1 mile south of the north end of the playa along its west edge. There is a small cabin in one bunch of tamarisks which I have not investigated. 2 (3) pools are about 6 ft. across and the others are small seeps. 1 of the large ones has been boarded up and contains clear fresh water. At one time there were Cyprinodont fish in one of the pools but they are gone now.

The salt pool is known as Pozo Salado and is the other big pool I believe.

I hiked in the dunes back of the springs, finding a few shards of Indian pottery among the dunes. Yesterday I found the upper half of a big olla sitting among the rocks of a spur at the mouth of Guadalupe Canyon. Al Allanson has found several stone implements and a lot of pottery sherds.

After locating the springs I drove up the north bajada of the valley to a long longitudinal dune that has accumulated to the east of a large spur. *Uma* was common but very wary. The animals would run when I was 100 yards away. I was hot and climbing the face of the big dune (100 ft.) really wore me down so I sat in the shade offered by a big green *Ephedra* (mormon tea) bush and panted a bit. Finally I began digging around the bases of bushes growing in the slope and quickly caught 4 *umas*.

I then drove to another dune where I did some half hearted collecting and then drove back over the long bajada to the playa and out to the pozo. One more short hike yielded some more pottery pieces, a cylindrical grinding stone, and 1 small *Uma*.

I then started to make camp just as the sun was setting over the Sierra Juarez. I gathered a lot of ocotillo wood and 1 precious piece of mesquite, built a fire, laid out my sleeping bag, and cooked a huge dinner of 1 full package of Minute Rice, 1 can of string beans, a can of boned chicken, a can of fruit salad, and coffee. This array only makes me feel comfortably full at present.

The rest of the evening will be spent writing species accounts and tagging specimens. So far the night is calm and clear. I expect the others either later tonight or tomorrow morning at some ungodly hour.

Laguna Salada, Baja California, Mexico

The extensive dunes to the west of this basin (see Crosby American Geog. Soc., 1929) are all occupied by *Uma notata notata*. The one adult animal (female) I captured had the characteristic latero-ventral red stripe.

The dunes at the edge of the playa are white in color. The sand is rather poorly sorted and in places contains much mica. The westward surfaces of the dunes are often of much coarser material than the east slopes (sometimes of larger grain size than that usually acceptable to *Uma*). This indicates a wind source from the west.

The dunes, quite obviously, have been formed in situ by water sorting (possibly, probably) beach action when the Laguna has been filled. It seems probably also that it was constantly full during the Pleistocene pluvial periods considering the level of the southern entrance. The source of alluvium is the Sierra Juarez.

On the northern bajada there is a localised deposit of wind sorted and transported sand. It is a light peach color and is much better sorted than the dunes around the playa. Small hummocks of sand, often held in place by mesquite or *Larrea* cover most of the eastern slope of the bajada.

Against the east face of a north-south spur which extends out to the bajada, a long longitudinal dune (very moist sand was reached about 1 foot down) has accumulated. It is possibly 80 ft. high at the spur and tapers off in about 175 yards. The *Uma* found here are definitely of a redder shade than the white animals occurring on the beach dunes.

Along the east side of the playa there is less sand than elsewhere. About 3 miles from the north end of the playa a limited area of sand blown up on both sides of the 2 or 3 spurs of the Sierra Cocopah may be seen. I could not see other localities.

March 17, 1950

¼ mile S. of El Mayor, Baja California, Mexico

I dreamt Dr. Hubbs was standing over my sleeping bag yelling over and over again his usual "Vamanos, vamanos, vamanos". I opened my eyes and realised that a family of coyotes were yelping about 40 yards from my bag.

I got up, tagged my specimens, ate breakfast, cleaned up camp, and waited for my friends to arrive. They finally showed up at 9:30 AM after I had gotten up at dawn (with the coyotes' aid).

When they arrived we seined all the larger pools but got no fish. Fish were taken in 2 of the pools in 1941 (*Gambusia* and *Cyprinodon*). We then drove around the head of the playa and down 12.8 miles to Pozo Salado, a hot spring which runs out from many small seeps near the fault line at the base of the first longitudinal ridge of the Cocopahs. Nowhere was the water much over 6 inches deep. The hottest water temperature was about 109 degrees C.

Back in the cool water along the edge of the stream and among the muck—even at the bottom of the stream—the temperatures were much lower, even as low as 81.5 degrees C. We found no fish. After lunch we drove on back to the Cantu-Mexicali Rd. and into town. We all went into a cantina and had a Mexicali Cerveza which was highly appreciated by all hands. Dr. Hubbs and Dr. Miller drove out to see Manuel Demara while the rest of us drove on down across the plain to El Mayor. This place consists of a couple of houses and a boat dock at the base of Cerro Mayor, along the Hardy River, which swings over, close to the base of the mountains. We made camp in a boulder strewn wash.

Dinner was concocted by Art and contained numerous mystery ingredients such as bean sprouts, jalapenos (chiles), meat balls, potatoes, etc. It was delicious! Drs. Hubbs and Miller returned and told us they had engaged Manuel Demara to guide us to a

hot spring containing fish on the east side of Laguna Salada. I will drive the 2 doctors and Manuel in on Monday.

During the return trip the 2 Doctors ran into a mound of road topping piled along the road center. They were going 47 mph at the time. The car stopped in 55 feet and luckily did not turn over.

To the sack—tomorrow I go to San Felipe.

March 18, 1950

¼ mile S. of San Felipe, Baja California, Mexico

I got up early, ate breakfast prepared (in masterly fashion) by Al, and left for San Felipe. The road passed along the base of the Sierra Cocopah and Sierra Pintada. The Rio Hardy passes close to the road most of the way and then passes out onto the flat. The mountains are dissected, rugged fault block peaks running in a north-south direction. At about the southern entrance to Laguna Salada the pavement ends. The road crosses the entrance on a high filled embankment that blocks the entrance. Just on the south side of the opening (which is a rugged playa-type material without vegetation) are a large series of dunes trapped in a V shaped gap. I collected here by digging around the bases of bushes. As it was early morning the animals were lethargic and I caught 4 with little trouble. Beyond these dunes the road passes through a series of low hills of volcanic origin. Shortly it became rougher and before long was a venomous washboard which was continuous to San Felipe.

A lone volcanic caldera was passed to the left of the road, with a little patch of wind-blown sand on its north face. The road passed along a broad, nearly level bajada which originates from a series of rugged north-south foothills of the Sierra San Pedro Martir. I could see the great granite peak of La Providencia (La Encantada or Picacho del Diablo), which is the highest summit of S.S.P. Martir—about 10,000 ft. or so.

Shortly Punta Estrella came into view. It is a volcanic peak which rises from the bajada and drops into the gulf just north of San Felipe. On its northern edge, along the beach is a small collection of pink sand. I drove over as close to the dunes as I could.

3 large arroyos blocked my passage. The spring had hit this area. A small *Oenothera* and *Abronia* were blooming as was the ocotillo.

I searched the dunes and collected some *Callisaurus* and tracked a sidewinder down, finding him enmeshed in a dense bush. *Dipsosaurus* was common in the mesquites and larreas of the arroyo bottoms. No *Uma* was seen and I feel sure it does not occur here.

After leaving these dunes I proceeded into San Felipe along the old road, which is much better here than the new one.

San Felipe is a little town of perhaps 500 people built on the slopes of Punta Estrella and along a big barrier beach dune. The bay is a beautiful crescentic one limited on both south and north by rocky headlands. A single beach dune lines the edge of most of the bay. It reaches its largest size at the southern [?].

Perhaps 2 dozen fishing boats of various sorts were anchored in the shelter of Punta Estrella. This is Totuava[?] season and these are part of the fishing fleet. Every house is surrounded by large mesh gill nets, drying on ocotillo poles stuck in the ground in rows.

I stopped at the Customs and inquired about roads to the south to a big area of trees I could see. The officer was puzzled and suspicious of me—principally I believe because the trees I saw turned out to be the shadows of a cliff. I found a road passing out of town across the small airport and back of the beach dunes. The road passes through pile after pile of Totuava heads and then out into the *Larrea* scrub.

I investigated the beach dunes and shot a number of *Callisaurus* and left for El Mayor. It seems obvious that *Uma* goes no further south than Laguna Salada.

It was after dark when I pulled into camp and found the others about ready to cook dinner. Dinner was eaten and I found that the rest of the crew had visited Tres Pozas (at south end of Laguna Salada). Near here they had found an Indian cremation site. Once in bed I slept like a rock.

March 19, 1950

Jaspar Dunes, near NW Bond's Corners, Imperial Co., California

We got a late start this morning. I had time to fix the truck top a little and clean the back before we left. Howard and I stopped in a couple of places to hunt. We collected a fine series of *Cnemidophorus* from 3 localities. I was told by a Mexican fellow that *Uta* was "muy veneno" (very poisonous). We then drove into Calexico and watched the Cavaleade which was progressing full blast. We saw a big parade including a lot of horses and silver saddles and old [?] and fat ladies on horses. When the "Saddle Pals" rode by, Dr. Hubbs said in a loud voice "Oh, the straddle pals"—much to everyone's surprise and chagrin (a little maybe).

After the parade we drove to Bond's Corners and the Alamo River. Doctor Hubbs decided it was too full of snags to seine so we drove on up the river (north). After deciding that we couldn't seine there either I asked the Doc if we could all go across the river and look for *Uma* in the dunes. This we did and caught about 10 animals. On one Al chased an animal furiously and stopped with his feet about 3 inches from the edge of a 20 ft. cliff along the bank of the Alamo. We went back to Bond's Corners and got food and gas. On the way back to the dunes (to camp) Art and Al got lost and went clear to Holtville. We all camped about 200 yards back of a negroe's house in the edge of the dunes. Dr. Hubbs brought in a gecko and Art, Louis, and I caught 2 more and a sidewinder. Al skinned the snake and we all hit the hay.

March 20, 1950

Ogilby Wash, Imperial County, California

Dr. Hubbs, Dr. Miller, Louis Gusman, and I left camp early and crossed the border to pick up Manuel Demara, who was to guide us to a hot spring in Laguna Salada.

We found him crouched down by the wall of his house, hat pulled over his eyes, covered with flies. He is a little Mexican with an unkempt handlebar mustache and a dark brown much wrinkled face. His pants were patched in many places and some of the patches had patches.

He was 79 years old and sufering from rheumatism. We finally convinced him to go after telling him we could return before dark. We drove off, after waiting for Manuel to eat his breakfast.

The paso-inferior was very dim and we decided not to attempt it.

Manuel described the flood of 1905-1906 when he piled his wife on a raft just out of Mexicali and pushed and paddled it clear over to Cerro Prieto. He told us that the Cocopah Indians were unfriendly when he first entered the valley. He said it was unsafe to travel alone. The spring he lead us to was one we had seen before and had no fish. Apparently this spring (Pozo Salado), which originates from the west Sierra Cocopah fault, has been altered and no longer arises from the same point. The fish, reported by MacDougall, are now gone. The spring is now cooler (109 degrees F.) than before (127 degrees F.) when MacDougall saw it.

Manuel let me photograph him after asking 100 pesos, at first. He is a sly old chap but is very flighty. He flew into 2 rages while riding with us. One, because we asked too many questions and he said he thought it was not good to give out so much information (for the good of his country). The second time he was mad because we did not inspect the spring he brought us to. On the way out we had a flat tire from a stick which rammed between the treads. After taking Manuel home we drove out to Ogilby and made camp by some big mesquites. The other cars, which had gone to the Salton Sea, were not there and they had most of our utensils. Dr. Hubbs tried cooking over a huge open fire. The pork chops cooked in about 1 minute in their own flames. In a similar disjointed manner we cooked coffee and vegetables. A cherry pie finished the proceedings.

I hit the sack about 11:15 PM after writing these notes.

March 21, 1950

15 mi. S. of San Luis, Sonora, Mexico

After breakfast and packing I left the main party and drove west to the Algodones dunes at Hwy. 80, along the All American Canal. By driving up and down the road Keith and I had gotten stuck on (resurfaced) I caught a fine series of *Uma*. I stopped in at Sand Maintenance Station for a drink and then drove to Winterhaven. There I got gas and oil from my Shell dealer friend and continued on across the border.

As I crossed the Colorado I could see a group of men in boots in the river. Closer inspection showed them to be Bob Miller, Art Fleshsig, Louis Gusman, and Howard Winn.

I dropped down to the river on a dirt road and we ate lunch together. I went out and got beer for the crew and we had a good chow-session.

Then I drove along the bluff east of Sommerton and Gadsen. There were some dunes of white sand, both along the bluff and scattered between farmer's fields. I found no *Uma*.

I took a 15 minute siesta under a big cottonwood and continued on to San Luis. The Mexican customs official was busy at a fiesta so I had to go find him. The fiesta was in honor of the owner of the "Club International" who was having a birthday. I was given a tortilla and meat and a Carta Blanca beer—a fine way to cross the border. I showed the gentleman (a Sr. Fernandez) my papers and he somehow got the idea I was Dr. Hubbs, Director of Scripps Institute, so all was very rosy. Another fellow showed me the El Golfo Road and then asked for 2 dollars, which I did not have. I had a ten and did not part with any of it. I do not like to pay for receiving such courtesies.

The road to El Golfo cuts diagonally across the airfield and out across a very flat monotonous *Larrea-Franseria* plain. At 4 miles the road begins to get sandy and by 15 it is almost impassable. None but a big truck or a 4 wheel drive car could go further.

As it was sundown I camped and cooked a scanty meal. The place is about the most lovely campsite I have used. Only the Alvord Mts. was worse. I tagged specimens and hit the sack.

March 22, 1950

2 miles East of Imperial Dam, Arizona

I got up at dawn and started back. Shortly I picked up an *Uma*. I was *U. n. cowlesi* and an extension of range of 100 miles or so.

Back in San Luis I had no trouble crossing and drove with a Mexican fellow to Yuma. I then drove up on the mesa at the western foot of the Gila Mts. Finally after a considerable search I took a big female *Uma*. Then I caught 4 more specimens. As I had suspected it was *U. n. cowlesi* also. More collecting in this general vicinity and I headed for our rendezvous point on the road to Imperial Dam.

By taking the road to Quartzite I came to a road to the left labelled U.S. Army Engineers Testing. This road is paved and cuts off of the Quartzite before the pavement ends. The road leads to Imperial Dam and a rather extensive group of USAE buildings.

I made camp about 3 miles down the road under a big ironwood tree. I prepared cocoa for the crew and cooked my dinner. They have not arrived as yet and it is about 9:00 PM. I do not expect them tonight.

Just as I had gone to bed a sedan drove up on the road and stopped. It was Dr. Hubbs, Phil Douglas (Fish & Game), and Art Fleischig. They were camped at Laguna Dam on the sand spit.

Finally, after considerable hemming and hawing I packed up, left my fine camp and pile of wood and drove across the river at Imperial Dam and down to Laguna Dam. A short hike down the sand spit produced 1 worm snake and a striped ground snake. The animals were not out. They were both found under rocks in moist ground.

Once more I went to bed.

March 22, 1950

Sand location, South of San Luis, Sonora, Mexico

4 miles south of San Luis on El Golfo Rd. the broad level plain becomes sandier. The bases of bushes hold small hummocks—at no place does the sand accumulate in great piles. At 15 miles south the sand has become deeper but still is only small hummocks (2 ft. high). *Uma* presumably occurs from 4 miles south of San Luis to the gulf. It is definitely *Uma n. cowlesi*. Plants are *Ephedra* and *Larrea* principally.

March 23, 1950

Van Nuys, Los Angeles Co., California

This morning I woke feeling really lousy. I decided to head for home rather than spend any more time on the desert.

Before long I was really sick and by the time I could get across the sluice gates (welders were blocking my way) I knew the drive home was going to be a real ordeal.

At the Algodones cut-off I stopped to get air in the tires and the woman in the station was very nasty. She wanted to know why I was getting air when I didn't buy any gas. Then she said she would turn the pressure on but instead went inside and sat down. I drove off and got air at Gordon's Well. By Niland I felt a little better and forced myself to eat some ice cream. I took naps about every 20 miles. The road at the east side of the Salton Sea was being repaired and I was greeted by a sign saying "Detour next 20 miles—97 bridges out." In my condition this pleased me no little bit.

I finally arrived home about 7:30 PM and very quickly went to bed.

April 23, 1950

Sweetwater Spring, Ord Mountains, San Bernardino County, California

Dick Zweifel came over to the house about 8:00 AM. I was still asleep after Neal Harper's wedding party and a secondary party which lasted until about 5. I got up (reluctantly) and helped pack. Bill Reeder showed up a little later and we left in the University jeep.

We drove out through Soledad Canyon under a high fog. By the time we reached Vicente the skies had cleared. The weather was clear, fairly cool, and windy.

We drove out to Peck's Butte (Piute Butte) and hiked over the sand hummocks on its northern side. It is all part of a dude ranch—the Golden Mesa Ranch—and is completely fenced.

We hiked over a considerable part of the "dune area" and saw no *Uma*. We saw *Cnemidophorus* and *Uta*, but only a few of these.

Next we drove to Wilsona Butte. The air was warm, the day was sunny, it was about noon, and everything looked perfect for *Uma* but we found none and no tracks. I am quite sure they do not occur on this butte any longer.

Along the east edge of the butte a large tract of land has been cleared and is for sale for homesites.

At El Mirage Dry Lake we hiked over a few rocky spurs and areas of gravelly sand covered with *Atriplex* and *Larrea*. We took a few *Callisaurus* and a *Dipsosaurus* (Dick). This latter animal has never been reported west of Victorville in the literature. We saw another individual. Both were juveniles.

On our way back to the road (which has just been fully paved from Adelanto to Palmdale) we came across the tracks of a desert tortoise. Dick quickly spotted the old fellow sitting in the sun. His body temperature was 34.5 degrees C. AT 27-28 degrees C., soil 46.8 degrees C. His concave plastron and abdominal prongs showed him to be a male. I was surprised to note how short his tail was. Considering the mating posture of the animals it is difficult to see how intromission is achieved. We left him to wander and drove to the road, continued on to Adelanto, and ate our lunch.

After a brief stop in Victorville we drove on to Barstow. I slept most of the way. Then we continued on to Daggett and turned left across from the Agriculture Inspections Station on a good graded road that ascends the alluvial fan to the Ord Mountains? The sparse lowland vegetation was soon left behind and we came into a denser vegetation of *Larrea*, *Yucca mohavensis*, *Ephedra*, *Atriplex*, etc. There were some annuals in bloom.

The road passed into a twisting open canyon and shortly we could see Ord Mt.? (6, 3-0') elev., from whose canyons flow (drip) Aztec Spring and Sweetwater Spring.

At Aztec Spring a ranch with 3 or 4 buildings is located. We thought this ranch was at Sweetwater Spring and were almost ready to turn around but decided to go "over the next ridge"—which we did—and saw the U.S. Geol. Survey sign pointing to "Sweetwater Springs". We drove up a reasonably poor unused rocky road to the spring. We were greeted with 3 buildings, 2 of which are in good repair for the most part. A long building contained 4 or 5 rooms, a stove, and 3 sets of bed springs.

The camp is set in the confluence of several rocky, steep, open canyons, tumbling down the slopes of Ord Mt. The mountain is volcanic for the most part, though the effects of secondary mineralization are apparent.

Amygdules are common in the vesicular lava. There seems to be a vein of calcite at Sweetwater Spring. This spring is located about 150 yards back of the camp buildings (mine buildings) and is dug into the rock and covered over with a wood box and tin lid. The water is piped to a tank back of the main building. *Bromus*, *Acacia gregii*, *Ephedra*, *Lycium*, *Sphaeralcea*, and annuals such as *Phacelia* were fairly numerous.

At the spring we took a *Sceloporus occidentalis* which is rather remarkable considering the arid desert conditions surrounding this area. It is another relic distribution from pluvial times in the Pleistocene. The camp is situated at an elevation of 4,319 ft. (car altimeter).

We cooked dinner and fixed up the bed springs and wrote notes. Dick and Bill worked on insects. I am now hitting the sack.

April 24, 1950

Iron Mts., San Bernardino County, California

After a first class sleep we got up. Dick and I worked on breakfast while Bill went out to pick up his traps.

After breakfast Dick hiked up the large left hand canyon while Bill and I looked in a mine shaft for bats. We didn't find any so we started the jeep and drove up toward Dick. We looked in another shaft. They are (were) mining a complex copper ore with lots of barite. We could see veins of the stuff in the tunnel—still no bats. The lower tunnel is dry and the upper is wet.

Up the canyon, which is a jumble of boulders, we could see a pocket of cottonwoods growing in a portion of the streambed where it cataracts in a series of steps down the mountainside.

This is Sweetwater Spring in all probability and not the small dug flow near camp. The moisture extended down the streambed for about 100 ft. There were a few small pools of clear good water. The desert vegetation grows down both sides of the canyon and mingles with the moisture loving flora growing around the spring. *Yucca mohavensis* was growing alongside cottonwood trees.

Among the plants noted at the spring were *Artemisia vulgaris*, miner's lettuce, cottonwoods, *Rula*?, *Larrea*, *Yucca mohavensis*, *Salix* sp., and several annuals growing in the water.

Sceloporus occidentalis was common close to the spring. It was taken 150 yards up and down the creek bed, above and below the spring. These lizards did not go too far up the canyon walls but seemed to prefer the walls near the bottom. The animals are very black; much more so than any coastal *S. occidentalis* I have noted, except possibly those near Cajon pass on the Mohave desert.

Their gular patch and latero-ventral blotches were either a beautiful shiny azure blue or emerald green. Individual animals could make this change. Males had a nearly black back with a line of dark green scales. The mid ventral area is slaty black on males.

After taking plant samples and a good series of *Sceloporus* we hiked to the car and drove down the canyon, taking 5 collared lizards on the way.

At Daggett we drove east on the Needles road and turned off northward on the powerline road to a group of dunes along the edge of the Mojave River (south of Yarmo). These dunes are composed of fine white sand vegetated chiefly by mesquite, though there is some *Baccharis* and *Populus* on the dunes. *Uma* was taken here. It is interesting as it does not match the white sand but is pinkish. These dunes are contiguous with the Newberry dunes which are pinkish away from the river. These latter dunes form the main mass and thus probably determine the selections for this area of non-isolated animals. This is interesting as the only possible explanation demands that the color be genetically and not individually controlled.

We ate lunch and left, driving toward Amboy. At Ludlow we bought gas. I could see some rather considerable blowups of sand on a southern face of the Bristol Mts., along the southeast side of the Broadwell Valley.

Passing Lavi Dry Lake we thought we could see sand on the northwest and southeast corners of the playa. On the northeast the playa nearly contacts some extreme flows from Pisgah Craters. Much sand has been trapped by the ridges of lava and *Uma* was taken here along with some *Uta*, who were very black. They lived on the black lava. The umas were light and lived on the light-colored sand.

At the alkali flat southwest of Amboy we could see what might be sand along the southern edge. As at Pisgah, sand has accumulated on the lava floor around Amboy crater.

We drove through Amboy to Chambless and cut south on a good graded road along the east side of Bristol and Cadiz dry lakes. The low mountain ridge that separates these 2 playas is covered with sand on both slopes.

By the time we had reached McCoy Siding we could see a high ridge of sand hills circling the north and east of Cadiz playa [drawing].

We drove down a road which took us close to the sand, 4.2 miles south of Archer siding. This road is quite sandy and dissected by washes.

We took several umas. Tracks were very numerous. *Larrea* forms almost the only vegetation of the dunes. I think this sand area is probably the most extensive on the Mohave Desert. The dunes are of the interlocking-burchane type. I suspect they get 80+ feet high in places. The sand is a very light peach color, as are the umas.

We drove on down to Chubbuck. I looked for marks of old drainages but the whole area is smoothly alluviated. The valley slopes fairly rapidly to the southeast into Danby Playa. Only a very thin veneer of sand could be noted south of the playa.

We drove across the playa at dusk. Near its southern edge it drops about 10+ feet for a distance of 200-300+ ft. It looks like secondary erosion of the old playa surface and may be pluvial.

We drove up the south alluvial slope of the playa to the base of the Iron Mts. and made camp in a sandy wash filled with ironwoods.

April 25, 1950

Warner Camp, Granite Mts., San Bernardino Co., California

We got up this morning and drove to the Rice Hwy. And eastward to Rice. Before reaching Rice, along the southeast end of Danby Lake and extending south across the road and up on an isolated peak were a series of sand hummocks which probably form the accumulations from which most of the specimens marked Rice have come.

About 4.8 miles east of Rice we turned south on an old dirt road. This road was very poor as it cut at right angles across the drainages from the Riverside Mts. to the east.

We jounced along for 8+ miles on this lousy road and reached the dunes at Rice, where they are noted on the map. They are a snare and a delusion. The sand is collected just south of the bottom of the drainage channel in a thin sheet. The low dunes sometimes reach 8-10 ft. in depth. Palo verde and ironwood form the chief trees. They are very lush, indicating water . . .

Dormer Camp, Granite Mts. San Bernardino, California

. . . close to the surface. *Dicoria* is common on the sand in shallower situations. Peripherally *Erigonum inflatum* is exceptionally abundant.

There are 2 patches of sand each approximately $\frac{3}{4}$ mile in length and $\frac{1}{4}$ mile wide at widest.

The northeast terminal spurs of the Big Maria Mts. are covered nearly to the summit with sand which looks consolidated. The east slope of these spurs support some fair dunes (very restricted).

We found a nest of a red-tailed hawk in the top of a dead palo verde tree. I climbed the tree, which was nearly rotten, with 2 cameras, lenses, and light meters. There were 3 large downy young standing on the nest. I took several pictures and descended, pleased that the mother who was flying around, hadn't objected violently.

This valley apparently drains nearly directly into the Colorado. There may be a slight barrier to the groundwater as indicated by the verdant trees.

We didn't return by the old road but [?] toward the Vidal Rd. between Riverside and Big Maria Mts. Once we got in a wash driving was easy.

At Vidal we ate lunch and then drove to Needles. Then we continued to the cut off above Saltus and drove to the Granite Mts. and Dormer Camp.

Dick and I took some *Bufo punctatus* in the dry stream by camp. There is no water until the willows are reached, 150 yards above camp. There was no calling.

April 26, 1950

Pachalka Spring, Clark Mt., San Bernardino Co., California

We got up and Dick and I hiked up the valley to a couple of streams issuing from the south face of the Granite Mts. One, just west of Cottonwood Springs had considerable standing water in it. There were small *Bufo punctatus* tadpoles. At the extreme west end of the valley we inspected a row of cottonwoods lining a dry stream course.

Back at camp we put up specimens and packed. The *Bufo punctatus* we had caught last night were all paralysed from being bitten by a (2) longhorn beetle (actually a species of tiger beetle), which had been put in the jar with them. 4 specimens died and the largest one is still alive (1 day later), but is paralysed (he can move his gular pouch and eyes). The toxin must be very potent.

We left and drove to the Kelso Dunes, where we dug out 2 umas from a *Dipodomys* burrow. We drove through Kelso and to Cima where we bought lunch (beer and crackers) and continued on into Ivanpah Valley. Just before reaching Cima we saw an old desert tortoise walking along the road at 3:00 PM. BT 33.6, ST 30.8, AT 29.6.

We drove through Ivanpah Valley. There are no sand deposits in the valley.

Then we drove to Laire Ranch and Valley Wells. Taking a road going northeast here, we cut off to the east on a 2-rut road 1 mile past the ranch. This lead up on a broad alluvial fan to the base of Clark Mt. It cuts down into a deep wash and up the other side and over a steep spur to Pachalka Spring. This spring issues from a limestone formation at 4,800 ft. on the west side of the mountain. There are willows, elderberry, peach, and apple trees. The soil was moist from the spring down the canyon about 150 ft. Several other seeps occur nearby. There are 2 buildings in good condition near the spring. The vegetation surrounding the spring is low scrub and quite sparse. There are some cat's claw nearby.

I collected *Eumeces g. ubriadatus*[?] and we got some *Xantusia vigilis*.

Notes and the sack for tomorrow we hike to the top.

April 27, 1950

Fairbanks Ranch, Nye County, Nevada

We got up early, drank a cup of grapefruit juice, ate a candy bar and left on our hike up Clark Mt. We had a pack sack and our guns.

The "trail" pitched up rapidly. We followed the ridge and after a while reached the crest above camp. The vegetation was a xeric mixture of *Yucca mohavensis*, *Ephedra*, etc. An interesting little *Agave* with white, fringed leaves is common.

At the top of the spur we stopped for breath (about the 10th time). Far off down the road Bill noted the glint of sun on a windshield. The car was coming to Pachalka Spring and all our equipment was spread out, including Dick's watch and camera. Dick decided to go back. Bill and I continued on up the mountain, shortly entering the pinon belt. The wind was blowing violently but it was not cold.

The mountain slopes are mostly limestone which has been eroded into rugged knife-edge ridges. This made following the ridge a hard task.

I caught a nice big *Coluber taeniatus*, lying in the sun on the ridge. Catching this "New Mexican" form made me realise how similar this area was to the Sierra Oscuro in New Mexico. The only striking difference is the much more rugged character of Clark Mt.

We hiked on for a considerable time. Bill caught an *Uta* with no side blotch, which I called *Sceloporus graciosus* until I got back to camp. I was all excited over him. He was taken at approx. 6,500 ft.

Finally we climbed over a pile of limestone blocks, past a spur and saw fir trees (*Abies concolor*) scattered up and down a steep north canyon. We hiked over to them and shucked our pack and began looking for animals.

The situation is a steep north facing canyon choked with chunks of limestone. Pinons and junipers cover the higher slopes and the more exposed ones and are mixed in with the firs in the canyon. Downed logs of all 3 trees are common. There is considerable duff of fir needles, rotted wood, and "puffy" black soil. There was much moisture though I noted no seeps. Moist rock rubble is common. Animal life is

remarkably sparse. I saw only a few birds and insects. Ants were the most common. Bill shot 3 *Sceloporus occidentalis*. We saw no skinks though the habitat looks fine for them. Much of the soil moisture must be due to snow melt. There are some diffuse bushes in the canyon, unidentifiable by me.

We ate lunch, took some pictures, and started back. On the ridge we could see for many miles. We could see the Soda Lake Mts., the Kingston Mts., Cima Dome, and the Providence Mts., Mesquite Dry Lake (sand on corner? Hummocks?), Charleston Peak, and possibly the Panamints.

We decided to hike down a steep south canyon rather than return by the ridge. We had no trouble though we had to by-pass a few small cliffs. We returned to camp after going through a very pretty canyon with steep walls, much xeric vegetation and many lizards (*Sceloporus occidentalis*) and birds (including pinon jays).

At camp we found Dick waiting with everything packed. We caught another skink, who was running from bush to bush in the hot sun, and left. The visitors had been 2 men in a jeep, 1 of whom was running cattle at the spring.

We drove to Baker, bought food, and left for Saratoga Springs. At the springs we found several parties camped. The rushes of the spring had just been burned off. The place was a shambles. The little fish will have to be resistant to stand the potash that will be dissolved in the water when the ashes blow in. We found the man who had done it. He said he was trying to kill the mosquitoes. He said he was going to put oil on the water next. We left, much disgusted with the whole thing.

Southeast of Saratoga Springs, on the other side of the gap through which the Amargosa flows is a stringer of sand extending from a spur. It is about 350-400 ft. long and 40 ft. high.

We drove up, on a gravel road, to Ibex pass. Above the dunes 2 mi. S. of Saratoga Springs the wash holds considerable sand and there are some blowups on the west face of the hills.

We drove to Death Valley Jct. and reported the Saratoga Incident to the Monument Rangers by phone. He informed me that the land was owned by an Englishman living in England, and thus private property, and that the head ranger was going down tomorrow and kick the people off for trespassing. Maybe he won't get to oil the water after all.

We met Larry Lambert at Death Valley Jct., a nice red-headed chap whose name's familiar though I can't remember from where.

Bill got permission from a Mr. McCall to camp at Fairbanks Ranch. There are 2 McCalls, who by various methods supposedly including shooting, has cornered most of the land in Ash Meadows including some valuable clay mines.

After much trouble we found the ranch. It is a small ranch of 6 buildings including a small ranch house. There are cottonwoods and tamarisks around it. A spring flowing several gallons per minute is right outside the door. There are fish (*Cremichthys*) and *Hyla* and bullfrogs and crayfish in the water. It is excellent drinking water. The ranch is situated in an open valley between low clay bluffs. The bottom land is alkali encrusted and grassy in some places. There are a few horses. Being very tired we hit the sack as soon as possible.

April 28, 1950

Lime Kilns, Wildrose Canyon, Panamint Mts., Inyo County, California

We got up quite late. I wrote notes while Bill and Dick collected insects along the streams running from the main spring.

About 10:30 we left and drove to the big pool of Fairbank's Springs. It is about 4 or 5 times as large as the one at the ranch house. It is composed of 2 pools 6-8 ft. across. The water flows rapidly from both. None the sand of the bottom boils furiously in the inflowing water. The water is somewhat warm (80+ degrees C.) and is very clear.

At the junction of the ranch road and the main road we met Tex McCall and son and an oily-looking character who stayed in the car. Mr. McCall is a rugged sort who has a quick mind—as can easily be told by his conversation.

He had planted *Rana catesbiana* in his springs. In this warm water and desert climate he claimed they came to maturity in one year. For food he planted crawfish in the springs. They were very numerous in the springs.

He had also planned to raise tropical fish in the pools and to sell the ooze from the spring bottoms as plant food. It is high in soluble calcium and organic matter he says.

We drove on up a broad valley to Lathrop Well (a small village of 8 or 10 buildings) and on to Big Dune, west of this locality.

Here the sand has been piled into a longitudinal ridge of whitish, fairly coarse sand. There is little vegetation except *Larrea*, *Franseria*, and another unidentified shrub.

Only *Callisaurus* were found on the dunes. It seems certain that *Uma* is not present. We ran several *Calli*'s down by tiring them out. The open country and the lack of mammal holes made this possible.

Leaving this locality (after taking a leopard lizard and a *Coleonyx* under the same bush) we drove to Beatty and bought gas and lunch. Then we drove to Ryolith[?] and showed the sights to Dick and ate lunch. Then we took the Titus Canyon Rd. It leads up on a good graded road to a summit of about 5,000 ft. and drops down into Leadfield. This ghost camp consists of many mine shafts and a few old buildings. Celestite seems to have been the main mineral mined.

After leaving the flat of Leadfield the canyon narrows rapidly and its walls go up in a series of cliffs over 1,000 ft. We wound around on the canyon floor for about 2 miles. We came to Klare Spring, a little flowing stream trickling out of the base of the cliff. Quite a few rushes grew around it. There are a number of petroglyphs on the rocks east of the spring.

The canyon became even narrower and finally there was only room for one car.

Shortly we emerged from the canyon onto a broad alluvial fan leading down into Death Valley. The entrance to Titus Canyon is scarcely visible.

We drove on to Stovepipe Wells and there saw the historic "four-holer" said to have been used at Rhyolite and Bullfrog.

Up the alluvial fan of Emigrant Wash, past Harrisberry Flats and down into Wildrose Canyon we drove. At Pipkin's place we got milk and then drove up to the lime kilns. We made camp in one. The air is quite cold outside and the warmth of our juniper fire inside the spacious kiln is wonderful. There are 10 kilns of stone and cement about 0 ft. high by 3 ft. wide across the base. There is an arch door about 4 ft. high and a vent on the opposite side 12 ft. up. Smaller vents circle the bottom. There is a nice flat floor.

To the sack.

April 29, 1950

Van Nuys, California, Los Angeles Co.

We got up rather early after a good night's sleep. The kiln had been warm all night even though it was close to freezing outside (it did freeze at Mahogany Flats).

After breakfast we hiked around Mahogany Flats but the ground was far too dry to support salamanders.

We started up the trail to Telescope Peak. This trail is a fine one as it is maintained by the park service and probably by the many Alpine Club members who climb the peak.

The trail passes along the east slope of the Mt. in an intermittent pinyon forest. Shortly the trail emerges onto a slate talus slope vegetated by miniature Great Basin sage (*Artemisia tridentata*) and then passes over the ridge into a 3 or 4 acre meadow (Arcane Meadow) filled with this sage.

Gopher burrows are very numerous in this meadow and are found nearly to the top of the peak. About ¼ mile before reaching Arcane Meadow we saw our first limber pine (*Pinus flexilis*).

South of the meadow, on a rocky limestone slope is a considerable open stand of contorted limber pines. There is a thick covering of soil here and many downed logs. Rocks are numerous. We searched diligently for salamanders here but temperatures were too low (+2 degrees C. at 5 ft., 16 degrees C. at 5 in.).

There was ice under the shaded logs. This locality seems to be one of the best prospects on the mountain for future collecting however.

We walked on around the west slope of the mountain over talus slopes, in a biting cold wind. We could see the peak close in front of us to the south. Its slopes are covered with a very open growth of foxtail pine (*Pinus balfouriana*? *aristata*). At about 10,100 ft. Dick turned a rock and a *Sceloporus graciosus* rushed out. We caught him. He was a beautiful male. Bill and I decided we wanted to go to the top as it looked so close. Dick wasn't so eager, perhaps being a little wiser. We crossed to the east slope again and started to go up. Shortly we came to our first foxtail pine. It is a very distinctive tree [drawing]. In habit the tree is more compact and erect than the limber pine.

We ate lunch (Vienna sausage, chocolate, and bread) in the lee of a barren slope and then hiked on to a series of rugged switchbacks which we ascended at much expense of energy. On this trail we met a group of fellows coming down from the peak. They said it was not far ahead (and up).

We continued on, eating snow from the occasional patches we met along the trail. Finally we hiked around a ridge and up ahead we could see the summit marker.

At the top I opened the Sierra Club register and found an item saying "Little Jimmie Jones, aged 3 ½, walked all the way." Dick about folded up (as did Bill and I). We also found notes by Sam Houston, T. Dobzhansky, William Hovarnitz, Robert Stebbins, and Wade Fox.

Back down the trail after rest and pictures. We caught a *Sceloporus graciosus* at about 10,700 ft. (gravid female) with her mate. The wind was cold and the hike long back to camp but the view and the flora and fauna had been well worth the hike. Dog-tired we started for home. The trip was an easy one. At Pearblossom we stopped in a little café by a gas station and met a group of strange characters including a bunch of big[?] men climbing over the house, a British wit called "Irish", and a drunk man and

woman who had “never heard of Telescope Pete even though we’ve lived in these parts for 35 years”—

At home I hit the sack.

Guiracoba trip

August 2, 1950

Tucson Mt. Park, Pima Co., Arizona

Late yesterday we left Los Angeles and drove as far as Palm Springs where we slept out in the dunes. We arose at about 7:30 AM and drove toward Yuma via Indio, the east edge of the Salton Sea. The road there is still under construction.

At the Yuma Dunes (Algodones) we shot a male *Uma n. notata*. It had the latero-ventral red patch which bears out my conclusion concerning this form.

Dick and I took a very refreshing dip in the All American Canal and then we (Bill Reeder, Dick Zweifel, and I) drove off toward Gila Bend. The day was hot (104 degrees), clear, and dry.

About 12 miles north of Tucson we turned right at Cortaro toward Tucson Mt. Park. This park proved to be a very fine stand of saguaro and other Sonoran Desert vegetation.

We made camp just after dusk near a streambed. This wash flows between rocky hills and is choked with ironwood, mesquite, and a great many animals. A recent rain has brought out many plants and animals. We found many very tiny *Bufo punctatus* and several small *Scaphiopus* sp. (looks like *couchii*). One 4 or 5 in. *Bufo alvarius* was taken. There was no standing water in the stream, only moist sand.

We watched millipedes walking around. The way the “waves of feet” are used in locomotion suggests that a slow nerve impulse might generate each locomotion wave.

There are hoards of insects out (solpugids, all kinds of beetles, noctuid moths (a colorful orange, black, and white one), mantids, etc.

So off to the sack—on a cot, thank goodness.

August 3, 1950

35.2 miles south of Hermosillo, Sonora, Mexico

We got up, ate a hasty breakfast and drove into Tucson. At the Pima County Clinic we obtained a prescription to obtain Chloroquin, a malarial suppressant drug.

After buying the drugs and other items we left for the border. We were able to get by the border with only a token inspection by the aid of a couple of well-placed dollar bills.

We drove on south between huge thunderheads which poured rain onto the surrounding mountains.

At dark we began picking up DOR snakes. We collected our first tiger rattlesnakes (*Crotalus tigris*), coral snake (*Chironactis*), and indigo snake (*Drymarchon*).

After investigating a chorus of *Scaphiopus couchii* in a series of roadside ponds, we drove until we found a camp spot. The *couchii* were seen floating inflated in the center of the pond, calling with their pained voices. In New Mexico I have noted that *S. hamondii* has this same floating habit and where *couchii* occurs with it, *couchii* is restricted to the pond edges.

Our camp was near the road under some big mesquites. A violent lightning display occupied the sky to the south of us.

At about 3:00 AM we felt rain which rapidly became heavier. We got up and packed up preparatory to driving through the storm. Our tent was deeply buried and it was so hot that sleeping inside it would have been very uncomfortable. Just as the packing was completed the rain stopped. We were beset with indecision and decided finally to stay. No sooner than we had finished setting up the cots than it began raining again. We said to hell with it and went to sleep. It rained fairly hard but we didn't get up and finally it stopped.

August 4, 1950

Just south of Obregon, Sonora, Mexico

We got up and drove into Guaymas. At the Instituto de Pesca we met Sr. Faro who informs us that there is another fish man arriving from University of Washington. The new man and Rene Nunez were in Mexico City at the time of our stop.

We drove out to the sand spit to the cantina and had a couple of beers and talked to Manuel the bartender. Jessie, the other bartender, was in jail at Hermosillo for some unstated crime. (He was teaching in the jail).

The paved road now extends 52 miles south of Empalme. We found that the Yaqui River pango (ferry) had been washed out so we had to drive to the new Yaqui River dam to cross. This amounted to a 25 miles detour over a lousy road. It was dusk when we crossed the Yaqui. We could see the river flowing near the road bed across the bridge—muddy and churning.

After a brief stop for dinner we drove on through Ciudad Obregon and camped in a flat south of town.

August 5, 1950

Arroyo Cuchiyaqui, Sonora, Mexico

When we woke in the morning we found a garden of flowers surrounding us. Thousands of bright orange flowers (*Melastomaceae*?) and equal numbers of *Geraniaceae* (pink) flowers were blooming in the flat.

The ferry across the Rio Mayo is a double one, and because of the swift current, is very fast. It cost us 3 pesos to cross.

Navajoa is a big sprawling unkempt place on the hot coastal plain. There is a huge building housing a market place, near the center of town. All sorts of fruits are piled in heaps on oblong cement benches, limas, sapotes, papayas, oranges, bananas, etc.

Outside in rows of little separate stores all sorts of things are sold—clothing, furs, leather work, soft drinks and all sorts of other items.

We bought some bread and gas, and left for Alamos. The day was very hot and muggy. It was amazing the amount of water we drank enroute.

The vegetation increased in density and verdure as we approached Alamos. Rugged mountains rise up before the valley of Alamos is reached.

We stopped in a deep arroyo (Agua Marina Canon) in the midst of the forest. After lunch we wandered around in the forests. All sorts of beautiful butterflies flitted around and Dick flitted after them. All sorts of trees—amapa, fig, manto, palo santo, laurel, and all kinds unidentifiable by me covered everything with greenery. We picked

up the 2nd or 3rd specimen of *Phyllorhynchus brownii fortitus* on the road. *Callisaurus d. brevipes*, a grid-iron-tailed lizard is quite common. This animal is one of the most strikingly colored of lizards of my acquaintance. Dorsally it is a rather drab brown unicolor but ventrally patches of brilliant emerald green and orange are found.

Before taking flight this lizard curls its tail and waves it from side to side.

In Alamos we bought gas and made enquiry about the road to Rancho Guiricoba. Johnny Hilton, John Hilton's boy told us the Arroyo Cuchijaqui was waist deep and we would have to take a long route which we could not hope to make without chains (which we don't have) because of mud. Another fellow—Tomas Garcia—told us the arroyo was only bumper deep and that we would have no trouble.

The town of Alamos is a beautiful place. It is old and partially deserted. A beautiful old cathedral chimes out the church call on its bells. The streets are narrow and paved with cobbles. Huge Indian laurels shade the plaza. The surrounding valley is bounded by high rocky mountains.

It is said that some of the streets are guarded and never have had an automobile on them.

We drove out of town past the "Skonk Works" (a tannery) after being "taken" by our guide for 10 pesos. I guess there are city slilckers everywhere to take advantage of us poor country boys.

The bark of a certain Mimosaceous tree (looks like a manto tree) is used for tanning. We could see where the bark had been sliced off these trees along the road. The instructions were to keep "siempre izquierda." After reaching the arroyo on a very poor road it became evident that we were on the wrong road. We turned around and took another road to the right and again reached the arroyo at the wrong place. We drove back 12 miles and found a road to the left that we had missed. After a fairly short time we came to the arroyo and crossed with water up to our hubs.

It was quite late and we camped shortly near the Indian village of Cuchijaqui and hit the sack immediately.

August 6, 1950

Rancho Guiricoba, Sonora, Mexico

We got up fairly early and started for the ranch. The road became rapidly worse. It was rocky and very badly eroded. In some places it was so steep that low range 4 wheel drive was the only thing that got us over.

We picked up a Mexican (Serapio Ramirez) with a 45 strapped to his belt, about 2 or 3 miles north of El Cajon and put him in the back. The rough road caused him to be continually hit on the back of the neck by the bow which holds up the top. Every time I got out to open a gate he was smiling like mad and making a big joke of the whole thing.

Finally we reached El Cajon, a sluggish stream flowing between rows of huge *Taxodium* (cypress) trees. These trees have swollen bases and great arched roots. In the stream jojarra (ciclids) were common. We let off our hitchhiker (he left his spurs in the truck) and crossed the creek. The road became somewhat better and before long we passed through a village of thatched roofed mud and wattle shacks and then through a bar gate (opened by 2 little ninos for 10 centavos—they objected that amount as too little, but we objected that it was too much, after our 10 peso affair in Alamos).

This was Rancho Guirocoba (meaning buzzard head in Mayo, the Indian dialect). The ranch was set in a foothill valley between short-tree forest covered hills. In the background we could see the scarp of the Sierra Madre Occidental. Many thatched roofed wicker work houses were scattered amongst plowed fields. Corn, cotton, and beans appear to be the main crops.

On a little rise, near the arroyo bank we could see a group of white stucco buildings surrounded by a rock wall. We drove in the gate and met Clay Montgomery, the caretaker. He is a gray-haired man with a moustache, glasses, and a sort of omnipotent air.

He was very hospitable and invited us in for dinner. We met Mrs. Hoy, his mother. She is a bright-eyed old lady, over 80. They sat down and dinner was served to us—some sort of ham, “strawberries” (a sort of bean mush), mashed potatoes, and manzana bananas with crystalline sugar. We met Angelita, Clay’s daughter, who is visiting from Mochis, Sinaloa; Marguerita, another smaller daughter, Rodney and Jimmie, two of his sons; and Clay’s Mexican wife, Rosa.

The house is finished with clear wood and has a stone fireplace, 2 screen porches, a shower bath (water is poured in a tank at the roof, and a kitchen with a unique cement stove. Half of the roof is thatched and the other half is tar-papered. We washed up a little in one of the bedrooms using an old wash stand and rainwater (full of mosquito larvae).

After dinner we were shown across the yard to a big storehouse where a corn room had been cleaned out for us. It is a high-roofed stuccoed room about 25 feet long by 10 feet wide with hand hewn cedar beams and a thatched roof and porch. We swept out the adobe floor and were supplied a cresote solution to spray around to kill cockroaches (the largest I have ever seen).

We unloaded the truck—I was completely amazed that there could have been so much junk in one small truck. We cluttered the whole room with it. With the aid of a pile of cedar planks and boxes we put up several long shelves and piled our material in them. We hiked down the arroyo and I located a couple of pools in which I saw ciclids and gobids (*Awassus*) as well as the ever-present pocciliids. As I couldn’t get Dick to seine we had to wait until the next day.

Back at our Hotel Guiricoba, with the aid of Clay, we set up a buying system for reptiles. Bill set his traps and Dick and I hunted frogs and toads. At a stone dam (presa) just below the ranch house we caught a culebra verde (*Thalerophis*) and a rana verde (*Agalychnis dacnicolor*). The latter is a huge hybrid frog (tree toad), bright grass green in color, with large expanded sticky toes. It lays its eggs on the under sides of leaves.

The ninos began bringing specimens. We got a large series of the common toad *Bufo mazatlanensis* (10 centavos por uno) and a few *Scaphiopus*.

We hit the sack. The heat was considerable and made sleeping difficult. However, to our pleasure we noted no mosquitoes.

August 7, 1950

Rancho Guirocoba

After breakfast Dick and I went downstream and seined the pool around the dam and got 4 species of fish. We went upstream and seined a few shallow pools. We took a few mojarra (ciclids) and a big gillicthys? (*Awassus*). Rodney (who speaks no english)

showed us the swimming tank where we saw several majoarras but it was too large to seine with our beach seine (10 ft.).

Back at our suite the reptiles began coming in. We got a small boa (*Constrictor constrictor insperator*), a hatchling coral snake (*Micruroides*), and a lot of *Sapos* (toads), and 2 or 3 culebra verdes. Dick and I tagged and pickled until we were up to date.

In the evening we talked to Clay and Mrs. Joy. They told us about the ranch. Before the agrarian movement was started there were several thousand hectares more of farming land on the ranch. At that time there were all sorts of artisans employed by the ranch—cabinet makers and blacksmiths. At present this ranch is about 12 miles long by 7 miles wide and encompasses a fair proportion of good farming land. The ranch is owned by a group of Los Angeles businessmen—Bill Scheffler, Ed Ainsworth, and others. Adrian vanRossen used to own a part of it. The northwest part is owned by Clay's wife.

Clay is quite a doctor and keeps a big supply of drugs and equipment in his house. At one time he was a medical student but quit for some reason. He has done all sorts of things. He has been chased by Pancho Villa's men and escaped by hiding in the hills. He has lead a survey party for a railroad to go from the coast to Mexico City, near the ranch. He has acted as a doctor and sold medicine all over southern Sonora. What else he has done I have not found out yet as he doesn't talk much about himself. He says less about Mexican politics as he says no opinion is the best and safest opinion. He is very shrewd in his dealings with the local Mexicans. His treatment is just from what I can gather up but he makes sure that they are indebted to him. When they receive their pay for their crops he rushes in a large stock of various items to his son's store in the village. They usually buy more than they can afford and thus the money stays with him and he secures their indebtedness. He tells about being treed by peccaries (javelina) in the midst of a bamboo thicket, on La Baristo Peak southeast of the ranch, and being able to hear the animals but not see them.

After going to bed I began to feel a little poorly and before long had a fine case of dysentery.

August 8, 1950

Rancho Guirocoba, Sonora, Mexico

By morning it had set in and there was no doubt about what was wrong with me. Luckily it was Bacillary and not Amoebic. Bill had all the medicine for both kinds (sulfamerizine tablets, bismuth subcarbonate tablets, perigoric, and sodium bicarbonate).

I had nausea, high fever, and stomach cramps. As soon as I took the tablets my stomach cramps disappeared and before the day was over my dysentery was gone.

Dick felt like he was getting it too so he took some remedy supplied by Clay.

All day long specimens kept pouring in. We got a live specimen of *Sonora aemula*, the third on record, a vine snake (*Oxyelis*), a red racer, 3 big green *Anolis* (young *Ctenosaurus*), and all sorts of lizards and frogs.

By night I felt good enough to play a few tunes on the guitar.

August 9, 1950

Rancho Guirocoba, Sonora, Mexico

Most of the morning was spent lying around in the shade to keep from breaking out in a sulfa rash.

The specimens keep rolling in. We got a 5 foot boa and an equally big indigo snake, among other things.

Dick and I went down to the dam to try out the emulsified rotenone supplied to me by Robert Miller of University of Michigan. We dumped in about a teacup full and succeeded in chasing the fish through a hole in the dam to a larger pool on the other side.

I went back and got about a half pint more and poisoned the bigger pool (about 60 ft. long by 15 feet wide, and averaging 3 feet deep). Mojaras (Ciclids) came to the top but none of the suckers or poeciliids or catostomids did. I caught a small series of mojaras.

Back at camp we learned that Bill had been having trouble. He had offered a woman 1 peso for each live animal (bat) and 50 cents for dead ones. She had returned with 35 live bats. He reluctantly paid her and emphatically demanded "no mas." He will be stuffing for days on this supply.

We have been learning some of the superstitions concerning snakes and lizards that the natives hold.

When the first rains come there is a turtle (*Pseudemmys*), known as "tortuga Juan" who is supposed to give forth with a call "Don Juan, Don Juan, Don Juan"—obviously the turtle call is that of one of the many amphibia of the arroyo.

They believe (as does Mr. Montgomery) that the Pichicuati (*Agkistrodon*) whistles—a single note repeated monotonously. This call probably comes from a *Bufo* (*mazatlanensis*?). They believe that the vingarbon (vinegarrillo) is more poisonous than the rattlesnake or the pichicuati or the coral snake. The vine snake is supposed to suck on the teats of cows and make them hard and dry. The story of the ajolote entering the female genital tract is also prevalent though the ajolote is not *Bipes* the two-legged lizard, but a skink, *Eumeces callicephalus*.

August 10, 1950

Rancho Guirocoba, Sonora, Mexico

This morning I went out with Bill on his trap line. He had it set up on the slopes of a mesa in the midst of the forest.

Quite a number of *Perognathus* were in the traps. Most of them were badly eaten by ants. He had set 2 steel traps in the arroyo but neither had an animal.

By the time we returned Bill was feeling very tired and before long he came down with bacillary dysentery. We gave him the remedy and put him to bed.

We started buying some bread and tortillas from Loretta, the Montgomery's cook. She also does our laundry (irons it too). The bread (biscuits) is very welcome for lunches and costs very little.

We got another big boa and a coral snake today.

August 11, 1950

This morning Dick and I went down to Canon Negra. I tried a little fishing in some of the big rocky pools. The moharra would follow the lure right to the edge of the shore but would not strike it, possibly because it was so large. Later I switched to using minnows for bait and started hauling in the fish.

Later in the day we went back to seine a big pool in which we had seen a *Pseudemmys* (turtle) swimming. The water was warm, muddy, full of moss and burro dung, and therefore the job was most unpleasant.

Furthermore the fish we got were not numerous or of any new kinds.

Bill was feeling better when we got back and ready to go tend his traps from which idea we could not dissuade him. The sulfa pills are apt to cause a rash if one becomes active too soon after taking them.

I took a short hike after an iguana, which I had seen in a tree. I was accompanied by Ernesto (Clay's son) who told me the names of plants and other things. He showed me the pitahaya plant, a tall cactus, which has wonderful fruit in May and June. The huge cypress of the arroyo are called "sabino". Another very spiny plant with a big knobby fruit is called "papanche". The fruit is supposed to be orange on the outside and black inside when ripe (or at least this was my translation). He pointed out encinos (oaks).

Later in the day I bought a big Mexican beaded lizard from a Mexican. We put it in a big can as it was alive and later we noted that there were 3 conical eggs in the can. We inspected the lizard and found that it had 2 purplish prominences protruding from its cloaca, closely resembling hemipenes except that they were not as large.

After killing her we found 11 more eggs in her oviduct. They are variable in hardness—some are completely calcified and others have very soft shells—none are pliable like a snake egg [drawing]. They are cream colored. Some are more rounded than others.

During the evening the valve trombone played and we could see lights in the village. It was a birthday party.

(These proved to be quail eggs in the gut of a male lizard—KSN)

August 12, 1950

Rancho Guirocaba, Sonora, Mexico

This morning we went to "Cienegita" with Clayito (another of Clay's sons) a kid of about 12 or 13 years. He has a typical Mexican haircut and rubber tire shoes consisting of a section of truck tire and 2 leather thongs.

He lead us up the arroyo by several fields, over a little ridge (where we caught a vine snake that was crawling on the ground) and down into a little draw, up over another ridge and into Cienegita.

The Cienegita is a small valley set between high peaks. 2 or 3 small streams flow along rocky courses forming series of pools. There are cypress (*Taxodium mucronatum*), sabal (*Erythea*) palms and many oaks madronos, and other trees. The floor was often covered by a 2 foot growth of a small mimosaceous plant.

We wandered around looking for bats. In the sparse fronds of the sabal we could see movement and hear squeaking sounds. Bill shot up into the fronds and a huge stream of bats poured out. There must have been 1,000 in the fronds (*Myotis*). Bill picked up about 20. We shook a lot more palms and saw a big blondish bat (*Lasurus*?) fly out. Bill thinks he saw a bat with mottled wings.

Dick and I and Clayito went hunting for skinks and caught one under some rocks. We saw another under oak bark lying around an old "palo seca". We caught a bunch of pocciliid fish with dark gold flecks over their bodies and then went swimming in a nice cool pool overhung by trees with bromeliads hanging from them. We caught a big

culebra preita (*Drymarchon*), ate a meager lunch, and hiked back. The heat had become intense, and cloud cover increased the humidity. All of us but Clayito were rather poohed out when we reached the ranch, not from the hike (about 6 miles) but from the heat. We paid him 5 pesos and lay down for a while.

In the afternoon it clouded over and began to rain at dusk—we had a nice rain, with lightning, until about 12 midnight.

About dinner time I smelled something very dead near the stoe. We searched around for about ½ an hour and finally Bill held up a sack with a dead rat in it saying, “Could this be it?” The thing smelled so bad we cold-blooded vertebrate zoologists couldn’t go near it.

Rodney or Ernesto shot a deer during the night (a forked horn in the velvet). Bill supervised the skinning and worked on the hide until we went to bed. The deer was killed with some buck shot I had brought along.

August 13, 1950

Rancho Guirocoba

A short hike to Canon Prieta at mid-day rather poohed me—the heat is intense and the nearly daily showers keep the humidity almost to saturation.

We got our first tortuga colorada (*Geoemyda*). It is a turtle without webbed toes, that looks something like a *Pseudemmys*—that is, it looks aquatic. Its marginal scutes are turned up at the edges, giving the animal a distinctive appearance.

Ernesto brought in a beautiful *Lampropeltis doliata nelsoni*, a red, black, and white king snake, which, of course, they thought was a dreaded coral (coral snake).

A micruroa was bought in during the day, alive. The animal was quite vicious and made sideways passes with its head when striking. A couple of times it bit itself with no apparent ill effects. The heat may have caused part of its fury. By evening I began to have qualms and lay down.

August 14, 1950

Rancho Guirocoba

I spent the day on my cot, ate a little soup, and read *Horse and Buggy Doctor*, a very good book. I could tell I had a good fever and a rather fast pulse rate. Since I also had dysentery I took the prescribed medicine every 6 hours.

The specimens kept pouring in irregardless of either Dick’s or my physical state. One little fellow came in repeatedly with grasshoppers. The little fellow wore a shirt and no pants. I think it is somewhat taboo to go around without a shirt here.

August 15, 1950

Rancho Guirocoba

Spent this day in the sack also. By evening, after dosing myself for dysentery for 2 days, I became convinced I was suffering from heat exhaustion.

I found I could eat salt and not mind the taste—so I ate more and shortly my fever lessened and my pulse became slower.

Clay told us a few stories of his youth. I guess he has always lived on a basic plane. For example while returning from the coast he stopped off at a ranch for the night. He had a Jalisco serape (with a slit for the head. The girl of the house admired the

serape and remarked that it would be nice to sleep under. Clay found that the father and brother were in town. When the mother complained of a headache his course was clear—he gave her sleeping pills. Later ('neath the serape I suppose) the girl began protesting ("Mama, Mama"), but ceased when she was told her mother couldn't be wakened by a freight train.

The specimens keep coming in—averaging about 7 snakes a day. Tomorrow I think I shall eat a little.

August 16, 1950

Rancho Guirocoba, Sonora, Mexico

Things look brighter today—that is I feel good but weak.

Clayito turns out to be the growing businessman. He has cornered the slingshot (tirador) market here (800 people) by controlling the source of rubber inner tubes. For 35-40 centavos one can get the materials from him. He does guide work for a fee and has formed a snake gathering company where the profits of members are split. As president I do not doubt that he gets a salary. He brought us water for our olla and wouldn't stop until I paid him. I had planned to pay him later in the afternoon but we would have been flooded out and broke by that time. He is 10 years old and has bought his own clothes and is planning on buying 2 heifers (200 pesos each) and no doubt will reap a great profit on their sale.

I ate some tuna and rice for dinner and still feel fine.

August 17, 1950

Rancho Guirocoba, Sonora, Mexico

I have been feeling better today except for stomach pains. I didn't do too much moving around. I thought it unwise and anyway the heat and humidity are such that a short walk at midday leaves one soaked with perspiration. In the afternoon I hiked up a nearby rocky canyon with the .32 rifle.

Some still pools containing lots of tadpoles occupied potholes in the arroyo. There were fig trees growing with pitahaya cacti. Many vines clung to the cliffs and trees.

I was disconcerted at the end of my hike by passing quantities of mucous and some blood—as I was no longer running a fever or week with dysentery this was a very unhappy development pointing toward amoebic dysentery.

I told Dick and was pleased to have him agree that we ought to leave to seek medical assistance if my condition warranted. Bill later agreed so we began to gather our stuff together.

August 18, 1950

Rancho Guirocoba, Sonora, Mexico

It was agreed to leave on the morning of the 19th, so we began packing. I took 3 .2 gram tablets of diodoquin after each meal. 2 doses stopped my stomach pains and by evening I felt completely normal but we still thought it best to leave.

The people at the ranch have been praying for rain. Their crops are not growing fast enough—up till now we have been watching with them but now we hope rain will desist untill we cross the Cucujaqui and no longer.

The specimens kept coming in. I was able to catalogue my first *Tremorphodon*. This form has well developed and differentiated anterior fangs. I was unable to see whether they were hollow or not.

All night long rain threatened and we could see much lightning in the direction of Alamos. Very little rain fell on the ranch.

August 19, 1950

A few miles north of Navajoa, Sonora, Mexico

We arose, finished packing, and said our goodbyes to our most wonderful and hospitable hosts and drove out of the ranch on a dry road. We took our 102d snake from the ranch at the house and the 103rd near the gate (*Coluber bilineatus*). The ninos were on hand to open the gate for 20 centavos—shortly we reached and crossed the Cucuhaqui with no trouble at all. We stopped and seined the stream taking a good series of catostomids, *Gillichthys*?, a small anchovy-like fish (*Thyrina*), mojarrahs, a few catfish, pocciliids, and minnows.

Off we went—toward Alamos. In a couple of places we had to go around muddy areas but we had no trouble. It was 20 miles from the ranch to the Cucuhaqui and 8 miles from there to Alamos. As I have said before the road is one of the worst I have ever driven, being gullied, rocky and steep.

At Alamos we met John Hilton and wife. He is a painter and writer (author of *Sonora Sketchbook*). He is a nice enough chap, somewhat vain, possessing a considerable fund of factual information with a decided tendency to gild the lily. He is working an amethyst mine nearby.

On the way to Navajoa the road became muddy (from a rain earlier in the day). Shortly we ran into a very heavy storm. Even though we passed through the fringes it was almost opaque for distances of more than 100 yards or so.

After buying gas at Navajoa we passed over the Pango. The river was swift and full. The approaches were slick and steep, making the entry onto the Pango rather tricky. 2 planks are placed down for the wheels of the car and you drive on board. The ferry holds two cars. It is poled across and adjusted to the current by means of 2 blocks and tackles attached to the big steel cable. Most of the motive power is supplied by the current.

The road was very sloppy and full of muddy pools. We drove along full of foreboding, for a while. We met a fellow in a Studebaker (with chains) who said he had been stalled 5 times with the high water and 1 time had had to go around by driving on the railroad tracks. The water was up to the doors in 1 arroyo and he had to pull through on the battery. He said he wouldn't try it again and thought we hadn't a chance without chains.

A little farther down the road we came to a big truck in the middle of the road, tilted at a crazy angle. It was in the middle of a 100 yard pool and had gotten just off the ruts a little. He blocked the road. I waded out and found the water was only up to my knees on the road but it dropped off steeply on either side and became a quagmire.

We backtracked and drove up on the new roadbed which is being constructed. It is full of rocks and made a bumpy ride but we got by. A fellow hailed us as we did and asked us to help with the truck. We had to drive down a slippery hill in the road on the other side of the truck to attach his cable. After a little pulling our tires became so slick

that we were sliding off the road and could not even get back up the hill. With the help of a half dozen fellows we did get up the hill. They said thanks and goodbye.

Off up the road we learned there was a nearly impassable stretch where one had to drive on the railway. We decided to wait for morning, praying it wouldn't rain. After nearly getting stuck we got off the road and into the sleeping bag. I was very nervous and downhearted—much more so than is usual in such predicaments. I was practically unable to suppress it. I could see Dick felt similarly but Bill was O.K.

August 20, 1950

About 40 miles N. of Hermosillo, Sonora, Mexico

No rain fell during thenight. I woke up several times to see and was pleased to note nearly clear skies. We packed and drove off. Before long we came to a place with water about hub deep. Water splashed up and stopped the engine. Finally we got it started and it stopped again. This time no coaxing seemed to work until a Mexican worked on it and off we went—only to get stuck in the mud by sliding (inexorably) off the road into a bottomless mass along the road-edge. We really needed chains—so I set about to making them by untwining a rope and winding it around the wheels. With the aid of our block and tackle (attached to a nearby palo verde tree and then to a telephone pole) we got out. I took over the wheel and shortly we came to the worst place—a 200 yard-long sea of utterly impassable mud. Here we drove up on the railroad track and bumped along until we were beyond the mud and then returned to the road—several trucks were stuck along the tracks and on the road.

After this we found no more difficult places and shortly merged onto dry roads and continued into Obregon.

The Yaqui River was low and we crossed on the repaired pango. Much to our surprise the paved road extended almost to the river's edge. It was a real relief to drive onto this pavement. We passed Guaymas and stopped at Bocochibampo for beer and Pepsi Cola. I slit fish and was somewhat dismayed to note that most of the fins were frayed by jouncing over the bad roads.

We ate dinner outside Hermosillo and drove for a while after dark and then camped south of Santa Ana.

August 21 1950

Madera Canyon, Santa Rita Mts., Pima Co., Arizona

At Magdalena I stopped to buy cigarettes for various people—Howard Winn, Art Fleschig, Doc Cowles, and Sy Perkins.

I wanted to buy "Delicados" but none were available so I had to settle for Belmonts (90 centavos a pack). There were several varieties ending at El Tigres at 15 centavos. I almost bought some for Art Fleschig. A cute young girl waited on me and spoke a little english.

We had no trouble at the border though we had a lot of dubious items such as deer hides and skulls, butterflies and other insects, and a hunk of cactus. We showed them a boa (alive) and he was passed all around—then they told us to go.

We drove to Tucson where I went to the clinic for an exam (I was unable to get the exam ad feeling O.K. I decided to continue), while the others had a tire fixed and

bought Bill a train ticket. He claimed to have work to do at home but it was obvious that his true love was calling harder than the mountains.

We put him on the 4PM train with 1 dollar extra. He probably nearly starved before reaching L.A.

Dick and I left for Madera Canyon, Santa Rita Mountains. It is about 25 miles south of Tucson. The road cuts off at Continental and over the broad mesquite and cactus covered bajada into Madera Canyon. There are many deciduous oaks low in the canyon and at about 6,000 ft. The yellow pines begin to appear as the road ends. We camped at about this altitude under some oaks.

August 22, 1950

Pena Blanca Spring, Santa Cruz Co., Arizona

After breakfast and packing we hiked up the canyon in search of good stands of pine with the hope of finding *Crotalus willardi* or *triscatus* or *Lampropeltus pyromelana*. We had a good hike and caught 19 *Sceloporus jarrovi*, a beautiful scaly lizard, which is very easy to noose. I saw a doe who was standing in the entrance to a mine tunnel. When I approached she ran back into the tunnel. A russet-backed junco was very common as was the redstart? (a bird with black wings and head and red and white underparts).

Back at camp we decided to leave for Pena Blanca. We travelled south for about 35 miles toward Nogales and then cut west on the Ruby Road, 6 or 7 miles north of Nogales. This road leads through rolling grass and oak covered hills. As we approached the spring the country became more precipitous and rock outcrops became common. The spring is at the edge of a deep arroyo which runs along the base of rocky cliffs on the south. Oaks and grass are the predominant vegetation. We noted some reeds and pot holes of water as we came in. There is a Coronado Forest Camp at the spring with water and picnic tables. A couple of line riders are stationed here. They are checking for hoof and mouth disease. Dick and I had a quart of milk each and a piece of cake in addition to dinner in honor of the U.S.A. or something. We are hoping for rain so the frogs will come out (*Rana tarahumarae*, *Microhyla*, *Eleutherodactylus*).

August 23, 1950

Pena Blanca Spring, Santa Cruz Co., Arizona

When Dick and I got up this morning we found one of the hoof and mouth disease inspectors (Mr. Forsythe) getting his breakfast. He knew a lot of herpetologists including Dr. Stebbins, C. Bogert, Joc Gorman, and Bill Woodin, all of whom had topped at the springs. He told us about the several vine snakes that had been taken in the near vicinity. He says he has seen them crawling in the grass and in low bushes. He also says where they crawl along the ground they have their heads raised. He told us that the "black frog" occurred at Alanco Spring nearby. This we suspected was *Rana tarahumarae*.

He drew us a map and we left for the spring—a corrected version is included. We drove down the Ruby Road 3.6 miles and turned left onto the Summit Motor Road. 0.2 miles past a tank (on the left) we turned off onto a very dim road (past an old camp fire and an oak tree), which we followed for 0.4 miles to a salting place for cattle. There we hiked down the riverbed, keeping to the left and downstream, for about 20 minutes. We came to a series of pools in a narrow rocky channel. The stream was edged with willows,

big junipers, *Yucca*, oaks, manzanita, and cottonwoods. The largest pools were 3 feet deep and 20 to 30 ft. across. Most pools were located below places where the water poured over rocks. We saw the first 2 *Rana tarahumarae* perched in a crevasse above a big pool. Dick caught them with a butterfly net. They look very much like *Rana boylei* of southern California except they are quite a bit larger. They are dark brown with banded hind legs and black and gold-flecked eyes. We caught several, including a series of tadpoles and metamorphosing young. The tadpoles are quite pretty—their tails are spotted.

Near the lower end of the water we came to a fairly large pool (20 ft. across and 3-3 ½ ft. deep) at the base of a little falls (6 to 7 ft.). The pool was full of *Gila* (*ditaenia*?) (*robusta*?). The little fish would rise to insects or little pebbles thrown in the water. We went “swimming” and tried to catch some but they were very elusive, even in muddy water, and we got only a few. The pool had a gravel bottom, rock sides, and was 22.4 degrees C.

I noted the fish in one other pool and no other. Apparently they have not been able to scale the falls. We noted numbers of very small fry so apparently they are doing well in this extremely restricted situation.

We caught 3 or 4 *Kinosternon sonoriense* in the pools. These little turtles smell lousy as soon as you catch them and from then on.

Rana pipiens was common. We took an adult *Hyla arenicolor* and one metamorphosing young.

After the hot hike back to the truck lunch tasted very good, in the shade of oak trees.

I forgot to mention that we took several *Thamnophis eques* in the pools, which had been feeding on tadpoles. Some were quite engorged and sluggish.

In many respects this area is linked to the south—the vine snakes, a cucurbitaceous plant with stinging hairs capable of penetrating pants’ legs (I saw this plant on the Cape (Baja California), vermilion flycatchers, and several other plants like those of south Sonora.

In the evening Dick and I went for a short hike upstream. Just as we turned back it began to rain. We were saturated by the time we reached camp. Later, after it had stopped we went out and caught a few toads that were out after the rain.

We caught a *Microhyla*, the narrow mouthed toad, the first live specimen either of us had ever seen. We also caught *Scaphiopus*, the spadefoot toad. The type we caught may be *hammondi* but it is different than any I have seen. It is red spotted like a *puncta*—[?] and has 2 characteristic red spots on either side of its axis.

August 24, 1950

Pena Blanca Spring, Pajarito Mountains, Santa Cruz Co., Arizona

This morning we drove over to Yank Spring and Sycamore Canyon, about 7+ miles west of this camp on the Ruby Road. The canyon cuts across the road a short distance west of the Bear Valley Ranch Road. It is a fairly broad wash and can be discerned by a road leading off downstream to the southwest, a wide corral (about 100 yards south of the Ruby Road), and the lack of sycamores. Big oaks and black walnuts form the vegetation.

A short distance downstream we came to the spring, which has been cemented into 2 cattle watering troughs. Across the stream are 2 old adobe ruins said to have been destroyed by Apaches.

We drove to the ruins and parked. The stream flows in a *Baccharis* thicket at this point—sinking into the sand one in a while and reappearing. The stream was full of *Gila ditaenia*, a pretty little minnow. The pectoral and pelvic fin bases are orange and some of the larger individuals show flecks of purple and silver dorsally.

I saw what might be a trogon though I'm not familiar enough with the bird to be sure.

At once place the canyon walls are vertical and pocketed with caves. Tall willows shaded the stream. After chasing a bunch of bats out of the cave I sat down and began tossing insects to the fish. The little fellows struck just like a bass or trout. While searching for insects I saw a bright blue flash along a rock I had moved. I was the tail of a *Eumeces callicephalus*, a beautiful little skink.

I finally caught him with his tail complete. He has orange stripes on his head, a bronze back, a purple tail base fading into a brilliant blue, and blue toes on the hind feet.

A little farther downstream we came to a deep (4 foot) rocky pool shaded by a big willow. In it was a big school of *Gila*, some of which reached about 4 in. long. I hiked back to the truck and picked up a seine and a bottle. One haul was all we made but we took a nice series and got a swim in the cool stream (27 degrees C.).

We discovered *Rana tarahumarae* in the pool and captured 4 adults. Back at the car we ate lunch and then drove back to camp, where we tagged and pickled specimens.

We drove to a tank, 2 miles west of the camp, after dark, but saw nothing but *Rana pipiens*. Back at camp we wrote notes and played the guitar a while and then went to bed. It is a beautiful warm moonlit night.

August 25, 1950

20 miles E. of Gila Bend, Arizona

Dick and I had no plan for today so we pickled specimens and tagged until we had caught up.

We went over to the corral and learned the fine points of a quarter horse from Mr. Forsythe. He raises them and told us all about them from their origination in 1611 in England. Then we hiked southwest up Pena Blanca Canyon about ¼ mile to Mr. Harvey's house. He is a fine old man and quite intelligent. Like Mr. Forsyth he knew the names of all the animals of the region. He lives in a little shack (very neat) under big oaks and walnuts. He has some nice chairs set out under the oaks and an old Model A Ford. From his conversation he has been all over the world and has settled down in his old age (75) to live in this fine climate. He has picked a very beautiful place.

We asked him a lot of questions about the country. These are some of the things he told us.

Yank Springs is named for an old settler, Yank Bartlett, who was ambushed and killed at the adobes near the spring in the 1880s. His killers were either Apaches or Mexicans or both. The adobes stood until 1915 or so.

The vine snake is fairly often seen in the vicinity and most frequently in springs. He had seen a big one (6 ft.) that disappeared under his house about 2 weeks before. He

had seen skinks at a ranch $\frac{1}{4}$ mile upstream from his house but our search there netted us nothing.

The chula (coatamundi) are often seen in spring time and travel in packs up to 40 animals. They are ferocious and kill dogs quite often. He had not seen any for 2 years but had seen their tracks.

Javelina are supposedly common. He seemed surprised that we hadn't seen any at Alamo Spring as they frequent the spot.

He had been visited by Loye Miller and A. J. van Rossem, and Dr. Sally Atsatt, Bob Stebbins, Chas Bogert, Mr. & Mrs. A. H. Wright, and Berry Campbell to mention a few. He knew their names and what they were doing and told us to convey his regards to Dr. Miller (which we shall do). He said he had recently visited Dr. Wright at Cornell.

Dick and I went back to camp and ate lunch. I've spent the afternoon packing and sitting around. I got a little fidgety—we were going to wait for dark and drive the roads. I couldn't stand looking at another bean or even at my tuna ragout (a mixture of tuna and mushroom soup poured over rice or mashed potatoes). I mentioned buying some steak to Dick and we were off. We tried to buy it at Tumacacori and Tubac but those stores dealt only in bologna and "carne por chile". Finally at Continental we got 2 huge rib steaks. We quickly drove off the road and cooked them with mashed potatoes and a quart of milk each. Nothing ever tasted better after 25 days of living out of cans.

Then we drove onto 20 miles E. of Gila Bend and camped. I seemed to have redeveloped dysentery (possibly from overloading my poor battered stomach). I'm inclined to think that dinner was worth it.

August 26, 1950

Van Nuys, Los Angeles Co., California

The drive home was uneventful, slow, and hot (106 degrees F. at Westmorland).

But strangely enough our specimens came through alive. We arrived home about 10:00 PM somewhat battered (15 lbs. lighter) but after a highly successful collecting trip.

May 27, 1951

Pushawalla Oasis, Riverside Co., California

After a very hot day (115 degrees F.) we drove up to Pushawalla Oasis.

At 7:45 PM (PST Daylight saving time) the first *Hyla regilla* called in the stream. The sun was just pink in the sky as it set. Air at 5 ft. 34 deg. C., Air 1 cm. above water 33.5 deg. C., water 25 deg. C.

8:10 PM. Two *Bufo punctatus* males caught hopping out of holes in bank toward the stream.

8:26 PM. First *Bufo punctatus* heard calling.

8:50 PM. 13 males and 2 females in stream—no calling except that of *Hyla regilla*.

9:00 AT. 31.4 deg. C. (1 cm over water). WT 25.5 deg. C.

2 adult males found hopping in palm fronds 15 feet from stream and 5 ft. above it (ledge). Skin dry and warty. Probably are what we heard rustling in the fronds. First definite calling of *B. p.*

9:15 PM. Calling very sporadic. *Hyla* in good chorus. *B. punctatus* can be heard calling when *Hyla* quiet—apparently they are not closely controlled by *Hyla*'s call.

9:20 PM. 12 males in ½ of stream, 2 females (both look fairly spent) and 2 small toads—apparently yearlings and not able to breed. Toads generally in pairs—no amplexus. Male and male and male and female.

9:35 PM. Two male and male amplexus. I note that when males are picked up now it seems easier to induce their calling. Toad chorus very sporadic.

9:45-10:30 PM. I placed the light on the bank near 2 *B. punctatus*. Before long one adult male reacted sharply to an insect flying around the light 8 ft. from him. It was a small noctuid moth. In a roundabout way he popped over to the light and began feeding. I don't think he was attracted by the light but by the flying insects. When feeding he leaned slightly forward and flicked his tongue out at the insect—moths. Moths, flying ants, small flies of one sort and another, and beetles were eaten. The type of insect seems to make no difference. He caught and ate small stones and bits of wood dropped in front of him. Often he saw very small beasts 3 or 4 inches away and hopped over and swallowed them, some so small I couldn't see them from 1 foot away. There appears to be a definite upper size limit to food at about the size of a medium-sized moth. Both this toad and a *H. regilla* followed one of these moths but neither attempted to eat it.

Peripheral vision is very acute. *B. punctatus* can detect movement almost directly behind itself. Many times the little toad turned nearly all the way around to catch an insect. Sometimes they jumped short distances for their food.

I suspect that most of their food normally consists of small insects which flit very close to the surface of the stream, as I saw 2 animals feeding on these insects. They were able to flick up food about 1 ½ inches in front of them.

Respiration is quite sporadic and sometimes only 1 side palpitates at a time, whereas the nasal valves both appear always to open together and in perfect synchrony with respiration.

At the base of the urostyle at the insertion of the hind legs, I noted 2 little palpitating spots—out of phase with respiration but still irregular but not spasmodic. Probably they are blood vessels reflecting heart beat.

11:10 PM. Occasional calling continuing. *Hyla* chorus has largely ceased at present. While the stream is full of toads very little calling is going on, and no amplexus. Temperatures are perfectly adequate (29 deg. C.) but apparently the breeding period is over. The few females are spent and do not have the bulging appearance of early spring females.

2 and possibly 3 sizes of tadpoles are present in the stream, one like this [drawing], and one somewhat larger [drawing]. I could locate no eggs on the bottom. No *Hyla* were seen in amplexus.

Male *B. punctatus* would move about the light with no attempt at amplexus with one another and a female tossed in front of them elicited no response other than avoidance though it was repeated several times. Thus the males as well as the females are not at the height of breeding condition

September 7, 1950

San Nicolas Island, Ventura County, California

Bob (Norris) and I drove out to Pt. Mugu Naval Station for the second day in an attempt to get a plane to San Nicolas. Yesterday we took off at 2 PM but couldn't land on the island because of heavy fog.

Today we flew past Anacapa and Santa Cruz and after a 25 minute flight we saw the coastline of San Nicolas. We flew the length of the island and circled to land into the northwest wind. This gave us a view of the terrain. It is very barren. There are no trees and most of the island is grass covered. The island is composed of a series of terraces (marine). There are several, one at 50 ft., a small one at 150 approx., an extensive one at 300 ft., another big one at 500 ft. The crest of the island is 907 ft.

On the west, at least, the terrace edges have been badly eroded into badlands. Bob tells me that the island is an anticline composed chiefly of Eocene rocks (sandstones and shales) overlain with Pleistocene and recent deposits which contain much shell material. We saw a volcanic dyke cutting lengthwise on the west coast.

Kitchen middens of mussel, abalone, and a big turban shell (and all sorts of other shells—limpets, urchins, etc.), mixed with charcoal fragments are very common on the lower terraces (up to 500 ft. at least). Also common are rounded stones, some certainly implements, all broken. We found one metate.

We are being put up in the B.O.Q. by the navy. Our meals cost us very little (30 cents for supper, 50 cents for dinner) and are ample.

Bob and I went for a short hike to an old Army barrack area (1940-1944) and to the beach to a seep he calls "Celery Springs." It has quantities of an umbellifer resembling celery growing around it. The water seeps out of an overhanging bank about 50 yards back of the beach at about the middle of the east side of the island.

Later we went hunting *Xantusia riversiana* under rubbish around camp. We got 4, 2 with one pattern and 2 with another (see species acct.).

Bob informs me that in the 1870s the island was subdivided into city lots. Later it became a sheep ranch—overgrazing has been responsible for much of the erosion on the island. In 1940 or so the Army used it as a lookout station and now it is in Navy hands.

I will be glad to get some sleep.

September 8 1950

San Nicolas Island, Ventura County, California

After a 7:00 AM breakfast we drove up to the high point on the island and began a series of samples and dips and strikes down a northeast canyon which cuts through the terraces from the high point.

At 750 ft. (summit 907 ft.) we investigated a big kitchen midden of abalone, limpets (keyhole and otia), and mussels. We could see the darkened earth where the fires had been. All the rounded stones were broken.

One peculiar thing, quantities of smaller shells (limpets and gastropods) were associated in the midden. It seems hard to believe that these small shellfish were utilized as food.

Considering the long distance from the midden to the shore line it also seems difficult to believe that the food was transported from the present shore line—possibly it was cooked along the shore when the water was at least to the 500 ft. level. This would have left an island about 2/3 the size of the present one.

Down in the canyon we could see numerous fox and mouse tracks. The mice make regular highways in the streambottom. They are very numerous.

Plants consist of a shrubby composite which sometimes attains 6 or 7 feet, a euphorb that forms low, spreading bushes, morning glory vines, a bush lupine with grey foliage and purple flowers that forms numerous low clumps on the hillsides, and several other species.

Near the edge of the 500 ft. terrace (450 ft.) we came upon a layer of quaternary material composed largely of shells of littoral invertebrates. We found a few bones (probably bird remains) among the fossils.

From this point the canyon pitched rapidly downward as the sandstone beds dipped on the northeast limb of the Anticline.

Before long we came to a place where the canyon floor was soggy with moisture. The sand shook like jelly when we stepped on it.

Before long we emerged at the old Army base and hiked up the hill to the mess hall and lunch.

In the afternoon we continued the canyon survey to the sea, this time accompanied by Alfred, the island German Shepherd. He is an amiable sort and spent most of his time being chased by ravens, and chasing them when they got too close.

After completing the canyon we began a stratigraphic column by measuring thicknesses of strata. We located 2 or 3 faults and traced these.

After dinner we had a few rounds of pool and took to writing notes. It was a beautiful warm clear day today and we could see Santa Barbara Island due east. It covers about 1 square mile.

A note of importance. We found out today that a well the navy intends to drill was located by use of an olive branch divining rod. One of the sailors sagely remarked on the fact that the navy which sponsored this olive branch geology also sponsored guided missile research on the same island. Bob thinks the best they can get is salt water.

September 9, 1950

San Nicolas Island, Ventura County, California

This morning we were driven over the ridge and down the southwest slope on a very steep road (41% in one spot) to the beach. The chief let us off there with 2 dogs, Ginger (a little cocker spaniel) and the German shepherd.

Along the beach were 2 or 3 big middens, 1 of which had a few human limb and rib bones scattered through it. This midden stands about 50 ft. high, a little above the high tide line. I caught 2 *Xantusia riversiana* under the remains of an old ship at high tide line. Bob was working on a stratigraphic column so we hiked upstream measuring the thickness of beds as we went. He took numerous dips and strikes and some samples.

We noted several faults running along the trend of the island and at right angles to the long axis of the island.

The high point of the anticline (structural divide) is skewed way toward the southwest, thus the slopes are steeper on that side. In cross section it seems to be something like this (drawing).

The stream channels of the southwest side have dissected through the structural divide all along the ridge.

Finally we emerged onto the high plateau at noon. The dogs had preceded us. We found a midden at 875 ft. approximately. I also took 2 *Xantusia* near this elevation thus establishing their presence on all levels with reasonable assurance. We hitched a ride back for lunch.

After lunch we rode back up Jackson Hill and walked southeastward along the ridge spotting in points and checking the exposures as we went. Near the southeast end iceplant becomes much more abundant and we noted a few opuntias of the staghorn type.

At the southeast end a sand spit juts out into the ocean a considerable distance. It was dotted with black objects that I suspect were sea lions. 4 fishing boats were moored to the west of the spit.

We visited an old cabin perched on the cliff (I caught 2 more *Xantusia*) and we hit out for the airfield in order to get a ride in for dinner. We walked like demons, making well over a mile in 20 minutes. All the radios were going in the control tower but no one was on watch. We phoned in to save a couple of diners and sat down to wait when the chief drove up. He had missed us at dinner and drove out to find us. We appreciably hopped in and got some chow. Tomorrow we work the beach from the spit to the radio towers.

Weather has been warm, cloudy, and windy in the afternoon.

September 10, 1950

San Nicolas Island, Ventura County, California

After breakfast the Chief (Haney) drove us toward the southeast end of the island and let us off at the end of the airstrip. We had Al, the German shepherd, along. I was carrying 2 lunches and other miscellaneous articles in my pack.

Bob wanted to establish a stratigraphic column of this end of the island. It is the top of the column and contains the youngest rocks. After setting another tower (Spur) we hiked down a deep canyon toward the southeast shore. It cut down through a section of massive sandstones and shales. Opuntias (both beavertail and staghorn) were fairly common as was a yellow composite with thick notched leaves. Fox tracks were common but we saw none. Several times we saw a large species of wren (about 2/3 the size of a cactus wren) with a black line over its eye, a grey breast with vague dark lines on the throat, buffy underparts, and brown wings and tail. Its bill is quite long.

Toward the bottom of the canyon we located a rather large fault (throw of over 100 ft.). Bob took a picture and we continued on toward the beach. At the beach we passed alongside a fair-sized cormorant rookery. There were at least 200 or 300 birds standing on the rocks. They seemed to be mostly Brandt's cormorants though I saw some individuals that looked like double crested cormorants. It is amazing how long it takes them to gain enough momentum for flight. They waddled in a continuous stream off the end of a 15 or 20 foot cliff and flopped onto the sand or into the surf without being able to attain flying speed. I frightened one old double crested cormorant off a higher perch (about 30 ft. or so) and he was just able to come out of his dive in flight. A few gulls were associated with the flock. The soil of the rookery was soft to walk on because of the accumulated guano.

We followed the beach northwestward noting the structure as we went. I caught 4 *Xantusia* under old boards just above the high tide line in *Salicornia* and grass. It was quite a fight to get them before Al did as he had his head under every board looking for mice.

We passed the old landing and beach where supplies for the island used to be landed.

Shortly we set up a marker at BM43 (Isle) and ate our lunch. Al got his share by hanging over our shoulders. We hiked on along the beach passing along where the sandstone dipped directly into the sea. We passed a battery driven lighthouse and came to a sandy area. In one place a fence had been buried about 3 feet over the top wire by southeast moving sand.

Bob decided to make a vertical section so we cut up across the terraces, up a steep little canyon, over more terraces, and out right near the BOQ.

After dinner I obtained a battle light and Bob and I went on a short jaunt to the local junk pile in an attempt to find something out about the activity period of *Xantusia*. It was about 17 deg. C. and we failed to see any lizards.

The day has been mostly cloudy and cool. The wind has not been bad however.

September 11, 1950

San Nicolas Island, Ventura County, California

After our 7:00 AM breakfast we drove up on top of the island and out toward the west end. Bob and I and Al started down the slope toward the southwest coast. The terrain is exceedingly barren and "fields" of calcified roots protrude from the soft rock in places. Wind erosion has created some rather fantastic effects on this barren rock.

The wind was blowing and it was cold at that early hour. I was glad to find shelter at times when Bob was taking dips and strikes of the beds.

We climbed over a precipitous slope and down onto the sea terrace below. The west end is exceedingly windswept and is covered with hummock sand anchored chiefly by a caulescent composite with numerous burred seeds.

The ravens performed acrobatics for us. They would glide along and suddenly fold their wings and go into a free fall. After perhaps 30 feet they would roll out of the dive by spreading their wings, usually after rolling completely over once.

We passed numerous exploded and unexploded shells and rockets, probably fired during practice invasions.

Up toward Land's End we could see and hear the seals (sea lions) barking. There must have been a tremendous number.

We hiked along the coast, Bob taking note of the geologic column and I just looking around. At one little cove we came upon about 12 sea elephants hauled out on the sand. They were nearly all piled together---young bulls and female and young animals. They are not particularly easy to disturb.

I got within 40 feet or so before they began to retreat for water. Their use of the hind legs for terrestrial locomotion is very limited. These limbs are highly modified into 4 flippers, each pair joined at the base. The front feet are broad but have normal toes and claws. The animals are very adept at scratching with these claws. In retreating the animals go backwards by hunching along on their bellies, thus maintaining a view of the intruder at all times. They are very fat and shake like jelly when they move. Bob describes them as looking like somebody tied up in a sack, which they do. They have the normal vibrissae on their upper lips and also large patches over each eye, directed backwards.

One small individual was too sleepy to run away. He yawned about the whole thing until I approached within 3 ft. or so and then he raised up, opened his mouth and hissed.

The sub-adult males were just developing the nasal trunk but were huge. They swam along pushing their huge head out of water every once in a while. On down the beach a short distance we came to a group of about 200 sea lions sitting on the beach. They are quite wary and rushed into the sea as we approached. Al was scared and retreated to the sand dunes above the beach when the sea lions started barking.

Some of the old males were reluctant to leave as the young and females plunged into the surf. They turned and barked madly at us as we approached but gave way when we were 35 yards or so away. The whole lot of them stayed among the breakers or just beyond, barking. The din was terrific. We could hardly hear ourselves talk.

After retrieving Al we continued on down the beach and ate lunch. Al left us and walked inland on a straight course, as if with a place in mind, after eating his share of the lunch. We noted a green area up the canyon and it turned out to be a spring. Al was there getting a drink when I arrived.

The spring occupies the mouth of a canyon and supports a patch of salt grass about 100 ft. in diameter. In one place, near the base of a hill on the north side, is a small patch of rushes growing from mucky soil and water. A small flow of brackish, though potable, water flows down the rock canyon bottom at the rate of perhaps 3 gallons per minute. The spring is along a fault line.

Shortly we turned inland and hiked toward the ridge. After 30 minutes or so we came to the top of a ridge and to our surprise saw a huge sand dune lying in the bottom of an amphitheater-like valley. The dune is about 100 ft. high and perhaps 500 ft. long. It is

surrounded by 600 foot walls of greyish-blue shale and yellow-brown sandstones. The sand blows over the crest from the west end of the island and settles in the valley to form the dune.

On the way up we saw a feral cat streak by. They are apparently well established on the island. I have seen one dead animal and found a skull.

We reached the top at the radar station. Al left us and we went out locating points (benchmarks, etc.) The wind was very strong and made sight taking very difficult. About 4:30 PM we got a ride and cleaned up for dinner. A couple of pool games and notes have taken the rest of the time. I am going to take a shower and hit the sack.

September 12, 1950

San Nicolas Island, Ventura County, California

This morning we drove out toward the west end of the island and took a road to Tule Creek and 1,000 Springs. We got out at Tule Creek pumping station and began fixing in various benchmarks.

Tule Creek is a small stream of water which has been dammed in one place. The water is greenish and has a distinct odor.

It is quite potable and is part of the water used to supply the base. A large type of coarse grass with big, puff-like seed clusters, resembling a small bullrush chokes the stream bottom. About 200 yards southeast of the north theodolite near the edge of a terrace a little below the theodolite, we came across a midden sprinkled with human bones. There were 2 femurs and other sundry items. Some excavation had been made but we left it untouched. There were also metates (2) on the mound as well as considerable shell material.

We hiked southeastward along the 300 ft. terrace. In 1 spot near a marker called "Canyon" we could see Corral Harbor up the coast a ways. It is a small embayment (100 ft. long) limited seaward by a ledge of sandstone broken in the middle to form a narrow entrance. Bob says the water is 8 feet deep. It has been used for small boats.

I wanted to collect *Xantusia* at an old army camp near the shore so we descended the mountain on the way back. I went down a very narrow steep canyon. In places I had to descend about 20 feet on nearly vertical rock walls—finally emerging at the camp. Bob was not far behind so I started turning boards and caught *Xantusia*. I waited a while and finally went back up the canyon in search of Bob.

As he was not in the canyon I hiked on to the B.O.Q. and he was there. He had come down a hill farther on—in plain sight—and assuming logically that I had seen him he went on in.

At lunch I learned that Mr. Thomas had seen a raven land (at Tule Spring) and catch a lizard (*Xantusia*) and fly off. This happened just after we left the spring. The lizard must be essentially diurnal as it is nearly always too cold for it to be active at night.

The scarcity of flying insects on the island is remarkable. Flies (not common) and 1 beetle have been all I have noticed. The insect fauna in protected situations is considerable however there are several types of beetles, silverfish, springtails, and among the non-insects spiders and sow bugs in abundance.

Apparently the constant winds, lack of cover, and small size of the island make it impossible for all but strong fliers to establish on the island.

I am perplexed at what an Indian would find to grind in his metate on this island. The metates are common enough but seeds or other grindable materials would seem to be scarce or non-existent. Perhaps they ground dried or cooked shellfish or some similar item.

I had intended to return to the army camp after dinner but a long afternoon hike along the crest of the island and a cold and strong wind changed my find in favor of pool and the sack.

November 27, 1950

San Felipe Bay, Baja California, Mexico

K. S. Norris and C. Lunbaugh[?]

[Drawing of cling fish]. Eyes: pupil black with small gold rims, iris light gray with horizontal black bar through pupil. Olivaceous bars radiating from eye.

Dorsal surface: very fine diagonal light colored (bluish tinge) barring irregular on head, complete on body. Alternate bars tan orange with olivaceous borders. Wide, dark bars along back—3, starting at pectoral, last at beginning of dorsal. Black spot cut by a light bar at base of pectoral.

Dorsal to spot a smaller orange spot. Directly posterior a larger olive green spot (separated from orange spot by a blue bar). Tip of caudal orangish. Venter olivaceous.

January 14, 1951

Yuma Mesa, 14 miles E. of Yuma, Yuma County, Arizona

In spite of a week's work gathering gear together, preparing and packing, we spent several hours completing these things before leaving on our trip.

Our trip is to last about 25 days and is to take us to Mazatlan, Siinaloa, Mexico.

The trip sponsored by Boyd Walker and UCLA is to collect fishes from the gulf, chiefly at Mazatlan. The party consists of Boyd, George Bartholomew (doing photography), Connie Limbaugh (diving), Art Flechsig (Boyd's assistant), George Barlow (general slave boy and seine puller), and myself (likewise).

Our gear includes such items as 2 trucks (one Dodge power wagon and a Dodge $\frac{3}{4}$ ton stake truck), 2 boats and motors, various seines, trammel nets, gill nets, trawls, fish poison, camping gear, cameras, etc.

I had breathed in some fish poison and was feeling rather poorly so I spent most of the time sleeping.

About 3 PM we finally left, saying our goodbyes to Dave Joseph and Boyd's family.

After an uneventful drive we camped on an emergency air strip on the Yuma Mesa.

January 15, 1951

Querobabari? Rd., Sonora, Mexico

Most of today was engaged in driving through Arizona, without particular event. While Bart was driving the stake truck near Tucson, he started to pass another car just as

a new DeSoto started to pass him. The DeSoto was forced over a rather steep embankment. Luckily it did not upset. We helped push him back on the road and continued to Tucson. Here we loaded up with good Tucson water and gas. I phoned Chuck and we continued to the border. The Santa Rita Mts. were snow covered and the hills around Nogales had a crust of snow among the oaks on north facing slopes.

The passage at the border was as usual except that the "armshaw" [?] rates had gone up along with auto insurance. To avoid a tedious inspection we were obliged to pay 2\$ American per car instead of the usual dollar. Insurance cost us 30\$ for 2 cars and a trailer which is about twice as high as before.

We drove on until well after midnight and camped in mesquite and palo verde. The air was thankfully much warmer than at Nogales, even though we did have a light frost.

January 16, 1951

El Miramar Beach, Bocochibampo Bay, Sonora, Mexico

I had a rather sad night as my stomach was giving me a bad time so most of my day was spent sleeping in the rear of the power wagon.

We reached Bocochibampo in the afternoon. I was to drive to Guaymas for bread while the other poisoned the lagoon. I succeeded in buying the bread at Bocochibampo so I was able to help with the catch. It was a huge one. Fish were coming up everywhere. We got 52 species at least. There were literally hundreds of young snappers (Lutianidae). Among others we took *Antennarius*, the toad fish, a peculiar lumpy little fellow with a bait antenna like an angler fish, and dozens of snake eels. These fish could be seen standing on the posterior 1/3 of their tail with the rest of the body arched and standing straight up in the water. They are very slippery and almost impossible to pick up by hand.

We made a few enemies by our poisoning. One fellow had been taking the Lutianids on flies and needless to say he was peeved to see so many of them dead. I can understand his point of view.

I had been feeling better and participated in the collection. After sorting fish and eating dinner we set out to seine Miramar Beach. It was 10:00 PM and we finished about 1:30 AM. Specimens were few in number but we got 45 different species. Among these were a sea horse and a trumpet fish (*Fistularia*). Back at camp we had a fish fry, coffee, and the sack.

January 17, 1951

Estero San Carlos, Sonora, Mexico

We worked on the huge collection of yesterday most of the morning and then packed and drove to San Carlos Estero, where we camped behind a high pebble beach. As it was fairly late Art and I took a boat up the Estero to seine for fish bait while the others made camp.

Art and I netted one large Eagle Ray and many small bass (*Paralabrax*). Evening fishing and night-light (with the Coleman lantern) netted a few fish. Late that morning we hit the hay.

January 18, 1951

Estero San Carlos, Sonora, Mexico

Connie, George and I set out this morning to do a deep water poisoning job. We picked a place where the rocky point dropped off into a 20 ft. deep pool. The poison was spread by Connie, who swam along (with the aqualung) with a 5 gallon can of mixed derris root (the consistency of thick mud).

Before long the fish began rising and we picked them up from the boat while one man worked the bottom with the diving rig. It was spectacular. Fish littered the bottom. We could take 5 or 6 out of every crevass. The bottom is not as beautiful as that off our coast. The algae is mostly a thin brownish mat on the rocks, though occasionally there are iridescent blue algae 3 or 4 inches across. We saw some sea fans, many urchins, and sea cucumbers, and matings of tunicates. Octopi and brittle stars were common. The octopi were good sources of fish. They are unaffected by the poison and scavenge the bottom. Some had 5 or 6 species in their grasp. The club-spined urchin lives in excavated holes in the rock walls and gobies (*Gobiosoma puncticulatum*) and Trypterygids were commonly found among its spines.

Some small morays were taken as were many Apogonids and Serranids (basses). Poison had been spread down to 35 ft. The water was quite cool (16 deg. C.) and we all had the shakes and shivers when we got out.

The trawling party returned after a rather unsuccessful attempt.

After lunch we did a similar poisoning job near the entrance to Estero San Carlos on Punta San Guellermo. Before many minutes had passed a big *Hoplopagrus*, a snapper, stranded along the shore. He weighed somewhere around 10 lbs. or so. Somewhat later, large snappers of another species (*Lutia*--?) began coming in. We caught about 10. Several other large fish were taken including another *Hoplopagrus*. Connie and George dove picking up many small fish.

Boyd and George and I filleted a large number of fish and we had a real fish fry, cooking a box full for lunch the next day. The fish was really delicious and we all stuffed ourselves, especially George who is emerging as a first class "garbage gut." He eats constantly and begs for more.

We hit the sack in a very cold night.

January 19, 1951

About 35 miles north of Agiabampo, Sonora, Mexico

Packing occupied most of the morning and then we drove on out to Guaymas, bought pan, wine, and gas. We had quite a conversation with Rene Minez at the Instituto de Pesca. He now has 3 biologists working for him—one in a town south of Mazatlan (Esquimapa). We learned that the road is paved from Mexico City to Mazatlan and about some of the coastline in Sinaloa.

The road is paved to the Rio Yaqui and for a short distance past Ciudad Obregon. Crossing the river this time was easy as the water was very low, almost low enough so we could use the ferry as a bridge. I could see all the spots in which Dick Zweifel, Bill Reeder, and I had been stuck this summer alongside the new road bed. This time we drove clear to Navajoa on the wide graded roadbed. The Rio Mayo was all but nonexistent, consisting of one small pool that came up to our hubs. Even though we used no pango to cross we had to pay a gaunt Mexican 1 peso for the privilege of splashing in his puddle.

After much indecision (which irked Bart no end) we received some instructions in a bar (plus some beer) on how to get to Mazatlan. The road laves the plaza, goes diagonally south 4 blocks, turns left to a brick wall at the edge of town, turned right 2 blocks, and then left down a wide road which becomes paved. At kilometer 9 (marked by a small cement post and sign saying Los Mochis) we turned left on a dirt road. [drawing]

A short distance farther we came to a banana truck stuck in a mudhole in the middle of a detour. A bridge had burned forcing traffic through the dips. After some work we hauled the truck out with the winch and a snatch block. It was quite a sight to see the big truck haul out of the huge hole it had made. Art, who was running the truck winch, was particularly satisfied at the sight. He twitched his moustache appreciatively.

We drove on over a two rut carretera to a junction with a wider graded road which we took, soon camping under mesquites and pitahaya cacti.

It was a cold night and my air mattress went flat so I am grounded for the trip I guess.

January 20, 1951

Agiabampo Bay, Sonora, Mexico

The area in which we had camped was a dense forest of *Pachycereus* cacti, a large multibranched species. There were occasional pitahaya cacti among the others. They can be told because they have larger and wider placed wrinkles [drawing]. Also the pitahaya has little balls of spines clustered at the top of the arms or littered around the base. These are fashioned into woman's dress combs by the Mexicans.

Tillandsia, the little epiphytic bromeliad was much in evidence on the tall branching ocotillo trees and on the *Pachycereus*. Mesquites and palo verdes were very common.

We passed through miles of this dense spring forest along a good dirt road. Bird life was becoming more common. Harris hawks and caracaras were seen perched on tall cacti. We saw Gambel's quail? running among the underbrush, cardinals, thrashers, and black vultures.

Boyd and I saw one beautiful little hummer colored with iridescent blue green feathers and a scarlet gorget.

Through a gap in this forest we could see a flat stretch of blue water and the tops of some date palms. The water was Agiabampo Bay and the palms were on the outskirts of Agiabampo. The town is a typical small village of several hundred people. Dogs, chickens, pigs, goats, horses, and cows roam everywhere. The houses are calsonined adobes or brick, built with roughly made Mexican bricks. Streets consist of the areas between houses. As usual, the church is the most ornate building in town. The inhabitants show a large percentage of Indian blood by their protruding cheek bones and dark skins.

We left the little town and drove northward to Agiabampo Bay, where we camped alongside a rather shallow lagoon and a white sand beach.

A party of people from Arizona and Oregon were camped along the beach. They were smoking *Scomberomorus*[?] *sierra*, the sierra. We had some and it was really delicious. The people were named Horst and were most pleasant.

We began our various fishing activities. Art and I took out the otter trawl and towed it up and down, hauling in great quantities of much and very few fish. We caught 2 species of puffers, a flat fish, and a goby.

Meanwhile the others were seining and poisoning a mangrove swamp.

After dinner everyone went to sleep but Boyd and I, who sat around the fire talking of this and that and writing notes. At about 11:00 PM we woke the others and went seining in the high tide.

We caught our first rooster fish and lookdowns. The roosterfish (*Nematistius*?) is a beautiful deep-bodied silvery fish with very elongate rays on the first dorsal fin. These are blue. [Drawing.]

I was really sleepy by the time we came in at 2:00 AM and went to sleep almost at once.

January 21, 1951

Topolobampo, Sinaloa, Mexico

We packed in the morning and left. While engaged in this many birds were seen. Forsters and Caspian terns were diving in the bay as were white pelicans. A pigeon hawk flew over.

Connie has gotten to the point where it is almost impossible to tell him from the Mexicans. He wears no shoes, does not shave, and wears baggy clothes and a straw sombrero. The only difference is that he is dirtier. He is one of the most casual people I have ever known. He never helps with the dishes, not because he is lazy but because he never does such things and doesn't think about them. Only about diving and women is he really critical. In Navajoa he and George had 2 cars of women talking to them shortly after we hit town. He is that kind.

The road leads up into some small rocky foothills vegetated by a deciduous short tree forest. Palo santo, the tree morning glory was very common and in bloom. Heilo trees were common (thick trunked trees with a yellowish paper thin peeling bark).

Shortly we dropped down into Las Palmas in the Rio Fuerte river valley. Las Palmas is a very dusty little village of clay and wattle shacks.

We crossed the Rio Fuerte over a small bridge, over which the boat trailer just passed. The stream was very small, about 8 ft. wide when flowing fast. The stream bed shows signs of holding a river 200 or 300 yards across during high water. The road leads directly into the old adobe and brick town of Charai across the Rio Fuerte.

Whereas stretches of untouched native vegetation are the rule in Sonora, above the river, fields of sugar cane cover huge areas below the Fuerte in Sinaloa. The country looks very productive.

In Charai we came to a paved road leading to Los Mochis, a sugar refining center. We had 2 Mexican kids about 16 riding on the truck. They were going to Mexico City from Mexicali. They had no money or baggage. One had an extra T shirt. They hadn't eaten for 2 days. They asked Connie to give them enough money for a haircut, so he offered to cut their hair with a pair of shears. They didn't take him up on it. Art gave them 5 pesos when they left us in Los Mochis. I wonder if they will make it, or what they will do if they get there.

Los Mochis is a thriving dirty farming town of several thousands of people. We stopped at the mercado to buy fruit and bread. The casual way in which wares are

displayed is interesting. Hats are sold from piles 4 or 5 feet high, as are baskets. Yardage and clothing are piled on benches or tables with no markings or reason to the arrangement. Fruits are heaped in great mounds. All the stores are little cubicles, open at the front or merely benches under canvas awnings in or along the street. Most everything is very dirty. The eating establishments are beyond belief in their kitchens. People are everywhere, men walking around hawking various items or carrying tables of bread on their heads, horsemen with chaps, carts loaded with nothing in particular and just people.

After buying manzanas, bananas, and oranges (we got the latter free from some fellows we had given gas to) we left for Topolobampo, through huge fields of sugar cane. The cane is apparently irrigated with sewage water as the canals leading through the fields smell terrible. The whole level valley is covered with large farms and looks very fertile.

About 12 miles south of Los Mochis we came up over a steep rocky hill to topolobampo. The town is composed of many shacks and rickety buildings clinging to the steep slopes of a rocky hill and point. Streets are precipitous and narrow, the whole place smells from the privys set on stilts over the lagoon. Juke boxes are turned on all the way and at night the town rocks with quartet music.

At the end of the point is the modern galvanized steel structure of the camarone cannery. Shrimps are the principle product and are caught both by large dredge (trawlers) and by a fleet of 180 dugout canoes[?] operating in the bay. The Mexicans using these canoas camp around the bay, catching the shrimp with throw nets (taraya). The shrimp are then picked up by barges and carried to the cannery.

We looked for a camp site and were forced to go out of town and camp on the baseball diamond. This diamond had been reclaimed from a mangrove swamp and was protected from high tide by a rock wall. It was a wet and dewy night. Art and I went up the hill and had a couple of beers with various Mexicans. One made friends with us. He was an herrera (blacksmith) and said repeatedly that he was "muy burro" and that we were "tres amigos". He bought us 3 beers.

After we had all gone to bed, Muy Burro (his name was Guillermo) came down the hill with 2 more beers and raced around the sleeping camp making loud noises pulling his revolver, and showing us how he would act if he were attacked. He affirmed that we were tres amigos and finally went away.

January 2, 1951

15 miles S. of Los Mochis, Sinaloa, Mexico

After our usual pancake breakfast we drove through town to a lagoon where we could launch the boats. Along the water's edge we were surprised to see dugout canoas being built. Each canoa was about 12 to 14 ft. long and made from a single tree trunk. Each one was about 2 ½ ft. deep and 1 ½ inches thick at the side. The bow and stem were thicker. Seats were inserted on little projections left by the workmen. The logs were alamo (sycamore) and some harder wood like mahogany (guinacastu). The latter type were considered much superior.

The original shaping was done at Sinaloa, inland from Topolobampo. No fire is used. Here at Topolobampo the workmen begin by using axes, taking off small slices. Then when the proper thickness is approached, adzes are used. The bottom is cut with the boat turned over. A hole drilled through the bottom serves as a thickness guide.

Connie and George and I set out to do a deep water poisoning. The bay is a large one. Rocky precipitous hills descend almost vertically into the bay in most places. Near the entrance there are extensive beaches. There are many inlets and islands. We took the boat a long way around the bay looking for a likely spot for poisoning and found none. Near the entrance we came upon a raft of white and brown pelicans. Later we saw some boobies, long billed curlew, oyster catchers, white ibis, scaup ducks, herons, and ibis. While poisoning fish frigate birds dove down, catching some of our fish. Some had white chins and breasts and others were black. We could see the red pouches on one male bird as he dove. Laughing gulls and Caspian terns were common over the bay.

We ate our lunch (what little Connie and I could wrest from George) while drifting with the outgoing tide. Before lunch was finished we had grounded on a sand bar and had to shove ourselves off.

We poisoned along a rocky shore with very little success. The water was very murky and our diving efforts were much hampered. The current had dispersed most of our poison before it had had time to take effect. The rocks under water were covered with a form of tunicate that extends a sort of translucent bell. White gorgonians were common and possessed a sting. Shell fragments formed a large part of the bottom where rocks were not present. A small labiid was seen swimming in schools. A pair of puffers (*Sphaeroides annulatus*) swam by.

I tried out George's rubber suit and had to have help getting out. Before George would help me he made me promise to give him my next morning's pancakes—what a bottomless pit.

The others had done some poisoning in a mangrove lagoon. They got few fish, mostly anchovies. When the dead fish drifted down the lagoon with the current they said the water was boiling with snappers taking the anchovies. They saw 2 bay porpoises (*Phocina*?) with their backs and blow holes out of water in one of these lagoons. The animals inch-wormed themselves rapidly into deeper water where the boats approached.

We packed and drove through town and up the hill. At night this ramshackle little cluster of huts rocks with music and the lights in variously shaped windows set on its steep slope overlooking a quiet moonlit bay, is quite impressive—if you are away from the smell.

At Los Mochis we were guided to the proper road (through the city dump) and camped shortly among opuntias and *Pachycereus* cacti.

January 23, 1951

Culiacau, Sinaloa, Mexico

The cactus forest was becoming more and more dense with underbrush as we drove south, over a fair road. I began to note papanche trees in numbers and tree morning glory (palo santo) formed an important component of the vegetation. We began to note patches of bromeliads on the ground under the taller plants. These agave-like plants were turning scarlet.

Before long we began to pass through wide fields of corn, all cut, and big cleared areas. The we passed through Guasave, a small town of thatched or tile roofs, ox carts, caballeros, etc. Passenger cars are becoming less in evidence.

Guasave was the first town we came to. It is strictly a farming town, set on the banks of a river, the Rio ? Southward we passed through fields and increasingly dense

thorn forest to Guamuchil, a somewhat larger town located on the Rio ? The river was crossed by driving over a stationary ferry (pango). Huge cottonwoods line the banks. Short tree forest elements are quite common. The vegetation is gradually grading away from thorn forest into a dense forest of 30-40 ft. trees.

Some fields have been hacked out of this dense dry leafless jungle. All the trees but the big *Pachycereus* cacti are cut down. These latter seem to die, whether because of exposure or having their roots plowed up, I do not know.

We saw our first magpie jay (Mexican jays?). A pair of these big beautiful birds flew out of the forest and over the road. They have great long blue tails, blue backs, a crest, a black face, and lighter underparts.

Shortly we came to Pericos, a small town shaded by beautiful big trees, some cottonwoods, other mimosaceous. There were many huge spreading fig trees with aerial roots hanging down from the limbs. Houses were woven work and mud with thick thatches of palm fronds. Some banana groves are dotted around the town.

We stopped to let the dust of the leading car settle when a boy on a bicycle informed us that we had a flat tire—which we did. We jacked up the car and started to take the wheel off when the brick under the jack broke and the axle fell. After borrowing home plate off the local baseball diamond as a prop a fellow came along with a large hydraulic jack and lifted up the car and changed the tire. Out of town we passed by a flock of 50+ green parrots—they were an iridescent blue-green on their backs.

The forest became denser and higher as we approached Culiacau. Bromeliads carpeted the forest floor.

It was dark when we arrived at Culiacau and we soon learned that the entire town (70,000) was out of gas. All their supply is shipped in and the train is 2 weeks overdue. Our tanks are too low to make Mazatlan so we will have to scrounge around tomorrow to get some.

We drove north of town and camped in the short tree forest.

January 24, 1951

Mazatlan, Sinaloa, Mexico

We arose amid screeching parrots and jays and drove into Culiacau. It was well into the afternoon when we got some black market gas under the nose of the Pemex gasoline distributor.

We drove on through the short tree forest, fording several streams including the San Lorenzo where the water reached nearly to the doors. These southern streams hold much more water than the ones further north.

It was dark when we came over a long detour through the forest and onto a paved road. A short while later we saw the lights of Mazatlan and entered town. It is a typical Mexican town with many ramshackle houses and some new modern ones, including a couple of modern hotels. The streets are narrow and of dirt, cobbles, and pavement. Nearly all the widows are barred. Some of the iron work is quite ornate. The streets are crowded with trucks, carretas, street merchants, and people. There are some street trees on side streets.

We finally found our way out of town to the Playa del Norte, a long clean beach north of town. We camped on the sand.

January 25, 1951

Mazatlan, Sinaloa, Mexico

When I woke up Connie was dangling a live sea snake over my sack. The snake had washed up on the beach. We packed up and drove on out the beach to a palm grove known as Cancaron Beach. We made camp in the grove (which has a caretaker and a barbed wire fence) for 30 pesos. The palms are loaded with cocoanuts. It is a very cool shady spot. Parrots are flying around us. There is a small restaurant on the beach and no people. We have plenty of room and will be largely free from worries about having gear stolen. We even have tables and chairs supplied us. This is the off season for beach life in Mazatlan. It is only about 75 or 80 deg. F and thus too cool for the inhabitants. The sea water is about 21 deg. C. or 68 deg. F. and wonderful for swimming.

Art and I were sent in town on various errands. We had the trucks greased and gassed up. Meanwhile Art and I climbed to the point on which the Colegio "El" Pacifico is located, where we looked for tidepools. On our way back we stopped in at one of the big hotels for a Coke. Brightly dressed musicians were playing and singing in the plaza. One of the instruments was a little deep-noted pot-bellied guitar called a Miguel. I would like to get one sometime.

We contacted Luis Pation[?], a spanish fellow who runs the marlin boats. He spends considerable time in the United States and speaks perfect English. He was quite helpful and let us sort over the catch of each boat. He also arranged for us to obtain fish from the shrimp boats. These boats are owned by Sr. Coppel. He is an excitable latin type and quite effusive. He does not instill confidence in one.

The boats come alongside a cement pier in the Astillero, a salt water lagoon. Business is booming for the sport fishing boats. They are booked solid till April.

We found that there are 3 shrimp packing plants in town and no commercial fishing except that from canoas. Most of this latter is done using tarayas (throw nets) and spears. The taraya is a cleverly designed net so made that when it sinks over fish and is pulled up by a central rope the leads are pulled in, leaving a bag around the bottom into which the fish swim [drawing].

Art and I went to the mercado to buy bananas and bread. It is a huge galvanized iron structure with all sorts of food piled on benches. All sorts of items are sold including clothing, baskets, etc.

We bought white gas in a drug store (after trying in a wine shop where the least we could buy was 15 gallons).

We returned to camp and found that the rest of the crew had made a fine deep water poisoning.

January 26, 1951

Camaron Beach, Sinaloa, Mexico

Bart and I got under way after much preparation and went over to Venados Island in the boat. The island is about 1 mile long and separated from Lobos Island on the south by a rocky isthmus. There are 2 small palm groves on the island, a well and a small spring (on the windward side). The summit is rocky and precipitous. Small, steep ravines support dense vegetation. Fig trees, a tree with yellow bignonia-like flowers and tangles of vines and small bushes make up the vegetation. There are rather extensive

grassy slopes, rocky tidal shelves, and one fine long sandy beach scattered with many sorts of shells.

We poisoned a high tide pool and picked up hundreds of small fishes of many colors. Some of the wrasses (Labridae) are especially beautiful. One is colored with longitudinal rainbow colors—pinks, yellow, green. Others have reticulations of bright emerald green.

We returned to camp and later Art and I went fishing and night lighting. With the Coleman we saw several kinds of fish including 7 *Stoasodion narinari*, a large ray with numerous white spots on its back and a long tail. We saw them flapping slowly through the light. Several flying fish were seen resting at the surface. The slightest disturbance and off they went in a trail of phosphorus. We caught several halfbeaks (*Hyporhanchus*[?] *unifasciatus*) in the dip nets, while they were floating at the surface. We also took some barracuda on hook and line and went back to camp at about 2:00 AM.

January 27, 1951

Camaron Beach, Sinaloa, Mexico

This day we all took the boats and equipment to the south tip of Lobos Island. Connie dove with a can of derris root in a little isolated cove, distributing the poison in throughout the water.

I put on a face plate and swim fins and swam around under water among the large rocks. All sorts of fish could be seen swimming among the rocks. The most common large fish was *Microspathodon*, a pomacentiid fish which is blue with long flowing white tipped fins.

A blenny, *Hepatoscartes*, was very common. He is an elongate fish with a steep forehead and pop eyes, colored brown and yellow. These fish sit on rocks propped up on their pelvic fins or wriggle over them. Small wrasses were very common, some are very brilliant. I picked up one little flabby fish that looked like an orange sack of jelly. It was a toad fish (*Antennarius*) and had algae growing on its back.

Gorgonian corals (sea fans) are common on the steep underwater cliffs. These delicate filamentous animal colonies are of several colors, reds, greens, yellows, and white. A large limpet the size of an abalone is quite common on the rocks. I pried off 2 and later cooked them. They tasted like an abalone only considerably stronger.

The diving was most interesting. Schools of a small herring were everywhere. Sergeant majors, a yellow and black barred perch-like fish were very common. We took several spotted moray eels and George saw a green-gray one about 6 feet in length.

At the entrance to the cove sierra (a spanish mackerel) and crevally were leaping and boiling the water as they took the small herring that drifted out. I caught one large sierra trolling through these fish.

We returned to camp very tired from diving.

Later Boyd wheedled Bart and I into going fishing with him. Boyd caught a 3 ½ ft. hammerhead shark (cornuda in Mexican, *Sphyrna tudes*). Shortly Bart became seasick and we started back. A thick fog began to close in around us and before long I lost sight of Orion which had been my landmark. We were in a dense fog shortly and could see only the wake of the boat and the rocket trails of phosphorescence left by large numbers of fish that were frightened by our oncoming boat. We had been out quite a ways and so we expected a long haul. It was longer than we thought. After a time I looked up and

saw stars—Orion was backwards and ahead of us we could see a high rock looming up vaguely through the fog.

Since we were camped on a flat beach with only a small headland we knew we had made a circle in the fog and were headed out to sea. We were looking at Lobos Island. We had apparently circled to the right though there was no real way of telling.

Boyd went close to shore and we crept along till we came to the beach of Venados Island (separated from Lobos by a small isthmus). We saw a small yellowish light gleaming on shore and a fire. It proved to be the camp of a Mexican fisherman Manuel Cardenas, and his young helper Raoul. Both were surprised to see us come out of the fog at this ungodly hour (1:00 AM). They agreed it was not sensible to try to go to shore until the fog lifted. Manuel assured us the fog would lift as soon as the breeze (brisa) came along. They were fishing with taraya nets and spears. They had some small fish and many sierra.

Boyd asked to go out with them to see how the throw net worked. Manuel would not go until it became clearer so we all gathered around the campfire beneath fig and palm trees. Large land hermit crabs were walking all around the area. Manuel called them "Chollolo".

Finally the fog began to lift and Boyd went out in the canoa with Manuel and Raoul. Bart and I talked for a while and then lay down by the glowing bed of coals. We were completely exhausted and dropped off into a sound sleep on the warm sand. We were awakened by Manuel about 3:00 AM and very reluctantly got up. After an extended series of halting Spanish sentences we hired Manuel to fish with us in the Astillero on Monday. He will meet us at Camaron. Bart and I were reluctant to leave our pleasant island and would willingly have spent the night by the fire.

We went through the surf, hauled the boat up and wearily hit the hay about 3:30 AM.

January 28, 1951

Camaron Beach, Sinaloa, Mexico

This being Sunday we packed up and left for Villa Union and the Rio Presidio to do some seining. Villa Union is about 15 miles southeast of Mazatlan on a good paved road. Just before we reached the river we cut westward on a 2 rut carretera to the village of Barrou. We passed through farm lands on a road bordered by many large broad leaf trees and numbers of smaller spiny ones.

Barrou is an adobe village clustered along a wide dirt street cluttered with the usual wagons, horses, and dogs.

We hired a boy to guide us to the river. Our first seining was done in the shallows. We caught several bagre (catfish). Seining some of the deeper holes yielded some gobies and much mud. We left with several kids hanging on the truck.

I spotted a large iguana (3 ½ ft.) (*Iguana iguana*) in a mesquite? I killed him with my shot pistol with excited Mexican children racing all around. This lizard is really quite remarkable. A row of very elongate scales run down the center of the back. The animal has a huge orange dewlap under its chin. The sides of the body are barred black and emerald green and the animal has a very long tail which is not readily dropped. I shot 2 more when the kids pointed them out. The animal is highly arboreal and climbs from tree to tree with much facility. They climb to the top branches and sun themselves. Their

green color makes them difficult to see. I saw one spiny tailed iguana (*Ctenosaura*) running through the bromeliads that covered the thorn forest floor.

We stopped at the river on the outskirts of Villa Union and seined. It was very mucky, stinking, and unpleasant. We were all glad to leave except Boyd who wanted more fish. We arrived home wet and dirty.

January 29, 1951

Camaron Beach, Sinaloa, Mexico

Promptly at 8:30 this morning Manuel Cardinez and his helper Raoul, appeared in camp all dressed up. We were nearly packed and left shortly for the Astillero at Mazatlan. At the boat landing Manuel rented a canoa and went to his house for a spear and taraya (throw net). We unloaded both of our boats (pangos). I set off with Manuel and Raoul in the dugout (made of gua wood, which looks a lot like mahogany). Raoul poled us out across the flats while Manuel threw the net.

The boats are long and narrow and tip easily from side to side but are apparently quite seaworthy as the Mexicans use them in rather rough weather on the open sea.

The taraya is thrown in a very particular manner. The center rope is coiled in the hand and several coils of the net. Then, one coil is thrown over the free elbow and the rest of the net is hung and taken out by throwing the leads backwards around his ankle [drawing]. The net is then thrown by whipping it sideways. The net spreads and falls as a circle of net with the leads on the outside. It is then pulled in slowly, keeping the leads on the bottom until the net is bunched and vertical and any fish therein are entangled in the net.

We caught very few fish by this method. I sat amidships on a few boards and asked questions. We saw many birds and Manuel knew the names of all of them. Ijereta-man of war bird, gavilan de la agua-osprey, alcatraz-pelican, garcita-heron, sopilote-vulture. Mangroves were called manglar.

Later we paddled to the beach where the others were seining and had them tow us up the estero to a place Manuel said was good for our chinchorra (bag seine).

We tried it and were rewarded with a good catch of many species. Manuel knew the names of all the species—even the ones that were hard for us to distinguish. He was really amazing. We followed his directions and were able to seine through rocks without getting hung up. He told us we would get the net full of mud (lodo) if we went out to the end of our seine ropes. We did and got a load of mud.

While rowing the boat along shore I saw a rooster fish chasing a 8 or 10 inch mullet which jumped repeatedly out of the water. The long dorsal fin of the rooster fish cut the water under the fish and finally the mullet quit jumping.

After a few more hauls we went in. We had taken 55 species. Back at camp we were glad to sit around a palm frond fire and watch the centroides scorpions running around.

January 30, 1951

Camaron Beach, Sinaloa, Mexico

This morning we planned to poison near the isthmus between Venados and Lobos Island. Harry Trevellet and his wife Polly asked to use our boat for a little trolling. We

towed one boat with the other. At the isthmus we unloaded, leaving our white surf boat for the Trevellets, who left around the point of the island.

Connie placed the poison in a semicircle along a rocky reef, to a depth of about 15 ft. A slight current caused the poison to drift somewhat but not enough to affect the potency greatly.

The fish began to splash at the surface and we got many good specimens. I used the diving rig last after most of the fish had been picked up and consequently got relatively little. With my very last breath I pursued a ray I had noticed swimming into a crevasse. I pried him out with the handle of my net and scooped him up and then popped to the surface 15 ft. above, gasping for air. The fish was a rare species (there are about 4 specimens known), *Urobatis concentricus*.

Art had been picking up floating fish in the boat and came in with a good series of fishes including a beautiful golden elongate blenny.

We returned to Camaron Beach and Art and I went to tow to pick up gas for the motor, bread, and bananas. The carnival was underway. This affair lasts for 4 days and consists of dancing, fireworks, much high pressure vending by streetside merchants, and considerable drinking—both soft and hard. The fireworks are shot up from several places in town including the plazas, apparently with no regard for where the burning remnants land. All sorts of huge bombs and star shell type displays were fired off. Many street bands walked among the crowds playing. The music was generally awful and I don't wonder. The musicians usually were forced to walk single file down jammed sidewalks, being jostled by dozens of people.

Everything stops for the carnival and we found it impossible to purchase gas from the pumps. Instead we had to buy a 15 gallon drum of white gas for about twice the normal price.

I had the pleasure of watching Art attempt to fade into the crowd. He likes nothing better than poking around Mexican towns, speaking to the natives and soaking up culture at every pore. He is a lot of fun to travel with therefore.

At this particular time he was leaning in a doorway, his straw sombrero tilted on his head, leisurely smoking a cigarette and watching the crowd pass, pleased to note that he was not recognised. The curious eye of a Mexican settling on him would have ruined it for him.

We returned to camp and I worked on fishes with Boyd.

February 4, 1951

Camaron Beach, Sinaloa, Mexico

Early in the morning we packed and drove about 4 miles north of camp to the edge of the beach. Here we loaded up the equipment on pack boards and began hiking through the beach sand. After about 200 yards of this we came to a large landlocked saline lagoon extending a mile or more inland. A high barrier beach blocks the lagoon from ingress by the sea. Only a high tide and storm waves would seem sufficient to flood the lagoon.

All sorts of birds were around the water or in it—8 or 10 blue herons, terns, pelicans, frigate birds, and many smaller shore birds were seen.

We seined the lagoon with the 100 ft. seine and common seine seines and caught many mullet, milkfish (*Chanos chanos*), halfbeaks, and gobies, and robalos.

The water was highly saline. I went swimming and was able to float with my knees, feet, and arms out of the water. I had convinced the rest of the crew it would be little work to carry the equipment in and out and in the course of this argument had promised to pack the 100 ft. seine in and out, if we would seine the lagoon.

The dry seine had been something of a load in the soft sand but the wet one full of sand and sticks was something else again. I made it but it was rough—when Art helped me out of the back board I about took off.

On our way back Connie caught an iguana (*Ctenosaura hemophila*). We planned to eat it that night as everyone wanted to taste the meat (which is very good).

Back at camp we ate lunch and left for the beach to do some daytime seining. Just north of Camaron Pt. we made several sets and took a good series of fishes. Boyd wanted to work the steep beach south of the point so I rowed the boat around and met the others on the beach. The surf was much higher on this unprotected beach and landings were much more difficult.

The first sets produced nothing spectacular so Connie suggested that we set the nets out farther which meant that we would have to wade out into the surf with the rope. Only one person could do this so the first 100 ft. or so were all pulled by 2 people. I took the first rope and got all wet so a couple of other times I did the same thing, going out to my neck—with Connie on the other rope.

We caught some 3 foot white sea bass and other species.

George, who had been protecting his dry T-shirt and hat was elected to take the boat rope on one haul. On the way out I was rowing and a wave broke under us. I was tossed into the bow and George into the stern, shirt still dry.

At the end of the set George was paying out the line when the end came up suddenly. He grabbed the line just as I gave a stroke to catch a wave and he flew out of the boat, did a complete twist and landed in the water—hat and all. Once wet George was in the water all the time—riding waves, hauling lines, and just horsing around.

I rowed back around the point against the wind while George swam.

Before dinner I started to clean the iguana. The knife slipped as I was slitting the tough skin and sliced into my middle finger about ½ way. I dropped the iguana, popped my finger in my mouth and began yelling for some bandage. Art fumbled around and finally produced a roll of unopened bandage.

He looked at it, rolled it around his hand, and finally deigned to open it. I was about ready to yank it out of his hand. Bart wrapped it up tight and I sat down.

Bart and I left after a few minutes for town as he thought I needed some stitches. I wouldn't have bothered but I agreed it needed sterilization as the blood supply to the tip had been badly restricted.

In town we picked up a policeman who showed us to the hospital. It was a large cement stockade-like building group with a barren dirt courtyard. I climbed the step to a door marked oficina and knocked. Finally a woman in a bathrobe appeared. With the aid of Bart and the dictionary I made it known I had cut my finger and wanted to have stitches taken. She said there was no doctor on duty and would be none till 8:00 AM next day. She said the attendant would take care of me, however and directed me to the end of the courtyard. We walked across in the company of a girl attendant who didn't look very clean.

Inside was a vault-like cement room with 3 single lightbulbs strung from the ceiling, a row of simple brass beds on either side of the room. These were occupied by all sorts of very sick-looking Mexicans who looked, in many cases, as if they had walked in and gotten into bed with no instructions. Hats hung on bed posts. The bedding consisted of a single sheet. We walked in through this room and into the operating room. If we hadn't walked through the ward and been introduced to the starkness of Mexican hospitals, we might have been visibly shocked by this operating room. In its center was a filthy operating table with no cloth cover, its paint chipping off. The room, about 10 ft. by 6 ft., sported a waste basket full of garbage. On one wall was a wash basin so dirty I would not have washed in it. Again, a single unshaded light hung from the high ceiling.

The girl started to sterilize her hands by gingerly pouring antiseptic over her fingertips, being careful not to wet her palms. She was being directed by a man whose glasses were so dirty I couldn't see his eyes. His clothes were in keeping with the rest of the atmosphere.

Bart and I asked for the doctor and when we were told he wouldn't be in, we left, my finger untouched thank goodness. It was quite a shocking experience to realize that this was the hospital for a city of 40,000 people—no doctor on duty during the carnival when dozens of emergencies must have arisen.

Bart and I drove up town looking for a doctor. He finally located the "Cruz Roja" (Red Cross) near Olas Altas.

It was a neat place dealing strictly with emergency cases, attended by a businesslike attendant and a clean nurse. He insisted my cut was "superficial" and needed no stitches. He sterilized it with merthiolate and sulfathiazole and then remarked that my 3rd finger needed bandaging too.

I looked and saw it had quite a gash too which no one had noticed. My middle finger had been numb through all this so the only thing I felt was the merthiolate on my 3rd finger. He taped the cut closed. At this time a grimy mechanic walked in holding the pan off of the ambulance to show me the injuries it had sustained. He was covered with grease and the pan was full of large holes.

We gave a donation to the Cruz Roja—they accept no pay—and started to leave when 2 men staggered in covered with blood and screaming incoherently. One had apparently grabbed the knife of an attacker. His hand was slit from wrist to little finger. I asked the attendant if it was superficial—he said no.

Back at camp I ate some belated dinner with Bart and we went out seining, I with my finger up in the air.

We hit the sack about 12:30 AM. My sleeping bag had been left open in all the excitement and was soaking wet with dew. In spite of this most uncomfortable bed and my hand I went to sleep.

February 5, 1951

Camaron Beach, Sinaloa, Mexico

Boyd, Connie, George, and I left camp to do a final poisoning near Creston Island. We left Art and Bart in camp to start packing.

We drove through town and out to the point where we selected an area of rocks and pools in the calm harbor

For a while it seemed that we wouldn't get much but then the species started coming in. Because of my finger I was forced to work the tide pools. Boyd, Connie, and George dove and really brought in the fish. We took 72 species—the largest list to date.

Back at camp we continued packing and prepared to leave in the morning.

February 6, 1951

North of Guaymuchie, Sinaloa, Mexico

After saying our goodbyes we left the palm grove and Camaron and drove to Mazatlan where I sent a belated telegram home. It was the first time I had been in town when the Post Office was open.

The ride to Culiacau[?] was uneventful except that we found our boat trailer slowly falling apart at the seams. We camped in a little clearing in the short tree forest north of Guamuchil. I built a nice crackling fire of palo santo limbs which we all enjoyed. This short tree forest is a fascinating place—full of birds and strange plants. I would like to spend a couple of weeks becoming familiar with it sometime.

February 7, 1951

South of Los Mochis, Sinaloa, Mexico

Today was another day of hard driving over the worst stretch of road we encountered on the trip. It was not bad but was washboardy. A passenger car could make it easily (in the dry season only). We camped in the cactus forest having watched the short tree forest change into thorn forest as we traveled along.

February 8, 1951

Estero San Carlos, Sonora, Mexico

A long day's drive brought us uneventfully to the old camp site before dark. I gathered up a lot of cactus wood—we had a nice fire. Boyd and I went fishing and in spite of a beautiful calm dark night and considerable diligence on our part, we caught one shark (*Mistiles*). We crawled into bed very late.

February 9, 1951

About 30 miles S. of Santa Ana, Sonora, Mexico

First thing this morning we poisoned a deep reef west of the entrance of San Carlos Lagoon. The results, while good, didn't seem like much after our 72 species collection at Mazatlan.

Bart had his first success in using the aqua lung and was completely elated at this success.

We had the help of 6 skin divers from UCLA who were down for the sport. One was a fellow who had been in one of the lab sections I had taught.

March 15, 1951

Enroute to Guadalupe Island, Baja California, Mexico

The present trip is a combined venture of the Marine Life Program and the Division of Marine Vertebrates, Scripps Institution of Oceanography. We are to spend 15 days trawling in Mexican waters. Both deep and shallow sets will be employed. The

deep sets will be set up to 700 meters and will be to collect deep sea bathypelagic animals and to investigate the deep scattering layer. The shallow hauls are directed primarily at sardine research, collecting larvae and eggs.

The nets are a 10 ft. beam trawl (designed especially for deep water work) which is the most effective net yet developed for this sort of work.

This net will also be used for shallower hauls. In addition a meter net for collecting plankton samples. Bathythermograph records will be taken and a program of recording whale noises and smells is underway, using sonar gear and a chemical recording machine.

The ship is the Scripps Vessel, the *Paolina-T*, an 80 ft. converted trawler.

Scientific members are myself (in charge of specimens and records); Bob Wisner, in charge of schedules and the whale program; Lon Kidd, in charge of nets and other gear; Scotty Walker, in charge of meter net hauls and plankton samples; and C. Wilson sonarman and radioman.

A crew of 7, headed by Captain Larry Davis makes up the ship's complement.

At 10:00 AM we lifted the hausers and slid away from Naval Electronics pier. The day was beautiful—clear, calm, and warm. Even when we cleared Pt. Loma the swell was slight. We went straight for Los Coronados Islands and passed between North and Middle Islands.

The thermatow was put over the side. This device records on a graph a constant surface temperature record. It will be in use for the duration of the trip except while we are at anchor.

As the Coronados grew dim on the horizon we came upon our first albatross (black-footed albatross). The grace of these great oceanic birds never fails to impress me.

I stretched out on the fantail and rested in the sun. Shortly I noticed the ship stop and swing around. When I got up to investigate I saw 2 large sei whales about 50 yards to starboard. They were swimming slowly along, rising up and sliding beneath the surface. First the snout comes to the surface. The snout-valve opens and the beast "blows" a misty spout into the air and then the animal slides up, revealing the small dorsal fin. The tail flukes can be seen only when the animal sounds [drawing].

The whale is dark grey above and light underneath. Twice female grey whales were seen with calves. About 3 mi. south of Pt. Loma grey whales were seen to turn on their side putting a huge flipper into the air between our ship and the calves. Whether this behavior allows the young one to nurse or is for its protection is not clear. All the whales were going northward.

I climbed the crow's nest and was able to see any invertebrates floating in the clear water—jellyfish, salps (borderline vertebrates), and some sort of large coiled egg case. These were 6 in. or so across and a translucent pink color.

At 5:00 PM we finally got the big net over the side and had the satisfaction of seeing it sink, unfouled, into the clear blue water. 1800 miles of cable were let out which will place the net about 375 meters below the surface.

The seas became rougher as the wind picked up. We began to get a small scale dose of the *Paolina T*'s rolling capacity. At about 9:30 we decided to haul in the trawl. Bringing up the net was much more laborious than . . .

After nearly an hour we called out "sight!" as the swivel hove in view.

The net came over the counter and I could see some of the deep sea creatures clinging to the mesh. The bag was filled with salps, a very primitive chordate. It looks like a big blob of jelly with a hard shell-like structure in the center.

We piled the contents into trays and began sorting. There were several different kinds of fishes—deep sea smelt (*Leuroglossus*), a little lumpy angler fish that was all head, long attenuate snipe eels with peculiar spreading beaks, little lantern fishes, and the bizarre hatchet fish [drawing]. All had their complement of light organs—all directed downward.

The roll of the ship swashed the contents of the tray back and forth in front of my eyes as we sorted—mal de mar began to set in and I finished the job in a rather sorry state. I stood up in the port passage way in the stiff breeze until I felt a little better—then I crawled into my sack without bothering to make it up.

March 16, 1951

Melpomene Cove, Guadalupe Island, Baja California, Mexico

I woke up this morning feeling much improved. Bob Wisner decided not to put the net over on account of the wind and sea.

Early in the afternoon we sighted Guadalupe Island. The crest of the island was hidden in fog. The lower portions looked very precipitous. Sharp pinnacles stand up from the almost vertical cliffs.

As we came closer the variegated layers of lava forming the cliffs could be seen. We cruised down the east side in a fresh breeze. Finally we came into the lee and the sea became calmer. On the crest of the ridge there are several patches of pine forest to be seen. The trees look scattered for the most part though we did see one rather dense stand. In the mouth of a canyon below one of these groves we noted a patch of green vegetation.

I looked through the field glasses and noted 2 houses—both small white buildings just above the seashore, among this vegetation. The only approach to them would be the sea and then over a rough surf and rocky beach.

Toward the south the island becomes less precipitous, consisting of a series of rugged lava flows sloping off into the sea. Nowhere are beaches of sand to be found. The best landings are over large cobbles.

As we approached Melpomene Cove at the south end of the island, cinder cones became a prominent part of the sky line. The small vegetation is very sparse and mostly confined to the canyons as far as we could tell from the sea.

Melpomene Cove is flanked by high basaltic cliffs and precipitous tufa slopes. After some indecision and searching we decided to anchor in the cove in spite of the breeze flowing offshore. It was the only place we could find offering water as shallow as 10 fathoms a respectable distance offshore. The west limb of the cove is limited by three islands—all precipitous.

During the day we had seen some interesting birds—beautiful young Bonaparte's gulls, black-footed albatrosses flying close to shore, and Xantu's murrelets. This latter bird may have been a Cassin's murrelet as our observations were from some distance.

Scotty Walker and I decided to try to reach one of the islands. I wanted to get ashore to look for lizards. In the '80s a lizard was reported from Guadalupe Island but subsequent parties have failed to find any reptiles. Slevin attributes their disappearance

to feral cats, which run wild over the main island. As they are not present, the lizard, I think, may survive on these isolated islands.

After much trouble we got the 16 horse power motor mounted on the little skiff. The skiff is very light, a 5 horse motor would be quite large enough but we had to use the large one. I was unable to increase the speed above starting speed to slow speed without seriously endangering the boat in the windy sea. We cruised westward toward the island and could see that its eastern face (the one nearest shore) was one large cliff of reddish smooth rock which had spalled off huge crescents in places, leaving overhangs. It rises straight out of the water.

We noted that the point of Guadalupe nearest this island supported a small cluster of houses. I turned the boat towards them and we saw some men in denims walking between the shacks—there were no boats visible. An anemometer spun on top of one of the houses. All were built on a little point of land entirely composed of basaltic boulders. A crude pier of stones protrudes a few feet into the water. We were picked up by the surge and deposited rather roughly on shore amidst rocks and Mexicans.

The inhabitants told me that there were 3 men here acting as weathermen and the others were fishermen (about 25 in all). One fellow offered to get us all the abalone we could use. He said black abalones were common around the shore and the yellow ones in 1 to 3 meters of water. I was told the blue fin tuna were biting at night when the moon was not out. No one remembered Dr. Hubbs, who was here a year ago.

As it was getting dark Scotty and I decided to go back to the *Paolina-T*. I could see that the west slopes of the small island were even more precipitous than the east—being a huge 200-250 ft. cliff rising straight out of the sea almost to the crest of the island. A lizard would have a sad time trying to climb it.

Going with the wind we made good time and were soon hoisted aboard—after another bout with the heavy motor—this time to get it off and aboard.

At night we lowered a 250 watt lamp and reflector over the side and collected a few blenny larvae, some isopods, a squid, and a series of little crabs with gleaming greenish eyes. Later we took a few horse mackerel with hook and line.

Notes and general bull sessions occupied the rest of the evening.

March 17, 1951

At sea enroute to Punta Abreojos, Baja California, Mexico

Before I got up I could feel the ship get underway and see the volcanic cliffs of the cove slipping past. We set out to sea along the lee east side of the island and set the trawl down. Our first set was made in 600 fathoms of water with the net down 200 fathoms.

After a 2 hour haul through the grey sea we hauled the net up and over the counter. There was relatively little in it. A few deep sea fishes (*Vinciguerria*) and many interesting invertebrates. Several *Phyllosome* larvae (the pelagic larva of the spiny lobster) were taken. These creatures are virtually invisible in the water as they are completely transparent. The main body is round and thin like a circle of thin celluloid, with a small jointed tail appended. The eyes are on long stalks and very long crystalline legs protrude. The whole beast is possibly 2 ½ in. long.

We suspected that our haul had not been deep enough as the water is amazingly clear, so our next haul was taken in 1,000 fathoms with the net at 500 ft. By the time the end of the haul had been reached we were in a great rolling sea—huge ground swell

coming in from the open ocean unchecked by the island. We took many fishes but nearly all were badly battered, apparently by the sides of the net bag rubbing together over the catch. One 8 in. fish with great teeth and a long barbel protruding from its chin was taken. The barbel was tipped by a bulbous purple light organ. Many battered lantern fishes (Myctophidae) and small stomatoid[?] fishes were captured.

We turned the little rolling ship and began to run southward with the swell and wind. The ship rides much more comfortably this way.

Lew and Bob and I installed a 5 gallon can in the end of the net, its bottom perforated by holes. This improved our catch a great deal, though most of the fishes slipped down around the outside of the can, under the mesh.

Lew and I put the net down, taking turns with Knox, the winch operator. We lowered it until 3,500 meters of cable were out, or converted to depth about 600 fathoms or so. It was past 1:00 AM and we all willingly secured and hit the sack while the *Paolina* chugged on at 4 knots.

By the time I got up in the morning the net was on its way up. It contained relatively few animals. Probably the fish move surfaceward at night and most of our fishing was done in sterile water.

The tedium of shipboard life is beginning to set in. The lack of space is acute. All sorts of gear littler the deck space. I notice the lack of exercise greatly.

To stand up on the bridge of this little ship, feeling the slight swell cause her to roll, and seeing nothing but limitless ocean, makes me wonder what we are doing out here—especially when we creep along under 4 knots with the net in tow. It seems a little presumptuous somehow. We haven't passed a ship since leaving the vicinity of Los Coronados Islands.

Routine is quite lax though adequate, compared to that I used to experience in the Navy. At night the ship is in automatic pilot (it is always in automatic pilot except when we anchor) and the anchor watch consists of one man who, like as not, spends his watch drinking coffee in the galley or reading Thorn Smith novels. When we are towing, flood lights are rigged to the booms aft and light up the whole stern of the ship.

We are not maneuverable with 1,000 meters or so of cable and a net astern and we travel very slowly. One can watch the long ocean rollers sweep past and look down the huge wave troughs.

I am reminded of how easy it is for chiefs in the Navy or on board this vessel to be fat. Virtually no exercise and 3 huge meals a day. Today we had rolled flank steak for lunch (dinner) and a half chicken fried for dinner (supper) with mashed potatoes, 2 vegetables, and chocolate cake, and milk. Thanks to Dramamine I eat heartily.

We made 3 more hauls today and got a good many deep sea fishes—chiefly lantern fishes and *Cyclothone*. We got a few good specimens of large species, one with a large barbel on its chin [drawing].

The sun was shining brightly and we were able to lie on deck while the net was being towed.

March 19, 1951

Enroute to Punta Abreojos, Baja California, Mexico

Another day of towing! Waiting between hauls and while the net is down—reading and sunbathing. Two of the fellows—Mac and Oolie, went over the side and swam alongside and used their paddleboard.

Scotty Walker spotted a sunfish (*Mola mola*). This peculiar fish swims along with its long sharklike dorsal fin out of water, flapping lazily from side to side. Sometimes the fish swims upright and sometimes on its side. The fish swam amongst 4 blackfooted albatrosses who were sitting in our wake. The birds took little notice of the fish (about 10 lbs. or so) at first and then swam over to it, peering at it from a distance of a few inches. Possibly the birds were searching for parasites to pick off.

Scotty and I fed the albatrosses bread soaked in cooking oil. Four of them came up and at once established a definite peck order—one large individual whistling painfully when any of the others got a piece of bread. He swam and ran over the water at these other birds with his beak open, screaming at the injustice that had been done him. The least aggressive bird sat 100 yards back in the wake and dove for pieces that floated his way.

The way these birds run and slide across the water is remarkable. They actually run, while using their wings and —plane to a halt by raising their toes and sliding over the water until momentum is lost and their feet sink. They always seem to run when taking off the water.

We made one long deep haul (about 1,000 fathoms) and a short 50 fathom haul. The former was relatively unproductive, possibly indicating that what we did catch was taken on the way up or down. The shallow haul failed to produce any eels or memlamphids and contained many lantern fishes. It seems evident that in the daytime we take more fish of more different kinds at 250-500 fathoms than in other layers. The 5 fathoms haul was taken after darkness and possibly represents a differential vertical movement of bathypelagic species—the lantern fishes moving close to the surface while the others remain below.

Hatchet fishes seem to be rather uniformly at fairly shallow depth—200 fathoms or so—and possibly as their structure suggests, live just at the lower limits of the photic or lighted zone. Their eyes are directed upward as if to aid in capturing food by use of shadows cast by light from above. Their photophores shine downward.

It is now 11:00 PM and we have secured the trawl and are proceeding at 8.5 knots to rendezvous with the *Horizon* for a combined operation.

March 20, 1951

Enroute to Punta Abreojos, Baja California, Mexico

I slept till about 8:00 AM as there was no trawl down overnight. As soon as we got near our rendezvous point with the *Horizon* we put the net over the side and began towing. We have been towing a temperature device (a thermatow) behind the ship that gives us a constant graph of ocean temperature. It read 17.4 degrees so I decided to go swimming over the side. Oolie and I lowered a rope from a davit and he climbed up the Jacob's ladder leading to the crow's nest and jumped off from about 30 feet. He made a grand splash in the blue water. The water is so blue that it looks opaque unless something floats by under water and then it can be seen at 40 feet.

I dove off the railing. Before long we had enticed Scotty and Lew in the water. Lew made the mistake of diving off the stern railing. He had a little trouble catching up with the slowly moving ship.

A pair of red billed tropic birds flew over. These pretty white birds have a long pair of streaming tail feathers and a bright red bill. They constantly flap their wings in flight and never seem to glide. Their wingbeat is quite rapid.

Our evening hauls were quite successful as we brought in an eel and a peculiar fish with a hooked beak which we hadn't seen before.

March 21, 1951

Enroute to Punta Abreojos, Baja California, Mexico

We were routed out of the sack at about 4:00 AM when the *Horizon* hove into view. Scotty put out a plankton net while we waited for the *Horizon* to put down her deep cast (Nausen bottles and thermometers). About 5:00 AM we put the net over the side and lowered it away—to 4,500 meters of cable out—or a depth of about 1,040 fathoms.

About 11:30 AM we began hauling in and 4 hours later the net was on deck with some very interesting fish—a hake (*Merluccius*), several Melamphids—a fish with a peculiar knobby bony head, black from snout to tail and a grenadier. This latter fish is a surprising creature with a lumpy body tapering to a long rat tail. These fishes occur over the whole world in deep water I believe.

The tow took 4 hours coming in and in the meantime we did a little swimming over the side.

In the evening we lay to while Lew and Bob ran some tests on net floats, testing their breaking strength by lowering them to great depths and recording their explosion (implosion might be a better word) on a hydrophone.

This work relates to some deep water hydrographic sampling gear that is being developed. The floats are to be broken when the gear reaches bottom and the noise picked up—thus the operator can stop letting out cable at the right time.

During all this I lowered a light and Scotty and I dip netted saury larvae from the water. We also collected a number of swimming crabs for bait. These pelagic crabs are quite interesting animals. They swim by a combined action of flipping their tails and bringing all their legs in at once. All the appendages are fringed with filaments, which probably aid in flotation. The crabs are orange red and very numerous in the water at night, swimming at the surface and as far down as you can see.

We put the net down as deep as we thought safe (5,040 meters) and repaired to the gallery to discuss this and that and write notes.

March 22, 1951

Enroute to Punta Abreojos, Baja California, Mexico

Spent the day and evening towing the net and working on specimens. Our last tow came up with tight kinks in the last 10-15 meters of cable so we were forced to lay off from further tows at 12 midnight. The water has shoaled up from an even 2,000 fathoms to 100 fathoms or so as we came over the continental shelf. Swimming crabs passed us in windrows at times early in the evening. Their total numbers must be literally incredible. I figure that there were 12 per sq. yard in sight at times tonight with

concentrations much higher than that. For days we have been steaming through waters that might average one crab per 12 sq. yards of surface.

I am now of the opinion that the filaments on their appendages may serve in filter feeding in addition to the possible service as flotation mechanisms.

The crew is beginning to emerge as a collection of rather rare birds. A scientific ship such as this seems to attract certain sorts—take the cook Stan McDade (24 years) for instance. He has been many places and done many things. He has prospected in Nevada, dug Indian relics for museums, collected snakes for a reptile institute in Brazil, and been to sea in many places. He knows something about a lot of things. He has missed his education and has hopes of returning to school, though he admits the call of far away places is stronger. He wears a little pointed beard and smokes weird shaped pipes.

The skipper—Larry Davis (35?)—is a most intelligent fellow. He has spent considerable time in the merchant marines and has been all over the world. He has been chased by jackals in Portuguese East Africa, been in several jails up and down the west of North America. He has the ability to make the most commonplace incidents into hilarious adventures. He is a rather slight, curly-headed fellow with a constant smile. He too entertains ideas of continuing his education in some phase of marine science.

Bob MacClendon, better known as Mac, is one of the seamen. He is part Indian and part Irish. His vocation is beach bum. Mac is a very smart lad of 22 or so who spends most of his time carousing around or surfing. Larry is teaching him navigation and it is amazing the way he catches on. He seems to feel some pangs of wanting to settle down to some type of study but the beach boy element is stronger—playing the ukelele and drinking beer. He lacks confidence in himself or he might well start in college.

And then there is Uli (Eckstrom)—a real beach boy concerned with little besides raising hell and making various sorts of jokes. He is sleepy looking all the time and in a constant good humor. He too is bright but seemingly ambitionless with the exception of his avowed plan of marrying an old rich widow, waiting until she dies, and “having himself a ball” with her money.

March 23, 1950

Asuncion Bay, Baja California, Mexico

I awoke with the winch operator, Knox, poking me, saying land was in sight. I finally hauled out of the sack and went out to see Punta Abreojos heaving in view. The bay at Abreojos opens to the south, a long, low sandy point rises to a long abrupt escarpment. 5 or 10 miles behind the beach this level country rises to a series of rather abrupt volcanic mountains—1,000 feet high or so. Behind these the rugged Sierra Vizcaino can be seen. We anchored in the cove about 500 yards offshore from the little cluster of shacks that make up the fishing village of Abreojos. Up on the rise above the town is the light house.

Most of the crew went ashore to the town. Scotty and I went ashore to a group of beach dunes about 500 yards down the beach from the fishing camp. Lew took us through the surf in the little skiff. The waves were fairly high and we caught one over the stern right down my back—in spite of the water we shipped[?], we got in all right.

The dunes are about 10 feet high and vegetated with *Atriplex* and other low perennials.

We dried our clothes out on the dunes and then went out hunting lizards. We saw many *Callisaurus d. crinitus*. For the first time I saw them burrow in the sand. As far as I could tell this burrowing was much like that of *Uma*. The day was quite cool and the sand only warm, not hot. Perhaps the animal is only able to burrow under certain temperature conditions. We took a *Cnemidophorus tigris* and a *Sceloporus m. rufidorsimus*. Scotty showed me where the *Sceloporus* had run down a kangaroo rat burrow. I dug it out and Scotty yelled "snake". When I recovered I saw a torpid *Chilomeniscus cinctus*, the banded burrowing snake, lying there in the sand. From its torpid condition—it was barely able to move—and judging from its empty stomach and emaciated body, I judge it had not yet emerged from hibernation.

We walked along the beach a ways toward the village. We lit a fire and piled *Salicornia* on it—making a lot of smoke. This was our signal that we wanted the boat to come in for us. Very shortly it began coming in and we were back on board. The boat pulled out for Asuncion Bay almost immediately—and better fishing.

As we rounded the point a school of *Delphinus bairdi* came leaping and swimming toward the prow. There were about 40 or 50 of these porpoises.

Their markings are something like this [drawing]. They rolled over on their sides and seemed to swim along at 8 knots completely effortlessly.

Larry shot a shearwater with the 30-30. The bird was nearly untouched and apparently killed by the concussion. It seems to be a pink-footed shearwater.

After a short run through a beautiful moonlit sea we anchored in Asuncion Bay. I immediately lowered the night light and we took a few interesting fishes—an eel, a halfbeak[?], a young *Sebastes*, and some larval lizard fish (*Syrodus*).

Lew and I took the skiff and went fishing in the kelp beds nearby. I got one strike that took off my hook but we landed no fish.

To bed.

March 24, 1951

Asuncion Bay, Baja California, Mexico

When I got up the ship was underway for San Roque Bay, a few miles to the north. Scotty and I got together a lunch and various gear to go ashore—including my shot pistol and rifle. We were to land on San Roque Island to look for a rare color aberration of the Heerman's Gulls that nest there. This consists of a few white fathers or a patch of them on the greater primary wing coverts. It seems to occur on one bird in about 1,000 or so, so I understand.

We rounded the north tip of the island and launched the skiff.

Scotty and I began rowing ashore. As we got to the kelp beds we were met by a skiff containing a man and boy. The man seemed quite excited when he saw I was going to land on a nearby steep pebble beach. He tried to make it clear that I should follow him around the island to the lee side. He even offered to tow us. I was in no mood for a long row so I continued on toward the beach. He got more and more excited saying "peligro" and telling me that the cormorants (patos) and gulls (gaviotas) would all fly if I landed. This didn't make much sense to me as the beach looked safe enough and I wasn't worried about the birds flying.

Finally I began following him and presently we came to a sheltered pebble beach below a group of buildings and a large corrugated iron shed 500 ft. long by 70 ft. wide.

He finally made it clear to me that San Roque is a government-owned island and no one is allowed to set foot on it in any place except the building area because it is a guano reserve. The keeper said Asuncion Island, Natividad Island, and San Geronimo Island were also government owned and protected. No shooting is allowed and even the caretaker doesn't visit any part of the island except in August after the birds have left. At this time a crew of workers pick up the guano with shovels and sack it up and store it in the large shed. He said that last year they had taken 4,000 bags of 40 kg. each (about 100 lbs.) of guano off of the island.

We were able to search most of the island with the glasses. There were many hundreds of Baird's cormorants sitting in groups. They have emerald green throat membranes.

Many many western gulls were scattered over the island. There were a dozen young gulls—a dark brown overall, that were probably young Heerman's gulls, and there were 6 adult Heerman's gulls—none with any white feathers in their wing coverts.

The keeper informed me that the gulls arrived in large numbers in early April and were present in large numbers until late July. They laid many eggs and the island was thick with chicks from mid-May on he said.

The only lizards I saw were *Uta stansburiana*, and these were exceptionally numerous. Two little kids caught about 15 for us by placing a five gallon can on the ground on its side by the corner of the houses and chasing lizards into them and then righting the can. We had a cup of coffee and then looked at the weather recording instruments he tended—an anemometer, a hygrothermograph, a max-minimum thermometer in a standard weather shelter, and a rain gauge. He had a new zenith transoceanic radio which wouldn't work and I told him I would try to get someone to fix it for him from the ship.

We left the island and rowed around it to some kelp beds. Scotty fished while I looked for birds through the glasses. He caught no fish and I saw no Heerman's gulls. Finally I rowed back near the landing and we caught some parrot fish and blacksmiths in the kelp.

A storm was approaching so I hauled in the anchor rope (tied to kelp) and rowed over to meet the *Paolina-T*, which we found around the point of the island.

San Roque Island is a crescentic rocky island with a few rugged pinnacles on its northern end which may be 50 feet above sea level, and a long, nearly level area on the south half where most of the gulls were sitting. There are only 3 pebble beaches that seem approachable [drawing].

Back on board we found that the radioman was asleep and when awakened, didn't want to go ashore.

We tried to catch schooling fish with the trawl with no success. The schools sounded at our approach and part, leaving the school on either side of the ship but none behind us in the trawl.

We sailed through a great raft of cormorants—there must have been 2 or 3 thousand birds. We sailed right through the raft and split it in 2. The birds dove and came up away from the ship—like the fish.

In a while we anchored near the north point of San Roque. I took the skiff and motor and inspected the entire seaward side for Heerman's gulls without noting any but a few young birds.

I returned to the ship in the face of a stiff breeze. It was rough going in the little skiff. On board they had been catching whitefish (*Caulolatilus*) and sheepshead, in good numbers.

We returned to anchorage at Asuncion. Scotty and I went ashore with some lysol and concentrated formaldehyde to see if we could poison a tidepool. We found one deep one with eel grass in it and caught a fine series of rudder fish (*Hermosilla*) and opal eye (*Girella*). The poison did not work very well but confused and blinded the fish somewhat so that we were able to dip them up with little trouble.

There is a small fishing village on the point and we got one of the Mexicans and his son to take us back to the ship. The old man pushed the oars while standing while the young boy rowed in the bow. The old man had his oars slanted at a very steep angle. Both took very short strokes. We gave them some canned goods for their trouble. We dip netted until 10:00 PM and hit the sack.

March 25, 1951

Turtle Bay, Baja California, Mexico

We shoved off from Asuncion Bay early in the morning and proceeded up the coast toward Turtle Bay. The coast line is exceptionally rugged. Volcanic peaks come right down to the sea. 2 sea level lines can clearly be seen along the coast for miles—one a 50 ft. above sea level line, and the other one less distinct at about 150 ft.

After 3 hours steaming we came to a peninsula which at first sight, looks like an island. It was Thurlow head, the south limit of Turtle Bay. Shortly we steamed into the bay, past the white coffin (a white guano-covered rock) and anchored off the kelp beds near the old cannery.

3 small fishing boats were in the bay and an LCI.

The bay itself is roughly circular and is largely landlocked. Much of it is 4-8 fathoms deep with a sandy bottom, affording an excellent anchorage. In a gap between two ridges of mountains on the north shore of the bay there is a group of 20-30 houses and an abandoned cannery.

Scotty and I went ashore west of town. We poisoned a small pool and collected a very few fish (*Gibbousia*, *Clinocotters*). Being out of poison we began hiking up a wide mouthed canyon. Nearly all the vegetation is concentrated in river bottoms—though there is no surface water. Everything is parched. Elephant trees, ocotillo, burrow weed, goat nut, barrel cactus, *Cereus* cactus, and many small shrubs I couldn't identify grew in the wash. As we continued up it, it grew narrower, and the walls steeper. In places the steep hillsides were literally covered with a low grey-green lichen.

We passed through areas where cliffs were exposed and we could see an underlying yellow shale, an unconformity and alluvial gravel on the surface. Some mud stones we saw were shot through with selenite—in some places 2-3 in. thick. We hiked nearly to the crest of a rugged peak—climbing over a couple of dry falls enroute. On the way back we stopped and dug out a *Salvia* (sage bush) for Dr. Epling that may be the species he is trying to obtain from Baja California. I toted the plant down the canyon in a pillow case I had brought along with about 30 lbs. of dirt and rocks in it.

Scotty yodeled at the ship and the skiff came in shortly and took us back out.

After dinner Scotty and I tried our luck shooting bats with the shot pistol as they flew around the larva trap light. This trap floats on the surface and is attached to the ship

by its light wire only—so it is often quite a way from the ship, depending on currents and wind. Finally, after some time I hit one and it began drifting away. Scotty jumped in and swam after it. I hauled him aboard with the bat. A little later he shot one and it drifted way out. I jumped in and retrieved it.

These bats are most interesting. They are quite large, having a wing spread of possibly 20 inches. The dorsal color is dark brown and they have white belly fur. I noted them flying over the water dipping their tails into the water at intervals, for a brief moment. One flew over with a shining little fish held in its hind feet. Thus we determined that they were fish bats. Their uropyquim[?] (tail and membranes) and hind feet are quite modified for fish catching. The tail is long and curves inward toward the belly and the tail membranes are quite voluminous and form a little pouch when the tail is curled. The membranes are supported by 2 processes from the hind feet in addition to the tail. These processes help to produce a pouch. Thus the animal has an efficient fish scoop. The hind feet are large and long and end in very large curving claws.

Small fish are scooped up by a quick motion of the tail. Then they are probably picked out of the tail pouch with the hind feet and eaten. A large process extends from the wrist of the hind feet and aids to keep the scoop open [drawing]. It seems impossible that these bats could locate fishes on the surface by echo location. How they do it in the dark is a mystery.

We noticed some small 6 legged parasites that are reminiscent of spiders, crawling around over the bats.

Most of the crew had gone ashore and had narrowly missed a bar-room brawl instigated by an Americano-hating Mexican. Notes, dip netting, preserving, tagging, and the sack.

[Drawings on following page of murrelet and man with a pipe.]

March 26, 1951

Anchorage south of Middle San Benito Island, Baja California, Mexico

We left Turtle Bay early in the morning and proceeded out to sea toward San Benito Islands. We each took a turn in the crow's nest looking for whales.

We sighted several blue whales going north off shore from Natividad Island. These are huge beasts, greying blue in color and having a ridiculously small dorsal fin. We clocked one at 7 ½ knots. We spent some time tracking the beasts on our sonar gear and even got one on the fathometer as he passed under the ship.

Natividad Island is a long rugged narrow ridge off Pt. Eugenia a few miles. Beyond it to the north we could see Cedros Island, whose rugged skyline stood above all of Natividad. We cruised to the seaward of Cedros. It is rugged and evidences of volcanism can be seen along the coast. Two main peaks may be seen—one in the north (3,000+ ft.) and a southern one (3,800+ ft.). I could not see the pines on these peaks but could make out dark vegetation on the higher slopes.

After a while we could see the volcanic peaks of San Benito. There are 3 islands—a large western one about 600 ft. high, a low fat middle island, and an eastern island formed from 3 volcanic cones. We anchored south of the middle island in the kelp beds.

Scotty, Bob, and I went ashore on the middle island there were a great many sea lions hauled out on the beach and rocks. They were on all parts of the shore. We came

upon several groups of sea elephants—mostly calves and cows. We saw 12 bulls in all and probably 85-90 cows. Scotty and I hiked around the island and succeeded in collecting a small series of *Uta*. The animal is larger and darker than the mainland form.

Only very low sparse vegetation grows on the island. A species of *Mammillaria* cactus is exceedingly common. As Scotty says the groups look like big cells in the process of division [drawing]. Most of the bushes are densely festooned with lichens. There were 2 species of *Opuntia* cactus and a malvaceous plant with a large blue and white flower like a hibiscus.

On board we put the light over and began dip netting. Xantu's murrelets and black petrels (a dark sooty black bird) began to fly aboard. 15 or 20 of these little birds must have been on the ship during the evening. It was easy to pick these birds up and set them loose over the side. I imagine they were dazed by the light.

A short poker game, notes, and the sack

March 27, 1951

Enroute San Quentin Bay, Baja California, Mexico

Early this morning Lew, Bob, and I rowed into the little fishing camp on West San Benitos and enquired about bait schools. They informed us there were very few in the vicinity of San Benito Islands but were plentiful east of Cedros Island near Morro Redondo. I bargained for the little kids of the camp to collect lizards for me to be picked up the next day. I left a pillow case with them to put the animals in. They said there were 3 classes of lizards on the island. As far as I know only *Uta stansburiana* has been taken from the islands.

We hauled up the anchor and proceeded straight for Cedros Island. When the ship crossed the 1,000 yard line (from shore) we began proceeding southward along the coast toward the point at the south end. The island is very rugged on the north end. We could see pine trees fringing the skyline of the northern peak and down in the saddle to an elevation of no more than 1,000 ft. Other than these trees the island appears rather barren and clothed with small shrubs.

I stood a watch in the crow's nest, relieving Bob Wisner. We were watching for whales, porpoises, and fish schools. I saw none of these during my 2 hours.

We rounded the south end and then Morro Redondo on the southeast corner of the island. We saw an airplane land on the point. Shortly we saw the village of Cedros. The houses are laid out regularly. A twin-spired church, a pier, and 2 large corrugated quonset huts of the abalone canery.

The ship was joined by a large school of striped porpoises (*Lagenorhynchus obliquidens*). The speed these animals swim with a minimum of tail motion is remarkable. In keeping up with us (7.5 knots) they made about 100 tail beats per minute. When leaping clear of the water they seemed to vibrate their tail from side to side just before leaping.

Our net hauls for sardines or other bait fish have been completely unsuccessful so far and I doubt that we will have any success except under unusual circumstances. The schools are frightened by the boat and sound before the net reaches them. Further, the schools split and the net passes through clear water. The net goes a maximum of 6 knots and these fish must be able to escape the net readily. Possibly if bait are being forced to

the surface by feeding fish and by gulls from above then we might catch a few bait fish. As a tool for studying bait fish I think the net is virtually useless.

We cruised up and down the lee side of Cedros looking for schools and finding none. We anchored in a small cove just south of the north end and had dinner.

Lew and I went up the Jacob's ladder to the crow's nest after dark and looked for phosphorescent schools. We saw about 65? porpoises come racing in to get in our bow wake. They look like torpedoes as they race through the water. We saw no schools. On the advice of an Italian fisherman we proceeded toward the cannery for bait schools. We had visited the yellowtail boat St. Rita. Joe Corona, the owner, had told us about wrapping up bait at the cannery. They put out a skiff with a light and when the bait rose the boat laid the net around the skiff and the bait was brought in. He gave us a stiff shot of whisky and we were off.

Still no bait! Our schedule will not permit us to return to San Benito Islands, much to my regret. I hope my young lizard hunters aren't too disappointed. However the fishing comes first and we want to chase schools at San Quintin so off we go.

To the sack about 12:30.

March 28, 1951

Enroute to San Diego, California

Most of this day was spent steaming along northward, out of sight of land. We passed Isla Geronimo. It is a small island with 2 low peaks and some outlying rock reefs. There is a house on the south end. Along the coastline near Rosario I could see 5 sea terraces along the shore. The highest is probably about 1,000 ft. above sea level. Many subsidiary terrace levels can be seen between sea level and the lowest major terrace.

About dusk we hove in view of San Quintin Bay and put the net out for bait hauls, to a depth of 6-8 fathoms. We ran through kelp on the first haul and took a few anchovies, a midshipman, and some larval flatfishes. One more haul produced nothing but salps, one midshipman, and one larval flatfish. With the net on board I gladly went to bed as we started northward.

March 29, 1951

Ballast Point, San Diego Bay, California

When I hauled out of the rack this morning we were off Punta Santo Tomas. The ship continued steaming northward through calm seas, past Todos Santos Islands, and then Los Coronados hove in view.

We washed the ship down from stern to stern with soap and water and secured all the nets and cables. A little after dusk we pulled into San Diego Bay and anchored adjacent to Ballast Point to await customs in the morning.

Bob and I put the light over the side and shortly Scotty and I began to catch anchovy larvae in numbers. We caught our best dip net collection in a couple of hours as far as numbers of individuals are concerned. There were pijoe[?] fish, anchovy larvae, *Atheriopsis*?[?] larvae, and adult anchovies. These adults were feeding voraciously on the larvae. I caught 3 on a small hook baited with a larva. Anchovies are supposedly filter-feeders and to see them striking at larvae like trout was something of a surprise to me.

A poker game (I won 60 cents in beans) and notes.

A purse seiner hauled alongside and asked for fuel. They had bent their screw and had run short enroute to San Pedro. They had been to Panama fishing for tuna. They have 120 tons on board a ship like ours (a load limit is supposed to be 57 tons). Their net is a 375 fathom net (4 inch mesh) 35 fathoms deep. They simply wrap a school of tuna and purse the net and haul the fish aboard. The net cost 25,000 and lasts a year they said.

Poulsen decided we could sell them the fuel so they pulled alongside in their tuna tender with barrels for the fuel. As it is now about 1:30 AM I will fold up my tent and silently steal away to the bunk.

April 14, 1951

Russel Palms Oasis, Riverside County, California

Connie Limbaugh and I left Van Nuys at about 9:30 AM and drove to Redlands and to Palm Springs. Skies were overcast as far east as about Ontario and sunny the rest of the way. A wind of 25-30 mph was blowing out of San Geronio Pass and out over Coachella Valley.

We tried collecting *Dipsosaurus* on the dunes but the animals had apparently been driven underground by the wind.

Air temperatures were warm enough for *Dipsosaurus*—we saw several *Uma*—but none were in evidence.

The effects of prolonged drought are evident on the dunes. The creosote bushes in particular, showed the effects. Second growth had come up from the roots inside the old dead stems and this too had dried up. Only those plants near water or along the road were green and blooming.

Dipsosaurus populations may well be fluctuating strongly as climatic shifts occur. In view of the fact that hibernating juveniles are generally in very poor condition at emergence in spring, they may or may not be able to survive, depending upon the humidity and their immediate source of moisture. A dry year might largely eliminate an age class by this means.

The adaptations of desert animals to aridity might be progressing with the changing climate—as the climate becomes more arid the animals continue to adapt to it. Their adaptations at any one time may give them little lee-way in which to survive.

Connie and I drove across the valley floor and up 1,000 Palms Oasis Road. We talked briefly with Paul Wilhelm. He apparently has sold a part of his ranch though I may be mistaken.

We met Ross Hardy and a class of 35 students. He had had little luck with his collecting.

We went for a swim in the pond at Russel Palms, went for a hike, and ate dinner.

Then we went downstream in search of *Bufo punctatus*. We found one adult male and I could verify no calling though Connie thought he heard a brief call. *Hyla regilla* were common and calling. Their tadpoles? were in the stream as were newly transformed

young. We saw a pair in amplexus. We collected some tadpoles and retired to the campfire.

April 15, 1951

La Jolla, California

Very successful collecting southeast of Indio. We took 20 *Dipsosaurus* in a region of *Atriplex*, *Franseria*, and *Larrea*. The lizards were very closely associated with the *Larrea*.

April 25, 1951

At sea, SW of San Clemente Island, California

This trip is to last 10 days and is to take us 700 miles off the coast and back. It is sponsored by the Division of Marine Vertebrates, Dr. Hubbs in charge. We are on board the *Paolina-T*, a converted trawler about 87 feet in length. The objective is to make a series of hauls with the mid-water trawl just off the continental shelf, in the center of the California current, and just outside the current. We hope to find out something about the density of the bathypelagic fauna in those regions.

We loaded and left Pt. Loma shortly after 8:00 PM today and proceeded out into a choppy sea. Skies were overcast and we passed through occasional light rain.

As we proceeded farther to sea the wind picked up and wind and waves began to toss us around. Most everyone got a little seasick. I retired to the sack and felt much better for it. Seas began to get rougher through the night—water breaking over the bow and swashing over the decks. About 6:00 AM Bob Wisner and the skipper got together and changed course toward San Clemente. With the sea following us things became much calmer.

April 26, 1951

Lee of San Clemente Island, California

Most of the day was spent uneventfully steaming toward San Clemente Island. In the afternoon we came under the lee of the island and entered relatively calm water. We made one tow of 300 fathoms. The fish came aboard badly skinned with some exceptions.

On orders from La Jolla we turned and proceeded out to sea. On our way we passed near a crew of destroyers that were firing at the island with star shells. We had to change course radically to get out of their way.

April 27, 1951

At sea approximately Lat. 30 deg. 00 min. N, Long. 120 deg. 00 min. W

Very little happened today except that we continued our cruising through calm seas. We saw a blackbird flitting along when we were 155 miles from shore (mainland). San Clemente Island is the closest land. At about 23:00 we put the net over and commenced an all night tow at 1,140 fathoms.

April 28, 1951

At sea Lat. 29 deg. 30 min. N, Long 121 deg. 00 min W. approx.

At about 4:30 AM we commenced hauling in the tow. Al noted a female blackbird resting on the boom (we are approximately 200 miles at sea).

At about 8:45 the net came over the fan-tail with a crash, breaking the cable and bending the heavy spreader-bar in a neat U. The bridle of the net fortunately hung over the guide rollers and so we were able to retrieve the net. It contained very little—a couple of big *Sternopteryx* (a species of hatchet-fish) and a few other beasts.

We put down another shallower tow (500 fathoms) and caught a few fish and some invertebrates.

The weather has grown increasingly bad as the NW wind had picked up and swells have grown larger.

Our final tow of 100 fathoms was put over the side. About 18:30 we hauled it aboard. We had 4 specimens of an amphipod, *Phronima sedcutaria*, and a few jellyfish.

The ship proceeded out to sea to make our 700 mile station. By 2:00 AM the seas were breaking over the bow and swashing constantly across the well-deck amidships. We were shipping water and rolling and pitching violently. Seas had become precipitous and the wind was picking up.

Larry Davis and Bob Wisner decided it was useless to continue, so we turned and proceeded toward San Diego. In making this turn we lost our radio antenna as seas crashed over the bridge. Our course quartered the swell and chop and we continued to roll and pitch though less than before. It was impossible to sleep comfortably. Most of us were somewhat seasick and very uncomfortable. I was so tired of lying in the sack that I got up periodically and went topside until forced back in again by increasing seasickness.

April 29, 1951

Proceeding toward Guadalupe Island

Seas continued to get higher as the wind continued between 30 and 40 knots. We had to bring the skiff inboard off the davits to keep from losing it as waves crashed over it. The nigger-head from the anchor winch came loose and boweled[?] around on deck until Lew and I hauled it amidship as Larry lashed it down.

I continued to be very uncomfortable (as did everyone else). There is no place to get away from this incessant pounding, pitching, and rolling. There is no way to get enough exercise to make lying down at all pleasant. I have been limiting myself to one meal a day as I have been spending most of the time in the sack.

Early in the evening it became apparent that our best move would be to run for the lee of Guadalupe Island rather than to continue to buck the increasing seas. We changed course and with a following sea things became much calmer on board. We stopped shipping water and stopped banging and pitching.

Al Allansore and I volunteered to stand the 12 to 4 watch. All during our watch seas began to increase in height and the winds to increase in velocity. Whole patches of the sea turned white as the swells broke around us.

April 30, 1951

Guadalupe Island, Baja California, Mexico

Our landfall was expected to be at 9:00 AM so we called Larry Davis at 3:00 AM to turn on the radar gear. I retired to the sack without having seen any indicators of land

but about 6:00 AM I felt the ship begin to buck and bang into waves and then slide into calmer waters as we came into the lee of the island between the two outer islands at the south end of the main land mass. It was a very nice feeling.

We dropped anchor in 18 fathoms along the east coast of the island.

About the time we shifted course for Guadalupe the radio informed us that an unexpected front had appeared and that we might expect winds and high seas.

Without bothering to eat breakfast I went ashore with Al, Lew, and Tom. We hiked down the shore over the rough lava rock-covered slopes. Tom, who is studying amphipods, and I hiked off together turning stones and collecting insects. Silverfish are very common as are several kinds of beetles and spiders.

A black wasp, yellow-jackets, and flies are practically the only flying insects though I saw one moth. The weaker flying forms probably cannot survive the attrition of individuals being blown out to sea.

We visited the remains of some old stone sealer's huts left by the Russians about 100 years ago. Back on board we had a turkey dinner and visited a purse seiner anchored nearby.

May 1, 1951

Guadalupe Island, North Anchorage, Baja California

Al kicked me out of a sound sleep so I could make it to breakfast. Shortly we upped the anchor and cruised up the coast toward north Anchorage. About 10:00 AM we pulled into the shallow cove under a huge 1,000 foot volcanic cliff. Great grey and black dikes cut at different angles through a black, white, and red matrix. Two narrow sand and pebble beaches stretch a short distance down the coast. A steep-walled, V-shaped canyon empties into the sea in the center of this beach. The remains of an old Russian weather station and fort are perched on the north side of this canyon.

Al, Mac, Tom, and I went ashore to make a sea elephant count before lunch. We counted 160 animals, nearly all cows and young animals, on the north part of the beach. There were 2 young adult bulls lying on the beach. The south segment of the beach was piled with animals. I counted 430 piled along the beach or swimming in the surf, including 8 sub-adult males. The beach is covered with little squares of hide and fur that have sloughed off the animals as they shed. Animals in all stages of shedding could be seen on the beach—the old brown hide hangs in tatters and you could see the grey glossy new hide between the tatters. Some of the young animals have a beautiful platinum blond hide.

We spotted a fairly large bull and prodded him with a few pebbles until he woke up. He rose up on his front flippers and gave the peculiar call of male sea elephants—it sounds like a sporadic squirting of milk in a milking bucket. The male raises his head and opens his mouth. His long proboscis hangs down into his mouth and the sound comes out—probably a combination of puffing through his nose and voice. [Drawing of sea elephant].

After inspecting the seals we took a look at the fort and adjacent buildings. There were 19 buildings in all—mostly adobes. Two cement and rock buildings of the fort are perched up the canyon wall above the other buildings. Both have gun ports and one has a gun tower. The lower building has some Russian letters made of wood along its front.

We saw many good carcasses—mostly old billies, and one feral cat slinking through the tree tobaccos in the canyon bottom.

We returned to the ship and ate a steak lunch and came back on the beach. Larry Davis, Mac, Tom, Polzin, and I went on a hike. We followed a switchback road up the side of the canyon. Apparently this was the old wagon road that ran up the mountains to the springs back in the canyon. The first of the ascent goes right up the steep canyon wall. The road is built on big rock-work walls and must have taken a tremendous amount of labor.

We hiked on up the mountain over an increasingly dim trail. Apparently the rains have washed the road away, leaving a pile of volcanic boulders. Because of this hiking was not easy. The ground is very moist and covered with a crop of annual plants such as ragweed, mallow, brome grass, and miner's lettuce in the moister crevices.

We were headed for the springs in the upper canyon. About 2 miles up the slope we came upon a herd of about 50 goats browsing on the green plants. The others went off after the goats, and I continued on up to the spring. It consisted of a series of rock pools of yellow opaque water.

On the slope across from the springs I saw a herd of about 100 goats including several shaggy old billies with manes and great hairy legs.

Far above me on the crest I could see some of the wind-swept pines with clouds of vapor sweeping over them—now visible and now hidden in the racing clouds. Al tells me there are palms and oaks in with them—all have been unable to reproduce since the goats became numerous on the island—branches are eaten off as high as a goat can stand.

I returned down the slope and found my associates rolling huge boulders into the 1,000-foot-deep, vertical-walled canyon below. The rocks made tremendous reverberations as they crashed into the canyon—like artillery fire.

We hiked down the slope and could see the *Paolina-T* far below under the eaves of the huge cliff.

Back on the beach we found 2 young elephant seals (about 300-400 lbs.) in the bottom (115 ft. down) of a fresh water well—unable to get out. Bob Wisner shot them to keep them from starving to death.

We shoved off in the skiff with all sorts of booty—goat skulls, horseshoes, and I had a plant collection.

A word about the fauna. Rock wrens are exceptionally common. They have light tan breasts streaked in some with darker tan—a dim light line over the eye, grayish tan upper parts, and a vaguely barred tail. Finches are quite common in the tree tobacco as are small hummingbirds. One little moth was very common on the windswept upper slopes of the island and I caught one grasshopper. We saw crickets, armored isopods, roaches, and many beetles, plus termites and ants.

We found scats that look like those of coyotes—full of elytras of beetles and hair (I have no idea what sort of animal could have left them).

I do not think there are any reptiles on the island as I had every chance to find them if they did occur. I rolled over boards and galvanized iron sheets for $\frac{3}{4}$ of an hour around the old fort and produced nothing but insects.

Back on board we could see goats wandering on little ledges of the huge cliff—in places you wouldn't imagine a goat could go.

Various bull sessions—chow, notes, and the old pad.

June 1, 1951

Middle Coronado Island, Baja California, Mexico

Connie Limbaugh and I went to the Coronados to do some diving and obtain kelp holdfasts. We were transported in the buoy boat piloted by the Red Scorpion (Sr. Norland) and his son.

We anchored in a little cove in middle island and dove into the amazingly clear green water. One could see possibly 100 ft. laterally. All sorts of fish swam around us—schools of blacksmiths (*Chromis*), big 8 lb. kelp bass (*Paralabrax clathratus*), brilliant orange garibaldi, great lumbering sheepshead, and trim silvery half-moons (*Medialuna*). The bottom was composed of rocky shelves and cliffs and caves—all clothed completely with red coralline algae, tunicates, sponges of several colors including brilliant chrome yellow, and colonies of tube worms. Rock fish, klip[?] or kelp[?] fish, and sculpins (*Artelius creaseri* and *Scopaenichthys*) were common in the crevices.

I captured a *Coryphoptera* (a little white goby) by running him into a bottle and clapping the lid on. Connie (a past master at this) caught a young tree fish, a zebra goby (*Lythripnus zebra*) and a couple of sculpin (*A. creaseri*). We pulled up a kelp holdfast and investigated it for fishes. A sculpin (*Scorpaena*) darted out of it.

Back at the surface we decided to go ashore. We swam in with our shoes held above the water with one hand.

The island is very precipitous though several small terraces can be located. Western gulls were nesting in some numbers on these terraces. We saw many nests containing two to three large mottled green and black eggs. It was close to general hatching time as many downy chicks were around, hiding in crevices while their parents swooped low at our heads. By rolling many rocks we captured two small alligator lizards (*Elgaria multicarinata*).

Back at the ship we moved to a little point and dove again, this time over eel grass, kelp, and rocks, and sand.

I had trouble keeping water out of my face mask and returned several times to the surface. About when my air was gone I developed an increasingly bad headache and climbed aboard, shucked my gear, and lay down. Lying in the sun felt very good. Soon Connie came in with some fish and we left.

June 13, 1951

Middle Coronado Island, Baja California, Mexico

Ten of us, 4 from UCLA and 6 from Scripps, gathered at N.E.L. Dock at 9:00 AM and proceeded toward Middle Coronado Island. Two hours later we anchored in the cove of the island.

After a hearty lunch the Red Scorpion (Norland), Connie, and I went north to Middle Rock to make a brief search for herps. We landed on a rocky shelf, and I immediately set about rolling stones in search of animals.

The island is very small and precipitous, being about $\frac{3}{4}$ of an acre in extent. It is vegetated with iceplant and *Coreopsis maritima* plus some *Echinocystis lobata*, the wild cucumber vine. The island is largely composed of jagged platy masses of sandstone and

conglomerates. On the east side subsidence has apparently taken place, leaving a 25 foot deep depression that goes below sea level at least 20 feet. This part is filled with sea water and is open to the sea through two crevasses and through a rather large subsurface tunnel. Thus it is an inland cave covered by a natural arch and filled with a beautiful emerald pool, teeming with fishes. Two sea lions barked at us as we walked in to explore. [Drawing.]

Up the hill were many birds' nests (Western gulls) and under one rock I discovered a Xantu's murrelet nesting.

On a very steep slope about ½ way to the crest I rolled a series of rocks from a sloping ledge used by gulls for nesting. Under one of these, in damp soil, were two *Batrachoseps pacificus*. What a surprise to see these animals on this desolate, tiny island in June!!

I went swimming and swam under the subsurface overhang (about 20 ft.) into the cave pool. It was a real sight to pop up in this calm water inside the cave. Three sea lions came in after me and cavorted around the entrance. With my face plate I could see them swimming in and out of the entrance.

Much more diligent searching produced no more salamanders.

Back in the lee we went south with Ted Walker to attempt a recording of fish noises on his elaborate apparatus. The records we made were indefinite and only succeeded in making us a little seasick. Once back in the cove we anchored, ate dinner (I fried up some bass fillets), and went to sleep under cloudy skies.

June 14, 1951

La Jolla, California

The morning was occupied doing a deep water poisoning (In 15 to 30 feet of water). We took such species as [list].

I spent the day photographing fishes—set up on a rocky tide shelf with all my gear. About 3:00 PM we moved to North Island. Ted Walker and I went ashore. This island is very, very precipitous, most places standing at over 30 degrees.

The first board I turned, at an old fishing camp, turned up a dead skink, *Eumeces skiltonianus*.

On up the hill we visited a couple of medium-sized caves filled with midden material—we found no artifacts but a few old cracked manos.

I caught another live skink and a *Gerrhonotus*[?]¹—both in rock rubble and low vegetation. And under a large pile of cracked sandstones we found two adult *Batrachoseps pacificus* (slender salamander) in moist soil.

This island has some patches of beavertail cactus and thickets of other low plants including wild cucumber vines.

The others dove off the precipitous shore and reported a vertical cliff going down into very deep water.

We boarded. I swam around the boat to get cleaned off, and we headed for home.

August 28, 1951

Punta Clara, Baja California del Norte

At 5:00 AM Al Allanson roused me out. We were to go on a temperature run from La Jolla to Punta Baja, Baja California. This survey, conducted by Dr. Hubbs, is accumulating data on temperature relations of the sea in areas of upwelling cold water and adjacent warm water throughout this distance. In addition the faunal relationships in this region are being investigated. A run is made approximately once a month. This particular run is being correlated with cruise temperatures being recorded offshore by the Scripp's vessel, *Crest*.

Dorothy Allanson and Johnny Fleet make up the rest of the crew. I was exceedingly sleepy, having gotten about three or four hours sleep before Al arrived.

There are approximately 55 stations in this distance. Each one is made by recording a water temperature taken by charging out to about knee depth with a small bucket thermometer. Rather striking temperature differentials are obtained –23 deg. C to 13.9 deg. C approximately. Warmest temps were obtained in bays and the coldest in unsheltered coasts with a pounding surf.

We were all riding in a single Chevy pickup ('51). After taking several stations on Mission Beach and Coronado Strand we crossed the border and headed for Ensenada, taking temperatures as we went. At Ensenada we began to investigate territory new to me. We first cruised out to Estero, south of town. This is a rather large lagoon blocked from Todos Santos Bay by a long sand spit. The lagoon entrance is rather narrow and the water piles up in choppy waves and rapid currents. It looks highly unsafe for small craft.

There is something of a resort at the Estero and is inhabited by American fishermen and their wives.

Next we went out the road to Punta Banda [drawing]. This is a bumpy dirt affair cutting through fields of ripening chili peppers (black in color), fields of tomatoes (being picked), and chaparral covered land. A thin drizzle, at times heartening into a light rain, had fallen on us from La Jolla and here served to dampen the dust. This road is usually very unpleasant because of deep dust, but today not a puff arose, and we slid and slopped through an occasional puddle.

Punta Banda is quite precipitous and clothed with chaparral plants. Agaves and sour pitahaya cacti are also very common elements in the flora.

I picked up three strands of kelp (*Pelagophychus*) and braided them into a riata. The strands were partially dried and still pliable. They are amazingly tough.

Johnny Fleet and I were unable to break two strands though we pulled with all our might. The best strands are from the long stipe just below the float. They are often 30 feet long. The riata is very elastic [drawing].

Our first station was made at Arbolitos. This is a fishing camp set on the edge of a rocky bay, defined on all edges by precipitous basaltic?? cliffs and rugged islands and peninsulas. The water in the bay is apparently quite deep and is beautifully clear, blue and green. All in all it is a most beautiful spot. Its name is said to come from a grove of eucalyptus which have been planted in a small valley back of the bay.

2:00 PM. We visited them at lunch time and ate under their shelter. Al and I hiked along an old abandoned road in search of an Indian cave he had heard about. We both got soaking wet, and I caught a 2 ½ foot red rattlesnake. This little fellow was coiled in a neat pad on a ledge of rock with rain actually falling directly on him. He was so lethargic he barely moved when I pinned him.

We made another station at Punta Banda Fish Camp and returned on a bumpy road, neatly circumnavigating the Customs checking station. We then went to Santo Tomas Canyon and drove down it to Bill Margerem's place. The old fellow is still there and peered at us out of his two pairs of glasses—one supplies the lenses and the other the ear arms and frames. He must weigh 350 lbs. anyway.

He reiterated what we had already heard—that a violent storm was headed our way and was now whipping over Cedros Island in hurricane force. The seas have, as yet, been very calm—perhaps the calm before the storm.

We continued on down the canyon and made camp in a hollow at the tip of Punta Clara. We whipped up a fine agave and cottonwood fire and a most wonderful dinner of fresh marlin steaks, an avocado salad fit for the gods, fried potatoes and onions, two kinds of wine to lighten our already light spirits, and a couple of cookies to complete it all—and, I mustn't forget—hot tea.

I was very tired and remained in camp as Al and Johnny went off fishing for lobsters with hoop nets. Everyone is one of the best as camping companions and this bids fair—hurricane notwithstanding—to be one of those all too rare trips with no strained relations whatsoever. All of us enjoy camping so much that every new thing offers its excitement to all of us.

August 29, 1951

Punta Cabras, Baja California del Norte, Mexico

Just after I had finished my note writing and hit the sack, skies began to drizzle. I had constructed a ditch around my sleeping bag and adjusted my tarp and so went off to sleep with rain pattering on my head. Sometime before dawn I awoke and found it showering rather heavily. I found all the ditches were full and I was sleeping in the center of a brown lake. Water had soaked through the bag in several places.

I cleaned out the ditches and went back to bed and to sleep in spite of the water.

In the morning I found that Johnny Fleet had been even wetter than I. Dorothy had shipped a little and Al was dry.

The rain abated and we ate a big breakfast of scrambled eggs (made of about 1 dozen eggs that had cracked on the previous day's ride).

After breakfast we spent an hour searching middens for artifacts. The bluffs above Punta Clara are covered with cracked shells and burned earth. I found some potsherds, Dorothy picked up an arrow point, and Johnny picked up another.

Before going up the canyon we went to Punta Santo Tomas, and at the mouth of this canyon I caught two *Thamnophis e. hammondi* in the fresh water, a couple of sticklebacks (*Gasterosteus*), and one tadpole. Many turtles were seen and must be *Clemmys marmoratus*.

A very strange habitat for *Hyla regilla*, the tree toad, was discovered. I caught two hopping about among the agaves and *Euphorbia misera* plants. The nearest permanent water is ¼ to ½ mile north in the Santo Tomas Canyon. I wouldn't be surprised that these frogs find water in the axils of the agave leaves and possibly even reproduce there.

We drove out, stopping briefly at Bill Margareem's place. He gave Al a pot of honey and we left. Johnny and I put our sleeping bags over the back of the truck to dry as we drove along. Skies were still overcast; fog banks hung low over the crests of hills

along both sides of the canyon. Even so our bags dried out quite well as we drove along. We bought gas at Santo Tomas and drove down the main highway to a sign saying Las Cruces Ranch, where we turned off for Punta Calaveras. The road leads up over a ridge, across a rolling barley farm and down into a sycamore and oak filled canyon. We let ourselves through a corral full of cattle and continued down the canyon with brilliant red poison oak vines tangled into dense matings over all the shrubs and trees. Though the plant is undeniably pretty I shrink slightly at a sight such as this.

We drove along a dune-bordered beach to rocky Punta Calaveras. Along this beach we found a couple of large live Pismo clams. We drove on down the coast to Punta Cabras. This rocky point is bounded on both sides of its base by white sand beaches. Strong swells and breakers crashed in on the south beach while the north side was quite calm. For the first time the skies were partly clear and we could see patches of blue.

Johnny and Al showed me how to dig for Pismo clams. They took digging forks and shovels and probed in the sand while wading up to their waists and between dunkings in the breakers. When the fork struck something hard it was pushed into the sand and the “lucky” fellow went down after the clam with his hands in the cold water (15.9 deg. C.). I caught one (with Al’s help, in this fashion).

After dinner we hiked out on the point with hoop nets to fish for lobsters. A “ripe” fishead is wired in the center of these nets and they are flung in the water alongside a rocky bluff and let set on the bottom all folded up [drawing]. The lobsters crawl on the bait and at intervals the net is abruptly raised. Lobsters were everywhere and Johnny and Dot took eleven and Al and I took eleven more—all larger than the legal minimum. We discarded all but 9—including several females with eggs attached under their tails. We saw seven or eight lobsters crawling on the bottom in shallow water or clinging to rocks just below the water line. The population here must be very large indeed.

It was very enjoyable, sitting out on the rocky point with the net on the bottom, listening to the swells swashing on the rocks and watching the phosphorescence. Along the beach at the base of the point the waves beat in a glowing white line on the sand. The air was warm and comfortable. Johnny’s eyes were really gleaming over such fine lobster fishing as this. So were Al’s, as he had been playing it up to Johnny for some time—thus a prediction come true.

We cooked the lobsters, ate some, and sat around a warm agave fire. A few stars glimmered through the clouds, and we probably will have no rain tonight.

August 30, 1951

2.5 miles S. Punta San Telmo, Baja California del Norte, Mexico

Awoke this morning with the sun brightly shining and everyone else scurrying around camp packing and preparing breakfast.

We packed and drove southward through *Agave-Euphorbia* association. We saw many *Sceloporus rufidorsum* (scaly lizards) sunning on the road in the morning sun. About 1.5 miles S. of Punta Cabras Al took us over the bluff just above the sea and down into a cove. In an undercut bank quantities of fresh water (very slightly saline) dripped from the roof from thick mats of porous green moss. Purslane and a small green vine

grew around the edges of the pond and much salt grass (*Distichlis*) clothed the bank in front of the spring. I am sure this spot of greenery could be seen from the sea.

Farther down the road we caught some *Uta* and a beautiful striped racer (*Coluber lateralis*). This snake was sunning on the road and I stalked up on him and grabbed him as he started to move.

We drove up over a rocky hill on a rather poor dirt road and came into Colonia San Isidro, a group of ranch houses and eucalyptus. 3.4 miles south of the Colonia we came to the point (San Isidro) where we took a very brief dip in the cool clear water. We saw a leopard shark swimming between us (3-4 ft.). A little farther on we sighted a blow hole in the rocky shelf along the shore. A hole about 1 ½ feet across lead downward into a subteranean cave. Waves swept in and forced the air and spume out the hole (30 feet from the water's edge) with a rush and a roar, sometimes 20 ft. in the air. The suction as the wave receded was also tremendous.

Johnny, after suggesting we put a whistle in it, placed a 4 lb. flat rock across about ½ of the entrance. The rock was moved to one side with a following "blow".

We continued on to the Johnson ranch and San Antonio del Mar. A ranch house and barns and fields comprise the ranch. We turned westward toward a low range of beach dunes. A short hike brought us to a clam camp where a buxom Mexican woman was washing her long black hair. The little valley in the dunes had a covering of sedge (*Carex*) and a spring.

Out on the beach we could see piles of Pismo clam shells as far as one could see. In two places men sat shucking out clams (in spite of the month, which is theoretically dangerous). The beach is beautiful, flat, and crescentic. Clams must be very common here and must also be being decimated by fishermen. Probably a deep water population of near-normal proportions still exists as the Mexicans do not dive for them as far as we can see.

We left the beach and drove up onto the broad (8-10 miles) Colvett Plain [drawing]. It is very similar in vegetative aspect to the San Quentin plain to the south. *Agave-Euphorbia* association is dominant. *Encelia* is very common. The plain abutts the water at steep bluffs and rocky slopes. We drove out a road (first road to the right) S. of two tall posts to the bluff. The road goes down a steep canyon and into a twisting wash to the beach. It was too steep and sandy for us to follow. We all hiked out to a nearby point to look at the beach about 400 ft. below. Shortly Johnny set up a cry—"fossil bones". Shortly we had collected a bag full of bones, all mineralized, including vertebrae, foot bones, ribs, and a horn base. Probably the beast was a deer or elk. They came from a ferrous sandy layer about 8-10 ft. below the surface layer of the plain. Johnny again set up the cry—this time "Come here—isn't that a point?" Sure enough it was a perfect spear point. He found another before we could get going. Several artifacts were found including a rough mano, possibly a stone hammer, several points and scrapers, and a polished operculum (ground flat on both sides and drilled) [drawing].

The points were made of a black chert and a green chert. Manos were of sandstone. Al thinks the points are pressure flaked and represent a later culture (contemporaneous with Digueno??). The manos appear more primitive and Al thinks they may represent a culture contemporaneous with San Dieguito). The oldest artifacts at least, appear to come from a layer of midden material about 8 ft. below the level of the Colvett Plain. In many places midden material was washed from this level and deposited

on top of lower levels. This layer extended along the cliff face, overlooking the sea, for ½ mile at least.

We drove on to the San Rafael River Valley. This valley contains some nice farms and much salt marsh (*Salicornia* association) area.

We drove up along the sea bluff and dropped down by San Telmo Lagoon. Here we noted phalaropes (either red or northern) feeding in the lagoon. They were involved in a peculiar maneuver.

Many birds, widely separated from one another and often solitary, were spinning around in circles in the shallow water (2-3 inches) of a salt pond. They apparently propelled themselves around with their feet. They could be seen picking at the water surface as they spun. Later I tried to shoot one for crop analysis and certain identification and found the bottom of the lagoon was covered with red algae and the lower inch or two was teeming with brine shrimp (*Artemia*). Apparently these birds swim in circles and thus stir the water and brine shrimp up and feed on them. There were no foot marks on the bottom.

We drove on and camped with the three volcanoes of San Quintin Plain visible in the distance. San Martin Island could also be seen.

Dinner (another glutton style), Johnny's stories of his no hit-no run baseball game, notes, and the sack. It's a clear, breezy night and pleasantly cool.

August 31, 1951

Punta Baja, Baja California del Norte, Mexico

We were roused out at dawn by Al and proceeded to Punta Camal. Here we took a temperature on a cobble beach. We then proceeded inland and very shortly captured a black racer which was sunning on the road. We stuffed him in a discarded water can (the striped racer had escaped by poking a hole in our snake sack). About 50 feet farther we came upon a dead *Crotalus enyo furous*. This is the third known specimen and is a considerable northward range extension. The snake was in very poor shape and crawling with beetles, but I preserved him anyway.

The surrounding terrain was a grain field on either side and a new dirt road. The nearest natural habitat was ¼ mile north on a rocky hill covered with *Agave*, *Euphorbia*, and sour pitahaya.

We proceeded to Colonia Guerrero and bought gas. Then we drove to the beach at a camp of some fishermen who used large nets and an army duck. They caught perch, flatfish, shark, and corvina the man said. He also mentioned that lisa (mullet) were present in the brackish lagoon just north of the camp.

After returning to the main graded road we drove rapidly to the San Quintin Plain and thence down to the old pier (muelle) once used by the British colonists of this plain, nearly 100 years ago?? We then got well lost in the pickleweed marshes (*Salicornia*) and finally emerged at Santa Maria Lagoon at the mouth of Arroyo Santa Maria.

Long rows of white sand dunes separate the flat beach from a reed-filled marsh inland. This marsh is supposedly full of fresh water bass. Forster's terns were feeding over it when we stopped. Pismo clam shells litter this beach as far as one can see. San Martin Island has been visible offshore all morning and is nothing short of tantalizing to me. It has a landlocked harbor, a crater, and an endemic *Uta*.

We drove back in our tracks and then to San Simon, a small settlement along the main road set among old eucalyptus trees.

We crossed Arroyo Santa Maria, passing some houses nearly buried in blown sand and up through rocky hills, down a deep canyon, past a sand-covered hill to Rancho Socorro—noted for its *Phyllospadix* covered beach and its warm tecate beer. I saw a flight of black bellied plover here.

We made various stations along the plain north of Rosario and passed along the rough road over the marine terrace. I took a photo at the type locality of *Crotalus enyo furosus* Lowe and Norris—and then we entered Rosario Canyon, first proceeding southward along the coast to a fishing camp at a beach with four natural arches.

The road up the canyon was rough and long and it was a great relief to see the valley and village.

I really have a place in my heart for this place and to see it appear in the V of the canyon, out of all the surrounding desolation, was a soul-satisfying sight. Its farms are lush and green—its fig trees, palms, cottonwoods, plums, pears, and willows are inviting. Its little adobes with their checked walls, great patches of raw adobe showing through the plaster, thatched roofs, gnarled and crooked supporting beams, and dusty streets are typical of everything nice that is Mexican.

In old town, across the river, we saw the bells of the old spanish church hanging on a beam swung between two trees, waiting to be rung each Sunday. The afternoon light, with its accentuated color and light and shadow set off the scene.

We continued on a good road through agave-covered hills to the coast south of Punta Baja. We drove out on the point. It is long, narrow, and barren. Winds must scour its surfaces relentlessly. A tarpaper fishing shack, a skiff filled with seaweed (to keep it moist) and an old spar and tackle, are the only signs of permanent habitation. Flat, rocky reefs line the north and northwest sides. San Geronimo Island can be seen offshore a little to the south. After temperatures we returned to the agave canyon, camped, ate our usual fine meal by a crackling agave campfire, and I wrote these few notes while the others went to bed. It has been a hard, jouncing day. Skies are clear with scattered clouds and it had been and is warm. To the sack.

September 1, 1951

Colvett Plain, Baja California del Norte, Mexico

Incessant screeching from Al finally roused me out about 7:00 AM. Johnny and I barked at a sea lion which was swimming by in the surf and succeeded in turning him around. He came clear up in the surf and stayed there looking at us. Several flights of pelicans strung by—gliding on the updraft from wavecrests. Flights of black-bellied plover, willits, and godwits flew by.

After I spent some time inspecting a series of middens around camp we drove out to Punta Baja and took the morning temperatures. The west side was 16.10 deg. C. and east side 14 deg. C.—quite a difference.

We then backtracked and drove toward Rosario through agave-covered hills. We saw a flicker, ladder-backed woodpecker, and California quail.

Just before we reached Rosario I spotted a black racer alongside the road. In the mad scramble that followed he almost got away. I grabbed the tip of his tail just as he was going in an agave. I swung him around to keep him from biting me, hitting Al on the

leg with him. Finally I got him in the water can and we drove on—down stream to Rosario Lagoon. This is a deep reed-bordered lagoon of very considerable size.

We caught a fair series of sticklebacks (Gasterosteus aculeatus) a new southern record for the form. Other larger fish live in the lagoon also—as we saw them jump. They may be mullett.

We investigated another part of the lagoon—near a group of *Washingtonia* palms. I walked into a great quagmire of mud and reeds and accomplished very little.

We drove on up to Old town and saw a pair of bronze bells hanging on a beam swung in a tree. They were dated—one was 1738 and the other 1800. Both were from Mission Santa Rosa—here at Rosario and now largely ruins.

These bells are still rung to call the village people to church. We rang them quietly and they had fine tone.

Old town is an interesting melange of adobe houses with thatched roofs, new plastered buildings—set on the slope of the canyon above fields of corn and vineyards and orchards of avocados, figs, peaches, etc. All in all this is a most verdant valley.

We bought gas at the main town and continued on up the Rosario Canyon road, out onto the marine terrace to the north toward San Simon and San Quintin. About 1:00 PM we came to a DOR red rattlesnake and stopped for lunch while Al skinned him out. The marine terrace above us is capped by a hard gray layer that breaks off in great blocks where undercut by erosion. This layer continues for miles and we had been having some discussion about it so I hiked up the cliff and found it to be a hard conglomerate underlain by soft sandstone.

I rode in the back for a few miles, jouncing along playing my harmonica, until we nearly got stuck in sand at Santa Maria Arroyo. Johnny and I jumped out and finally Al drove it through by trying a couple of times.

A house of clay and wattles has been built in the middle of this dune and what a dream castle it is—sand swirling in the front door, nothing growing in the yard, and several eroded grimy looking people in the house or trudging through the dune—on both sides are fields and farms.

Though we tried valiantly, no wine was to be had at any of several stores where we asked—such a barbaric country—what do they do to raise tired spirits at sundown. Our wine at sundown has become a ritual on this trip—so much so that we made off with all 4 bottles and are now desperately destitute.

We drove on past San Quintin—bought gas at Colonia Guerrero and drove to Cahualu and to Arroyo San Rafael. I shot a phalarope (northern) that was whirlygigging in the lagoon to check the identification and stomach contents. The first shot had no effect on the sitting bird, but a second shot dropped him in flight—which surprised me no little bit as I was using my .22 shot pistol. Stomach contents revealed very little except the elytrae of small beetles and what may be partially ground-up brine shrimp.

We gathered great mounds of dry agaves and drove up onto the barren Colvett Plain and camped in a low defile.

Skies are partly clear—the day has been beautiful—a 15-20 mph breeze passes us in gusts.

September 2, 1951

South of Punta San Jose, Baja California del Norte, Mexico

We were greeted this morning by grey foggy skies. At breakfast (a hearty meal at Dorothy's insistence) an immature cowbird came hopping into camp. He was very tame and went around picking up seeds nearly oblivious to us. A little cottontail fed unconcernedly a few yards away.

We drove along the coast on a fairly good dirt road to Johnson's Ranch and further down the coast to Punta San Isidro (Ysidro??). Before reaching the point we searched the shores for a cork raft we had seen on the way down. We stopped at the blowhole while I took a picture of Johnny dropping orange peels in it.

Shortly we turned up San Vicente River Canyon. It is a deep, sandy-bottomed canyon with a dense growth of willows, blackberry vines, and other streambottom vegetation.

Water flows down the canyon both in a little stream and in a diversion ditch lined with a dense growth of plants. Sticklebacks were seen in both.

About 3.5 miles upstream we could see scattered pines clinging to a rocky cliff. We stopped and Johnny and I hiked up over the ridge. A dense stand of these pines clothes the north slopes of perhaps 150 acres of this rocky mountain. The pines are closed-cone pines with 2 needles of medium length (equal) to a bundle and a knobby cone with the largest projections on the upper side.

Chaparral species were associated around the fringes of the pine stand—*Quercus dumosa*, lemonade berry, *Rhus laurina* (sumac) and others were common (manzanita).

I saw no animals in the pines but noted several downed and rotted logs lying on a thick duff of pine needles.

While we were hiking, Dorothy and Al were not idle—they were out stealing tomatoes from a nearby tomato patch.

A short way farther upstream I saw a turtle (*Clemmys*) slide off into the shallow stream. While catching him I also caught a garter snake. This turtle has been smelling up the truck ever since.

We continued up and out of this beautiful canon at San Vicente and then down the pavement to Santo Tomas. There we picked up a bottle of Chianti for our sundown ceremony and drove SW on a dirt road toward Punta San Jose. This road is steep and rocky but quite passable. First it cuts up over a hill back of Santo Tomas and then tends right (another road goes left) and enters a pretty farm valley with rolling grain fields and a green vineyard. The streambed is shaded with huge sycamores and great, spreading live oaks. A real live oak woodland continues downstream for a mile or so. We passed through a couple of ranch gates, by the adobe ranch house and buildings, and down the canyon wall.

Shortly we emerged onto the rolling marine terraces four or five miles from the sea and finally dropped down onto the broad terrace just above the sea. We continued in a northward arc to Punta San Jose. The sea was all white caps in a strong northwest breeze, which swept across the point unabated.

Al and Dorothy and I hiked out to the end of the point (leaving Johnny to hunt abalone below the shark fishing camp where the road ends).

It is a wild place. The wind whips across a barren wave-fluted sandstone point. Just offshore to the northward are two rock pillars covered with guano. On one cormorants have nested so long that each nest site is now an individual guano-mound, giving the rock a warty appearance. Behind the point a great 150 ft. cliff of sandstone

risers from the water. Monster cirques have been cut from its face—not by ice but by the incessant undercutting of the waves.

We hiked up a steep slope to the top of this cliff and looked over at the seas and point below. I then left Al and Dorothy and went across the agave-covered terrace and hiked down into a pretty L-shaped canyon—out of the wind—and proceeded down it to the car.

We gathered wood at the fish camp. I hiked down on the beach while Al and Johnny took a water temperature. A broad, sandy beach stretches out toward the kelp beds offshore. On it were numbers of an organism I cannot even place in its proper phylum (colonial tunicates). They may be coelenterates or sea-cucumbers or tunicates. They are flattish, pale yellow, and uniformly punctate and range from 1 inch across to 6 or 7 inches. They look like this: [drawing]. They are quite jelly-like. I did not dissect one to check its internal workings.

We drove back down the coast and up a side canyon past an abandoned adobe ranch house and up onto a sumac-covered bench. While backing the truck around to make camp Dorothy scared out a 3 ½ ft. Southern Pacific diamond back rattlesnake. He raced off through the brush, and I finally shot him and preserved him.

We ate our usual fine meal in the calm dusk of the canyon with the company of a warm camp fire. Skies are clear and the night is warm. Our canyon protects us from the wind that still rages over the ocean below.

We have been keeping a fairly complete bird list. It is as follows:

Raven, Double-breasted Cormorant, Heerman's Gull, Western Gull, Western Kingbird, Anna's Hummingbird, Great Blue Heron, Brown Towhee, Meadow Lark, Brewer's Blackbird, Marbled Godwit, Western Willet, Sanderling, Hudsonian Curlew, Royal or Caspian Tern, Killdeer, Horned Lark, Mourning Dove, Ruddy Turnstone, Brown Pelican, House Finch?, Sparrow Hawk, Pintail Duck, Loggerhead Shrike, Ladderback Woodpecker, Scoter, Northern Phalarope, Mockingbird, Wrentit, Yellow Throat, Forster's Tern, Calif. Jay, Calif. Quail, Cooper's Hawk, Black Phoebe, Cactus Wren?, Audubon Warbler?, Road Runner, Turkey Vulture, Belted Kingfisher, Yellow-headed Blackbird, Yellow or Pileated Warbler, Red-tailed Hawk, Brown Thrasher, Common Loon, Marsh Hawk, Black-bellied Plover, Sandpiper (species?), Semipalmated Plover, Dowitcher, Red-shafted Flicker, Rock Wren, Marsh Wren?, Cliff Swallow, Common Cowbird, Chipping Sparrow??. Western Tanager, Hooded Oriole, Ash-throated Flycatcher, Gnatcatcher, Spotted Towhee

September 3, 1951

La Jolla, California

We got up fairly early and drove southward in hopes of finding a road through to Punta Calaveras that would save us the trouble of returning to the Highway 18-20 miles inland (by road).

The road took us slowly into the foothills past some desolate, abandoned ranches, now sprouting fine crops of young agaves in their fields.

Farther inland we entered rolling valleys set in among chaparral-covered peaks. Sycamores seem to indicate farm houses and more than once, when we could see the trees, farm houses were nearby.

We entered a grain ranch and shortly stopped when Johnny and Al heard a rattlesnake buzz in the bushes along the road. It proved to be another Southern Pacific rattlesnake, about 3 ft., 6 in. long. Al skinned it.

We drove on through chaparral-choked stream valleys. Doves were common everywhere as were quail.

Finally we hit the road we had taken out to Punta San Jose and shortly were in Santo Tomas. About 20 mi. S. of Ensenada Al screeched to a stop and I leaped out and caught a garter snake crossing the road.

This was Labor Day and it took us about two hours to get across the border; cars were backed up so far from the gates. The drive home was uneventful.

As I had thought at the start my company proved to all be fine campers (among the best I have ever traveled with), humorous and free and easy. It was a most enjoyable trip.

October 13, 1951

Arbolitos Camp, Baja California, Mexico

Finally after much last minute arranging and buying, we (Bill Walton and I) left for Punta Banda. This trip is to be the reconnaissance for our thesis work in Todos Santos Bay. Bill (Isaac) is studying foraminifera distribution in the bay and I, the temperature relations of the fishes.

Our drive was uneventful for the most part, all the way to Ensenada. Passing over the beautiful canyon at San Miguel, north of Ensenada, reminds me that I must drive up it some day.

A new cut off takes one into Ensenada through the slums instead of through the gate.

We bought bread and gas and continued out to Punta Banda, making only a few minor mistakes on the way.

At the head of the estero we took a mud sample (for forams) as the tide was out and the entire flat was just a series of puddles. Several huge flocks of ducks passed overhead, flashing and wheeling in the sun.

At the whaling camp we found skiffs to be 3\$ per day. It was [?] so we decided to go over to Arbolitos and make camp.

This beautiful rocky cove, dotted with rugged islands, is a truly beautiful spot. Seas were calm and skies clear.

Skiffs were 3\$ here too. We saw a fellow carrying a guitar down in the fish camp and when the camp cook, Bernardo, came up to talk to us, we asked him about it. He invited us to come down and listen.

After dinner we went to the camp and were shown into a chink-filled, slatted shack lighted by a single kerosene lamp. About seven fishermen were seated inside. An old guitar (with fine tone) was produced and the music began. One fellow picking the guitar with a toothpick and later a tooth out of a comb, made wonderful music on the instrument. He played all manner of difficult chords and runs. We heard Guadalajara and Mexican Mule Train, Rancho Grande, and others I can't remember.

Bill and I gave them about ½ a bottle of port. An old fellow fished out a quart of 192 proof alcohol and diluted the 20% wine ½ with it. All hands drank up as the Mexican harmony poured through the chinks onto the moonlit mesa around us.

We sang a couple of songs for them and joined them on Cielito Lindo. Our songs sound without rhythm after their singing.

We left as they rise at 3:00 AM and went to our campfire. We were joined by three curious people from Van Nuys and Bernardo. He and I had a fine time talking. He came from Sonora and we had seen many similar things.

He told us of the Seris of Tiburon wearing wooden crosses and various colors of paint on their lower lips and faces. I learned that a quail is a Lechusa and about a cameleon that lives in the sea.

He left and I took a hike up the road, wrote these notes, and retired to the hard, hard sack on the cold ground.

October 14, 1951

La Jolla, California

We got up early, ate breakfast, and drove towards the Bufadora (blowhole or roarer). We did not drive down to the coast at Papalote Camp but instead hiked out onto a promontory to see if we could catch a glimpse of the water which is supposed to shoot 90 feet in the air. It was nowhere to be seen.

After inspecting a midden on top of the point, we drove on out a mine road toward . . . [end]

February 8, 1952

N.E.L. Dock, San Diego, California

. . . [missing material] running along the sand spit at about the Estero entrance. The *Scripps* left us and shortly was invisible.

We took temps in the surf zone along the shore and proceeded out along the point. I saw an adult Heerman's Gull with white wing feathers (primary coverts) on both wings.

The offshore wind picked up and reached 20 knots or so in gusts.

We rounded the point and encountered a very confused sea with 5-8 ft. waves just outside the lighthouse. We took the skiff southward and the seas got higher tossing our little skiff around. White caps became common and we finally decided to turn around and head for the lee of the north side of Banda Pt.

Jack and I landed and ate lunch in the shelter of a calm cove. We built a fine agave fire and dried off a bit. Then we examined a big midden in a cave back of the lighthouse. It had been excavated (by Al Allanson) revealing at least five feet of shell layers.

We tried to run down the coast again and failed and finally met the *Scripps* out in the channel between the end of the Pt. and Todos Santos Island.

About 12 midnight we docked at N.E.L.

February 22, 1952

La Mora? Canyon, Laguna Salada, Baja California del Norte, Mexico

At about 5:00 AM Al Allanson phoned and I left for his house. We drove to San Diego, had breakfast, and went across the border at Tijuana.

We drove eastward on the Mexicali road, over Rodriguez dam (1/4 full of water or so), up into the foothills of the Sierra Juarez to the crest at Alaska (an area of granite boulders, pinon pines, and various chapparal plants) and then down the Cantu grade. This grade is a most impressive series of switchbacks descending down the steep eastern scarp of the range. We passed about four busses loaded to the scuppers, on the way. The rocks are highly metamorphosed and shot through with pegmatite dikes. At the bottom vegetation was typical desert type—desert willow, mesquite, etc. A stream of green fetid water flows for a short distance in the streambottom, and a small village is located along its banks. The buildings are partly company sheds housing various road equipment and partly most incredibly decrepit shanties of cardboard and canvas.

We drove on, onto the playa and down it to Demaras Well, where we ate a fine Albacore lunch and watched the phainopeplas in the mesquites.

The road then lead us up the bajada, past the Virgin of Guadalupe, a prominent, spire-shaped rock, and southward into a veritable wonderland of little island mountains of granite boulders. We investigated some pictographs just south of Guadalupe Canyon. Some were done with charcoal or smoke and others were done with red ochre. The former were of several types [drawing], whereas the red ones were of people in this fashion [drawing]. The red ones were painted in a little overhang along the wash edge. We found a bedrock mortar nearby and potsherds on the ground. These are apparently Yuman culture, and may be Cocopah in origin.

We drove on through a forest of palo verde, ironwood, and ocotillo, past several rocky promontories to which we attached various obscene names.

We crossed the mouth of a large SW-trending canyon (upstream)—proceeded down the slope of the alluvial fan, finally stopping next to a big granite hill.

I climbed it and determined that we were about at the southern extent of the valley and since the road had given out further progress was virtually impossible. We turned around and shortly became stuck in the sand. Until dusk we worked our way back along the bajada by putting boards under the wheels, finally arriving in the mouth of La Mora? Canyon once again.

Here we camped, ate dinner, had a nice campfire and talked of this and that. The night is calm and warm and beautiful and it is fine to smell the campfire smoke once again.

Al dug a *Urosaurus graciosus* out of the sand and gravel of the bajada. The animal was about eight inches below the surface in hard-packed sand and ran off when disturbed (about sunset). I saw *Uta stansburiana* and *Callisaurus* active at this early date.

Tomorrow we hike up this canyon we think is La Mora. We can see palm logs in the wash and the marks of recent flooding. To the old sleeping bag on the hard sand. I have had enough digging and hiking today that I will probably sleep well.

February 23, 1952

Palms Canyon, Baja California del Norte

We woke up this morning after a night spent dozing on the sand evading bass-voiced mosquitos. Al cooked some fine french toast and bacon. We hiked up the canyon

toward a big rock (looks like Sentinel Rock, Yosemite). I took the right side of the canyon and Al took the left.

I came upon an old Indian campsite in the canyon bottom. It was composed of two large boulders propped together. Under these rocks the whole surface was smudged with old smoke marks and potsherds were strewn everywhere. I found a mano and several old deer bones. Along the way I found 3 other places where ollas had been but had either been broken, disintegrated by erosion, or removed.

After a while I came to the meeting place under the rock and climbed a big boulder to wait for Al. While sitting on the rock I saw phainopeplas flying from palo verde to palo verde. The rock was cool and comfortable and I sat there looking around me. Great rocky cliffs rose behind me and off to the east I could see the Laguna Salada as a white salt flat. The wash below was a flat expanse of white sand with boulders at its edges and dotted with palo verde and mesquite trees. Small elephant trees grew from the crevasses behind me. Several times I noted butterflies orienting themselves to the sun. They would land and shift themselves around with wings outspread until they were perpendicular to the sun's rays. They would rest immobile in this position for 30-40 seconds and then begin to twitch their wings and finally take off; their thermal supply recouped. I wonder if this wing-twitching is not some sort of test to see if body and muscles are not at a good "flying temperature".

Al finally came up after having investigated many caves and finding lots of pot fragments and one good bedrock mortar.

We hiked on up the canyon together looking for palms. Finally we saw five *Washingtonia* growing from a steep, rocky hillside above a travertine seepage. No water.

We were getting quite warm and thirsty by the time we stopped for lunch in the shade of a big granite boulder. We planned to go over a saddle nearby and look for palms in adjacent canyons but we soon saw a group in the canyon ahead and hiked toward them. There were 35 of them, some in the canyon bottom and some growing on the hillside. Several pools of clear cool water were found in the rocky canyon bottom. One pool was choked with rushes. We both took long drinks and caught a *Hyla arenicolor* among the rushes. I observed these toads in rock crevasses above the pools but could catch no more.

While hiking up to a nearby cave I noted some petroglyphs pecked in the rocks across the canyon above the highest pool. There were several designs: three suns with ten rays (2 ½ inches to 6 inches in diameter, not counting the rays), two inverted U's and others as illustrated [drawing].

Al hiked up the ridge while I followed the rocky canyon bottom. Shortly I came to 35 more palms growing on a small seepage in the canyon bottom. Most of these had skirts of fronds extending clear to the ground. After another drink I hiked to the top of a nearby hill and surveyed the area. I was on an extended rocky bench dissected by many shallow washes rising directly from the final precipitous scarp of the Sierra Juarez. A continuous pinon forest lines the top of these mountains. My wash swung southward on this bench, becoming lost in a morass of boulders and finally rising to a big saddle two miles or so to the south. Beyond this is probably the upper gorge of Palomar Canyon.

I finally sighted Al and hiked over to him. He had a small adult female chuckwalla which he had captured with a stick. It is surprising to see them out this early. He had also seen *Uta mearnsi*, and I saw a small *Cnemidophorus* active

We decided to hike northward and try to go down another canyon on the return trip. We traveled along the bench for a while over a dissected area of granite washes and knobs until we came to a very deep canyon, obviously a tributary of our other canyon. We were both too tired and hungry to hike farther in search of a canyon so we clambered down the steep slope covered with loose boulders and gravel and down the canyon to the main wash. I found the horns of a Borego (desert sheep), which I presented to Al, rather than carry them myself in addition to my packsack.

I tried the water of a green-rimmed tinaja which had innumerable noctuid moths and mosquito larvae in it. It was delicious after our hike.

We hiked down the wash, becoming more and more tired. The thought of the car, cool water, a cup of wine, some dinner, and a good campfire were about all that kept me going.

Finally, just at dusk, we saw the car. After a cup of water and one of wine (a good pint of sweet wine is just about essential at the end of a long hike like this one) we cooked dinner—potatoes and onions (fried), spam, hamburgers, peas, bread, jam, pickles, cookies, and good stout coffee.

Both of us are a little stiff and tired but happy after our trek. The day has been pleasantly warm and clear—ideal hiking weather.

One remarkable thing about today's hike—we saw absolutely no evidence of man's presence—except prehistoric. Once I thought I saw a gum wrapper and it turned out to be a piece of mica. I might add, a bit smugly, that we left no evidence of our passing but our footprints.

February 24, 1952

La Jolla, California

We got up a little after dawn after another bout with the @#\$\$ mosquitoes!! We drove on toward Guadalupe Canyon becoming stuck several times. Finally about 1:00 PM we stopped at the foot of a long granite spur which descends as a series of disjunct boulder piles into the bajada.

I packed a lunch and we hiked toward the canyon up a broad, flat, white, sandy wash. The sand is very moist and carpets of evening primrose bloomed over it. Shortly the vegetation became more dense and we walked along deep-rutted cattle trails through forests of *Opuntia* cactus as high as our shoulders. Ocotillos in leaf and the ever present mesquite, ironwood, palo verde, and creosote bushes made this into a desert jungle. Phainopeplas were common everywhere, presumably feeding on the berries of the desert mistletoe, which abounds in the palo verde, mesquite, and ironwood trees.

After about an hour we came around a big granite spur into the gorge of Guadalupe Canyon. Shortly we came to water and then to groups of low palms and occasional cottonwood trees. The stream became a series of clear pools.

Upstream the stream grows even more and in places there are pools large enough to swim in.

We stopped along the stream on a little sandy beach and spread our lunch out on a flat granite boulder. The sun was warm and to put aside the pack sack and stretch out was most comfortable, particularly as some of the aching muscles of the day before still

remain. Al promptly went sound to sleep. I finally started slowly upstream catching *Hyla arenicolor*.

These little canyon toads were very common and most of those I caught were sunning themselves on streamside granite boulders. One pair was observed in amplexus. The smaller male on top of the large, distended female. Neither moved and finally I tired of waiting for developments and popped them in my collecting jar. There was some desultory calling up and down the streams, which increased markedly as dusk approached.

I saw Al picking his way slowly up the wash and whistled to him. He returned the call and looked directly at me (but later I found he hadn't seen me). He then disappeared and I assumed he was up to his old tricks of stalking me. I hiked on upstream to a big pool and waterfall and then, as it was getting fairly late, I started back, a little worried about Al's long absence.

I decided to go back to the trail and look for tracks to see if he had returned to the car. Shortly I heard a war whoop and saw Al, naked as a jaybird, standing on the top of a boulder on the edge of the alluvial bench above the inner canyon. I hiked over and found he had been soaking himself in a warm sulfur spring. Though I had heard of it before and had been up the canyon twice before, I had never seen this spring. When I arrived Al was reclining in a steaming pool under the mottled shade of palms smoking a leisurely cigarette. He had not seen me and had been even more worried than I. He had gone out onto his promontory and called once every 15 minutes or so. I quickly got into the pool also. It is a most wonderful feeling to slide your aching body into the warm water.

Old Manuel Demara had dug trenches from the nearby (1,000 ft. upstream) springs to these palms to allow the water to cool sufficiently. He built a little rock house with palm log beams and a palm thatch roof on the bench about 30 yards from the pool.

There is one room for Manuel and one for his burro. He had occupied this place occasionally since he developed arthritis. He was one of the very early settlers in the Salada, having arrived shortly after the turn of the century.

What a fine place he chose! From the bench one can look down on the whole gorge filled with palms, across the canyon at the great sheer granite ramparts of the Sierra Juarez scarp, and out over the white hot Salada.

We went up and looked at the springs where they pour from the cracks in the granite. It is steaming hot and the rocks over which it pours are coated with red and orange colored algae. Palms grow nearby with their roots dipped in somewhat cooler water, but still quite hot.

We reluctantly left and hiked down the trail as dusk approached. Neither of us walked very fast and we spread out a hundred yards apart as we hiked.

A pot of coffee and another sandwich and we drove off, over the Salada and up Cantu Grade. At night this grade is really remarkable. It is about 3,000 to 4,000 feet of switchbacks and often we could look down below us and see cars and trucks creeping along at three or four levels and up where distant headlight gleams moved through the Big Dipper and Draco.

The drive home was uneventful except that I began to develop a fine cold. Arrived La Jolla at 2:00 AM.

March 5, 1952

Punta Banda, Baja California, Mexico

Pa and I started out from La Jolla about 7:15 AM, ate breakfast in San Diego, picked up a little food, and crossed the border at Tijuana.

The day was calm and clear. We could see all three Coronado Islands as we drove along the coast. South of Ensenada I noted that the kilometer signs had been moved (apparently because of some new road cuts that had been made up north. The cut off road now stands at K123 instead of K119.

We left marker signs along the road in various places for Sam Hinton and Ben Cox, who will follow us a day later. The road is rutted and there are many muddy pools, both from the rain of yesterday and the day before.

We avoided most of them by driving around them and passed along the Estero. All sorts of wildflowers were in bloom—mallow, shooting stars, purple sage, *Encelia*, owl's clover, *Coreopsis maritima*, *Isomeris*, *Lupinus*, *Cryptantha*, carpets of *Linanthus*, *Castilleja*, lemonade berry, etc. The ground is clothed with green grasses and all sorts of small annuals. The horse chestnuts are in full luxuriant leaf.

We drove through the fishing camp, up the Arbolitos road and cut off on the bay side, driving down toward Tres Hermanas. We camped on the first terrace above the shore on top of an old midden. We soon had a cooking fire burning (wood is plentiful) and a good hot lunch ready. It is a beautiful camping spot overlooking the broad arc of Todos Santos Bay.

After lunch I put on my pack and hiked down a nearby canyon to the beach. In this canyon a shallow 6-10 foot well has been dug—apparently the source of water for the fishing camp on the hill.

I poisoned a large, shallow pool just as tide started coming in. In one small area I took eight *Hypsoblennius*.

Back up the hill I hiked up to the next terrace above and dug out some old fence posts for our campfire. Pop whipped up a fine meal of rice, hot stuff, coffee and peaches just at dusk, over his fine-smelling wood fire.

We can hear an occasional coyote in the hills behind us, ravens on the cliff below, and the sound of the surf.

The air is calm and the night pleasantly warm. Though it is only about 7:00 PM I am going to crawl in the old sleeping bag.

March 6, 1952

Punta Banda, Baja California del Norte, Mexico

Arose this morning at daybreak to attempt the temperature run around the point.

We got about 2 stations down the coast and the motor stopped. After checking everything—gas, valves, etc. we returned to the fish camp and borrowed tools—we were out of gas. Finally we got a start but it was too late in the day to attempt the run.

We fished and I made a poison job in a tide pool near the end of the point with little success.

We returned to camp and cooked dinner. Ray Haworth and his friend Larry Bradshaw were there.

Later in the evening Sam Hinton and his family arrived. We all waited for Ben Cox to arrive with the tank truck. Finally Sam and I drove back looking for them and

found them walking down the road toward our camp. They were stuck in the lagoon. We had a shovel and it wasn't long before we extracted them.

Billy Hedrick had seen what must have been a *Batrachoseps*, from his description on the embankment nearby. Back at camp we sat around the campfire and ate our dinner etc.

March 7, 1952

Punta Banda, Baja California del Norte, Mexico

Up early again. This time Sam and I tried the temperature run and got to the point and two stations beyond before 20 knot winds turned us. We rode into stiff offshore winds all the way back. As Sam was piloting the skiff he got quite wet.

Back in camp we took the car over to Arbolitos camp. It was really a wild scene with the high waves dashing themselves to foam on the rocky cliffs and stacks offshore. We drove out to Papalote (Banda Fish Camp) and visited the Bufadora there. This is a big blowhole, which even at mid tide was spectacular. It shot spray 40 ft. or more into the air. At high tide it must be very exciting to watch.

I was most interested to note that various limpets (*Acmaea*, *Lottia*) occurred far up the cliff 60 ft. or more above mean sea level, under the influence of the spray. Furthermore, no plants grow on the rocks for 150 ft. on each side of the blowhole and far up the cliff, presumably because of the salt spray.

We returned (Sam almost got stuck on the steep road out of Papalote) and then some of us went down to the Estero where I poisoned a little section of estuary while the others worked a small pool. We had reasonable success in both places.

Dinner, songs, fishes, and notes, and now much rain. It is coming down in sheets outside (I am in the cab). How we will get out is a mystery at present though I am sure we will eventually make it OK. So to the sack with the rather unwelcome patter of much rain on the car roof (we have a leaky stationwagon).

Postscript: Just as I finished writing Sam appeared at the window and after some discussion we decided to leave. We woke the others and I went down to the nearby canyon to take our skiff around to the fish camp (we had pulled it up above the high tide line). After pushing off with the aid of Ben, Moon, and Sam, I rowed through some low breakers and finally started the skiff (no light) and proceeded toward the fish camp in a driving rain—saturated to the skin—even through my parka.

I beached the boat and pulled it up as best I could—tossing the anchor high on the cobble berm. Then I started out hiking along the coast back to camp. We then packed the truck and cars and families. I tried to move my station wagon and it bogged down before I had gotten a foot. Even the big truck could not pull us out. So back to bed we went after three of us hiked back to the fish camp and hauled the boat up above high tide. *Scaphiopus hammondi* were calling in the ponds on the road (tadpoles were later taken from some of the pools). I caught three toads as they were calling or hopping about in the low growth of mallow and grasses. One pair was found in amplexus in broad daylight floating in a pool.

A miserable night was spent by the Hintons and Moon and son. Pa and I slept quite well in the bed of the station wagon.

March 8, 1952

Punta Banda, Baja California del Norte, Mexico

When I awoke the rain had gone and Mattie Hinton and LeeAnn Hinton were racing around playing games.

I stayed in camp with Ben and Pop and we straightened out camp while Sam, Leslie, Moon and son, LeeAnn, and Mattie went fishing.

At noon Ben and I dragged ourselves up and carried motors and other gear down to the canyon where we met Sam with the skiff. Ben and I went fishing and set traps. I caught a *Coryphopterus* (goby) in one of my traps and we took a series of live senioritas (*Oxyjulis*).

We returned and had dinner. Thunderheads stand in the sky in various places and we have occasional heavy showers (even a little hail). The rain is once more pattering on the car roof. Tomorrow we pick up our traps and seine and leave with low tide.

March 9, 1952

Punta Banda, Baja California del Norte, Mexico

Sunday morning! We looked around us and up the slopes and peaks of nearby mountains about 2,000 feet higher than our camp was snow clothing the hillsides.

We broke camp and loaded the truck and cars. Ben took the truck on ahead and very shortly became bogged down in a mire of mud. With the aid of boards and much brush we moved on another 50 feet and began all over. After half a day's work we got the truck on up the slope to a very steep section where it mired down to the axles and differential. A new verb was born: "transed," which refers to the act of having a car resting on its transmission in the mud. We were "transed" at this time also, I might add.

The remainder of the day was spent getting the two cars up the road behind the truck and digging drainage channels to allow run-off to pour off the road.

Dad and Johnny Hedrick decided they had better go back to the USA (rather Moon, Johnny's dad, decided Johnny was to go to school on Monday) so Sam and I and Dad and Johnny walked down to the fish camp and launched the boat. Sam and I carefully removed our shoes, as we were tired of having wet feet, and placed them in the boat before wading out into the surf. We intended to beach the boat somewhere near Estero Beach, where Dad and Johnny could catch a bus to Ensenada and thence home.

It was pleasant cruising along in the late afternoon watching the colors on the hills and watching V's of black Brandts fly overhead.

As we approached Estero Beach I could see long trains of spilling breakers pounding over the long sand spit that extends from the entrance seaward. We knew we could not land so I took the boat out to sea farther, 100 yards beyond the breaking waves and we decided to go on to Ensenada where the protected bay would make landing easy.

Suddenly I looked around from the beach and saw a big wave (only 50 yards long or so) about to break on our boat. I tried to swing the bow into it but there was no time. I remember seeing the boat up on its side and seeing green light shine through the wave above us and the curling foamy crest, vague views of two or three people bracing themselves in the front of the boat. The next instant I was in the water and foam in the bottom of the slowly sinking overturned boat. My foul weather jacket had become entangled with something. I remember being quite calm while I worked it loose, deciding if I didn't make it soon I would take my coat off. It came loose, and I popped to the surface to see everyone clinging to the boat.

Sam swam away to retrieve the floating oar and we tried to right the boat. Over she came, barely floating but quickly another big wave flipped it over on us. I swam under this time. Finally we oriented her bow inshore and we took positions. Dad at the left bow, Johnny (12 years old) on the stern with me, and Sam on the right bow.

We took stock of the situation and found we were out 200+ yards in a confused surf but that tide, waves, and wind were carrying our gas cans rather rapidly inshore. One was attached to the motor by its gas line and I tried to disengage it. Finally it broke loose and floated away. Dad's pipe floated by (I said later it was still smoking but that is not true), the Spanish dictionary floated by, and one of my shoes. Johnny was quite frightened, saying, "I'm cold—I can't hold on much longer"—Sam and I both kept a grip on him on and off. Johnny was splendid however and did as he was told and did not panic. We bent our knees over the stern and each wave pushed us farther toward shore as it broke over us. Johnny said, "Gee, I'm glad I learned first aid in the Boy Scouts."

A plane flew over and we wondered if it had seen us. The anchor had fallen out and I retrieved it to reduce the drag when a big wave broke over us, sweeping Dad ahead of the boat. Though he didn't say anything, I saw the fear of death in his eyes as he wallowed in the foam alone. I threw him a line and pulled him back. Shortly we touched bottom and pulled the boat ashore. It was a long time before little short Johnny could touch.

Sam had been perfectly splendid, carrying on a light conversation with me the whole time (we had both been afraid of cramps because of our hard work during the day). The only time Dad needed help was when he was in knee-deep water and then his knees became a little weak. I saw he was wearing his tall field boots!

Right around the corner from our landing spot was the Estero Motel (Prop. Sr. Novelo). We rented a room quickly. Sr. Novelo gave us all (except Johnny) a shot of whisky.

In the room I tried to light the furnace but was shaking so badly I couldn't open the match box until I put it on the floor. Then I had a terrible time striking the match. Shortly the place warmed up and we all took a steaming shower. A visiting fisherman (Bob Vahy) lent us clothes and helped us beach the boat and retrieve the motor (still dogged to the stern). He then cast out and retrieved our gas can with his fishing pole. A real angel.

Sam and I had to get back to camp as they would all be worrying as it was after dark.

A farmer named Bill offered us a ride, which we gratefully accepted as we were wet and barefoot and 12 miles from camp. We drove to his house and got a pickup truck and commenced the journey. Just past Maneadero we came to the Chula Vista Arroyo, which was a raging torrent. Sr. Bill promptly went "plunk" in the middle of it—the lights went out and the car stopped and water came in through the door. Sam and I formed a basket carry and took him ashore dryshod.

He walked back to Maneadero while we struck out (on a strange road) for camp, 7.9 miles away. We walked, talked, and cursed the small, dark, invisible rocks. Finally I recognized the road and we continued on under an overcast sky, praying it would not rain. For some obscure reason it did not rain. About 150 yards from the fish camp we got a ride and drove into the camp to find Moon looking out to sea holding a Coleman lantern. He was naturally worried about his boy.

We staggered up to camp and found Leslie with an inflamed eye. She had something in it that we could not see, though Sam finally removed a little white speck and she felt better.

After dinner Sam hiked down to the cars (200 yards) and barely made it on his aching feet. What a day! I went to sleep under a tent on which rain tapped its unwelcome time.

March 10, 1952

Estero Beach, Baja California del Norte, Mexico

After breakfast we dug! And dug! And pushed and pulled brush. Finally I saw a Model A station wagon descend the road above us. Two wood-gatherers got out. They tried to pull our truck out with no success. Sam and I decided we had better take Leslie and the kids home. These fellows offered to take us to Estero after we said we would pay them 5\$.

Ben asked to stay and watch the camp. None of us fought for that dubious honor.

At the fish camp Senora Gonzales said we could not make the trip in the old Model A and so we decided to take her Ford pick-up. It would not start so we pushed it and it promptly (100 yards) ran out of gas. So we piled in a '37 sedan and drove off with good Mexican music playing on the radio.

After about a mile the car ran out of gas and our driver trotted off to get another one. He returned with a much battered '36 with no rear seat. If you leaned back you fell into the trunk. Tired as we were all this began to get funny. So when this car refused to go up a little hill we all started laughing, and when two cars came at it from opposite directions to push I failed altogether to control myself [drawing].

After some bumper locking we split our party and half went in the Model A (the same one that wouldn't make it) and the others in the tired '36.

We almost collided at one time and the lights on the A failed to work, but we finally arrived, took a room, and went to bed without dinner. Next morning Sam's sister rescued us in her Mercury, and outside of becoming stuck briefly in a muddy river that was crossing the highway, we made it home uneventfully.

March 12, 1952

Punta Banda, Baja California, Mexico

About 2:00 PM Sam and John Stackleberg and I started out on a rescue mission in the jeep, with a house jack, two hand winches, a block and tackle, 4 2x12 ramps and miles of rope. We got stuck briefly in Chula Vista arroyo but arrived with Ben's wine (he would have shot us all if we had forgotten this precious stuff) just as he had gone to bed.

Sam pulled out one of the wine bottles to give Ben and it had had a hole knocked in its bottom and all the wine had poured out. Luckily the other bottle was intact.

We ate dinner and went to bed. It rained that night.

March 13, 1952

Punta Banda, Baja California, Mexico

We winched and planked and dug all day, getting the truck over the hill and driving the two cars a little closer to it.

We went to bed early with a patter of rain on the canvas.

March 14, 1952

Punta Banda, Baja California, Mexico

While we were hitching the block and tackle to Sam's car, seven Mexicans headed by Leo Cortaro from Maneadero rode up on horseback in search of strayed horses and cows. They were a jolly crew. When we worked the block and tackle it gave 12 feet for every foot the car went forward and when the car began to move fast we had to run downhill, over bushes, often falling ungracefully in the mud.

With their aid we got all cars past the grade and on high ground. Rather than try to return with the jeep (which was stuck) we packed up camp and portaged it up to the truck 200 yards away. We were pooped!

We drove on and promptly became stuck in a long, soggy, grassy swale. It was dark and we were hungry and tired and so we set up camp on the hillside, lugged rainwater up from the creek, dug a big area for the tent, and I cooked dinner while everyone else tried to get a little relaxation. This was the real low point. The constant pressing oneself to the limit of physical endurance, attempting to maintain civility to one another and constant fear of rain were beginning to tell mightily.

John said it could not rain this night and it didn't for the first time in 8 days.

March 15, 1952

Punta Banda, Baja California, Mexico

By planking, digging, and pulling, and various other means we finally all got on the good hard Arbolitos road at 2:00 PM, but not until we had become stuck 8 or 9 times. I looked back and could see great muddy splotches over the grass where we had been stuck—like the footprints of some giant beast, marching back down the hill.

We drove without event, even fording Chula Vista arroyo safely, to Ensenada where we all ate a vast meal of tacos, beans, beer, sirloin steak, soup, salad, and then home through a driving rain which we could see descending on Punta Banda in force. It rained so hard at Rosarito Beach that I had to stop as I couldn't see the road and John, who was driving the jeep, couldn't see at all.

Home at 11:00 PM, a blessed bath and a blessed sack with a blessed paved road out front—let it rain!!! Through all this, everyone on the trip maintained good humor and worked to his limit. Sam and Leslie were superb company, and the more I get to know them the finer people I am convinced they are—including their two children.

Ben Cox worked himself until his lower lip practically dragged in the mud and was willing to do more and yet never lost his good temper.

Moon Hedrick and his son were good company and help and my father was wonderful, even considering the fact that he came along for a vacation. He particularly showed his best in the boat accident. I'm glad it's over, but it was an experience I shan't forget.

May, 1952

Rock House Canyon, San Diego County, California

In the morning we ate a big breakfast of french toast, bacon and coffee, and drove on to Anza. There at Jack's Place we met a big 6-footer named Harry Bergman. He wore a stetson and side-burns. He apparently knew the surrounding country like a book as he told us about several of the trails. He said he was "the original hillbilly." His name translated means "mountain-man." "Lived here 65 years, man and boy." He invited us to come and see his museum on our return.

He lives just north of Aquanga on the Anza road. We drove on, towards Palms to Pries Highway, seeing a bobcat lope across the road on the way. At Santa Rosa Indian Reservation we turned off the main highway and followed a good dirt road, always keeping to the right, driving through a rather open grove of oaks (*Q. wislizenii*) with a dense understory of *Artemisia tridentata* (Great Basin sage). Shortly we came to a forestry gate, stopped the car, and began hiking eastward up a nice little stream lined with willows and cottonwoods. Before long we came into scattered yellow pines and finally onto a big brushy rock covered flat where the stream turns northward and up onto the rocky slopes of Toro Peak?

Al and I hunted on this flat and found much evidence of Indian inhabitation. Al found the top of a big olla, an Indian pipe, and a serape. All I found were pot sherds. Leaving the stream we hiked on to a low divide and looked over into the Borego, Clark Dry Lake, and off in the distance San Felipe Creek, Superstition Mt., and the Salton Sea. It was a real view. We cut back to the southwest and crossed rocky, broken country. We were attempting to reach one of the benches on the flanks of Santa Rosa Peak in hopes of finding an untouched Indian site. We passed through a little sandy hanging valley with a single yellow-pine growing in its center and then down into a beautiful narrow canyon that descended as a series of sandy and rocky steps through pinons and huge ribbonwoods (to 25-30 feet tall).

We had previously eaten lunch and thought we might turn back before too long when I made a misstep and sprained my ankle while jumping off a big boulder. I lay down on the sandy stream bottom for a moment to get a hold of myself and then hobbled off a few yards, down the creek. Al and I decided to hike on down into the Borego, rather than attempt the 12-mile uphill climb over the rocks back to the car. We hiked off down the canyon and after ½ hour my ankle no longer hurt me badly but remained weak so that each step had to be considered.

Shortly we saw we would have to cross 2 or 3 ridges to get to Colin's Valley and the Borego so we decided to hike into Clark Lake.

We descended quickly down bouldery slopes (the worst hiking of the day) and finally into the highest reaches of Dry Wash. We felt the desert heat for the first time as we passed through creosote bush and ocotillo. Hiking was much easier as we were walking in a broad sandy wash. I tried to shoot a quail for dinner with my shot pistol and attempted to eat some mistletoe berries but I fail to see what the birds like about these bitter little objects. For dinner we were planning on what we could catch plus a piece of cheese and some bread I was carrying in my pack.

Al turned lizard hunter. I told him to shoot them in the head as there was less meat there.

We found a nice Indian site where upper Dry Wash passes southward through a winding narrows, a few miles upstream from Rockhouse Canyon [drawing].

We found many potsherds and a fine bedrock mortar. I was getting thirsty by this time (we had one canteen of water) and spent some time digging in the moist stream bed. I imagine water would have been reached at 2 to 32 feet down but I wasn't that thirsty.

We hiked on in the afternoon. Our chart told us we should be within 5 to 7 miles of Hidden Spring in Rockhouse Canyon. I told Al I thought a big scar on the mountain would be close to the spring. We hiked for it over large alluvial benches.

We passed over an area of nice fine clean sand and found some excavations which we later determined to be the "Spindle Whorl Indian Site." Very shortly we came up close to my scarred mountain. It was dusk and the light was fading fast. Then we came to the brink of a 400 ft. deep canyon abruptly. In the bottom we thought we could see Jeep tracks. Neither Al nor I could figure how to hike down the steep slope in the fading light.

Al said, let's hike along the rim a ways, which we did. Shortly Al said, "Hey, a trail marker!" It was a huge granite boulder with small ones piled on top of it. At that moment I saw a nice broad sandy trail leading down the slope. We took it and before we got ½ way down, darkness had fallen. Shortly we stopped and I heard the calls of *Bufo punctatus* and *Hyla*. These amphibian calls told us water was near and that we had come upon Hidden Springs. The trail came out right at the spring. This old trail is marked on the chart and I wouldn't be surprised if it has been used since Indian times.

It had been a long day and we had hiked close to 30 miles. We built a fire and lay down beside it—after drinking our fill at the spring. Al said, "Break out the cheese and bread and let's eat." I said, "You do it, I'm too tired." So he rummaged around in the pack sack, throwing gear right and left—no cheese. We had left it in the car. So we ate a sumptuous meal of two slices of brown bread (vitamin-enriched) and all the water we could drink.

The spring is a small one—a small pool perhaps 6 feet long and 2 ½ feet deep at the base of a rocky cliff. *Hyla regilla* was present and gave a single note call very much reminiscent of *Hyla arenicolor*. I estimated the populations of *Hyla regilla* and *Bufo punctatus* at about 25 individuals each. These amphibians live in a place isolated by 25 miles and a range of mountains from the nearest populations of the same species. They must have been isolated since pluvial times and probably have undergone wide fluctuations during moist and dry periods since then. These animals represent one of the most isolated relicts with which I am familiar.

Hubbs and Miller (1945?) say Clark Lake did not overflow during pluvial times into Borego but this is hard to believe.

While lying by the fire we heard the rocks of the cliff above begin to clatter and slide. I jumped up (on my poor aching bare feet) and so did Al. They proved to be on the opposite side of the canyon—probably some animal coming to water.

We decided the more we could hike at night the less would be left for tomorrow in the desert heat—so we wearily got to our feet (we had frozen up considerably) and hobbled down the sandy wash in the moonlight. After a while, we limbered up a bit and hiked on fairly easily.

At about 11:00 PM I said to Al, "Right here, I'm going to sack out, not another step farther." I shuffled around looking for a spot of soft sand to lie down on. There was [?]. Everything was crusty. So I ended up in the ruts of the Jeep trail and continued on.

11:30 PM. Shortly Al said, “Here, no farther.” So I built a fire and we lay down on the hard sand near it. I gathered wood and stoked the fire—neither of us got much sleep.

5:00 AM. At the first signs of light we got up—ate a big breakfast of one beechnut gum and a swig of water and started out. We both had frozen up badly—my ankle and calves and knees. It took 20 minutes of hiking to break loose this time amid much cursing.

May, 1952

La Jolla, California

Before long we came out onto the long slope past Coyote Mountain down into the closed basin of Clark Dry Lake. The road was nearly straight and seemed utterly interminable. Al’s stomach was gumbly and I heard him say, “Shut up stomach—I’m just as hungry as you are.”

We saw many vinegaroons digging their oval burrows in the road ruts, but I couldn’t work up too much enthusiasm.

Finally, just at dawn, we reached the playa. It stands at 425 feet above sea level. We had started at 6,000 feet more or less.

In a grove of mesquites we saw a trailer and an old Pierce Arrow. I saw someone stirring inside so I said “Good Morning” and hoped to refill our canteen and maybe get a ride. No luck! The man inside didn’t say a word but sat and looked the door. Such desert hospitality!! Reluctantly we hiked on by and began the long hike up the Clark Lake Divide. The heat had begun to close in and there is utterly no shade except that under low creosote bushes. We were both hungry, stiff, thirsty, and weak, so we stopped every ½ hour for a ten-minute rest under a creosote bush to let the strength run back into our muscles.

About 2 hours after passing the trailer we saw the car coming up the road. Al was 100 yards behind me and he waved and jumped up and down. The man waved back and drove on!! He did the same to me! I made every gesture I could think of but he did not stop. I watched him until his car and trailer disappeared over the crest in a distant cloud of dust. It had felt good to know we could stop and wait for him to pick us up if we had to but now we knew there was no one behind us!

Al said, “I’m going to stop at 9:00 AM if we don’t see our way out and stay during the heat in the shade of a bush.”

A wise idea indeed for it would be suicide to hike in the heat for any distance and we were already very thirsty and hungry.

Just at 9:00 AM I topped the divide and looked into the Borego. Two ranch houses were near. After a rest in an old movie set (*Desert Fox: The Story of General Rommel*), I went for one and Al for another.

I walked up onto the porch of the ranch house and saw five people eating ham and eggs inside. Ham and Eggs!!!! I told them our story (through the screen door) and got absolutely no reply. I was not about to leave as I was too far gone. Finally one said, “Would you like a drink of water?” I allowed that that would please me a great deal.

A man came out, antiseptically closed the screen door, handed me a glass of water, and retreated inside. Not another thing occurred but the chink of plates, cups, and utensils for five minutes. Finally, I was offered a cup of coffee, which I drank. Then I

heard them discussing—“Do you think we should take him into town?” “I don’t know—maybe...”, etc. etc.

Finally, they got out a car (it turned out they were going into town anyway) and we drove off. We found Al under a big creosote. He never had reached his farm house.

We were let off at a restaurant when we called Dot Allanson, washed up, and went in to get breakfast. They had a “Prospector’s Special” for \$1.50 with everything under the sun on it. They didn’t have it, so we ordered a “He-Man Special” for \$1.35, ate that, and ordered a stack of pancakes. The waitress said, “I sure do like to serve boys who like to eat.”

We slept under a tamarix until Dot and Johnny Fleet came out in the pick-up and got us. We drove to the Santa Rosa Reservation, picked up my car (and the cheese), and drove down to Harry Bergman’s—what a fabulous place!

He has a nice ranch with all sorts of fruit trees, a pasture, and so much junk that he has built a separate museum for it. A sign over the door reads “Bergman Museum of Natural History—Harry Bergman, Curator.” Inside he has a fabulous Indian artifact collection—thousands of points, spindle whorls, ollas, baskets, etc. In addition, there are crabs, stamps, butterflies, old hats, political buttons, knives, lizards, dried fishes, swords, rifles, deer horns, cows, fabrics, Greek orthodox icons.

(Then we went home. I must have been too tired to finish this—K.N.)

August 5, 1952

At sea enroute to Sebastian Vizcaino Bay, Baja California, Mexico

After an unusually intense last minute frenzy involving obtaining diving gear we boarded the *Paolina-T* for a 19-day cruise to Sebastian Vizcaino Bay.

We are planning to do a lot of fish collecting at several locations around the bay, in an attempt to correlate the fauna with the temperature structure of the bay waters. We think a warm layer of water floats over colder deeper waters. If this is true and constant we should find cold water fishes living on the bottom of the bay and warm water ones in tidal areas. This last we know to be true.

The scientific party consists of myself in charge, Jack Littlepage (interested in crabs) and Wes Farmer (interested in nudibranchs), Howard Harper (interested in wildlife management), and Bob Howell (a technician from the Marine Life group).

We will seine, poison, dredge, trawl, and use dip nets to obtain our specimens.

The skipper and cook came on board about 11:30. Newbigen, the skipper, left his wife in the hospital, but came along anyway.

Finally we sailed out of the bay, past North Island and Ballast Pt. Seas were calm and all was lashed securely so I went to bed, satisfied that all would go well.

August 6, 1952

Enroute to Sebastian Vizcaino Bay, Baja California, Mexico

The day has been calm and mostly clear. No one has shown any signs of seasickness, which is amazing on this rolling craft. I got up quite late after having lost much sleep during the frenzied preparations period. We saw several whales, which I think were finbacks. The dorsal fins were quite large and fairly well forward. One had obviously lost a portion of his fin. I saw three whales myself and all were apparently proceeding northward. We saw many sharks about 5 feet in length lolling lazily on the surface.

Murreletts were common and usually were seen in pairs. Black-footed albatrosses and shearwaters were also fairly common. Phalaropes flew from the water in large groups in front of the boat. Wes discovered that an essential part of our diving gear was missing—a little collar which allowed us to refill our diving bottles. After some stewing we thought up an idea and the engineer constructed one for us. We have radioed for the original one (to be brought down on the *E.W. Scripps* when she comes in two days), but I don't think we will really need it now.

My crew is most enthusiastic, most of them never having been to sea before. They marvelled at a small showing of phosphorescence off the bow and were most excited by porpoises swimming along in front of us (unidentified). Our work will start tomorrow at 7:00 AM when we release a bunch of drift cards. I will go read a book now or discuss vital issues with the crew.

August 7, 1952

Camp at Rompiente Pt., Baja California, Mexico

We got up at 7:00 AM and prepared to release drift cards in Vizcaino Bay. These cards are numbered and encased in a watertight plastic bag. Instructions are listed in English and Spanish, telling where cards may be sent and explaining that they are for studying ocean currents.

We sighted Cedros Island through the clouds and began releasing cards in packets of 15, every 30 minutes.

It is suspected that water circles in a clockwise fashion along the coast of the Vizcaino Desert and up along the east coast of Cedros Island. [Drawing] A convergence line has been noted extending shoreward from the north tip of Cedros Island, indicating the meeting of two opposing currents.

We could see the scraggly, closed-cone pine forests on the crest of the island as we sailed down the coast. At the central saddle I noted a fine wide canyon leading into the island. We hope to hike it soon.

Off the north tip of the island we were joined by possibly 100 striped porpoises, *Lagenorhynchus obliquidens*. Numbers of them played around the ship for 15 minutes or so.

Skies cleared and by the time we reached the south end of the island, all was sunny and bright.

We continued on between Natividad Island and Punta Eugenia in the Dewey Channel. Off Morro Redondo we saw a huge school of porpoises, possibly 3 or 4 hundred animals, playing or fishing 2 or 3 miles away.

As we continued on down the coast the wind picked up and we began getting south swell. Seas breaking along the shore looked quite ominous for landing.

Finally we entered the cove. Big swells crashed on the headlands but we could see fairly calm shores next to an old lobster camp. We loaded our skiff with all our gear and hopped aboard. It was really loaded. Just as we were about to land a series of large swells came along and crashed on the beach. Finally we raced in using the outboard and made it safely to the beach. It was not a seaman-like job but it worked. We took all our gear above tide line and set up camp in a little draw. We poisoned a little reef adjacent to the camp obtaining many individuals of a few species. Then Howard and I took the skiff through the surf with one seine and rowed down to a nice sandy beach.

I took the skiff in stern first but just as we were nearly in, a wave caught us and flipped the skiff. I pushed clear and looked around for Howard. Finally I started to turn the boat over when I felt him swimming out between my legs. He had been trapped under the boat and as the water was very shallow he was having trouble getting out from under. I was mighty pleased to see him pop to the surface and I am sure he was even happier. We beached the skiff and tipped it up, pouring out the water.

We could see that it was impossible to go back through the surf so we decided to beach the skiff until tomorrow morning when the surf would be lower.

I had Howard take a hold of the braile of our seine and we hauled it out into the surf. Jack and Wes took the other end and we went out into the surf. It tosses us around and battered us under but we managed to make two hauls this way. We caught vast quantities of shredded algae and a few guitar fish.

Our second haul produced a big bay perch and a rudder fish (hermosillo). We spread the seine, hauled up the boat, and hiked back to camp. We ate a big meal of spanish rice, beans, coffee, peaches, and bread.

We built a fire and sat around enjoying the good fellowship. It was a beautiful moonlit night so we sat around yakking until we got hungry again, so we cooked up a portion of the shovel-nosed shark (very tasty) and a can of corn. Howard produced some remarkable items from his pack sack. One was a plastic bag which folds into a small packet. Its use is doubtful but it is very compact. He claims it is for a raincoat but it has no arm holes or head holes. We are all perplexed. He also has a fine nylon pup tent which we spent much time trying to get him to put it up in the rainless land.

We then sacked out on the welcome ground.

August 8, 1952

Puerto Rompiente, Baja California, Mexico

We got up with the warming of the sun. After a brief breakfast we went down the beach and launched the skiff. Waves were still high but Wes and I made it through after shipping a little spray.

Very pleased with our success we rowed around the headland and beached the boat. We then walked back down the beach and helped Howard and Jack with the nets and brailes.

We arranged all our gear so it would be ready for loading. Then we took a little walk up a nearby wash. Vegetation is very sparse hereabouts, consisting of recumbent elephant trees, goatnut bushes, saltbush, and very occasional cardon cactus.

A series of gypsum and mudhills bordered the stream bed. In some places white outcrops of gypsum showed though the soil overburden. I shot a female leopard lizard and a big desert scaly lizard (on the run). Along the beach we saw several *Callisaurus d. crinitis*, apparently feeding among the algae, washed up on shore. These lizards were not seen at all in the badlands back from the shore.

We ate a good lunch at camp and just as we finished we saw the *Paolina-T* rounding the cape. We took the skiff into the water and stowed everything aboard and then put the outboard on. With the oars manned we started out through the surf. We went through one wave taking a little spray on and then a big one broke over our bow, virtually filling the boat. I decided we had better go back in so we did. Shortly we were filled and the skiff began to drift onto the rocks. I leaped out and tried to head her into the waves. We got it up toward the beach and had a mad frenzy of unloading gear etc. onto the boat. Some gear was lost but we got most everything ashore safely but wetly.

Finally we emptied the boat and hauled it ashore. The motor had been wet and there was a hole in the bottom of the boat. I patched the skiff with a piece of plywood we found, nails pulled from the shacks, old mattress ticking, and Wesson oil, which we poured on the ticking. It works perfectly and doesn't leak a drop.

Soaking wet from head to toe I climbed a nearby hill and lit a white signal flare indicating to the *Paolina-T* that we would be forced to stay ashore but that everyone was O.K. We laid gear out to dry and hauled everything up above tide line.

I found a big barrel and we worked on the outboard, shortly getting it running again. Wes lost some fins, a head lamp, towel, and shoes, and Howard lost a pair of shoes. Other than that everything was O.K. My notebook is a bit soggy but intact.

Howard cooked dinner. We had a 4-lb. can of corn beef which we attempted to eat in one meal. We did not entirely succeed. We also had brown bread and spanish rice. A few timbers borrowed from the dilapidated lobster camp supplied us with a good fellowship campfire, which I am enjoying while writing these notes. We hope for a calmer surf in the morning to launch our skiff. We will see in the morning. To the sack which I hope is not too soggy!

August 9, 1952

Chester Rocks, Baja California, Mexico

We got up close to dawn and cooked our breakfast. The surf was lower but still a bit ominous. I hadn't slept too well thinking over ways of getting off this cursed beach. It seems like it has a hold on us. Just as breakfast ended we heard a couple of toots out in the bay and saw the *PT* riding at anchor.

Quickly we loaded the skiff and started out to the surf. I saw the load was too heavy so I decided two loads would give us more chance. We unloaded the nets and diving gear and Wes and I took the skiff through without shipping a drop. We unloaded at the *PT* and I returned, making it through the surf by the skin of my teeth, safely.

We picked up our gear including the barrel and shoved off. We went through a couple of breakers but without shipping much water. I had Howard push us through and swim out to us. He forgot to take off his shoes so it proved quite a swim and he lost one shoe. We were all more than glad to get back aboard and sail out of this bay. We went up the coast toward Natividad Island and met the *E. W. Scripps* in Dewey Channel. She was riding at anchor taking current measurements.

We then continued on to Natividad Island where we landed in a beautiful little cove with a white sand beach extending up to a vertical sea cliff. We climbed up a steep trail and onto the barren undulating surface of the south end of the island. The surface was dotted with Western gulls and some downy young, larger than their parents. The gulls flew off in a screaming cloud when we walked on top. I decided it would not do to frighten them further as it is against the law to land and frighten the birds. The island is a guano reserve.

We hiked up slope into a little swale near the crest. The vegetation is very low and scrubby and very thorny. A sort of *Opuntia* cactus is very common and very vicious. I got a couple of nice lizard specimens. We walked down a little defile back to the beach. Amongst a pile of abalone shells on the beach we caught a splendid series of *Uta* (brown-shouldered lizard).

We then took the skiff around to a landing below the lighthouse and talked to the wife of one of the two men on the island (employees of the guano company). She lives in a barren wooden house which was quite neatly kept. We told her about drift cards and drift bottles, explaining we would pay her for any she picked up.

Back on board we upped the anchor and crossed Dewey Channel to Chester Rocks. These rocks harbor a large population of cormorants and sea lions. The smell is nearly overpowering for a long distance to sea.

I took my crew ashore and we luckily found a good tidepool and made a fine collection before sunset. The fauna was just a little more indicative of warm waters than the La Jolla fauna. We went back aboard, ate a belated dinner, and took care of specimens.

High surge forced me to abandon plans to attempt a deep water poisoning on the reef ashore so we loaded out beach seine and worked a pretty little beach near the reef we had worked the night before. We caught a fine series of leopard sharks and some other fishes.

Back on board we started down the coast in a considerable swell. The ship rolled and pitched a great deal. Newbegin took us in where he calculated our next stop should be, which we planned for ½ way between Chester Rocks and Punta Malarrimo.

Low bluffs line the shore and rose in two terraces to barren, sand-covered mountains. A scraggly forest of palmas del monte (*Yucca valida*) could be seen on the crest of one slope, and an incredibly decrepit fishing camp adorned the point where we planned to land. I could see nothing that promised good collecting at all but planned to poison (with rotenone) a cobble beach we could see through the glasses. I also thought I saw a good way through the surf, near the camp.

We left the boat in heavy swell and twisted the outboard and were off.

Shortly, as we came into the lee of the point, the swells decreased and seas became calm. We landed through waves no higher than 1 ½ in. and stepped out dryshod for a change. Six Mexicans were in the camp taking a siesta. I talked to one and he said they were abalone fishermen. They used a look box and a long pole with a hook on the end. They spotted the abalone through the box and then hooked it aboard.

We had an hour's wait for the tide so we took a short hike up a barre arroyo. There is an airfield here on the desert pavement and a truck trail up the arroyo.

We saw two of the tireddest coyotes I have ever seen. They sat down in plain sight 100 yards away. When we walked toward them they walked away. The only time they ran was when Howard bombarded them with rocks.

We poisoned a fine rocky pool and collected a fairly typical warm water fish fauna. Wes had a fine time collecting nudibranchs of which he got quite a number of ones new to him.

We went back to the ship through fairly monstrous swells and boarded, unloading the skiff with some difficulty as it pitched up and down alongside the *Paolina-T*. The skiff is too large to be lifted on the falls and has to be unloaded by hand over the rail and then pulled up astern, over the net roller.

We worked up our specimens and Newbegin dip netted a fine series of needle fish (*Strongyluros*) for us. To the sack in a pitching-rolling bunk.

August 11, 1952

Off Cedros Village, Baja California, Mexico

This morning we began trawling for bottom fish across Sebastian Vizcaino Bay. We rigged our 35 ft. otter trawl and put it over the side offshore from Punta Malarrimo. Shortly it became tangled on some bottom obstruction and we stopped the ship. The winch was left with the clutch off so that any heavy strain causes it to slack off and thus not ruin the gear.

We were proceeding into a considerable swell and cable occasionally slipped out on a large swell.

The net was easily freed and we obtained a good collection of kelp-dwelling fishes.

On the next haul, as we were bringing the otter boards onto the fantail, the cod-end of the net drifted under the stern of the ship. Just then Newbegin kicked the screw around a few times to head us into the swell. The net caught on the screw and we could not free it. The only thing to do was to dive down and cut it loose. Since I had had more experience with the aqua lung diving unit than the others it was my job. Diving under the stern of a pitching ship in the open sea did not, however, appeal to me. Newbegin and I got in the skiff and I put on the gear. Stan McDade brought me a sharp knife.

On my first attempt my mask filled with water and I had to come to the surface. The ship and skiff drifted away from me in a swift current and it was all I could do to swim back to the skiff, even considering my swim fins.

Next attempt we hauled in the retrieving line, which was attached to the cod-end of the net. I went down it hand over hand to the screw. Everytime the ship pitched it pushed me 15 ft. up and down in the water causing terrific currents. I had to wrap both arms around the stern post to hold on and attempt to cut the net loose as best I could.

The retrieving line had wrapped around the net, enclosing a lot of fish including one very large amorphous blob I could not identify. Finally I got the net cut loose and it was hauled aboard.

I got back in the skiff and on board. They had considerable trouble bringing the skiff up because of the swell.

The blob in the net proved to be a large electric ray who was not yet dead. There were also several hundred lizard fish, a species I have seen before only in ones and twos.

We took several more dredge hauls (using a small pipe stem dredge). The heavy swell told a bit on Howard, Wes, and myself but Jack apparently felt fine all day.

We anchored off Cedros Village in a very pleasant calm anchorage. We loaned some chain and an anchor to the *E. W. Scripps* who had just lost hers off the south end of Cedros.

Most of the crew either went ashore or visited various craft in the bay. I pickled fish and more fish. Wes caught a mess of barracuda on a jig over the side of the ship.

August 12, 1952

Off Cedros Village, Baja California, Mexico

About 8:30 this morning my crew and Ken Armstrong, the cook, piled in the skiff to start on an inspection of Cedros Island. We took the skiff along the steep east coast of the island northward until we came to a large alluvium-filled canyon called Gran Canada.

We landed at a fisherman's ranch. He came down to greet us and helped us land our boat. He fished for bass and halibut. He had several huge skiffs; one about 25 feet long. His name is Martinez. He showed us the trail to the pines.

We hiked up this beautiful big canyon, passing alluvial fans covered with dense forests of large elephant trees. Goatnut and lemonade berry were common in the creek bottom.

After a while we came to a major divide in the canyon. On a spur above the two entering canyons we saw a partially ruined rock house. The left canyon had many roses growing in it and a small stream of CaSO₄-saturated water. This was surprising as water is shown on the map only above the village. I caught some tree toads (*Hyla regilla*). We observed many deer tracks around the stream edge.

We ate a fine lunch at the rock house (which had apparently been connected with a nearby mine) and continued on up the canyon. Shortly junipers became common and we saw many big sumac bushes (*Rhus laurina*). Finally we cut off the canyon up a steep little draw towards the pines which we could see on the ridge above us. Fog lay in a huge white blanket over the crest, resembling a tremendous snow cap which extended down the draws and vanished in the sunlight.

Our draw was just a V between two talus slides of small fragments of shale. It was very steep and slid from under our feet. Finally just before we reached the crest, it became so steep we had to use our hands and knees to climb it. The sun was hot and we wished most fervently that we were on the cloud-covered crest of the ridge. Once we reached the top of the canyon it was a short hike along the ridge to the pines. Fog whipped through their branches causing them to sigh.

Festoons of moss hung from their branches. The pine needle duff was thick and wringing with moisture. I searched under punky fallen logs for salamanders with no success. These pines (*Pinus remorata*??) occur in small, isolated patches along the ridge and are apparently maintained by the almost constant cloud cover. Lemonade berries were common around the fringes of the grove and just down the hill were elephant trees. It is a great spot to see. We had to leave in order to get back to the ship before dark so we started down the steep talus slides. I had my harmonica. On one particularly long and steep slide I lead the way and skied down the slope very rapidly, playing "Skater's Waltz" in rhythm as I went. It was a fine descent except that Wes twisted his ankle. He managed the rest of the hike though. The walk back was long but pleasant. We were all glad to arrive at the skiff. Sr. Martinez gave us a halibut and a drift card his son had retrieved.

We cruised back along the coast against the current and arrived at about 6:15 on board.

In the evening we all went on board a purse seiner, the *Liberty Bell*, but they sighted no schools so we did not make a set. About 12 midnight we came aboard the *Paolina-T* and went to bed at once.

August 13, 1952

Lagoon Head, Sebastian Vizcaino Bay, Baja California, Mexico

At 7:00 AM we hauled up the anchor and began trawling operations across the bay. The damaged otter trawl was repaired and we used it almost entirely. Once with the dredge we brought up a bag full of green mud; so full that we could hardly hoist it over the fantail. There were many interesting invertebrates; sea feathers, sea pens (both colonial coelenterates), nudibranchs, many sorts of shells, octopi, crabs, etc.

Late in the afternoon I decided to do the last haul with the trawl and then to put on the dredge as the chart showed we would be going up an incline at that time. The trawl is not so good for rough going as it is relatively unprotected. When we tried to haul the trawl up it stuck fast in the bottom, the winch stopped and the lights went out. Our generator had quit and we were effectively anchored with no idea if we would lose the net or not. Finally by use of batteries we hauled ourselves over the net (in 40 fathoms) and tried to haul it loose. The winch strained until the wire was vertical. The clutch slipped several times (it is meant to prevent snapping the wire) and finally we inched the line in. It was free! It came on board perfectly intact. Mud on the otter boards makes me

think that the wire had dug into a mud hill and dragged the boards into several feet of mud. It is fortunate we didn't hit rock.

We anchored in the bay behind Lagoon Head at about 11:30 PM. The lee was most pleasant after all the rolling and rocking of today.

I climbed the crow's nest to shoot a bat I saw flying by. I thought it might have been a fish bat. It proved to be a petrel on closer inspection. Off to the sack.

August 14, 1952

Lagoon Head, Baja California, Mexico

After breakfast my faithful crew and I piled in the skiff and went ashore to do a bit of seining. Lagoon Head is a volcanic peak with two rather indistinct cones rising from a sandy undulating plain. In the distance inland, perhaps 30 miles, one can see a range of jagged peaks. The point protects a shallow bay from the north and affords a fair anchorage for small craft from prevailing NW winds.

Vegetation is everywhere very sparse; the largest plants are *Yucca valida*, the "Palma del Monte". Back of a narrow barrier beach is the Lagoon de Manuela. It is long and narrow and edged with dunes on the beach side. The water is quite deep in many places.

Our seining on a flat beach by the point produced relatively few fishes. We went down the beach and walked over to the lagoon, across the dunes.

Jack and Wes decided to walk to the lagoon entrance while Howard and I took the skiff in. The only idea of the entrance I had, came from the 1868 survey chart of the *U.S.S. Ranger*. The bar shown on that chart is now non-existent. We tried to sneak in where the old channel should have been and had an interesting few moments with the surf but made it through by dint of riding a few waves.

We met Wes and Jack walking along the lagoon shore. We made one pass with the seine and caught the net on a rock tearing the bag fairly badly. Even so we got a fair net full of fish.

We went out the entrance between lines of breakers and had no trouble at all. It was choppy before we got back to the *Paolina-T* and we had a wet ride. I spent the afternoon preparing the fish.

After dark we hopped in the skiff and headed for the beach. It was pitch black. Much phosphorescence in the water was all the light we had. I could make out a dim outline of the point and headed for shore through shoal after shoal of darting fish. I had to feel my way along as we could not see the shore at all. Finally it was upon us. The thin line where the little waves lapped up on the shore was about all we could see. Seining proved very successful. We caught a fine group of fishes including many big-eyed bass, thornback rays, corbina, halibut, topsmelt, butterfly rays, etc. etc.

Back on board we got gear ready to go ashore tomorrow at Scammon's Lagoon. I finished fixing collections at about 1:00 AM. I have to get up at 5:30. Gadzooks!

August 15, 1952

Scammon's Lagoon, Baja California, Mexico

Up at 5:30. The ship was still underway toward the lagoon entrance. My crew and I finished our packing for the skiff run into the lagoon. We are scheduled to spend 3 days collecting in the lagoon.

At 6:00, after a good pancake breakfast, we hopped in the skiff and started for the lagoon entrance. The sea was a glassy calm and the shore dunes could clearly be seen 4.5 miles away. We had a heavy load in the skiff, but it rode well and barring rough weather on the return trip or some other unforeseen trouble we should have no mishaps. We carry signal flares in case of emergency.

Bars line the lagoon entrance on both sides but the waters were so calm that we could not detect them. After a hour or so of riding we rounded the cape and entered the two or three mile broad lagoon entrance. We were startled by a small school of bay porpoise (*Tursiops gilli*), which came over close to the skiff and swam along, porpoising out of the water 15 feet away.

Skies were cloudless and sunny by the time we entered the lagoon proper and cruised along close to a sand dune lined shore. The lagoon is a vast expanse of calm water extending as far as the eye can see in some directions. Far in the distance it can be seen bordering a line of low barren mountains to the southwest. A few low reed-covered islands could be seen to the east.

I nosed the good skiff into the shore and we stepped ashore dry shod onto a little sandy flat between low dunes. With our gear unloaded and the outboard noise quieted we all became aware of the incredible quiet of this isolated and uninhabited lagoon. Howard swore he was awakened from his siesta by a little shorebird noisily padding down the beach. An occasional tern screeched as it flew overhead and we could hear the noises of birds calling from a nesting island two or three miles across the lagoon. The day had become hot and I decided everyone could do with a little rest, so we built various shelters from the sun and went to sleep on the warm sand.

We walked up and down the beach. All sorts of drift wood, some from wrecked vessels, was strewn over the dunes. We ate a fine lunch of veal chops and loaded the skiff and cruised across the lagoon toward Shell Island. This island is surrounded on the north side by a growth of eelgrass (*Zostera*) and pickleweed (*Salicornia*) flats. After running aground once I went slowly along the north shore until we came upon a clear channel to a sandy cockle-shell covered beach. This entrance is sheltered on both sides by reeds and low sand bars.

We pulled the skiff up right next to a cormorant's nest. The young fluttered their yellow throat pouches at us as we unloaded our gear. A small heron with a rusty red head and crest and a gray body had a nest in an old crate a short distance down the beach. The island is roughly crescentic, about 500 yards long, composed entirely of sand and apparently covered completely during spring high tides. There were many cormorant nests and heron nests on the island. A large flock of brown pelicans occupied the west end. A large flight of wheeling, screeching Caspian terns circled the island several times as we landed. These birds were in two discrete flocks, one would take off when the other landed. A single osprey sat on a piece of driftwood near camp. Oyster catchers, dowitchers, willets, sanderlings, black-bellied plover, and curlews were common. We watched two herons fight with each other, jumping up and down and erecting their crests just like game cocks.

We put our bags down on soft beds of dried grass. I constructed a little shelter for our gear of driftwood, of which there was an abundance. We dug a pit in the sand for our campfire and for us to sit in. We ate our dinner and sat contemplating a beautiful sunset. This island was ours for the moment and we all felt good about it.

We seined the cockle shell beach and obtained a good collection including a big white sea bass, too big to preserve. We took him back, built a "good fellowship" fire in our pit, and I fried him up for the crew at about midnight. We talked as the fire burned low, drank a couple of cups of boiled coffee (in bean cans) and went to bed.

August 16, 1952

Scammon's Lagoon, Baja California, Mexico

After getting driven out of the sleeping bag by the sun I walked around our island and photographed young birds. One little dizzy heron clacked his bill at me in a most ferocious way.

I tried poisoning some of the small channels in the *Salicornia* marsh without great success. We then hopped in the skiff to look for a place to seine. We crossed the main channel to the sand dunes and found a nice level plain and a small lagoonlet that looked fine for seining. The day had grown hot and we didn't feel much like dragging the seine. I decided to move camp to this spot in hopes of making a good haul. Back on the island we all had a good siesta and then packed the skiff. I checked my poisoning and found a good kill of *Gillichthys* and another unidentified goby.

We went across the channel in the face of a good wind and landed on the edge of the lagoonlet. As dusk set in it became apparent that we were on an island (created by the rising tide) and that high tide would soon submerge us completely. Finally we loaded the skiff and landed at the base of a sand dune above the reach of the tide. This constant loading and unloading gets very wearying.

Our evening's seining proved something of a disappointment and was very very hard work as the high tide beach is composed of very fine aeolean sands. We sank to our knees at every step. I almost lost my shoes. Then, on a somewhat harder beach we encountered tidal currents so strong that we could just haul the net in.

Back at camp we had a fine fire and coffee, and Howard showed us Jupiter's moons through my 7 x 35 field glasses. I had never seen them before. To the sack very belatedly.

August 17, 1952

Scammon's Lagoon, Baja California, Mexico

After a hearty pancake breakfast we packed the skiff and shoved off down the lagoon toward the entrance. At one place a 100 ft. dune drops off directly into the lagoon. The sand stands at its maximum angle of repose.

Jack and I climbed it and lay puffing at the top. It was quite a sight to look down this perfectly even slope at the little skiff and Howard, 100 ft. below. We lured Wes up with his camera. I gave him the contents of my pockets and dove over the edge, sliding right down to the water's edge.

We then went swimming, following the skiff as it drifted along. The water was warm and clear. An occasional porpoise swam lazily along within 8 to 10 ft. of the shore—right by us. We dried off and continued on around into the lagoon entrance. We landed on a fine beach and made camp by a huge old cast-up mast, partially buried in the sand. I dug a shelter behind it and we all piled driftwood boxes and logs up until we had a fairly windproof shelter. The afternoon breeze picked up and whipped sand over the

dunes and beach. We had sand in everything. Even with our "good fellowship campfire" we were not very comfortable.

Howard and Wes took a hike up the beach and returned with seven drift bottles they had found on the beach.

In the evening we made several seine hauls, catching puffers, needlefish, and some other interesting fish. A heavy dew had fallen and everything was damp in camp. Jack and I brewed up a pot of coffee and talked for a while and then went to bed. My ground cloth had been sacrificed to keep the motor free of sand and moisture so I slept with much sand in my sleeping bag. We hope for a calm dawn tomorrow so we will have no trouble leaving the lagoon.

August 18, 1952

Lagoon Head, Baja California, Mexico

I woke before dawn and noted a fair amount of fog and a slight breeze. At dawn I kicked out my crew and we loaded the skiff carefully without stopping to cook breakfast.

We launched though the low surf with no trouble and the blessed motor started right off and we cruised out of the lagoon. The *P.T.* was somewhere 10 miles beyond at anchor awaiting us. After a long time Wes sighted a mast showing dimly through the haze, above the horizon. It must be the *P.T.* So I headed for it and 2 ½ hours after our launching we boarded the ship and immediately (after unloading) descended upon the galley for breakfast. We were all glad to be back on board. I, for one, had felt a constant strain sweating out the weather while we were in the lagoon. Bad weather would have prevented our departure. But we were lucky.

We trawled over to Lagoon Head and towed the try net at night, obtaining some good specimens and many shrimp close to the surf. Back to the ship and to the old bunk.

August 19, 1952

Lagoon Head, Baja California, Mexico

This day we piled in the skiff and started for the entrance to Manuela lagoon. It was clear and calm. I took the skiff well down to the lagoon entrance and still failed to hit it exactly. We had a few anxious moments with small breakers piling up behind us and pushing us into the entrance as if we were a surf board. The bow stuck out of the water four or five feet at times. Finally we entered the calm waters of the lagoon and put out the try net. Much towing produced very few fishes except diamond turbot, young halibut, and sting rays.

Finally we hung the net up on some obstruction and retrieved it rather badly torn. There were again large purple sea urchins in the net indicating a rocky bottom.

The entrance is easy to find going out so we cruised right out into relatively calm waters. Six or seven foot sharks were seen jumping from the surf zone through which we had passed on the way in. They looked like mackerel sharks.

We had a wet ride back bucking the wind chop but made it back in time for chow.

After dark we loaded the beach seine in the skiff and headed for shore over calm seas. It was dark as a pocket and I stood up in the stern while steering in an attempt to see the shore. Finally, I could see a thin white faintly luminous line of the low surf. I cut the engine and we rowed ashore without even getting our feet wet.

We made four hauls in the dark water. When we rowed the skiff out to set the net, thousands of flashes of luminous light shot away from our bow—fishes shooting through the water. We took many fish—croakers, many accursed sting rays, thornbacks, a couple of numb fishes, hundreds of smelt and big-eyed bass and quantities of edible shrimps. Stan and Gene helped us and particularly helped us with the shrimp and fishes too big to pickle.

As we cruised back toward the masthead lights of the *Paolina-T*, the whole bottom seemed to rise periodically below us and in front of the skiff as shoals of fishes shot through the phosphorescent water.

On board I spent some hours preparing specimens and then repaired—a bit pooped—to the sack.

August 20, 1952

Santa Rosalia Bay, Baja California, Mexico

We left the ship fairly early and cruised along Lagoon Head in search of a poisoning spot. Nowhere did it look too promising. Almost algae-less volcanic rocks dropped through the clear water to a clean sandy bottom. Finally we located a stretch of rocky bottom near a natural rock arch and anchored.

We had a few sea lions from a nearby rookery swimming around but they didn't come in too close. I placed the poison. In the process I saw large numbers of four to five-pound kelp bass, many big opal eye, and schools of big hermosilla. It looked like a good spot but the poison did not hang too well. I dove down a little later and found only a very few fishes on the bottom.

Howard and Jack and Wes dove too and produced little but bubbles.

We all climbed aboard shivering as the water was about 16 degrees C. Off to the ship for chow.

We hauled anchor and piloted up the coast 25 miles to Santa Rosalia Bay. This place holds memories for me as it was here that Arlene Lowe stepped on a stingray. We had come down a long canyon after two dusty hot weeks in the desert to this beautiful arc of sand, put on our suits, and ran into the surf.

It looked less lonely from the ship. We could see the main rocky headland, a low sand-dune filled gap, a series of low bluffs topped by a level terrace, and then the canyon and beach.

In the evening we took the net ashore and seined the beach taking a fair series of fish. Gene, Stan, and Newby went surf fishing and had prodigious luck. They caught 61 croakers and corbina. Most all were six lbs. and over in weight. About 7/8 were large spotfins.

We had to take Stan back with us as their little skiff was nearly level with the water because of the big load of fish. We cleaned them until 12:30 AM.

August 21, 1952

Enroute to San Diego

Ted accompanied us this morning as we went around the point, and across the channel to Elide Island. I looked for a poisoning spot and finally decided on one between two large seal rookeries. The island is small, about ¼ mile long by 1/8 wide and is covered with guano. A guano keeper's house, a tent, and a small cement loading dock

are all beside sea lions and cormorants, that grace this lonely spot. The channel between the island and the shore is very shallow and apparently quite rough in any sort of a wind.

Aside from numbers of sea lions the poisoning spot was beautiful. The water was calm and clear and about 25 feet deep, covered with algae and stands of kelp.

We made a fairly good collection in spite of the fact that I was the only person who caught a single fish with the diving unit. Ted got a big kick out of the proceedings.

Back on board we worked on specimens as the ship stood out to sea toward home. We took a course that would put us 50 miles off shore in albacore grounds.

August 22, 1952

Enroute to San Diego

Little to report today except that we caught 17 albacore on jigs from the stern. These are splendid plump fish and very tasty. We had one for dinner, baked. It fed all of us amply.

August 23, 1952

La Jolla, California

We pulled in to the dock about 9:00 AM. It has been a fine trip. My crew was one of the best I have ever worked with—all were very young but willing and competent.

The ship's crew was more cooperative than any I have worked with previously and there were no strained relations that I noted during the entire trip. This is nothing short of phenomenal. The next trip on the *Orca* is bound to be different I suspect.

August 27, 1952

Cabo Colnett, Baja California, Mexico

This morning at 7:00 AM we boarded the research ship *Orca*. She is a 100 ft. converted ice breaker owned by Mr. Joseph Sefton. She has been built from the hull up as a utility research vessel and is very well equipped and arranged for all sorts of biological work. She rides beautifully and is powered by two caterpillar diesel engines. We have fine state rooms, good food, and plenty of working space for all hands. Mr. Sefton (Joe) is most enthusiastic and energetic about all the work.

Our crew consists of myself, Al Allanson, Connie Limbaugh, Gordon Alexander (a teanatode[?] specialist), Howard Harper, and Al Ebeling (a diver interested in various fish species). There is no deck force so we carry out these duties including standing lookouts and wheel watches, and cleaning the ship.

We stowed our gear in the ample locker space and tidied up the ship as we proceeded out into the bay. Al and I repaired a couple of dip nets and put a fine mesh liner in one.

I stood a couple of watches on the wheel, including one as we came into anchor at dusk in the lee of Cabo Colnett.

Vellela (by-the-wind sailors) were present on the sea in large numbers today. We saw many groups of shearwaters resting on the water north of Cabo Colnett. One very large whale swam southward about 100 yards off our beam. His long, sleek (barnacle-less) body humped out of the water as he sounded. There was a ridiculously small dorsal fin, very far aft on his back. I think he was either a finback, sei, or blue whale.

We plan to carry out a series of collections (fish) along the coast of Baja California from Punta Rosalia northward to San Geronimo Island. This is presumably an area in which cold water upwells along the coast and we will probably find a considerable number of cold-water types in evidence.

Connie just dip-netted our first specimens—a lizard fish [?], and a couple of anchovies. The lizard fish was eating an anchovy. We are anchored in eight fathoms of water.

August 28, 1952

San Geronimo Island, Baja California, Mexico

The gong sounded at about 6:00 AM. I cheated Joe out of the joy of beating it in my ear by getting up. This gong is a piece of Chinese brass and it is beat every morning and at meal times. Thus it has a Jekyll and Hyde personality.

We upped the anchor (I was put in the chain locker stacking chain). We steamed out past the imposing cliffs of Cabo Colnett into a large N.W. swell. The *Orca* is remarkably steady in a sea such as this. I have had no twinge of seasickness at all.

As we were on course to Geronimo Island a Mexican navy cutter came alongside. We dipped the Mexican ensign to them and Joe saluted the bridge. They turned away abruptly and left us in a cloud of smoke.

Al and I sat aft and mended one of the seines. Shortly we came in view of San Martin Island. Capt. Ellis took us inside, between the island and the long point enclosing San Quintin Bay.

The island is composed of two craters set close together and a series of lava flows extending from them into the sea. On the east side of the island a considerable sand spit extends out into the channel. In the curve of this spit, above a sandy beach [drawing], we could see several fisherman's shacks. The island looks as if it is vegetated with dense brush in most places. There are abrupt cliffs on most sections of the shore. The sand spit ends in a small boulder island over which swells were crashing from both sides. South of the spit we could see the entrance to a small lagoon. It surely looks interesting.

We sailed past the long spit of San Quintin for a long time. It must be 12-15 miles long.

The ship passed through large areas dotted with *Pelagia*, the large purple jellyfish. Alex and I noted schools of small fishes swimming among the tentacles. We tried to dip net a specimen but did not succeed. The tentacles appeared to be twisted in many individuals into a long, frilly appendage from the center of the bill.

After an uneventful bridge watch we came to Punta Baja. Shortly we entered an enormous raft of shearwaters. We sailed for a half hour through this huge flock. So many birds were taking off constantly in front of the boat that the noise of their feet as they ran across the water sounded like a heavy rain. Many did not take off but dove as the bow approached and swam beneath the surface, much as a murrelett swims, using their falcate wings in quick strokes. The birds seemed ponderous and had difficulty in making a quick take-off.

They dive like a swimmer making a kick-turn, legs and wings stick awkwardly into the air as the bird goes beneath the surface. A tremendous stream of flying birds swept completely around the ship and out as far as the eye could see in some directions. Most of the birds landed far ahead of the ship making it virtually impossible to make a

sensible estimate of numbers, but certainly there were several tens of thousands of individuals.

Through this flock of birds we saw the outline of Geronimo Island come through the haze. An abalone cannery boat, a coastal freighter, and a fleet of many large agar skiffs were at anchor in the lee of the small island. Many pelicans dotted the slopes and hoards of cormorants made the north part of this island black.

We dropped anchor amongst the other craft, lowered three skiffs, and a tuna tender and set about doing a poisoning job in about 20 ft. of water.

The water temp. was 16.2 degrees C. at the surface and much lower at the bottom. A considerable surge dispersed our poison so the attempt was not overly successful.

Back on board we had a splendid spaghetti and meatball dinner cooked by Jackson, Joe's good man Friday.

We worked on specimens in the splendid lab and dipnetted over the side, all with good Spanish music being played over the loudspeaking system. This ship is a wonderful work boat—by far the best I have been aboard. Everything is operative and useful and in good order. The ship is kept spotless. Joe is gruff, bluff, and good-natured unless pushed in the wrong way. He stands for no foolishness, but if one does his work willingly and reasonably well I am sure he will be of the best to work with. I must spend a little time planning our next day's stations and then the sack as dawn and the gong come early.

August 29, 1952

Santa Rosalia Bay, Baja California, Mexico

We awoke this morning to look out at a thick fog. The ship got underway at 7:04 and we passed inside of Sacramento Reef. Joe was fidgeting about taking this course in a fog and before he finally got his point across to the skipper we were a ½ hour past the reef. The fog lifted and we could see the rugged coastline of bluffs, rocky ridges, and great lava-capped plateaus off of Bahia San Carlos.

Down the coast a way we noted two whales. One lifted a huge long straplike pectoral flipper into the air and then its deeply incised tail fluke and sounded. These whales were probably humpbacks.

Huge mixed schools of the dolphin (*Delphinus bairdi*) and the striped porpoise (*L. obliquidens*) came to our bow and played about the ship. The dolphin has a small black triangular dorsal fin and a beak whereas the striped porpoise has a larger, slightly falcate dorsal, edged behind with greyish white and has no prominent beak.

As fog was closing in the skipper decided to anchor in Santa Rosalia Bay rather than at San Rosarito Bay, eight miles to the south. Onshore we noted a pick-up truck and then we saw a small skiff coming towards us. Connie saw the two men on board were wearing white identification buttons and said "Scripps Buttons"—and indeed they were. It was the Scripps crew down walking the beach for drift cards and bottles. The fourth man had gone to Punta Prieta to arrange for a guide as they intended to drive in to Scammon's Lagoon, Black Warrior, and Manuela lagoons. Roads to these places must be very obscure at best.

We found they had been stopped by customs authorities in Rosario. For fear they would be arrested one of the group had dismantled their rifle and put it piece by piece, along with their ammunition, into the big gasoline drum they were carrying. They hadn't

figured out how to remove it. Joe invited them aboard for dinner and the guided tour of the ship.

After dinner we went ashore and seined a bit, taking three stargazers, among other fish. These fish are Gulf of California types. They burrow down in the sand and trap prey that walks or swims over the sand.

Back on board we found that too many lights had been left on by our crew so we all got a lecture from Joe. He is right, however, as the generators shut down when we are at anchor and all lights operate on a bank of batteries. To the sack.

August 30, 1952

Santa Rosalia Bay, Baja California, Mexico

Up at 7:00 AM by the gong. After breakfast we gathered our gear together and put an additional small skiff in the water. We towed two skiffs with the 40 horse tuna tender. This little boat (16 ft.) pulled us along at a fine clip. We followed the shoreline through very clear waters. The water was dead calm and skies were clear and sunny. The water was a warm 23.1 degrees C. We could see enticing kelp beds and areas of eel grass and cobbles as we went along. Once we passed by a school of bait being worked by yellowtail.

The shore is a low bluff dissected by a few deep arroyos. Inshore about a mile are various 500 ft. peaks. Vegetation is low and sparse. The biggest plants are *Yucca valida*, the "palma del monte". A few inconspicuous agaves could be seen on the benches. Two big ragged ospreys flew along over the caravan of boats.

As we neared Punta San Rosarito the land became lower and composed mostly of cobbles. The point itself is low and barren and bounded on all sides by inhospitable-looking cobble beaches over which low breakers were splashing. In rough weather it could be a wild place.

We could see an interesting bottom of kelp columns, large eel grass patches, and cobbles clothed with low covers of coralline algae. Many fish could be seen, mostly big bass and opal eye.

This looked good so we stopped and anchored for a deep water poisoning. I mixed up a big can of rotenone and so did Howard. We gave them to Connie who had on his diving gear. He spread the poison in a circular patch on the bottom. Al and I put on our face plates and swam around catching some fish, mostly klip fish and bay perch and sand bass which came to the surface. Later I put on a three-tank unit and searched the bottom, picking up a considerable number of fishes—pipefish, sheepshead, least perch, bass, and others.

The eelgrass (*Zostera*) was growing in very deep beds on rocks. It was quite exciting to swim along through this dense grass scaring lobsters and big bass as you went.

Out in the open areas big seven- to eight-pound sand and kelp bass patrolled the area snapping up dazed fishes that swam toward the surface. Once I swam down to get a bay perch I could see lying on the bottom. While scooping it up my net touched a large grey rock which resolved itself into a big sculpin, which dashed off into an eel grass bed.

A six- to seven-foot mackerel shark was seen by Al Abeling and Al Allanson. I saw a five- to six-foot leopard shark swimming lazily along. Porpoises were also near. At the surface I saw Joe rowing his skiff around and bellowing like a bull at the seagulls

and terns that attempted to pick up fish. He appeared highly indignant that these birds should attempt to steal our catch.

We rounded up the skiffs and ate lunch and then rounded the point to the south, entering San Rosarito Bay. It is a shallow bay without much protection from prevailing winds and none at all from south winds.

Up the shore from a cobble beach is a small Rancho of two houses. Our UCLA friends were there with their jeep. We tried to come in near this beach but scraped the rudder of the tuna tender on the rocks. We went down a little farther and anchored our power boat and rowed the big skiff in.

We took two seine hauls here. The most interesting fish we took was a big puffer or botete.

By the time we started back a breeze had come up. I swam out to the anchored tender while the others rowed out in the skiff. The ride back was into the wind and swell. Connie, Al, and I sat up front and got saturated for our efforts. We saw many flights of pintail ducks, two frigate birds, and a big shark seven to eight feet between the dorsal and the tail. All in all he may have measured ten feet or more.

We were all pleased to get back on the *Orca*, both because we were tired and wet and because fog had come in, cutting off our sunlight. Coffee was more than welcome. It was virtually ambrosia. I spent the rest of the evening working on our collections. Tomorrow we go northward to the rugged Punta Roca.

August 31, 1952

Santa Rosalia Bay, Baja California, Mexico

Up at 7:00 AM. We ate a good breakfast of pancakes and sausage. Loading operations took an hour or so and we were off to Punta Roca, the next main point north of Punta Santa Rosalia. We cruised along through calm seas, following the shoreline.

Just north of inner Santa Rosalia Pt. we stopped to look at a large group of sea lions. They had a long sandy slide coming from the top of the hill, possibly 40 ft. to the water. Tracks where they slid down made a long line on the hill.

We cruised between Isla Elide and the shore. Some white canvas tents had been put up on shore near the permanent guano shed and house. A crew was working sacking guano. A large pile of bags lay on the little cement dock. The ever-present odor and beach flies assailed us as we passed by.

North of this little islet is a long clean crescent of sandy beach, backed by interconnected barchane type sand dunes. These dunes sweep over a low divide into the Santa Rosalia Bay area. In places black lava promontories jut up through the sand mantle, making a beautifully contrasting terrain. North of this beach tall barren reddish hills back the beach and often extend into the water as jagged points.

We saw belted kingfishers flying low over the calm sea, lonely vampire-like frigate birds high in the air, and the rather comical red-billed oystercatchers hopping on the rocky headlands. The shoreline becomes more and more rugged as Punta Roca is approached. Only occasional pocket beaches are present between rocky headlands.

South of the point is a guano covered rock. On it were many sea lions, including many little pups. In crevices we noted a red substance. On closer inspection it proved to be the chiton of swimming crabs passed by the sea lions.

We circumnavigated the point and could see Punta Negra to the north. Just south of the point we anchored in a little sheltered cove and put our poison down. The water was crystal clear, about 20 ft. deep and 19.5 degrees C.

Shortly we began to get fish at the surface. I put on a diving unit and went down. In places the current had concentrated the fish and I scooped them into my net. Kelp fish and klip fish were excessively common. The long brown feather boa alga (*Egregia*) was very common as were *Gigartina*, *Gelidium*, and *Zostera*. Rocky cliffs, often overhanging came down to white sand at 25 ft.

I chased a moray through the algae, trying to get him in my net. Finally he wriggled to safety in a deep crevice filled with big lobsters, all waving their antennae at me.

Lobsters were everywhere as were black and green abalone. A white sponge was common growing under the overhangs. We caught several tube-snouts (*Aulorhynchus*), a fish never before taken south of Coronado Islands as far as I know. While swimming back to the skiff I turned to look a five-foot sea bass right in the eye. He didn't move away as I swam toward him but merely turned to face me. I started to count his fin rays (he was 10 ft. away) when he flicked his big tail and was gone. Connie tells me he watched a big horned shark swim over me and sit on my tanks.

Al Ebeling came to the surface too quickly and became a little sick. He rested in the tuna tender. After lunch we went down the coast and stopped at a little sandy cove for a hike. We could see midden debris streaming down the hillside from a couple of small caves. We hiked up to them, finding some house rings. These are circles of stones used by Indians as a base for agave log huts. Shells and evidence of fire were very evident.

We hiked to the ridge and found seven caves in all and twelve house rings. I found a pounding stone and some worked fragments. The day was hot and I was tired from my swim so I lay down on the floor of the little cave and enjoyed the cool shade while the others were out chasing a bobcat. We walked back over hillsides covered with green lichens, so thick they looked like bunchgrass.

Low, spreading elephant trees were common and the Baja California ocotillo (*Fouquieria peninsularis*) was blooming. There were occasional cardon cacti and *Idria*. *Mammillaria* cactus and barrel cactus were also common. Back at the beach Al and I decided to swim out to the tender anchored 100 yards offshore. We took off our clothes and waded into the clear water while the others rowed out. It was most refreshing. Our trip back was uneventful except for seeing a huge V of sprig ducks flying south and a surf scoter.

We arrived just in time for a fine chicken dinner. The rest of the evening was spent with the fish and notebook. Tomorrow we go to Playa Maria.

September 1, 1952

Playa Maria Bay, Baja California, Mexico

We got up early and the ship got underway for Playa Maria Bay, 25 miles north of Santa Maria Bay. The cruise was uneventful and before long we dropped anchor in the calm leas of Playa Maria. The shore is one of rocky headlands alternating with dunes and long crescentic sandy beaches.

Al and Alex and I took the tender out and towed the try net in the bay. We caught great bags full of sand dollars and a goodly number of fish species, various flat fishes, and midshipmen.

We cruised along the coast looking for likely poisoning spots. We found some pretty fine reefs at the point. As we followed the bay around literally hundreds of big bat rays flapped along in front of us, some even broke water. In one cove we saw three coyotes walking along the edge of the water. Al took us in close and one coyote did not leave until we came within 25 to 30 yards of him and yelled. He then trotted off into the sand dunes. A big osprey flew from a rocky yucca-covered promontory in this cove and we saw big halibut skitter along the bottom as we approached.

We inspected a rocky point just inshore from the *Orca*, finding many six-foot leopard sharks and hundreds of big bat rays cruising around. I decided it was a good bet for poisoning as there were good rocks and eel grass beds.

We went back to the ship for a good bunch of lobster and coleslaw. Joe, in his usual booming-voiced boisterous way, saw Alex eating lobster without cracking the last joint of the leg. He began giving instructions at once, including grabbing some legs from Alex and cracking them with his teeth, saying, "Here, this is the way. I'm not eating your lobster."—whereupon he handed the cracked leg back to Alex. We all got a laugh out of this—including Alex.

We poisoned the reef and got a fair collection. It was too shallow for the aqualungs to be their most effective. It was a little strained at first to swim among the sharks but they soon left. Al and I took a short walk around the bay to a berm made entirely of pismo clam shells. Alex and I swam out to the anchored skiff and we went back aboard. Al, Alex, Al Ebeling, Howard, and I went ashore again for a hike.

I hiked up a little sandy canyon filled with Joshua trees, up over a ridge and into a low area filled with huge accretion dunes, 40 ft. high. A scrubby composite was the anchoring bush.

The only life I saw was a pair of LeContes? thrashers. Back at the boat Al and I put on our face plates and went diving for pismo clams. One can see them under water because their siphons stick up. With the slightest disturbance the siphons are retracted and only sand remains. The technique is to locate a siphon, dive and dig the clam out. They were very thick and from 10 ft. of water Al and I dug out about 40 in 20 minutes or so. This bay must have literally millions of clams in it as their shells often touch.

Back on board I fixed our fish collections and ate dinner. About 9:00 we loaded the skiff and went ashore to do a bit of seining. The moon is nearly full, the night and water warm and calm. We made a set on a calm beach and pulled in hundreds of pounds of *Ulva* (sea lettuce) and a fair number of fish. The strain was too much and we ripped our net. I decided it would be better to go back and seine again tomorrow night with a patched net on a clean beach. Notes, tea, toast, and the sack at 11:30.

September 2, 1952

Playa Maria Bay, Baja California, Mexico

We got up and right away started preparing gear for a poisoning job on the point. After breakfast we piled in the tender and cruised the short distance to the point. The poison was placed along a steep eel grass covered rocky reef. I dove with a three-tank unit and picked up quite a number of good specimens. Abalone (greens and blacks) were

common. Connie tapped me on the shoulder and beckoned me to follow him. He lead me out past the point into 35 to 40 ft. water and there we saw several huge sheephead bulls (30 to 35 lbs.) and lots of perch and bass and garibaldi. Then we swam in view of eight big black sea bass weighing upwards to 200 lbs. One took a pass at my flipper. Connie sunk his spear in one and promptly lost the spearhead.

After a long dive I climbed aboard. Connie came up and we went back to the boat in time for lunch. The specimens were prepared and we went back to the beach. Al and I swam around. We skin-dove and picked up nine nice abalone. Then we stretched out in the warm sand on the beach and did nothing but watch the frigate birds and ospreys and sleep. The rest was most welcome.

This evening we again loaded the skiff and cruised over to a quiet beach and seined. The night was perfectly beautiful—calm, warm, and a full moon. The water is over 70 deg. F. We hauled in many big spotfin croaker and jack smelt. Tomorrow we get up at 6:00 and go to Punta Cono, one main[?] point to the north. It is late (11:30) and I must get some sleep.

September 3, 1952

Playa Maria Bay, Baja California, Mexico

Joe had us all up with his g. d. gong at 6:30. Everyone was tired from yesterday, and he was a bit annoyed when we didn't snap to before breakfast.

We unloaded the seine and washed it and reloaded with diving and poisoning gear and were off to the next point to the north—Punta Cono. A southwest wind had come up and the sea became quite confused as there was a NW swell running counter to the SW wind chop. We shipped a lot of spray and everyone got soaking wet.

The shore north of Playa Maria is low and sandy and backed by big red barren hills. In one place a broad wash enters. The mouth is blocked by a series of cream-colored dunes back of which is a large dry lagoon. The coast swings in an arc westward to Punta Cono. Wide washes filled with *Lycium*, *Opuntia*, and *Yucca* sweep down from the hills. We could see the shells of Indian caves high on the mountain sides.

Put a Cono is a Lambolo[?]. The point is shaped like a cove but appears granitic. At its south end is a V, ending in a sandy beach at the apex. Sea lions rested on the outer rocks looking like men tied up in bags full of oil.

We cruised a ways north of the point but found no suitable poisoning points. Going back we bucked the chop and got really soaking.

The lee of the point looked like our only hope so we anchored and Al Ebeling put the poison down. We were moderately successful taking some Cottids never before taken this far south. Lobsters were everywhere and I didn't see a small one. After the poisoning we upped the anchor and sailed over to the beach off our Indian middens. We took the small skiff ashore and hiked up the canyon to these caves.

Great piles of limpets, abalones, clams, chitons, and other shells were piled in front of two caves, each 15 feet deep or so. The roofs were coated with soot, ages old now. Al and I sat down and I made a stone hammer to give to Joe for his birthday (tomorrow). This hammer was made on the midden in sight of the spirits of red men long gone. Al made him a back scratcher out of a pelican bill. We will present them with due ceremony tomorrow.

Al and I went swimming and diving for clams. There were many of them all over the bottom and windrows of shells on shore. We didn't take any clams as we are still eating chowder from the last batch back on the *Orca*.

September 4, 1952

Blanca Bay, Baja California, Mexico

We awoke this morning to find ourselves socked in with a thick fog. We had to wait until it cleared a bit so we could pilot up the coast to Blanca Bay.

Finally we shoved off and started up the coast. It quickly fogged up again and we sailed blind down the coast. The skipper said, "The fathometer should show it is getting shallower—just then the depth dropped—22-20-18-17-14-13-12, etc. At 5 fathoms he ordered the hook dropped. When the fog lifted a few minutes later we were anchored in Blanca Bay. There are three main rocky headlands, the western two volcanic and the easternmost sedimentary. We investigated two of them and another volcanic one to the south in the tender.

We saw the long stretches of sandy beach that separates the headlands and some very high cobble berms in little pocket beaches. A lone coyote wandered down one long sand beach and we were followed by several large *Tursiops*, the bottlenose porpoise.

After lunch we gathered our gear together and sailed to the outer point of Blanca Bay where we found a cove occupied by dozens of sea lions. We chased the sea lions out by tossing mussels at them and rowing around yelling and slapping swim fins in the water. Then Connie placed the poison. We had a big surge but the cove didn't let much poison escape so we got a fine kill of many big cabezon, cottids, various perch, etc. Lobsters were everywhere and so large as to be frightening. Their antennae protruded from all the crevices. I took a long collecting dive with the lung and shortly thereafter we returned to the ship.

Today is Joe's birthday. Jackson had cooked up a fine cake and meal—ham, soup, salad, etc. We gave him our gifts—the hammer, the backscratcher, some sand dollar money, and a comb made of a deer's jaw. Joe was properly appreciative and gave us a little speech and then cut the ham. A jolly meal was had by all.

After dinner I worked on specimens and then Alex, Al and Al, and I took out the try net. We captured barrels of sand dollars and a couple of agonids and an ophiethid eel. It is now 11:30 and I wish to go to sleep.

September 5, 1952

Blanca Bay, Baja California del Norte, Mexico

The first operation this morning was to land on the beach adjacent to the ship and make a few seine hauls. We inadvertently left Joe behind and he later gave us hell for this. The water was warm and the skies clear so it was a pleasant job. Rowing through the surf was fun. We took some 6 to 7 lb. spotfin croakers and big corbina. We returned to the ship for lunch and returned to the beach for a hike and a swim. Al anchored the tender and we swam ashore while Howard and Al Ebeling rowed the little skiff in. (Al Ebeling shall henceforth be referred to as Chuck.)

Al and Howard and I put on our clothes and hiked toward a wide canyon we could see across the salt marsh that lies behind the beach. As we hiked up the canyon we saw signs of deer, cirios, and cardon cactus. *Lycium* and some unidentified shrubs carpeted

the canyon floor. Shells were everywhere, possibly midden material and possibly reworked Pleistocene fossils.

High above a rocky cliff we noted a buteo hawk (red shouldered??) resting motionless in the air. He jockeyed for balance like a man walking a tight rope. His tail shifted nervously from side to side. At times he was completely motionless. Then he nearly completely folded his wings and swooped down as if to land on the tip of an agave stalk. At the last instant he opened his wings and soared upward again on a wind current. We watched him for six or seven minutes and then continued on up the canyon. Far ahead we could see the greenery of sumac plants and scattered Joshua trees. Under one of these latter plants I caught an emaciated alligator lizard (*Elgaria multicarinata*). I was across the canyon when Al called me. I hurried over and he stood before a five-foot cubical boulder of stone. On it were dozens of petroglyphs. There were swastikas, men, and many other unidentifiable (by me) objects represented. I took a photo as did Al and Howard. Signs of water were everywhere—mosquitoes, petroglyphs, white-winged doves, Bewick's wrens, and then we jumped three black-tailed does that had been bedded down in a big dense sumac bush. They were within 50 ft. of all of us and ran gracefully away up the rocky hillside. A trail follows the east side of this canyon. It may be an old Indian trail. The canyon bent around and opened into a long, broad canyon going into the interior. It appears to have been an important Indian route. We could see a forest of Joshuas and cardons and distant ranges of bluish mountains far up the broad canyon. Dust devils kicked across its floor.

We had to turn back because we have to load the boats onto the *Orca* today. The hike back was uneventful. We were hot and dusty when we reached the beach so we took off our clothes and dove in the clear water. Al and I tried to grab hold of the tips of bat ray's tails. These rays were common and about three feet across the wings. They always flapped off before we could touch them. Jackson and Chuck had had a couple of tussles with big black sea bass that took their bass away.

Back on board we loaded and washed down the skiffs and I worked on the fishes and got everything in order. I am sleepy. Tomorrow we go north to Punta San Carlos.

Up at 7:00. Shortly after breakfast we shoved off for Punta San Carlos, 55 miles to the north.

We put the dredge over the side in 22 fathoms of water. Joe had a field day getting the operations underway. I was sleepy and tired so I tried to steer clear for a while. Just as we hauled the dredge aboard the bottom line opened and dumped our haul—too bad as it looked good.

The next haul was taken about 10 miles to the north off [?] Rocks. We collected many interesting invertebrates and good series of typical bottom fishes. On the last haul off Punta Escarpada we brought in a vast amount of green sand and very few fishes. The winch [?]ostat burned out and the wire became kinked. The *Orca* is equipped with a special 7,200 lb. test spring steel wound strap cable. It is of very small diameter compared to the average cable of similar strength.

We came to anchor in San Carlos Bay about 3:00 PM. A low rocky point that is an island at high tide juts out to form the point. The bay is a crescentic one lined by a series of cobble beaches and small rocky points. The shore is a much dissected series of hills and peaks forming the foothills to a 2,000 ft. bluff capped by an old lava flow. This

bluff extends southward at least 10 miles to Punta Escarpada (bluff in spanish) and ends at Santa Catarina Landing, the old port for shipping onyx from the El Marmol mines.

The night is a beautiful one with the huge dark form of the bluff, a near full moon, and a calm bay and clear warm night.

Night fishing produced some sharks (one a sharp-nosed shark—*Scoliodon*). I worked up the collections and am about to go to sleep. Tomorrow we go by tender south to Punta Escarpada.

September 7, 1952

Bahia San Carlos, Baja California del Norte, Mexico

We unloaded the boats and then went in for breakfast. After this we loaded the big skiff with diving and collecting gear and started off to Punta Escarpada on glassy seas. This point is a big bluff 6.8 miles south of our anchorage. We found no good poisoning spot and had to work on a surge washed reef which proved to be not particularly productive.

Dozens of Heermann's gulls patrolled our poisoning area and "ganged-up" on the few Western gulls that wandered in. I did not use the diving gear but collected with fins, face plate, and collecting net.

We ate lunch and picked up a few more fish and then made a wet trip back (the wind had kicked up a considerable chop). After a fine chicken dinner, Al, Chuck, Alex, and I took the try net out around the ship with good results, bringing in three kinds of flat fishes, [?] midshipmen, and a sculpin (*Artedius notospilotus*). After dinner we shot the breeze with Joe and worked on our fishes.

Insert September 8, 1952 [can't locate it]

September 9, 1952

Bahia San Carlos, Baja California, Mexico

Up at 7:00 AM. We loaded the skiff with our diving gear before the breakfast gong sounded, in preparation for our trip to Punta San Fernando. After breakfast we all piled in the tender. The wind had picked up from the northwest and we knew it would be a wet trip. We obtained a couple of canvasses and huddled under these as we started out, bucking the chop. When the tender rounded the point of Punta San Carlos it ran into large swells, partly a product of the main sea swell and partly composed of water pushed up over the shallow reef. Water poured over the bow constantly. I sat in the foreward seat with Al. We both were soaking wet shortly. The canvas saved only to break the force of the spray as it was not in the slightest waterproof.

The engine kept cutting out on a couple of cylinders as water got on the plugs. We would slow down and the motor heat dried off the plugs and it would cut in again. Far in the distance we could see Punta San Fernando jutting out. Our progress was so slow Al didn't think we would make the point. I could only see it once in a while when I could see through the rain and salt water. Finally we came upon a big kelp bed and it was remarkable how it broke the wind chop and seemingly the swell too. Once we left its lee we began shipping water again in considerable amounts.

Finally we came into the south end of San Fernando Bay and knew we would make it into the lee of the point. After what seemed like an interminable run we came

into a lee from the sea swell but not from the wind, which continued to whip around us, cutting the tops off of breakers on shore and sending them over the sea as sheets of spray.

There was no place where we could work; the cliffs were all of sandstone and there seemed to be no good reefs, the water was very murky and swells were big, in addition to trying to work in a 20 to 30 mile wind. We anchored and tried to huddle down out of the wind. The surf was too forbidding for any of us to attempt to go ashore. Al and I crawled into the motor cockpit and were warm and out of the wind. Incessant moaning from the others finally caused us to trade off. Charlie tried to get in. He is about 6 ft. 2 in. and well built and he took up all the space, deposing both of us. The groaning ceased at once. We ate lunch and waited, hoping the wind would drop. Finally, it appeared better so we started back. The little tender skidded down the big swells but we didn't ship water as we had when bucking the swell. Our two skiffs in tow were the main concern as they whipped and jerked about.

We saw many medium-sized terns with white tails and a black line through the eye and a white cap. I think they were Forster's terns, but they may have been common terns. We noted large flights of shearwaters with whitish underwings. At Punta San Carlos we went way out to sea and thence directly in to the anchored *Orca* to avoid the waves at the point. The sea was spotted with big white patches of foam and the swells were sizeable. We were glad to reach the ship and get in and out of the storm. Joe greeted us with an "I told you so" sort of reception, which didn't please me much. Later the wind continued to pick up so we stayed on board and did no fishing.

September 10, 1952

Bahia San Carlos, Baja California, Mexico

Directly after breakfast we jumped in the tender and then we had to wait for Joe, who was going with us to poison a nearby kelp bed but who had disappeared below. I was quite impatient by the time he appeared as I wanted to get our work done before the wind rose.

Five minutes after he jumped on board we were at the poisoning spot. Chuck went down for reconnaissances with the lung. We poisoned a nice rocky ledge in the kelp bed in 20 to 25 feet of water. Surface water was 17.8 degrees C. but the water from the bottom up 7 to 8 ft. was close to 12 degrees C.—definitely frigid to work in.

I put on a rubber suit to cut the cold and took a 3 tank unit down. The place was a beautiful series of potholes and caves and ledges covered with coralline algae, big gorgonian fans, and bright yellow sponges. Rockfish (*Sebastes auriculatus*) and sheephead (*Pimelometopoa pulchrum*) were everywhere. I found some cottids (*Artedius creasii*, *Orthonopias tra*—[?]), a horned shark (*Heterodontus*), and a small toad fish (*Liparis mucosus*). Connie captured a live ronquil (*Rathburnella*), a rare little fish usually taken in deeper waters. By the time we had finished the wind had picked up to the point where we could barely row the laden skiff with two sets of oars against it. Once again we were glad to get back to the ship. I read most of the rest of the day an exciting book, *The Study of Instinct*, by Niko Tinbergen.

Tomorrow we load our ship's boats in the calm of the morning and proceed to San Martin Island and Hassler Cove, which we hope will be unoccupied.

September 11, 1952

Hassler Cove, San Martin Island, Baja California, Mexico

We were up at dawn in order to load the boats while the sea was still calm. Once we had completed loading (the tuna tender is the hard part) we stood out to sea into large NW swells. The wind was light. We cruised along pitching rather hard until we came into the lee of San Martin Island, about 1:30 PM. I stood a couple of stints at the helm (our automatic pilot is shot) and spent the rest of the time sacking out in the sun on the afterdeck as I had just a touch of mal de mar.

We anchored in 8 fathoms ahead of an abalone canning boat in Hassler Cove. We have a good lee from the swell but get some of the wind that whips around the north side of the island.

The large skiff was put over and Joe, Al, Howard, and I went ashore to look the place over. We landed on the sandy beach of the sand spit near 3 fisherman's shacks constructed on the hill. Two Mexicans were working on lobster traps.

We hiked over the spit to the south to the little circular lagoon. This lagoon is contained from the ocean by a high berm of big volcanic cobblestones and has a 35 ft. wide entrance. Pelicans and gulls rested on the calm surface. The water looks fairly deep. On one side little points of lava extend out into the water. Two sides are bounded by smooth sand beaches.

The main portion of the island is formed by two cones of considerable size and their attendant lava flows. This lava surface is extremely rugged and full of deep crevices. The slopes are vegetated by an almost impenetrable jungle of 4 foot high *Lycium* bushes heavily bedecked with lichens. Amongst these bushes are numerous *Opuntia* cactus plants and on the surface a carpet of iceplant. A big white *Dudleya* with a circlet of long flowering stalks was common, as was a green Hydrophyllaceous plant with dead, scorpioid cymes of a flowering season past.

I captured 4 specimens of *Uta martinensis*, which turns out to be a good subspecies of the mainland *Uta stansburiana* and nothing more. Its pattern is a bit more bold and its colors a bit brighter but that appears to be all. A bit of digging in the dunes of the sand spit produced no silvery footless lizards (*Anniella*).

I talked to the two Mexicas and they informed me that no guicos (*Cnemidophorus*) lived on the island but that a bejori (*Sceloporus*) did as well as a corallilo (king snake) which they described as having bands of brown and yellow. Al Allanson and Howard Harper found some snake vertebrae and a snake track and the tail of an alligator lizard (*Elgaria*).

I hiked north of the sand spit along a narrow trail following the shore. Debris of wrecked ships was everywhere—engines, fuel tanks, planking, barrels, etc. On the north side of the island is a rookery for gulls and cormorants as well as for sea lions. The birds dot the hillside far up the slopes toward the crater.

I met Joe on this trail and he showed me some harbor seals and pups and a pair of yearling elephant seals. We sat down on a rock about 10 feet from these big beasts. They looked disgustedly at us out of their round, pupilless eyes and hissed at us in disgust. They didn't go into the water but remained watching us. We left and on the way back passed a cormorant perched on a rock a few feet from the trail. His upper bill was bent grotesquely sideways. He didn't offer to move but merely blinked his eyes at us and gaped. The bill was healed and the bird looked otherwise healthy.

As we walked down onto the beach by the skiff the siren on the *Orca* wailed, signifying that dinner was ready. Al and Howard walked up. They had been in the crater and reported it large with a fissure in the bottom. This later proved to be a fish tale designed to lure us up the rugged peak. We rowed back to the *Orca*, had dinner, dipnetted, prepared specimens and notes. Tomorrow we poison the kelp bed.

September 12, 1952

Hassler Cove, San Martin Island, Baja California, Mexico

After breakfast we went ashore near the beach and commenced poisoning operations. Connie had a cold so I spread the poison. I saw very few fish as I was placing the poison and was not very enthusiastic over the possibilities of the collection. However we collected 25 species including one warm water fish I believe (*Neodisius stephensi*-paratype).

I had to do nearly all the diving as Chuck did not have a rubber suit and no one else was diving. The water was 16.4 degrees C. on the surface and a couple of degrees colder at the bottom so he didn't dive long.

Underwater there was a series of ledges and boulders encrusted with coralline algae, sponges, and tube worms. Many columns of kelp (*Macrocystis* and *Egregia*) rose from the bottom giving the impression of swimming through a dense forest. Parts of the bottom were covered by a dense growth of eel grass. When swimming through this, one could see only a few inches in front. I happened on small open patches occasionally and big opal eye (*Girella*) dashed into the grass from most of them.

Out on the sand at the edge of the rocks the bottom was littered with fish. Little flesh-colored cottids (*Artedius creaseri*) and hundreds of brightly colored klip fish (*Gibbousia*). After returning to the boat I couldn't repress shivering for 10 minutes or so. I had been under water nearly 45 minutes.

After returning for lunch we made a few hauls with the try net and then went ashore. Joe and the Captain came marching down the beach and Joe was carrying a gopher snake. I, of course, would have liked the animal as I was collecting on the island. I told Joe so and he said "Hell no." He was going to give it to Klauber. He asked for something to put it in. I said I had a box but that he would have to give me the snake first (joking). He said, "Give me the box or I won't allow you on board." So, I gave him the box. I went off collecting and captured some nice specimens of *Uta martinensis* and an *Elgaria*. I saw snake tracks.

Then Al came down the beach clutching a gopher snake about twice the size of Joe's (Joe had returned to the ship), and gave it to me. I was very pleased to show it to Joe when I got on board. Joe was crestfallen as he thinks it may be new. I think it is not new. I had showed the snake to the Mexicans on shore and they said it was not the banded snake they had previously described. They called the alligator lizard "ajolote". They were collecting owl limpets which they called "lapas" and said were fine eating.

On board we ate a fine hamburger steak dinner and worked on specimens. Our species list now stands at 101 species.

September 13, 1952

Hassler Cove, San Martin Island, Baja California, Mexico

Our first venture this morning was to pile the seine in the big skiff and tow it (the skiff) and a smaller one to the beach. We let Joe off on shore and cruised around the boulder breakwater to the narrow entrance to the little circular lagoon. We anchored and rowed the skiff into the lagoon over the shallow entrance. Pelicans and gulls flapped off the calm water producing a complex series of interlocking rings on the surface. A sea lion swam past us and out the entrance. Joe bellowed advice from the beach. We landed and piled the seine on the skiff. Howard and I set the net while the others horsed around and skipped rope with the end of the line.

Our haul produced bales of dead eel grass (*Phylospadix*), many gobies (*Covelandia*), and hundreds of young opal eye (*Girella*). I could see that further hauls would produce little else so we loaded the net and returned to the *Orca*. After lunch, Al, Connie, Howard, Chuck, and I went ashore. All of us but Connie hiked around the north side of the island.

We stopped to look at one young elephant seal lying on the lava beach. He looked at us with a baleful eye and reluctantly slipped into the water. I counted 16 harbor seals in the water in one cove. These curious creatures watched our every move with their round heads protruding from the water.

We noted black turnstones and a wandering tattler flying along the rocks of the shore. Hundreds of gulls and cormorants left the rocks as we approached. The northwest side of the island is largely vegetated by ice plant (*Mesembryanthemum*).

Large dusty open patches checkered with innumerable gull and cormorant footprints and guano-whitened rocks indicated that this area is a permanent rookery. Young cormorants, just too young to fly, ran in frightened troops up the hill and over bushes at our approach.

Over the 40-foot lava cliffs we saw the remains of a large ship on the rocky beach. Winches, generators, motors, decking, and all sorts of unidentified wreckage is strewn along the coast for ½ a mile. Big swells swept unchecked through the dense kelp bed that circles the north and west side of the island, and crashed in big curling breakers against the cliffs. The water was so clear one could look into these waves as they rose up like looking in a window. Kelp columns and long riatas of the feather boa algae (*Egregia*) swept up and waved in the clear water. Rocks and eelgrass could plainly be seen. Offshore, sea lions rested in the water, their flippers raised out of water as the animals lay on their sides. So many sea lions were lolling in the water that their flippers looked like a peculiar forest. One fellow swam along with his flipper out of water, looking for all the world like the dorsal fin of some malformed porpoise.

I caught a young gull for a picture. Al and I decided to hike up to the crater and Chuck and Howard wanted to go around the shoreline. We all went up to a big white rock—we, on our way to the top, and Chuck and Howard, for reconnaissance. Al ran a young cormorant down and captured it. It was a double-crested cormorant (*Phalacrocorax penicillatus*), having a dull yellow throat pouch. Howard saw a cave and before we could get over to it he was shouting various things about it having no end and being big.

The entrance was at the rim of a small crater slightly south of west of the main crater and about 300 to 400 yards distant. The tunnel was high enough to walk in, stooped over, and had a dirt and boulder floor encrusted with bright green moss near the

entrance. The rock of the ceiling and walls was blackened as if with soot and encrusted in places with a fine hairlike mesh of pinkish moss or mould.

Al went in first, feet first, feeling his way along. His expletives became stronger as he went deeper and found no end. It was obviously a large lava tunnel, a conduit for molten lava surrounded by layers of cooler rock during the volcanic activity of the island. It might well continue for a long distance.

We went in 50 to 75 yards until the light from the entrance was but a small fleck in the pitch blackness. A smaller tunnel joined ones coming in from the side and going upslope. The tunnel grew larger until we could stand and barely touch the two walls. I wailed at the canyon branch to be sure we didn't take the wrong turn on returning. Chuck and Howard and Al went a short distance farther until Al's matches were gone. A gentle cool draft of air could be felt coming up the tunnel.

Howard was all for returning to the *Orca* for line and lights but we didn't have enough time.

Outside we investigated a big osprey nest and I had my picture taken while sitting cross-legged in it.

Our party split and Al and I went up the mountain. We passed over some other lava tunnels but did not investigate them.

We noted that as we walked among the cormorant nests and the parents flew away, the nearby gulls closed in immediately and attacked both eggs and young, breaking the eggs and eating the young.

The crater is a symmetrical cinder cone 497 feet high. When we scrambled over the rim there was Alex sitting there. He had hiked up the other slope.

The crater is not too impressive, being about 50 feet deep and about 50 yards across. The view however, was worth the climb. The sand spit was particularly interesting as it resembles the spit of San Nicolas Island. [Drawing.]

Fog closed in and we hiked down the east slope over jagged broken lava flows. All the rocks were so densely covered with grayish green lichens that it felt like walking on a heavy carpet. We crossed one big lava channel and one could well imagine the glowing lava river that must have flowed down this precipitous slope. As we approached the shoreline the vegetation increased and we had to break our way at times. I caught an alligator lizard under some flat pieces of lava.

We launched our skiff and returned to the *Orca* where no one believed our tale about the tunnel.

Dinner, notes, washing and loading boats, and general discussion occupied our evening. Up tomorrow early to shove off for Todos Santos Islands.

September 14, 1952

At anchor off S. Coronados Island, Baja California, Mexico

Up at dawn for a day of quiet uneventful cruising. We started out in a thick fog which lifted toward afternoon enough so we could see three or four miles. Joe decided we should not anchor at Todos Santos as he had never been there before. How he ever anchors in a completely new place the first time I don't know.

A word or two about Joe. He is a lonely old man and I can understand why. He is intelligent, individualistic, and highly fixed in his ways. He is self-centered and often

quite rude. To get along with him one has to back water on many points, agree with his decisions and ideas for there is no chance for discussion or controversy.

He is extremely frugal in some ways and rather lax in others. He saves tin cans, string, and old boxes, but he feeds us quite well and offers the use of his ship for free. He insists on keeping a neat ship and works very hard maintaining it himself. He has a good sense of humor and tells a good story, but he tells too many and even the good ones are tiring. He has the habit of cornering a person to talk to them. This is highly odious to me. I found his ship very well arranged and equipped for our work. It is fairly difficult to carry out an operation under him, in particular if he is in a position to be boss. He is the sort of boss who tends to every detail and each in loud excited tones. There is no relaxation and no free and easy air on board. I would rather not travel with him and particularly on a long trip.

We dropped anchor after dark off S. Coronado Island. It is a beautiful starlit night and clear and sparkling.

September 15, 1952

La Jolla

We were up at dawn, crossed the channel, and came alongside the fuel dock at the Harbor Boat works in mid morning. Everyone was glad to get back.

September 24, 1952

Avalon Harbor, Catalina Island, California

Yesterday evening we boarded the *E. W. Scripps* by going through the surf at Scripps in the DUKW. This amphibious beast plows right through the surf with no trouble.

We are accompanying Otis Barton and party in his attempt to break the record for the deepest dive into the sea. He holds the present record at somewhere near 5,000 ft. One or two of our party will go down in an attempt to look at the organisms composing the deep scattering layer.

This layer is a diffuse layer of some sort of organic material, which migrates up and down with the diurnal cycle. It migrates upward from 200-400 meters at dusk toward the surface. What animals compose it is uncertain at present.

Our party is composed of myself in nominal charge, Andy Rechniter[?] (who will probably do the diving as he is our ranking deep sea fish specialist), Dave Arthur, who will go down to identify invertebrates, John McGowan, his alternate, Ed Brinton, an invertebrate specialist who is along for the observation, and Jim Kittredge, biochemist, who is also along to see the show.

We sailed to Avalon Harbor, arriving about 12:00 PM. We anchored and John, Ed, Dave, Andy, and I went ashore and swilled down a couple of beers. Avalon is quite dead at this hour. The tourist season is largely over and the total population is probably two or three hundred.

We arose about 7:00 and proceeded southward in company with the *Monsoon*. This boat is a yacht owned by Jack West, an advertising executive. The ship is a converted aircraft rescue boat and looks like a splendid craft of 75 ft. or so. On board are several newsmen from *Life* and *Time* magazines, various photographers, Dr. Maurice

Nelles, who is in charge of the operation, and Otis Barton. Nelles is an engineer in the employ of Bog-Warner Instrument Co. Otis B. says they manufacture "mechanical mechanisms". Nelles runs the operations with a iron had and bosses Barton around like he was a little child.

We cruised south of Catalina Island about six to seven miles and there met the Harbor tug *Pacific Rocket* and the crane barge *Cherry Picker*. The *Pacific Rocket* is a top heavy rust pot and has been renamed by John McGowan—the *Pacific Bucket*. He has also dubbed the benthoscope the "proctoscope". The cast steel ball called the benthoscope was sitting on the barge when we arrived. It is very much like the older bathysphere, though of better design and greater strength. The benthoscope is a sphere 54 in. in inside diameter bolted to two wooden runners and reporting a long fin and rudder [drawing]. There is remarkably little room inside and *Life* magazine men have crammed a complex automatic stroboscopic camera inside with all its attendant power packs and gear. There are oxygen bottles (enough for 60 hours or so), barometer, thermometer, a small fan, gas absorption chemicals, a light, and the diver.

Barton was put down about 25 feet to test out the gear. The big winch is not used at first as the benthoscope is first swung over the side on a big crane and then, after the ball is lowered 25 feet, is switched to the main winch. The main cable is $\frac{3}{4}$ in. steel and is attached all the time. The crew operating the winch and unwinding the electric wires are a competent lot and inspire confidence. They work quietly and with precision.

Otis, on the other hand, is excitable and seems to get his thumbs into things. He kept having his fan shut off and the window fog up, and various other minor complications.

Nelles, a quietly efficient man, gave orders over the telephone system, carrying on a constant conversation with Barton. At one point he gave instructions as follows: "Now Otis, turn off the fan switch. Now Otis, take a bit of paper on the ends of your fingers and wipe the glass carefully. Don't smudge the camera mirror. Now Otis, put your hands in your pockets; leave them there." Otis made no intelligible reply. Barton is a fairly tall bald-headed man with a small mustache and a bit of a leer on his lips. He is quiet and seems somewhat nervous and excitable. He knows the names of some organisms though he talks of "globs of gunk" and "fiery dragon fishes". He is not a scientist but designed the original bathysphere and then lost most of his glory to William Beebe, who accompanied him on many of the early dives. He is naturally a bit bitter about Beebe and is now writing a book entitled *One Mile Down*, a sort of answer to Beebe's *A Half a Mile Down*, I suspect.

The barge was fairly swarming with camera men. Jay Eyerman, of *Life*, is in charge here. He is a likeable sandy-haired fellow. Also from *Life* is Sandy Thompson, a little bald-headed, red-moustached Scotsman. He is a jolly sort and has a good word for all occasions.

The benthoscope was sent down 100 ft. and brought aboard without making a deep dive. Tests run yesterday had finally stopped leaks around the quartz glass ports after the sphere had entirely filled with water on one occasion.

I might note that an egg and a can of beer are suspended from the fin. The egg has already survived being lowered to 2,000 ft. without breaking.

As a chop had come up we returned to the *Scripps* and thence to anchor off the old Casino in Avalon Bay.

Ed, John, Jim and I went ashore in search of amusement. There was not much to be had but we settled down in one of the local spas and had a few beers. A cadaverous, seedy-looking individual joined us in song at the piano and later launched into a discussion of nature foods. It seems he had seen the light some years ago and was now natural. John, he decided was natural too. John has a beard, which adds, I am sure, to his naturalness. Try though I did, the best I could achieve was a pat on the back and a few words explaining that with proper application I too could become natural. Jim Kittredge, who insisted on watching the television set was beyond the pale and obviously had no chance to achieve naturalness.

I found that 1) women are natural, 2) sex is natural, 3) uncooked vegetables are natural, 4) television, autos, insurance, police, and the general American public are decidedly unnatural. With this bright future before me we rowed back to the ship and climbed below to our bunks.

September 26, 1952

Avalon Bay, Santa Catalina Island, California

We followed the *Monsoon* and the *Pacific Bucket* (with *Cherry Picker* in tow) to south of the island and began operations. After some testing Otis entered the sphere and was lowered over the side. I took the job of laying out electric cable before it was tied to the steel cable suspending the ball. One man ties this wire to the cable as it is payed out in 20 to 30 ft. lengths.

Otis reported that he could still see the image of his camera in the port at 871 feet. Below 1,000 ft. he began to see various flashes of light and described some long light chains and blobs. He took many photographs with the strobe camera but had no flood light so could not identify any organisms. Once he identified a piece of ice floating by (at 1,500 ft.). We decided it must have been heavy water.

He reported oxygen pressure and barometer reading to Nelles at the surface at periodic intervals. The ball was lowered to 2,000 ft. and he reported that the temperature was 42 deg. F. inside the ball at that time. It took a long time to raise him as the electric cable had been twisted by the rotation of the sphere as it descended. Each tie had to be cut as it came to the surface.

Otis had gone down in his shirt sleeves and was a mighty cold fellow by the time he came to the surface. The dive took about three hours to make. After lunch we returned to the *Cherry Picker* but Nelles called off further operations on account of choppy seas.

Andy had to return so we sent him in on the television boat. He had been very silent and obviously much worried over his projected dive. Once he knew he was not going to dive he became jovial for the first time on the cruise. Either Dave or I will now make the first dive. We will flip to see who makes the dive. I continue to get more excited over the prospect. A good job of observation might prove quite valuable.

We returned to Avalon and anchored. Several of us had a nice swim in the warm clear water. Dave, John, and I swam across the harbor to the pier at the center of town.

Later I took the skiff over to the *Monsoon* and visited all the people on board for a while. We then returned to the *Scripps* for a guided tour. Then I sailed the skiff around the harbor. It is a beautiful moonlit night with broken clouds scattered across the sky. The lights on the bay and the boats rocking at anchor created a calm and magnificent scene. I

spent a part of the evening writing notes while the others were ashore soaking up a bit of beer.

September 27, 1952

San Clemente Island, California

We knew that Barton was going to make a shallow (1,500 ft.) photographic run this morning so I told Gus there was no need for us to rendezvous early in the morning with the *Pacific Bucket* and the *Cherry Picker*. So we started out at 8:00 AM and cruised down the precipitous SE shore of Catalina Island. Just after we cleared Land's End I heard the *Monsoon* talking to the *Pacific Bucket*, saying they were going into Avalon to pick up a new oxygen flow valve. I cut in and found that the valve had been damaged when the tug banged into the barge, knocking Nelles off his feet. He was holding the valve and it was bent in the fall.

No valve could be obtained in Avalon so frantic calls were made to the mainland to obtain one.

It became obvious that we would have no chance of diving today so Gus took the *Scripps* in close to the *Monsoon* and, after considerable conferring, John and I decided to go aboard the *Monsoon* while the others returned to San Diego. We could not keep the *Scripps* out longer.

We were all a little bit unhappy at the slowness with which this operation seems to move but it really is unavoidable and I feel happier considering Nelles' cautions.

The *Monsoon* is a far cry from the *Scripps* in some ways. There is beer in the ice box and everyone is constantly clutching a highball.

Much conversation of this and that—a good swim in which John and I each recovered a sea cucumber from 25 ft. by surface diving.

The valve arrived and we immediately upped the anchor and sailed for Wilson's Cove on San Clemente Island. We arrived before dusk and dropped anchor near a pier (air force or navy). On the hill are a number of buildings of several kinds—barracks, store houses, etc. A couple of fellows came out in a skiff and challenged our right to anchor. Jay Eyenman said we had a signal letter for Admiral Frou-frou permitting us to do so. Without asking to see the letter they departed.

We ate dinner and yakked of this and that and went to bed.

San Clemente Island, at this cove, looks volcanic, at least in part. There are two good terrace levels in evidence, one at about 20 ft. above sea level and another at 75 or 100 ft. above the sea. The hills are rather low at this end so it is impossible to note any higher levels.

September 28, 1952

San Clemente Island, California

The *Monsoon* got underway before dawn this morning and proceeded to the deep trough south of San Clemente Island. There we boarded the *Cherry Picker* and the benthoscope was soon lowered over the side empty. Nelles had it run down to 5,331 ft. before he stopped it. There was only one row of turns on the drum. The sphere was hoisted and brought aboard dry. One of the lights had been smashed but the benthoscope had withstood its test well and I feel it will make its descent well, providing Barton doesn't foul something up. At one point I saw him doing a sort of dance on the stern of

the barge, as if from nervousness. John and I have decided we will not go down unless we do it together without Barton. I think he increases the risk at least 100 times. He seems determined to meddle with the equipment and likes to change things around while he is down.

At about 1:15 PM the benthoscope was lowered over the side for the deep dive in which Barton intends to go 5,280 ft. Before the door was clanged shut I poked my head in and Barton said, "There's plenty of room here (pointing to the deck), you can come in now." I had to convince him that I had no intention of going on this particular dive.

He was lowered to 2,000 ft. or so and reported "clouds of limy flakes" in the water at about 1,200 ft., or the depth at which we would expect the scattering layer to occur. Try though we did, we could not get any more information out of him. His lights went out and we could see the wind was picking up so it was decided that no attempt would be made to make the deep dive. Dr. Nelles did not think it wise. We all got back on the *Monsoon* and headed for Pyramid Cove and anchorage.

September 29, 1952

La Jolla, California

We upped the anchor before dawn and proceeded out to the Clemente Basin. Very quickly the camera gear was checked and Otis entered the benthoscope. He was bolted in and swung over the side. Seas were as calm as a lake, not even a wind ripple was in evidence. Otis saw hatchet fish larvae and other creatures including small crustaceans. He took a considerable number of pictures. Everything went well for a while. John and I are ready for our dive to follow his. We have a detailed observation procedure planned. I will observe on the way down and John on the way up. We have a can of beer and an opener and are going to drink a toast at the bottom. I know John is now engaged and I will announce this at the bottom also—drinking a toast to him in Schlitz, and to his bride to be. This plan is quickly forgotten at the time Otis is down 3,331 ft. He says over the phones, "Oh, Dr. Nelles, something is wrong. Dr. Nelles! Dr. Nelles!" Then his voice cut off completely and contact was lost for good.

We immediately began to bring him in as fast as was possible. The entire crew worked with tremendous precision and speed—cutting the ties that hold the electric wire to the steel cable as they flashed out of the water and toward the big pulley and eye through which the cable passes onto the drum. The winch engine was soon steaming and boiling. Everyone was tense. We felt that chances were 50-50 that Otis was dead as we knew something was wrong in the ball and it would take us at least 40 minutes to raise him. I found that every newsman present had a byline prepared in case Otis had been killed. Photographs even had been taken of the ball for this purpose.

Finally the electric cable became so tangled that it had to be cut loose. Shortly we hoisted the ball on board and could see at once that it was not full of water. A light burned inside the port from a battery. The bolts were feverishly loosened and a hand with a flashlight came out the port. Otis was OK. He yawned and announced that we had awakened him by banging on the bolts. He had gone to sleep! Curled up in a blanket and gone to sleep!! He did not take a single picture on the way up!

Nelles was so tense that he called off further operations, deciding he could not send us down with a patched cable.

John and I were quite disappointed as this was our last chance. We despondently boarded the *Monsoon* and headed for San Pedro. Jay Eyeran and Frank Champion put us on a plane (from their expense account) and off we went for San Diego, a good meal, and La Jolla. Bah!

October 24, 1952

San Miguel Canyon, Baja California, Mexico

Al Allanson and I set out this morning on a trip scheduled to last eight days. Our main purpose is to collect fishes in some of the streams in northern Baja California. It will take us eventually to the crest of the Sierra San Pedro Martir and up three of the canyons.

We left La Jolla at 6:00 AM and had a good breakfast in San Diego and shortly crossed the border into Mexico. Out a short distance on the Rodriguez Dam[?] Road we cut down to the Tijuana River. It is a slow, meandering stream formed of several small rivulets flowing through a reed-filled river bottom. It is a mess, with beer cans, trash and bottles, old tires, etc. in the stream. We seined in this and retrieved a series of green sunfish and mosquito fish.

We saw some larger fish with a lateral dark stripe swimming in a large pool but were unable to catch them with our little common sense seine. We went back to the car and unlimbered our 25 ft. bag seine. We soon caught our mystery fish which proved to be a small mouth bass. A large carp eluded our net.

We tried to find a way to get to the lagoon portion of the Tijuana River, near its mouth, but only succeeded in finding a place where the International Border fence had been knocked down and people were blandly driving across and coming out in the main highway at Dairy Mart Road, in San Ysidro California. We crossed at this point twice and no one bothered us. The dope traffic must have an easy time.

We returned to Tijuana and went upstream near Rodriguez Dam. There we saw only more of the same species we had been taking, including several more bass. After a couple of beers we drove on down the road toward Ensenada. Before long we came to San Miguel Canyon, and we cut down the embankment beyond the old mission, past a house with abalone door knobs, into the canyon. It is a magnificent canyon with high, nearly vertical basaltic walls, a lazy little stream choked with watercress, reeds, and algae, and banks bordered with dense grey-green thickets of willows and arrowweed.

Cottonwoods and sycamores form a patchwork in the streambottom. We followed a white sand road up the canyon past a lone palm and a lone pepper tree to a ford. Here we stopped for lunch. The day was cloudy and cool but very pleasant. We had two captive rattlesnakes which we set free, one a small Pacific diamondback and the other a young adult red rattlesnake. Both were soon lost in the underbrush.

We seined in the stream at this point and caught a good series of *Gambusia* and *Fundulus*. We continued on upstream passing first through a gate on the left hand side of the stream, past a group of Mexicans shucking corn and on up the canyon amid oaks and sycamores.

The walls of the canyon closed in somewhat as we proceeded upstream and then opened out into a broad hidden valley. It is a beautiful place, rimmed with hills and covered with fields of cornstalks, wheat stubble, and lush grape vines. We hiked up a

side canyon to the left under a canopy of huge, spreading oaks. We followed a road to its end in an oak-covered flat just beyond a corral made of woven willow staves.

Once back down we drove on up the valley through fields of grape vines to a couple of adobe ranch houses. Afternoon was closing as we drove up a nearby mustard-stalk-covered slope in search of a dam we had heard existed on this stream.

On the way up Al and I shot three doves with our 22s. We will cook them later. Finally we were stopped by the steepness of the hill; the wheels of the carry-all slipped on the slick grassy slope.

We hiked over the remaining few yards of the slope and looked down on a bend of the river that formed a huge natural amphitheatre of grand dimensions. A few cattle straggled across the grassy bottom, far below us.

We returned and drove the car through the fields and out of the valley, across the stream to a little sandy flat. We were briefly stuck in sand but shortly made camp next to a tall stand of arrow-weed (*Baccharis*) about 150 yards from the stream.

Dusk was falling and the surrounding hills faded into graded shades of gray. The sky in the west was faintly tinted rose in the V of the canyon. I walked down toward the creek with my gun. The cool air made the edges of my ears and the back of my neck tingle—a delightful feeling that heightens one's acuity. The smell of river bottoms, of willows and arrowweed and bogs was heavy in the air. A great ponderous silhouette of a great blue heron flapped across the sky and a ragged line of swift doves entered the trees—birds coming to roost for the night, in from the dry hillslopes.

As I shuffled back to camp a number of noises awakened my notice from various directions. Ahead on a far slope coyotes were already yipping at one another. Ravens called garrulously to the skies from their roost in a big hillside oak. I heard the laughter and screams of small children downstream. Crickets set up a pleasant base-level for it all.

We ate a fine meal of ground round, potatoes and onions, green beans, avocado and tomato salad, and tea. A passing vaquero joined us in a drink of wine and told us of the dam two miles upstream. A good fire, dishwashing, bugs around the light, notes, and then to the sleeping bag 'neath clouded skies. Tomorrow we head for Meling Ranch at San Jose, in the foothills of the San Pedro Martirs.

October 25, 1952

Santa Rosa Valley, Baja California, Mexico

After a leisurely breakfast of french toast and bacon, Al and I loaded the carry-all and drove up the valley. We had hopes of hiking to the dam. We drove through the big vineyard and to the edge of a broad sandy wash. Al thought we could cross it and drove down into it. We shortly bogged down in the soft sand. Both of us agreed it was better to work back than to try to go ahead. We decided we needed a board or two to help us so we started hiking toward a little adobe shack on the side of the hill. After a hundred yards or so we decided to go back and get our guns, which we did. I had a couple of fine stalks after doves in the dry corn fields. Finally I got two birds and we reached the little house.

What a spot!! This little adobe overlooked the entire valley—vineyards, grain fields, and distant hills. Water was piped down to a water trough and several kinds of fruit trees grew down the slope in front of the house. Melons and squashes were ripening

among the corn stalks. Several spreading oak trees shaded the place and high rocky cliffs guarded the back yard. We saw jays, doves, and a brilliant oriole in the oaks. Al made a fine standing shot on a dove standing on a rock.

We found a surplus plank on a little willow shack and a couple of Model-T floorboards, which we hauled back to the car. After working quietly for a while we heard the calls of quail nearby and dropped our shovels and picked up our guns. The birds were not more than 50 ft. away, clucking and walking towards us. I shot one.

We pulled out and drove down the valley (it was too late to hike for the dam). We got another quail in the vineyard and drove on down the canyon. Near La Mision we noted a huge bird standing by a corral. It was an eagle with huge leg ruffs. He took off in ponderous flight and we watched him sail up a nearby canyon and disappear.

We drove to the mouth of the canyon and seined in the lagoon there, catching nothing but *Fundulus*. A net haul farther upstream netted us more of the same species. We saw a group of water birds standing in the shallow stream. They may have been yellow-legs. One lone American egret stood in the water far upstream. His white plumage shone like it was illuminated against the gray-green willows of the stream border.

We packed our seines, had a beer, and drove on into the Santa Rosa Valley and down a tributary at the southwest end. We camped near a sycamore on a little grassy flat by an old corral. Al and I took hunting hikes. I returned at dusk and several flights of quail rocketed into the oaks near me. I shot one after it was so dark I could hardly see my sight.

We had 7 dove and quail for dinner, a good salad, wine, and a fire. An old great-horned owl "wakked" in the oaks nearby. It was a foggy night, but I didn't notice it.

October 26, 1952

San Telmo River Valley, Baja California, Mexico

All night I could hear fog dripping from the tips of oak leaves and was thankful that my sleeping bag was in the open. Al cooked breakfast while I hiked around the vicinity.

The skies cleared and we had a beautiful calm clear sunny morning. We packed and drove out past the corral and gate. A short time was spent seining under the road bridge. We determined that the water does not drain into the sea from this SW tributary, but into the valley and thence in the direction of San Miguel Canyon, through a narrow gap. We caught mosquito fish and green sunfish. Before long we entered Ensenada where we bought gas, bread, and beer.

South of Ensenada we bypassed the checking station by driving through fields. Al swiped a few peppers and showed me how to eat them and how not to eat them. All is palatable and cool except the fibrous part that holds the seeds. This is hotter than hell! My mouth burned for miles.

I filched a few tomatoes and we continued on down the highway past Santo Tomas Valley, San Vicente Valley, and Arroyo Seco. 11 miles beyond the end of the pavement at Arroyo Seco we came to the San Telmo cutoff. We motored up through the beautiful winding canyon to the little valley that holds San Telmo. The village is small and surrounded by heavy growths of tuna cactus. A few *Washingtonia* palms stand in the

village and several ruined adobes are to be found. Cows, chickens, and neat Mexican girls wandered about.

Up over a dusty ridge east of the village, we drove and were greeted with a view from the crest, of the broad fertile river valley above. A huge ranch with much machinery, a big cement warehouse, young orchards, spray watering, and literally miles of plowed fields occupies the river bottom. It looks as if it could well be worth \$1,000,000.

We drove past this, hunting all the while for a ground squirrel to cook for dinner. Al saw a nice spot to camp and as it was late we pulled off and up against an agave-covered slope. I saw a covey of quail on the slope and we both went hunting immediately. Before I had finished I had three brush rabbits. We ate them for dinner with wine, salad, coffee, and corn. It is a beautiful warm calm clear night—one to be enjoyed and remembered. I will put my book down and sit for a while by our agave fire before going to bed.

October 27, 1952

Arroyo San Telmo, Baja California, Mexico

Al and I got up at dawn and set out with our guns looking for rabbits. I walked a mile or so upstream and shot two rabbits and saw several roadrunners. I returned before Al and sat down to enjoy the morning.

A shrike swooped down among the bushes chasing a young cactus wren. The pair fluttered around the shrubbery and finally the shrike pounced on the wren, holding the hapless creature in his claws and pecked at it. The wren was swiftly killed (by what means I am not sure as there were no marks on the bird, at later inspection).

The shrike impaled the little bird on the sharp twigs of the bush when I interrupted the meal. Later the shrike returned and carried off his prey.

We piled in the carry-all after breakfast and drove toward Rancho San Jose, 14 miles away. The road leads out of a broad valley and up onto barren buckwheat-covered hills. As the San Pedro Martirs are approached brush becomes more dense and scattered junipers appear. *Artemisia tridentata* (Great Basin Sage) covers hillsides and valley floors with its silvery foliage.

Two north-south trending parallel mountain ranges form the western ramparts of the San Pedro Martirs. The scarp itself is abrupt and impressive. A thick matting of pines can be seen along the crestline. The road is much improved since my last visit, about four years ago. Any car could make it now. Al was not very happy about the looks of the situation. He suspected prices for animals would be high at the ranch and he didn't care too much about the hike I prospect.

I had been excited and eager but this unexpected attitude dampened my spirits a little bit as I doubted that his feelings would change.

When we came to the ranch I could see some changes had been wrought. A new guest house had been built and Mrs. Meling's daughter was in charge. Al was quite right about the commercial air. We "bought" a beer—it was offered to us and we paid for it. A pack of four animals and a guide cost \$15 per day, not exorbitant but this would allow us only three days on the mountain.

Al was willing to spend his money but I felt he was little interested anyway so I decided to abandon the attempt this time and go up Arroyo Santo Domingo instead.

We talked for a while with Mrs. Meling. She is a wonderful person and very helpful. She drew the appended map of the mountains for us. We found that trout are well established on the top of the Martirs in several localities and that logging attempts have been abandoned in the vicinity.

On the road out we turned right before reaching the crest above the ranch and drove northward along the small airfield north of the ranch and into San Telmo Arroyo above the ranch. We stopped near a dug dry well. We hiked on up the canyon through dense plant growth toward the mountains. It was hot and calm. Finally Al and I met by a big rock outcrop and decided to hike to the next spur. The stream that flows at Rnacho San Jose is underground here and we were dusty and dry and hot. We hoped to find water around the bend. Far up a spur canyon I noted some cottonwoods growing in a cleft in the granite. I hiked toward this and after leaving a well beaten horse trail, clambering over boulders and scaling a few small dropoffs I came to a tinaja in the rock filled with greenish water and rushes. On farther the water was clearer and potable. I called Al and then set out to investigate. A big frog jumped into the lower pool. I caught him and he proved to be *Rana aurora*, the red-legged frog. There were many in the rushes and water.

Al and I caught 9 for dinner. I know the animal has been taken here before and MVZ has specimens so I took none for museum specimens. We had frog's legs for dinner. We drank our fill and lingered in the shade of the sycamore and cottonwoods. Late in the afternoon we began the hike back. I shot another brush rabbit and put two shots through a bush that looked exactly like a sitting rabbit in the dusk. It was nearly dark when we got to the car.

We cooked a fantastic-sized meal of frog's legs, salad, three rabbits, and two rusty-buts (cheewinks, brush robin), potatoes, and onions, and two bottles of wine. We both became tipsy. I raced through the brush pulling up bushes with my bare hands while Al lay on the ground shouting instructions. Later we had a plant-pulling contest and cleared a considerable area of greasewood. I retired—bloody (from many scratches) but unbowed. The healthful outdoor life is certainly the best.

October 28, 1952

Rio Santo Domingo, Baja California, Mexico

Before we had finished packing the car the !@\$ gnats closed in and began buzzing in our ears. Al stoked up a fire and we had no more trouble with them, why I do not know.

We drove on toward San Telmo, stopping a couple of times to hunt quail and rabbits. One time we stopped to inspect a big hawk which we saw sitting in a bush. It was a large bird with dark brown upper parts and a white belly and leg ruffs. We think it may have been a ferruginous rough-legged hawk.

Just before reaching the main road we stopped to eat lunch amid the agave scrub. On down the main road to Colonia Gerrero over the jouncy graded main road. It is very tiring to travel on and Al dislikes it very much. At the Colonia we bought gas and some cerveza Carta Blanca. We received directions for driving up Rio Santo Domingo. We drove up to the big arched building that looks like a theatre, to the east of the main road, cut north and just at the edge of the arroyo we turned eastward and shortly crossed the stream bed (here we helped to start a Mexican whose car had stalled). Once across the

river we drove up the north bank and shortly came to a little village shaded by many trees—figs, willows, sycamores, oaks, etc. All sorts of poultry ran loose in the streets and corn fields. How ownership is decided I have no idea. Turkeys, chickens, ducks, and geese wandered about. Many of the adobes had little kitchen gardens of green beans, radishes, lettuce, onions, etc. and patches of bright flowers. The ruins of the old mission Santo Domingo stand in the mouth of a small tributary arroyo. The walls are crumbling but doorways and windows faced with stone attest to the craftsmanship of the old Franciscan padres who directed the construction. A ditch supplies water to the village and one wonders if it was first dug under the eyes of these same men.

We continued on up the canyon on a good road between precipitous high walls. Ranches disappeared behind us as the canyon narrowed and willows, cottonwoods, and sycamores choked the river bottom. A small clear stream appeared and in one place we had to pull some Mexicans out of the river. They had a burro helping and three fellows chopping willows when we arrived. We hitched up a chain to their car and snaked them out with no trouble. We then filled the roadbed with cut branches and drove across, as did they.

As we continued on upstream the water disappeared. We passed through the dooryard of a small ranch and made camp above it a short distance next to a steep agave and goatnut-covered slope. We ate dinner and went to bed.

Home the next day via the Rio San Vicente, where we made a collection of sticklebacks.

January 1953	Colorado River Trip
March 1953	Pushawalla Palms
November 1954	Off Santa Barbara
November 1954	Baja California

January 16, 1953

Bank of Colorado, 1 mile above Winterhaven, Imperial County, California

This trip is one being carried out for the Division of Marine Vertebrates at Scripps Institution. We are scheduled to float down the Colorado River from Yuma into the Gulf of California. Our purpose is to make collections of fishes and molluscs along the course of the river with the idea in mind of shedding some light on the origin of ancient lakes which once filled the Cahuilla Basin (now occupied by the Salton Sea). These lakes have left marks of their presence in the form of shore lines etched into the rocks surrounding the basin and by deposits of fish bones and huge numbers of molluscs in the old shore sands of the lakes. Of the modern day representatives of these animals, how far upstream do they now occur? Are they restricted to salt water or could they conceivably have been introduced into the old lakes by overflow from the river? We will try to shed some light on these questions.

In Dr. Hubbs's absence I have been placed in charge of the expedition and its planning. For boat work and gear I put Al Allanson in charge. He is a wonderful boatman and a splendid companion and outdoorsman. He asked two others to go along—Johnny Fleet and Charley Snell—both are excellent men in the field and good field companions. Two others will drive trucks and pick us up at San Felipe in the Gulf and at one portage point in the river. (Ben Cox and Ted Walker).

After much preparation including a plane flight over the river and conversation with several people about river conditions, we left this morning at 6:00 AM with two trucks and three boats (two of which will be used on the river). Both of our river boats are 16-footers built by Johnny Fleet. We have 2 10-horse Johnson motors.

We drove to Winterhaven, arriving at 12:00 Noon. While buying gas a car drove up alongside of our rig. The driver was a Mr. Porter of the State Police. He struck up a conversation and when he found we were going down the river he offered to drive us to Morelos Dam so that we could see the weir over which we must pass.

Before we had gotten halfway to the dam I could see this man was a real politician. His business was having connections and doing favors. He is the district head of the state highway patrol. He waved to a dozen people at least and regaled us with all sorts of tales—how he got stolen cars back from Mexico by use of his connections, his poaching forays up and down the river—with and without the warden. He did a large part of his work by use of the people he knew apparently. It is easy to see, that if this is the general rule with police officers that graft would be impossible to ferret out of forces. I suspect this is often the case.

We saw the dam keeper and walked out to the weir. Two feet of water flowed over it and passage will be quite simple. Back at Winterhaven Al and I met the others who were talking to a Mr. Dover. This man offered to let us camp on his ranch alongside

the river. As it was on the California side this would mean that we wouldn't have to undergo the border food inspection and stand the chance of losing our fresh vegetables.

The ranch was a large alfalfa field along the muddy river. It was a fine place to camp and to launch our skiffs. We set up camp and prepared the gear for the boats. We will start early in the morning.

Shortly after we had settled down a couple of surly looking characters drove up in a jeep and asked us what we were doing. It was obvious that they "owned" the river and that we were trespassers of a sort. They had used this field for hunting and somehow had seen us.

My talks with Porter, Dover, and these two men convince me that many of the natives of Yuma and Winterhaven take a proprietary interest in their river and probably look on such as we with the sort of scorn received for neophytes. Eyes were watching us and our venture from all sides.

When we were planning the trip back in La Jolla we had not even thought of the people along the river—we had thought about tides, tidal bores, whirlpools, dams, food and gasoline and the like. Perhaps we will join their society when we are done, and establish a La Jolla chapter.

We ate a fine dinner—ground meat, salad, potatoes, coffee, and wine. Al drank more than his share of the last item and gave us a splendid imitation of an airplane and then told endless stories in a loud voice. Finally we went to bed under a bright starlit sky. The railroad noises of Yuma blotted out the ripples of the river. It froze and I was thankful to have my sweater on in the bag.

January 17, 1953

Near Gadsen, Arizona

After breakfast we launched our boats and loaded them. Shortly we shoved off into the swift current of the river. It is perfectly a perfectly soundless mode of travel, floating down a big river such as this. Quickly we left the two men on shore behind as we floated around a bend in the river. Some little Yuma Indian children ran along the bank laughing and screaming at us. We could see their clay and wattle house back among the willows. We passed under the railway bridge at Yuma and floated on down the stream between tree-lined banks. The stream is perhaps 200 yards wide on an average and lined with thickets of willow, arrowweed, tamarix, and cottonwood trees. All sorts of birds flew from the trees as we floated along. Many big black-crowned night herons were scared from their perches. Ponderous great blue herons flew away to land on teetery perches in trees, with their long necks outstretched, or stopped on the mud banks where they stood perfectly erect and became so thin that they looked like plants. We saw bitterns, several kinds of ducks, geese, coots, and all sorts of smaller birds such as vireos and savannah sparrows.

After a time we lashed the boats loosely together and floated down as a raft. What a life! We lay back on sleeping bags, took off our shirts and enjoyed the sunshine. A minimum of rowing is needed to keep the skiffs in the main current, but this chore came up only once in every ten minutes or so.

From the air the boils of water and whirlpools had looked ominous. However, on the river they presented no problem. So I am told, these boils are caused by ripples building up in the bottom mud until they are unstable and are suddenly washed out by the

current and the bottom is scoured clean. The rush of water thus released boils up to the surface. Several times these came up under our boats but did nothing more than startle us with their noise. This turbulence serves to keep the river full of sediment in suspension.

Before too long we came to Morelos Dam. It is a diversion dam used to shunt water into the Mexicali canal. This canal supplies the water for irrigation of the large and productive Mexicali valley. The dam extends only $\frac{1}{2}$ way across the river above the water surface, the eastern $\frac{1}{2}$ being a concrete weir which normally lies a foot or two beneath the surface. The western $\frac{1}{2}$ is a series of big metal gates which can be opened or closed to regulate the level of the river, part of which passes out to the west into the canal.

Johnny and I went over the weir first. It was a very short little rapid and we slipped by easily, as did Al and Charlie. I had worried about this and was glad to be by it.

We lashed our skiffs together again and made up lunch as we floated along. Al broke out the stove and we cooked up a fine pot of coffee using river water. All this keeps reminding me of *Huckleberry Finn*. I used to live that story and his raft life. It enhanced my pleasure here I suspect.

We shot a couple of coots and some doves before we began searching for a camp spot. About 5:00 PM we saw a little backwater and a little sandy clearing on the top of the bank among the arrowweed plants and screwbean mesquites (*Prosopis jubiflora*). We pulled in completely out of the current and unloaded onto the clearing. I gathered wood for a fire while the others started preparing supper.

I took a walk with the gun in hand, along an old abandoned dirt road. I saw several rabbits and covey after covey of quail but the dense brush prevented me from shooting any. As I came back to camp a blazing sunset turned the sky and the shining river pink and red and finally orange and brown. Later I was pleased to find that coots are fine food. They are easy to obtain and when rolled in corneal and fried in an inch or so of hot oil they were tender and no more gamy than a wild duck.

Tomorrow we will probably pass San Luis, Sonora and be all in Mexico. Here $\frac{1}{2}$ the river is in Arizona and the other half in Mexico. We will make our first collection too. We travelled about $7\frac{1}{2}$ hours and averaged about $3\frac{1}{2}$ knots, if I calculate correctly. We used no gas and rowed only once in a while. It is getting cold and it is 10:00 PM so I will go to bed.

January 18, 1953

South of San Luis, Sonora, Mexico

We were underway at 9:12 AM today after a good breakfast. Last night while Al and I were writing our notes we heard repeated splashes in the river. We thought they were fish or some sort of rocks or soil falling into the river. I suggested that they might be beaver but didn't really believe it. Finally, because of cold air we went to bed.

I was cold all night long and awoke only when I heard Al building a fire in the cold gray of the dawn. Next morning we ate breakfast and afterward I went on a brief hike with the gun. I saw several Gambel's quail but shot none. We loaded and shoved off into the river. Today was beaver day. First Al and Charlie spotted a beaver house and two beaver—one of which swam across the river and flapped its tail. The sound was identical with that we had heard the night before.

As we floated down the river we saw many birds including the Florida Gallinule—seen near Gadsen. This is the first of the species I can definitely say I have seen.

Before long we spotted a large flock of Canada geese standing on a sandbar. What magnificent birds!! They flew away with a rush of wings and flapped slowly off to the northwest. We passed the San Luis Bridge—a wreck of old pilings and a collapsing span. In its place was a ferry (pango) which was crowded with dozens of people all standing up. The pango itself was stuck in the river mud and men were in front of it trying to free it with dredges.

We ate lunch and made a collection in a backwater. The water was cold (12.2 degrees C.) and we obtained few fishes even though we made six seine hauls in the freezing water.

Lunch was welcome and was eaten as we floated along lashed together. We had coffee and albacore sandwiches with pickles and other sundries.

About one mile south of San Luis we came upon a slough in which a large flock of snow geese could be heard honking. Charlie and I stalked upon them through a sough of cold, waste-deep water. They took off with a noise that was indeed like thunder. Johnny estimated 1,200 of them. What a sight!

As we drifted down the river Johnny and I sighted four beavers. I was amazed at their size. They weighed easily 40-50 lbs. apiece.

The bank of the river collapsed into the stream continually in places when it was cut into by the full force of the river. The falling soil made sounds like the shots of a 12-gauge shot gun as it crashed into the swirling waters. Without doubt these falls of soil would swamp the unwary skiff that ventured too close to the cliff. As the strongest currents always veered us close to the cliffs it was a continuous job to scull away when they appeared.

We shot six coots and sailed along in the swift current. Finally we made camp at a point some 20 kilometers north of the railroad bridge. This remaining distance will be run in the morning. Our coot dinner was again delicious. The day's collections shed little light on our central question. Perhaps it is not a good time to think of you, Phyl, but nonetheless, I do, and in full force—

January 19, 1953

10 miles N. of El Mayor, Baja California, Mexico

We ate a breakfast of buckwheat cakes and ham and shoved off into the river. Johnny and I floated along looking for beavers on the bank. We could see many evidences of them—dozens of cottonwood and willow trees had been gnawed or felled by them. Their work seemed most often present when the bank was covered with rushes and small willows and cottonwoods were scattered among the brush. Many ducks and great blue herons were sighted as were a few small groups of snow geese and Canada geese. These latter birds were generally quite wary and flew with a great rush long before we approached them closely.

We stopped on the muddy bank alongside a still mud[?] filled backwater to make a collection. Al mixed a can of derris root and I spread it among the plants. Our collection was extremely small. It appears that the fauna is small. We waded around in the cold water among the reeds sweeping the bottom with no success.

As we floated down the river Johnny saw a goose that apparently could not fly. I quickly nosed the skiff over into the bank and Johnny jumped out with the 12 gauge. I set the anchor and ran after him across the mud flat. The goose was swimming into a broad backwater lagoon with his neck held low parallel to the water. I saw he would escape us unless he was headed off so I waded into the cold water (55 deg. F) and finally began swimming after him. I was successful in turning him back toward Johnny. Several Mexicans on the bank became excited and one rode off on horseback. I pursued the goose swimming and he got closer and closer to Johnny. Just then the Mexican returned with a gun. I swam on. My arms, which I had been exercising by rowing, showed signs of becoming cramped because of the cold water. Johnny shot the goose and I retrieved it before the Mexican could dispatch it with his gun. We proudly, and I shiveringly, presented it to Al and Charlie. Dinner!!

A short time later, as we rowed our way through an area of rapids and whirlpools we saw another wounded goose. This one swam into the swift stream with Al and Charlie after it, using their outboard against the current. After a long chase Charlie shot it with his .22 and hauled it aboard. Two geese for dinner!

As we cruised along the stream we passed many ranchos and at each the children rushed out to see the “pangos” floating down the river. We were apparently something of an oddity. We shouted greetings of various sorts and floated on.

Ahead of us we noted a group of people on the bank, one of which dove into the river and swam across. As we neared, this man, clad only in shorts, shouted for us to take him back. Johnny and I cut loose and rowed over. After a time he climbed aboard and we rowed him across. He was quite drunk. He thanked us and introduced himself as Manuel Tores. We gravely shook hands. We showed him the directions to his clothes and left.

I took the stern sweeps and rowed as we floated down stream. The other boat had floated out of sight and it was $\frac{3}{4}$ of an hour before we caught them.

Shortly after we had reunited a small plane was sighted overhead—it proved to be Giff Ewing in his Cessna. He circled us several times and dipped his tail. We released sea dye to show that all was well with us. I thought I could see Phyll in the cockpit and noted that the right side of the plane was always toward us as it circled. Then an object, like a paper carton, fell from the plane. I knew Phyll was aboard then. It fell in the reeds along the bank. Excited Mexican voices said “Nota, nota!!” We had no chance to retrieve it but I didn’t have to—whatever else might happen during the trip I was quite happy. I hope she comes back when we are in the lower river!!

We held up our geese for the occupants of the plane to see and then rowed on down the stream, passing under three ferry wires that hang low over the stream. It is very difficult to gauge the distance to those wires as you float up to them, as there is no plane of reference.

Finally we saw the railroad bridge and sighted Ben and Ted and the trucks. We nosed up onto the bank and loaded our gear into the trucks and trailers. We drove toward El Mayor and made a late camp in the desert. I had a little tiff with Al, because I thought he was being unnecessarily rude to Ben. I hope he recovers as I wish no hard feelings. The geese were cooked and were tough but edible. Tomorrow—off down the Hardy. I hope Phyl comes back with Giff. I want to know she is up there. What a time to be out exploring this way!

January 20, 1953

Just N. of La Panga Ferry, Rio Hardy, Baja California del Sur, Mexico

At dawn we stirred out of our various beds and began cooking breakfast. Al and the rest of us were once again on an even plane with no hard feelings. We loaded everything and drove off along the paved road that passes close along the eastern scarp of the Sierra Cocopah. These are rugged, rocky mountains and are extremely barren. There are said to be no sprigs in them. The Hardy is high and fields along its shore are flooded—shacks standing a foot deep in water. A big flock of American egrets was seen stalking along in one field and many ducks—baldpates, shovellers, teal, and others—flew as we drove by. The road swings between the base of the mountains and the westernmost bend of the Rio Hardy at El Mayor. Here we launched and loaded at 9:45 AM.

The stream is broad here and has practically no current. This spells a long siege of rowing for us as we must save our gasoline for the long journey in the Gulf to San Felipe. We will probably need to row 25 of the 50 miles to the Gulf. I took the sweeps first with Johnny in the bow. We all row standing up pushing against the oars. This is Portuguese style. It is much easier after one gets used to it. You can throw your weight into each thrust of the oars and blisters on hands and bottom are reduced in number or absent. We slid along through the brown water between mesquite and willow-lined banks. After a while we nosed into a fish camp and bought a round of cold beer—a welcome item after a row in the sun. We are all getting good suntans even though it is January. Days have been sunny and warm.

We tried to buy some beer to take along with us but off limits sales are illegal in Baja California just as they are in California.

We rowed along easily, enjoying the calm and warmth. I like to row and don't mind long periods of it if not required to make much speed.

The bank became lined with a dense growth of willow saplings four or five feet tall, and occasional patches of rushes. A stream cut in from the north and the current in our river increased noticeably. After we had rowed four miles or so other streams had cut in and the current was such that we saw that continuous rowing would not be necessary.

We heard the calls of many birds—coots, rails, great blue herons, and ducks—from within the rushes along the river's edge. There were also many calls none of us could identify. Trills, groans, honks, and screeches—it sounded all the world like the soundtrack from a jungle movie. Katherine Hepburn was nowhere to be seen. Neither were any of the birds. All this din and not a bird in sight.

A short distance downstream I noted a cormorant-like bird flying along. It was the first aubringa[?] or water turkey I had seen. A belted kingfisher flew low over the water. Behind us, over the rushes was the rugged Sierra Cocopah and Cerro Mayor, its highest peak.

As we slid along I could see through the scree of willow saplings into calm backwater ponds. These are exciting looking places of shaded water, big towering cottonwoods, and willows half in and half out of the water, and of beaver houses. I wanted to stop and investigate but we kept on.

We slipped past several ranchos whose buildings and equipment stood in muddy water. No one was to be seen.

Fish were collected from a little slough. We had our usual quota of times in the mud above the knees and the other joys of such work but we obtained a good series of fishes including the young of the mullet—an ocean fish and one which has colonized the Salton Sea. We are probably 25 miles above the highest brackish water.

Just below the collecting location I spotted a beaver house at the edge of the bank. We rowed over and inspected it. It was about 3-3 ½ feet high and composed of sticks no larger than one inch through and mud. The animal apparently spends some time sitting on top of his house judging from the dung collected there.

On down the river—plants became lower and open areas along the banks more prevalent. Finally, on the south bank a low growth of *Salicornia* (pickleweed) occupied the flat plain to the south as far as one could see. The gray peak of Punta Estrella at San Felipe can be seen in the far distance over this plain. It is our ultimate destination.

We stopped and anchored along a low vertical bank. The gear was passed ashore and we made camp. Driftwood was everywhere and I am sitting by a fire writing these notes after a supper of sauerkraut and weiners (with hot mustard), corn, coffee, and salad. We have just brewed up a pot of cocoa and can hear bats squeaking over us. There are a few mosquitoes for the first time which we hope will be dispersed by the breeze or numbed by the cold.

Well Phyl, we made about 25 miles good today and should place ourselves in a position tomorrow to make the run through the tidal area around Montagu and Gore Islands on the following day, as we had previously scheduled.

January 21, 1953

Between Panga Ferry and Montagu Island

As I retired to the sack I could hear the voice of a coyote upstream. He had a peculiar cracked voice as if he was having trouble barking. During the night I got up twice to check the anchor lines on the skiffs. The low banks could be heard crashing into the river all night long as the river cut into them.

At dawn we were up cooking breakfast and by 8:30 we were loaded and floating down the river. Shortly the water lane passed between tall barricades of willows and cottonwoods on both sides. There was much evidence of beavers but we saw none. Ducks were everywhere, flapping up and away from the streamside reed beds as we floated by.

I saw a little backwater and we landed to do a bit of collecting. Immediately as we stepped from the skiff we were over our knees in soft mud. In places there seemed to be no bottom and I do not doubt that one could sink out of sight. We searched around for a place to seine and finally tried in the main channel of the backwater. We obtained a vast load of soft mud and some young mullet. We left without further attempts in the morass.

We floated on. Al and Charlie nosed over between the roots of some big willows and soon we had floated out of sight of them. We anchored against a sandbar and waited. Across the river, in a big eddy, were a dozen or so coots swimmig in circles with the current picking bits of food from the foam that had congregated there. A Mexican rancho occupied the land back of the bank. We could hear the laughter of children and see pigs of assorted sizes running along the bank among the willows.

Finally, Al and Charlie showed up after having explored a backwater and we floated on. A flight of anhingas flew by. They are peculiar black attenuate birds that look like skinny cormorants. They flew with a crook in their necks.

A northwest wind began to come up. Before long, on the northward leg of the stream meanders the surface water became a confused mass of small wind waves. Here the current opposed the wind direction. We had to row continuously to maintain headway. On the south legs we fairly flew along.

We came together for lunch and just then Giff flew over in his plane. There were passengers but I could not identify anyone. I guess Phyl was sensibly at Scripps trying to get some work done. As they circled us we split up to pass under the wire at La Panga Ferry. This is, I believe, the nearest ferry to the Gulf. We hooked up again and started a pot of coffee but we came to a northward leg and had to row again. Finally in the lee of the bank we anchored and ate a peaceful lunch.

We made another collection, this time obtaining a fair group of fishes before becoming mired in the mud. The wind became constant and we rowed in shifts. The afternoon wore on and we decided that we should camp soon. The terrain had changed—the banks were getting higher and higher and signs were many that the water often rose 8-10 feet in the channel. There were no more rushes; the banks being covered with tamarix or mesquites. The ever-present coots were now absent and various sorts of sea birds had become common. We saw flights of graceful avocets, curlews, and groups of huge, white pelicans.

Finally we pulled off into a side channel and unloaded the skiffs up on top of a 8-10 ft. mud bank. We fought the skiffs up on top of the bank too. There was plenty of evidence that the water sometimes flooded to the top of the bank but the ripple marks and debris appear to have been deposited 3 or 4 days ago. We hope it will not come up this high tonight.

We cooked a carp (it was really delicious—the secret is that they must be skinned before they are cooked) and had hash, limas, coffee, and bread and jam. Al got plenty of exercise hunting for a lost fork.

We placed a marker stick in the mud and we can see that the water is rising quite rapidly. Now Phyl, off to my bed, which I wish will stay dry all night tonight.

January 22, 1953

Rio Hardy Estuary, Baja California, Mexico

After a rather fitful night's sleep I got up to sounds of breakfast cooking and a campfire burning. I arose, somewhat the worse for wear and went over to the fire and had breakfast—french toast and ham.

We seined in the little channel below our camp and caught pounds and pounds of little 1-inch mullet. I preserved about 1 quart of them and we released the rest.

We pushed our skiffs over the bank and launched them into the muddy river. It had risen about 4-5 ft. during the night, leaving us plenty of lee-way for a dry camp.

We rowed down the stream, taking turns at the oars. The current had become slowed as the stream broadened. It flowed sluggishly between low muddy banks. The wind was quite strong from the north and we had to row strongly at times to keep the skiff clear of the eroding banks.

The river banks were now perfectly flat except for occasional tidal channels and were of bare soggy mud except where salt grass clothed them near the stream border. We passed a tidal gauge set up and maintained by the Mexican division of the Boundary and Water Commission. It showed that stream waters sometimes reached at least 7-8 ft. above the present stream level. As we were hauling out on a sandbar we saw Giff Ewing overhead. We released some dye to indicate that all was well. He wiggled his tail to indicate receipt of the message and flew off. I am more grateful to him than I can express, not only for seeing that we are all right, but for easing the minds of those who might be concerned about us at home—you Phyll—I wish I were with you now—and Dot Allanson.

We made a collection which netted a few species including what may be a young goby and a young humpbacked sucker. If this latter is correct it is a rare find.

On down the river—we tied together to eat lunch. Many shore birds were in evidence. Avocets in considerable numbers, terns, curlews, and willets. The banks are becoming totally barren except for sporadic patches of salt grass (*Distichlis*). All else is mud or brown water and sky. At one place we found that by burying our legs in the mud we could lean over, either frontwards or backwards at outlandish angles. This occupied some time for photography.

The wind continued to rise and blew us along at a great rate on the southern leg and retarded us greatly as the river course swung northward.

The river became very broad—300-400 yards, and the channel very difficult to follow. Some trial and error was involved before we located it in several cases. Both Johnny and I had to hop out several times to push off sand bars and back into the obscure channel.

At one place we pulled up along side of a muddy bank and tried to sneak up on a group of feeding snow geese. We were unsuccessful as they flew off in a great rush of wings and honking. I did, however, find a fine collection of molluscs on the bank, some of which occur in the Salton Sea.

Finally, as we entered the estuary we hauled up along the bank and made camp within sight of the mouth of the river.

We attached long anchor lines on the boats, set a watch, and cooked dinner on the bank. Later we laid our bags out on the salt grass and Al and I wrote notes while the others slept.

The tidal effect is plainly evident here. Sally lightfoot crab burrows are everywhere. The flat back of us is covered with periwinkle shells and acres and acres of salt grass cover the highest ground. The banks bear the marks of repeated tidal incursion. We can see Montagu Island at the entrance. This is an historic spot though unmarked by bronze plaques. Francisco Ulloa investigated this very place in 1520, only about 30 years after Columbus originally discovered the new world. Ulloa was one of Cortez' men and sailed for him. He investigated the Gulf of California and showed that it ended in a river mouth.

A short time later this information was forgotten and California was considered an island—the island of “California”. This belief persisted until the late 1600s when Father Kino proved that the Gulf was blind.

Up this channel have passed steam boats to Yuma. Explorers have been turned back and upset by the wild tidal bore which coursed up the river prior to the

establishment of dams. At present the tidal effect seems limited to a large scale change in level—of the order of 23 feet at max.

We are busy at present pulling the skiffs up with the advancing tide.

Mosquitos are here but not in any great numbers—I hate to think what this place must be like in summer, with heat and clouds of mosquitos.

Well—I have been fighting to let this trip proceed as it will—slowly if necessary for safety's sake, but I can no longer hold my feelings. I have tried to convince myself but it is no use. My main object has been for days and is to get back, Phyl. This is an exciting trip and I will not forget it, but still I want nothing more than to be with you in stodgy old La Jolla and to see the surf and talk to you.

I know it is not good for any of us for me to become detached so I have fought this, but it is here and I will be honest. Wait Phyl. I'll be with you.

January 23, 1953

San Felipe, Baja California, Mexico

During the night I got up several times to look at the boats. The tide only came up a short way and then began receding. We pulled the skiffs up and set the anchors as we did. In the morning they were several feet above the water level. We seined along the bank and caught only a few mullet. The shell collection was better, containing several different species.

I cannot interpret our collections yet as I do not know nearly all of the species we have taken—particularly of the shells.

We shoved off into the broad muddy estuary and rowed for a time and then started the motors. The river is about 1 mile wide at the place and bordered by interminable mud banks. All vegetation excepting salt grass was left behind. This river mouth is a place of vastness, low relief and uniformity. One travels along with the motor pushing at 6 knots and nothing seems to change even though banks go by and new ones loom up before you. One can look backward and cannot determine the channel through which he has passed. It's a huge expanse of muddy brown water ending in vague distant desert mountains.

What had been a thin line of black on the horizon materialized into Montagu Island. We cruised up near to shore in an attempt to land and make a collection. The skiff grounded and Johnny jumped overboard to haul us onshore. He sank up nearly to his waist in the mud. Old John didn't let go of the rail of the skiff—he was afraid to for fear he would sink out of sight. This island is above sea level some 40 ft. in the highest places. Why it does not sink into the Gulf I do not know. It is a mound of nearly liquid mud. I even found myself wondering that the birds were able to walk on its shores without sinking. It was impossible to make a collection along its shores so we cruised on, passing among the gill net fishing boats. These boats are about 30-40 ft. long and fish the estuary for totuava, a large (120-140 lb.) white sea bass.

We left the island behind and started out into the Gulf, headed for a distant bluish triangle of land to the south. This is Punta Estrella, the point that marks the north entrance to San Felipe Bay. Several gannets flew from the water and off across the Gulf. We saw flocks of herring gulls and small white terns. Surf scoters flew ponderously from our bow as we cruised into their flocks. They seem to have a very hard time launching themselves into the air. The launching is accomplished by furious beating of the wings

and running along the surface of the water, breaking through wave crests, and finally, blessed flight.

The afternoon came and we had traversed over half the distance—65-70 miles in all.

Giff appeared high above us and flew low over us several times acknowledging our sea dye signal with a wiggle of his tail. Then he passed over us very low to the water, the door opened and a big package fell out and into the water a little way from us. It landed with a sodden bloop and disappeared. (It was later determined to be 6 cans of beer). Then another package was dropped—this time with a small parachute. We retrieved it and found a loaf of very special bread, a package of ice cold beer and the morning paper.

What a racket! Here we are cruising along over the calm gulf, our shirts off, enjoying the warm sun, drinking ice cold beer, eating avocado sandwiches, and reading the morning paper!

We cruised along, helped by a tailwind and the outgoing tide. I wanted to make it to San Felipe rather than camp on the shore as I was most anxious to get back. So I bided my time knowing that Punta Estrella at San Felipe would look close later in the afternoon, and that I could convince the others to go in then. This worked and we continued cruising through the beautiful sunset until well after dark. We ate a scanty dinner as we sailed—tossing sandwich materials from skiff to skiff. We even had a tossed salad—a head of cabbage thrown across the water.

As evening came so did a reverse in the tidal current. We had to buck this current and I suspect it cut our speed a good two knots. It was a long long time before we rounded Punta Estrella and cruised into the bay. Many fishing boats were at anchor and a few were moving around—all without lights of any sort.

We nudged up against the steep sand beach just below the parked trucks and were greeted by Ben and Ted on shore. It was quick work to unload and lift the skiff to the top of the berm—then we built a fire and drank a couple of bottles of Mexicali cerveza and discussed the various perils of our respective trips—of which there had been none in actuality.

Ben was a little full of tequila and poured his troubles out on me after the others had gone to bed. This commiserating cost me some yearned for sleep but Ben felt better, I think.

January 24, 1953

San Felipe Bay, Baja California, Mexico

Though there had been talk of hikes and seining for today, we went home instead. Al asked me if I would like to go home, and I told him there was nothing I wanted more. So he said he wanted to go home too and finally, without my suggesting it, the others decided to go too. This pleased me a great deal. The trip home was long and uneventful. I spent my time checking off the miles.

Phyl, I have never felt this way or missed anyone . . . [page missing!]

March 27, 1953

Entrance to Split Mountain Canyon, San Diego Co., California

At 3:00 PM Phyl and I left Scripps in a University jeep to explore Fish Creek in an attempt to see if fish populations still exist in the area. They are supposed to have lived there prior to a flood in 1916. It was a nice day, sunny and warm, and driving was pleasant.

We passed Julian, stopping for a cup of coffee and went down the desert slope. The hills were dotted with fragrant purple and blue lilacs. At Banner Ranch we bought gas and watched a big peacock strutting and displaying for a reticent female. We were interested to see the way he vibrated his tail feathers against the huge feathers of his train. This was done as he attempted to corner the female. It sounded like dropping a lot of fine pebbles on a screen door.

We drove on, turning off at Ocotillo and reaching the wash of Split Mountain Canyon just at dusk. I skirmished around and gathered up firewood and built a nice cheery blaze. We ate our dinner and enjoyed the moonlit night and the fire. George and Binky Harvey drove up just as we finished, ate their dinner, and we all went to bed.

March 28, 1953

Pushawalla Palms, Riverside County, California

We were up with the dawn and shortly had scrambled eggs and bacon ready. We then packed and drove up the canyon. The Harveys, in their little Singer, lead the way. When we had passed all the way through the canyon they stopped and hopped on the jeep. We drove on up Fish Creek wash, passing through miles of mud hills in the Carrizo Badlands. The wash is, for the most part, broad and sandy—easy jeep driving.

Finally at the junctions of two stream courses alongside a fairly large cliff of alluvium, we turned to the left and after 2 miles or so, came to the end of the road at the base of a high cliff, in the foothills of the Vallecitos Mts. We hiked up to the cliff. Ocotillos were in bloom giving a beautiful show of red at the ends of the long waving branches. Blue asters were everywhere—several *Oenotheras* (evening primrose), indigo bush, creosote bush, chuparosa, yellow California desert poppies, and others added their colors.

The creek lead up to the face of the sandstone cliffs which are about 200 ft. high, columnated by erosion. In one place water has worn a narrow fissure, generally not 3 feet wide into the cliff down at least 150 ft. from the top.

Seeing that there was no chance that standing or running water would be found here (we are looking for desert fish populations), we returned to the jeep and drove back to the junction, this time taking the right hand wash. This wash passes at almost right angles to the main Fish Creek Wash, ascending directly into the Vallecitos Mountains. [Drawing]

The wash is often composed of cobbles and is rough riding. In one place the road is forced to go over a boulder reef and it is a hard pull, even in a jeep. We made it easily, however. Once above this narrows the wash widens greatly and becomes very soft. We drove in four-wheel drive, low range most of the way. Many little purple flowers were scattered over the wash and the sand dune primrose (*Oenothera deltoides*) was common. It is a beautiful big white flower. As we climbed the slopes of the Vallecitos the vegetation became more brushy. *Yucca mohavensis* was common and junipers made an appearance. To our left, as we drove up the slope was the main peak of the Vallecitos, sparsely clothed with pinons and junipers.

I looked hard for signs of water in all of the rocky canyons but saw no evidence. The road passes up and over the main divide of the mountains on an alluvial apron that sweeps down from these peaks. Presumably this road comes out somewhere in the San Felipe Creek drainage system. We could look back and see across the entire Carrizo Badlands and out to Signal Mountains on the International Boundary.

It was a pretty day and I was pleased to see Phyl enjoy the ride completely. I had to drive the twenty miles or so back to Split Mountain Canyon quickly as we were pressed for time. In the way out of the side canyon George noted a bee hive far up a cliff. We stopped to look at it. The combs hung from a crevice in the rock in sheets. The rocks were coated with bees. Apparently the hive had settled on a seepage to build their combs, or so it appeared from 30 feet below.

We ate lunch in the shade of overhanging cliffs in the upstream end of Split Mountain Canyon. The shade was comfortable after our long ride in the sun. A wind came up before we had finished and swept down the canyon. Leaving the Harveys at the entrance we drove on down Hwy. 99. The wind blew unchecked across the flood plain that borders the Salton Sea. This seemed to deflect the car-speed wind behind the wind shield, giving us a very blowy time of it for the 40 miles along the sea.

Finally, after a very windy ride we arrived at our rendezvous with Francis and Nan Haxo, Johnny and Barby Haxo, and Colin Hough at the entrance to Pushawalla Canyon. They were waiting for us. We loaded Nan and the two small Haxos on board and drove up the wash. Wind and water had all but obliterated the road. Smoke trees arch over the road in the canyon just before the palms are reached. The old road that passed through the pond in the main oasis is now blocked with a dense tangle of bulrushes, fallen cottonwood trees, tamarisks, and other plants. A new trail winds among the streamside palms. I stopped the jeep amid these palms. It was a beautiful shaded spot in the center of this dense grove—a little sandy clearing with full skirted palms all around and a creek full of bulrushes on one side. Phyl and Nan were properly impressed with the beauty of this native oasis. After unloading I drove back down and returned with Francis and Colin, and their camping gear.

When we returned the wind was coming in gusts so we made camp above the palms where we could have a fire without danger of setting the skirts on fire. After some [?] we had a fine supper of hamburgers, potatoes and onions, salad, coffee and beer, and a desert of mock angel food cake. Nan cut cubes of bread out of an unsliced loaf, soaked them in Eagle Brand condensed milk and rolled them in coconut. We toasted these cubes over the coals and they were splendid.

Bufo punctatus did not call this night. At sunset *Hyla regilla* was in full chorus with air temperature 1 cm. above the water standing at 17 deg. C. A few toads were seen sitting in the creek, both males and females, but none called.

After the children retired to their tent we sat around the fire and sang songs and had a couple of rounds out of Colin's bottle. He said it "was just cheap American stuff but it would have to do." It did.

Phyl and I hiked off down the canyon in an effort to shake off its anesthetic effects. We proceeded fairly well and went to bed on a little shelf under the palms along the creekside. While we lay there looking up at the stars I called up a great horned owl and had the satisfaction of seeing his big black shape flap silently across the moonlit sky

(full moon) and settle on a palm frond almost directly overhead. I shone the flashlight in his eyes and they gleamed back at us.

We looked at the moonlight filtering down among the palms and drifted off to sleep.

November 3, 1954

Off Santa Barbara, Santa Barbara County, California

Mr. Smith stopped by the house at 6:30 AM and we drove off to Santa Barbara. There we drove out to the harbor and found Frank and Boots out rowing in the harbor. As there was no surf we loaded our gear from the beach and sculled out to the *Geronimo*.

Santa Barbara has a nice snug harbor but a sand spit is building up at the end of the jetty and threatens to clog the harbor as happened at Santa Monica.

The day was cool and perfectly calm. We steamed out westward in search of basking sharks. These huge beasts (to 40 ft. and 5-6 tons) are common during the warmer months just offshore where they sometimes cruise by in large schools. We are late in the season and expected our chances to be slight for seeing these brutes.

As we cruised eastward about a mile offshore we saw a large group of birds circling just off the kelp. Then we could see some black fins cutting the water. Before long we were in the middle of a screaming flock of gulls and 8 circling killer whales. It turned out that they were feeding on two dead basking sharks which had been killed the day before. The sharks had become caught in a purse seine laid by the Cecilia, a seiner. Vic Castagnola the skipper shot the beasts in the head with a 12-gauge shotgun loaded with 00 buckshot. The sharks were in about 60 ft. of water.

The old males were enormous. Their backs and fins came well over six feet out of the water when they surfaced. The blow of these animals is explosive. It is as if the air is forced out under high pressure against much resistance by the nasal sphincter. I could see the mauve saddle running across the back in front of the dorsal fin and the bold white markings of the body. The dorsal is so tall that it quivers back and forth as the animals rise above the surface. Frank estimated that the old males weighed over 6,000 lbs. There were two adult females, one of which swam up directly under our skiff (which was towed behind the boat about 8 ft.). She turned over and then came up and blew right alongside the skiff. She eyed the skiff and rolled on her side looking at it. What a magnificent creature she was! Her bold pattern of black and white is very striking.

One of the adult females swam directly under the stern about 6-8 ft. down with her mouth full of basking shark flesh. The ragged fragments streamed from both sides of her mouth. She rolled over and took a good look at our boat as she swam by. There was one immature male and two young animals weighing perhaps 400 lbs. We circled them several times disturbing the gulls from their feeding on big blobs of basking shark liver which had floated to the surface.

Off Summerland, Boots spotted the low profile of a basking shark dorsal fin. The animal was swimming along about 3 ft. below the surface with only the tip of its fin out [drawing]. This habit is called "finning" by the fishermen. It must have been very large. Frank said 20-25 ft. long.

Later we saw these huge fish jump clear of the water. This happened twice. Two or three tons of fish burst from the water nearly vertically and fell back the same way it

had come. Apparently this habit occurs only in the fall months first before the sharks disappear. It is thought that they hibernate on the bottom and lose their gill rakers. Perhaps this seasonal jumping is an aid to shedding the old rakers.

Back in port we ate a superb T-bone steak dinner whipped up by our redoubtable cook Mr. Brocato and then launched into a fiery poker game. After several hours I emerged with 75 cents in addition to my original hoard. Mr. Smith went to bed and I went ashore and drove home.

November 21, 1954

San Felipe Bay, Baja California, Mexico

After the usual loading exercises the trucks left for San Felipe. Mac drove the small one with Boots and Frank and I drove the big rig with Pat Patterson. Pat and I stopped for a few hours sleep at Alpine. We slept inside the live car. It was a fine hotel with screened windows and a roof. The only trouble—we parked alongside Hwy. 80 and big trucks kept rumbling by our ears at a distance of 4-5 ft.

No trouble at the border for a change. We arrived at San Felipe to find the others about to eat dinner. We met Julio Berdege and Mahadeva from UCLA. With Julio's help we learned that the boat we had chartered was still out to sea at the Islas San Luis. She was trying to get a load of totuava before coming in. A substitute boat was available but she needed to have her shaft realigned. This was supposed to be completed by nightfall. It wasn't, so we went to sleep.

November 22, 1954

San Felipe Bay, Baja California

Much inquiry today revealed that the *Felipe Angela* was being worked on—doubtless in the typical Mexican fashion—and should be done sometime in the afternoon. We fidgeted around and finally went to hear the UCLA-USC game on a wheezing-crackling old radio at Angia Riviera. The game was a joy to all as UCLA won 34-0.

We checked back with Manuel at the Cooperativa and found that repairs had been postponed until tomorrow and the boat would certainly be ready at 10:00 AM in the morning.

So we ate dinner and then Boots and Mac and I attended the local cinema and saw a boxing match in which a Mexican won the welterweight title and a remarkably miserable movie entitled "Tres Carinosas". It concerned the affairs of three fine looking young ladies in their attempts to catch three young men—all of whom looked exactly like Errol Flynn. The movie stopped three times and the sound once (a welcome relief). We sat in a cavernous hall which was mostly unfinished and the screen was made of plaster. The seats were of wooden slats and high enough so we could swing our feet—quite pleasant! The floor of course was dirt.

We walked back to our open air motel under a beautifully bright starry sky amid the yelps and whines of a dozen coyotes.

November 23, 1954

Roca Consaga Golfo de California, Mexico

We had all our gear ready to go at 8:00 AM and began waiting for the arrival of the Felipe Angela. 10:00 AM passed and she didn't appear. Boots and I drove to town and found she was loading fuel. Finally we loaded some gear in the skiff and cruised over to her. Her skipper, Fortunato Valencia, said since it was noon his crew was going to eat lunch. Boots and I unloaded the gear. I left him to pack it. I returned with another load and found everyone but Boots gone. He said they had gone ashore to eat!

Gad! Finally we had loaded all personnel and the live car over and hitched it up when they arrived. A little while later we cruised off at 6 knots for Consag Rock. The boat is quite clean for a Mexican boat though it has its share of cockroaches, but it is better than most.

There are no bunks and a little galley with a smoky butane stove (only one speed on the burner). The trip out was uneventful except that we learned that the cook, Simon, was a remarkable chap in that he often slept 24 hours at a stretch and had once gone 37 hours without waking. He is a gangling dark-skinned fellow with long black hair.

At the island we set the trammel net in 5-6 fathoms in the lee of Consag Rock. It was too late when we arrived for us to scout the ground properly and we caught nothing. The water was filled with phosphorus which makes the net light up like a big luminous screen, thus reducing our chances of catching anything.

Mac, Pat, and I slept on the stern and watched the sea lions rocket under us in the lumious water leaving brilliant cold greenish blue trails.

November 24, 1954

Eroute San Luis Gonzaga Bay

We got up and set the trammel net before dawn at the place where we had previously seen the grouper and other colorful fish. We caught 5 seals and no more. Obviously the fish which are here either have moved out because of tide or water temperature.

We loaded the net and then went ashore on the gravel and cobble bar. I wanted to see if there were tide pools. Even though the tide was nearly high I am sure there are none on the bar. There were plenty of sea lions. I counted 400 of which about 2/3 were pups. The air was full of flapping pelicans and blue-footed boobies and the yelps and howls of displaced sea lions. I climbed one rock occupied by a young blue-footed booby. He moved over but not off. We walked around and around. Finally, I cornered him and he flapped and tried to hang on but finally flew off. I was within touching distance for the whole time.

There was no use staying so we started for San Felipe after bailing the live car dry.

On the way back I tried to plan and decided the only solution was to send Mac and Pat back in the Stake truck and for the three of us to leave as soon as possible for the region around the San Luis Islands. We found that terms would have to be discussed at the Cooperativa in San Felipe. I doubted that we could meet the price as nearly all the boats were fishing in the south and making up to \$700 per day on totuava. However we finally arranged for \$70.00 per day. I was agreeably surprised as our crew is good and the boat is in fairly decent shape. I think the credit must go to Frank and Boots who have impressed these fishermen that we are not turistas but are workers like themselves.

So we unloaded some gear to send up to Marineland and off went Pat and Mac. We three went back to the boat, cooked our dinner and waited for our crew, who promised to come by 9:00 PM. They had to load ice and the loading chute could be reached only at high tide. Finally, at 9:30 they came aboard and we backed under the chute and put 2 tons of crushed ice in the hold. After a while I laid out my bag and air mattress in the bottom of the skiff and went off to sleep. Frank is sleeping all curled up in the pilot house and Boots sleeps in the galley. The crew bunks down in the foreward hold. There are no bunks, just padding and blankets piled over the ribs of the ship. What with cockroaches and a closed hatch it must be jolly. I guess it is all what you get used to.

November 25, 1954

San Luis Gonzaga Bay

When I woke up this morning we were quite far out in the gulf. Apparently we had gone out to sea to avoid any shoal water in the night. I could see the San Luis Islands (Encantadas Islas) in the distance and farther still I could see bits and fragments of another island, lifted and distorted by the air's refraction. It was Angel de la Guarda Island some 75 mles away.

The sea was a flat glassy calm as we cruised southward and not a trace of a cloud in the sky. The air was warm but not hot—thoroughly wonderful.

Boots shouted—"Look, could that be a shark?" I had Fortunato circle and we came upon a wonderful sight—a peze sapo or toadfish to the Mexicans—but a whale shark to me and the largest fish that swims the seas. This one was only a baby at about 12 feet. He looked like a huge overgrown tadpole and he had a broad blunt head and a body which tapered back to a slim tail. The first dorsal fin is set remarkably far back on the body. The beast was a reticulated white network over a gray blur background. We saw a school of small bait which the beast was following. Also amongst the bait was a beautiful jack—greenish-gold with bold vertical black bars. We left the shark lolling at the surface and cruised on toward El Muerto Island, 5 miles to the south. This is the first of the Encantado group [drawing].

Our cocinero (cook) brought out an amazing meal of burro stew, spanish rice, french fries, and salad. It was really delicious.

As we passed El Muerto Island (so named because its volcanic cone is supposed to resemble a dead man with his hands pressed together in death). Fortunato decided to try for some bait. We cruised along the north shore of the island and dropped some ¼ stick charges of dynamite into bait schools. The bait was too small so we abandoned the effort and headed south. In this one spot we passed over 50 or more tons of bait so tightly packed that the water appeared black. I don't see how there is sufficient oxygen in the center of such a school for the fish to survive. The center fish would probably asphyxiate if the school became static.

Frank and Boots repaired our trammel net as we cruised along. They are wonderfully skilled craftsmen. I watched in awe as they sorted out the broken places, cut the net, and reworked it. My awe is increased by the fact that I tried this a while myself and spent three days doing badly what they did superbly in 20 minutes.

Later we passed San Luis Island (Encantada). It is probably wholly volcanic. It lies offshore about five miles—one end is composed of flows and the other a perfect cinder caldera.

Frank caught a bonito on a bone jig. The bonito has little finlets on its tail which I think serve as vortex generators to sweep passing water down into what would otherwise be a drag—producing a vacuum area [drawing]. What a wonderfully streamlined creature. Its eyes are faced perfectly into its body. Its dorsal fin fits into a groove and its pectoral fins occupy a recess during fast movement.

Lupe, an old man on the crew told me about the antelope which come down along the shore in the heat of the summer. Inshore from San Luis Islands he says he has seen them wade into the sea up to their necks and stand there to escape the heat.

Chicho and I had quite a conversation. He is a little brown smiley man in his forties. He had been in San Felipe years before the road came through and had made his living fishing from canoes with a hand line. It often took 24 hours to get to Mexicali in a truck as they almost always had trouble on the tidal flats at the mouth of the Laguna Salada. For eight years he had had what were apparently stomach ulcers and he almost died a couple of times. He still has trouble but eats his peppers with the rest.

The skipper is Fortunato Valencia—a grizzled man of about 55 years. He is probably mostly of indian extraction as his skin is dark and his nose flat. He is a very astute man and from what we can see, widely respected in the local fleet. He moves like a seaman—watching clouds and tides and is reported to be about the most successful fisherman in San Felipe. Many of his observations have paralleled Frank's for our coast. His rule is by respect. He has never issued an order as far as I could see. He is friendly and answers all our questions with a smile befringed with white whiskers.

We passed the islands offshore of us and finally rounded a point of land and entered San Luis Gonzaga Bay. It is completely land-locked and one of the most beautiful places I have ever been. The mountains surrounding the bay are rugged volcanic peaks and mesas all virtually devoid of vegetation. Along the inshore limb is a crescentic white sand beach with a long winding lagoon behind. The bay is divided into two parts connected only at high tide. [Drawing]

There is perfect shelter from all winds. The south section of the bay is called San Francisquito Bay—the north San Luis Gonzaga as nearly as I could tell.

It was nearly dark when Frank and Boots and I set the trammel net. Once again we hadn't had the chance of scouting our grounds before using this net. We didn't catch much—three bonnet head sharks (all of which died) and a porgy.

Back on board we set out for night fishing and found a good spot on the outside of the bay along a rocky cliff. We had good luck and came back with some small groupers and a nice group of pargo muleta[?]*—a pretty banded snapper. They are red, bronze, black, and white. After dumping our fish in the “vividero” (what the Mexicans call our live car) we went to bed. I slept on the stern. It was clear, calm, and moonless. Where the 2 in. waves lapped on the beach a line of phosphorescent fire flickered.*

November 24, 1954

San Luis Gonzaga Bay

Before dawn the three of us were up and off in the skiff to make a beach seine haul. We had heard of a lagoon entrance and cruised over to where it was supposed to be. There we made a set but the tide was out and so were the fish. We caught a flock of diamond stingrays, botete, and one little jack. Off we went, knowing more sets were useless at this tide. Back on board we hauled up the anchor and headed out of the bay

and up north about a mile when we entered a broad mouthed bay which proved to be the northern half of San Luis Gonzaga.

The crew took our panga and rowed over into the estero we had been looking for. There they got mullet by throwing dynamite into the fast-swimming schools. Meanwhile Boots and I caught a few bonefish and little *Prionodes*.

Off we went with our carada (bait). Just at the south edge of the entrance we stopped under a big basaltic cliff and began fishing. The fish went wild over whole mullet. It wasn't many minutes before we had 3 or 4 big pinto cabrillos. I took off my clothes and got in the live car to wield my hypodermic needle to deflate them. Then they really started to come including big garupas (groupers) and more pintos. In 30 minutes we had 20 in the car and I was going crazy trying to care for them all. I was all covered in slime and regularly getting poked in the rear by the spines of passing fish. I called a halt as I thought the live car was at about capacity. The other fish went on dock for the crew to sell. Frank and I looked ruefully at each new addition but I remained firm against his "just one more". Finally all were deflated and swimming well. Some were 4 ½ in. long.

We left the grounds when we were out of bait and cruised back to the bay. I wrote in my journal while the others went off after more mullets.

At dusk we went out to try for some small reef fish with the gill net. It was very discouraging as they all went to bed under rocks and we caught only three passing porgies. I had developed a rather nasty cold and after a little more hook and line fishing I cancelled a proposed midnight seining trip in the lagoon and we all went to bed.

November 25, 1954

Enroute to San Felipe

Today is Thanksgiving. Frank suggested that we cook a pelican but I say that the groupers are enough for us to be thankful for. We agree. All are doing well this morning except one small one which died. We were off at dawn with the volcanic hills and the occasional cardon cactus standing as jet black silhouettes against the orange sky. Back on the grouper grounds we caught a few more for the crew and then left for the islands to try for totuava. I had saved space for a couple if we should catch them.

I wanted to try obtaining some reef fishes with poison (rotenone) and so Boots and Chicho and I loaded the skiff as we cruised along and took off with the outboard for Isla San Luis Gonzaga 2 miles distant.

The island is wholly volcanic. A long spit of sand stretches out on the inshore side. Great cliffs of carved volcanic ash and pumice form the south end, a big cinder cone stands in the middle and a smaller cone and massive flows of rhyolite lava and obsidian form the north end. It is forbidding and beautiful. We came upon many long stringers of black volcanic rock stretching out into the ocean at the shore. I tried poisoning and caught a few sergeant majors and opal eyes but all died from the poison even though they were all given clean water at once. We saw two golden groupers—bright orange over all. We had no success in catching them.

Boots and I walked up on the island among big *Salicornia* bushes and numerous gulls nests to the nearest cinder cone. Back on the skiff with some samples of pumice to show Frank. We started out for the boat but Chicho told us of a lagoon nearby so we went for it. He led us to the north end of the island to a place where little fjords [?] in to

the lava cliff . We followed on such into the cliffs. On either side of us jagged cliffs of red, black, and brown lava seamed with volcanic glass rose up 40 feet or so, while the water under our keel was 30-40 ft. deep. At the end of the fjord Chicho hopped ashore and waved for us to follow. We did, scrambling up the rocks and at the top we saw a completely landlocked basin of sea water about 100 yards long lying at the base of the lava mountain and completely surrounded by floes. In one place tidal water was pouring in from the sea in a small brook. The level was about 1 ft. lower than the sea outside. Green caliciferous algae had built stalagmites up from the bottom, giving the pool a weird hot spring-like look. I saw a fair number of fish including opal eyes, sargeant majors, and one grouper. Chicho said a skiff could enter at high tide and that turtle were sometimes trapped in the lagoon.

Outside again we made a dash for the boat and caught them at Isla Choyula where they were unsuccessfully trying for totuava.

At Isla Muerto we fished in the midst of a flock of diving pelicans. They close their wings the instant before entering the water and enter with bill closed. Young Heermann's gulls were picking up fish that escaped as the pelicans squeezed the water out of their pouches prior to swallowing their catch.

Every diving pelican had his attendant gull screaming in his ear.

We are now heading for home on a flat calm sea with the vividero towing along behind. The barometer is dropping and there are clouds to the north. With the new moon here we expect to make port tomorrow morning, just before it begins to blow.

March 10, 1955

Four miles N. of El Mayor, Baja California, Mexico

Frank and Boots and I are on our way to San Felipe to attempt to capture some totuava (Mexican white sea bass) for the tanks. We will be relying on the nets of Boyd Walker of UCLA. He is trying to catch fish to stock the Salton Sea, and is particularly interested in yellow-mouthed corvina. This is a big and plentiful game species at San Felipe.

On our truck we are carrying a splendid new transport tank which has just been built by Frank and Boots after two weeks of loving labor. They really slaved over it and we have great hopes for it. The trip down the coast route was uneventful. When we reached the mountains on Highway 80 we began to realize that we were carrying a load on the truck (10,000 lbs. of sea water). We had dinner in a little Hungarian place. The old lady serving us had muscles like a shot-putter and the expression of a surly bulldog. Her husband was a meek little quiet guy. He was a good cook but I don't envy him his job.

Once on the In-Ko-Pah grade road and going downhill, we really began to feel the load. I drove slowly and used the brakes sparingly, but even so the brakes began to get slick, and finally I geared it down to low gear and we crept along with the motor roaring. At the bottom we stopped for gas and I could scarcely bring the truck to a stop with the brakes. The brakes are definitely too small for the load we are carrying. Also, after this we will take Hwy. 99 home. There are fewer grades. We got coffee in Calexico and crossed the border, well after dark. As we pulled up to the border gate, a U.S. official rushed out and hollered, "Hey, don't you know you can't go across the border without paying duty on that furniture?" He pointed to Frank and Boots's tank. There could be no greater flattery than this. Both of them swelled up visibly. Obviously we had a Louis XIV fish tank on the back, created by certain San Pedro artists.

The Mexicans came out too. Finally one official went into a nearby restaurant to get the big boss to decide what to do with us. I had papers but have learned to sit still and be quiet and usually, after much jabbering, you go on your way. The big boss came out, munching his dinner, looked at our rig and said in a most insolent and patronizing manner to his assistant: "You dope, don't you kow these people were through this mornig and got

permits and visas?" The crestfallen fellow waved us through as the boss stalked back to his interrupted meal. We rode joyously through on Boyd Walker's coat-tails.

Before long we got sleepy and I pulled off the road. Frank, as usual, slept in the cab. He is leery of sidewinders and other critters of the desert floor. I perched on the edge of the new tank and worried about falling off all night. Boots slept in the back.

March 11, 1955

Fish Springs, Imperial County, California

We pulled in at San Felipe about noon and had breakfast at Herman's. The we hunted up Boyd and crew and found them gathered around a *Tamarix* tree, out alongside the airport. They had a nice camp. As near as I could tell there were about 12 fellows, all eating voraciously. Old Mac was there feeding his face. He had just finished cutting the skull off a big male bottlenosed dolphin lying on the beach. I looked at the remains and the animal is much darker than the Atlantic species. The dorsal surfaces are almost black and are patternless except for some faint markings. After we helped in the feeding frenzy we all went out and set the big net. When I say "big" this is no exaggeration. It is over 600 ft. long and of 1 in. mesh. Two portable gas winches are used to haul the ends of the net onto the beach. From there it is done by the slaves. It is hard, back-breaking work, even with 16 of us. The first haul netted us little except 12 corvina and a lot of anchovies. Boyd mentioned that he would like to plant the Salton Sea with anchovies. I was anxious to test run our tank and volunteered to take a load up for him if we got anchovies on the next hauls. On the very next haul (each haul takes 2-3 hours), we hooked the corner of a school of these anchovies and Boyd gave the word that we should load up. We did, and Dick Whitney (a biologist on the Salton Sea project) and I and general handyman named Clarence hopped in the truck and left, after getting papers from Sr. Patino, the local fish lord. It was 1:00 AM when we arrived at Fish Springs on the Salton Sea and planted our load. The tank had done well but we were overloaded and lost a fair quantity of fish. Finally at about 3:00 AM I sacked out on the lab floor.

At 6:00 AM we were up and away. The trip back was uneventful and we arrived at San Felipe about 12:30. That afternoon we loaded the Fish and Game truck with more anchovies and they left. As a crew, they don't work too hard. One in particular, colloquially called "Jello Gut" sat very still all day and griped about conditions in general. He had an immense paunch and won Boots's and Frank's immediate dislike.

Briefly, we went to sleep in the evening and got up at 1:00 AM to catch the incoming tide. We set the net out 1,200 ft. by tying lines together. When it was hauled in we had some immense diamond sting rays and a lot of *Rhinoptera* rays. Before we loaded the rays, we drained out the truck of all its dirty water and filled it up again with the Fish and Game portable gas driven pump. This is a wonderful gadget as one can fill up anywhere and can go to the site of collecting with an empty truck. We loaded the truck and Frank and Boots and I rumbled off down the road at 4:00 AM towards home. 80 miles south of the border, just at dawn, the northern sky lit up in a flash. It was a miniature atomic bomb being set off in Nevada over 300 miles away. We each ruminated with our own thoughts for a long time. It made a reality out of the atomic age and a frightening one at that.

We ate a welcome breakfast in Westmoreland and then drove for home, reaching Marineland at 5:00 PM, cramped and tired, but with our charges still alive.

March 20, 1955

Truckhaven Trail, San Diego County, California

Bob, Phylly, and I left for a sand dune trip. We met at Van Nuys and drove down through the Coachella Valley in a fine windstorm. The sand was whipping down the valley floor. As we passed Travertine Point we acquired some lee.

I wanted to look for some Indian fish traps which are supposed to be on the alluvial fan below the old Lake Cahuilla shoreline. We were told that these traps were about a mile up the slope from a quarry just south of Salton Station.

We hiked through the quarry and up the bajada for a way. I climbed onto an old shoreline beach but failed to find the traps. They are supposed to be V-shaped and open at the apex. The V's are supposed to be open widest on the upslope side. We saw no signs of them. I found a few pot shards and we picked up firewood and drove off up the Truckhaven Trail to camp. It was dusk when we came to our wash filled with smoke trees. The car got well stuck as we tried to drive up above the wash bank. Leaving it in situ we set up camp, built a nice smoke tree fire, and ate a vast dinner of steak, fried potatoes, salad, peas, tea, and peaches. Phylly really stowed it away, much to Bob's and my delight. A nice lot of speculation about sand dune origins around the campfire and then bed. It was brisk. Phyll's feet were cold.

March 21, 1955

Bajada above the Algodones Dunes, Imperial County, California

We had a thorough-going morning constitutional getting the car out. We had to turn the car around by jacking it up and pushing it off the jack. We built an excellent cobblestone road and made it out in one splendid effort. All preparations had taken a couple of hours.

We were off. On Highway 99 we looked westward up the old lake bed slope and could see a beautiful barchan dune (u-shaped), pinkish in the morning sun. We found a good road which took us within a mile of this lone dune. It was about 45 feet high and rested on the old dissected lake bed just below the old shoreline. We hiked over, passing over a couple of vertical walled arroyos. The soil was covered with ventifacts in all sizes and shapes. The wind, with sand-grains as its cutting edge, had polished many stones to a dull sheen and had eroded others into little pinnacles, arches, and such.

Where we had parked the car the soil was a mass of self[?]-rising ground tufted with saltgrass—*Distichlis*. Apparently there is a seepage. Bob tested the salt, made a wry face, and pronounced it mostly epsom. I found a perfect little Indian bird arrowpoint of red stone.

The weather was cool and sunny—perfect for hiking, but by the time we reached the dune we were all a little tired. Phylly and I sat down in the shade of the dune. I dug out a scorpion burrow for her. It was low-arched in cross-section and extended into the dune about 1½ ft. The scorpion came out with tail raised and pincers “en-guard”. Phyl was most interested in the grotesque critter.

The dune rests alone on a surface of desert pavement. The nearest sand deposits are perhaps 1½ miles away. It is composed of fine uniform peach-colored sand. From above it looks roughly like this [drawing]. One cusp rests in an arroyo (tule arroyo)

about 10 ft. deep. The other cusp is much longer, extending out over a flat surface. We could see hardened layers on the side of the dune, which much represent old surfaces. They lay at lesser angles than the present surface.

On top of the dune a secondary crest had built up—probably due to a period of reverse direction winds. I wonder if there are seasonal differences in wind direction, with the “effective” wind at one season only. [Drawing]

The cusps indicate the effective wind direction is about WNW, and blowing directly toward other barchans far down the slope at Salton Beach. The dune sand contained some fragments of sea shell material from the old lake bed.

We staked the dune—running stakes along the lee slope and two out in the middle of the arc. We should be able to detect movements by checking these stakes.

I have a notion, that though these barchanes are considered “moving dunes”, they do not move after they reach a certain size but merely shed sand off their cusps and over their drop slopes while the main mass remains stationary. We’ll see.

In Tule Arroyo I noted some roots of a mesquite bush which had been exposed by the stream cutting into the bank on which the plant was growing. These roots extended 65 feet before disappearing into the riverbed again.

We hiked back to the car, arriving about noon. After a stop at Westmoreland for milk (where the Chinese groceryman bowed and scraped to my “professor” brother) we drove up to Superstition Mountain. Bob photographed the dunes while I dug up some desert lily bulbs for Phyl. The flowers were beautiful. Many of these white lilies were in bloom and sand verbena and giant sand primrose were all around. A splendid lunch was eaten alongside the old ruins of a quarry keeper’s house.

Bob found a dead sand lizard (*Uma*) and so did Phyl. Perhaps this is a mortality connected with spring emergence.

April 27, 1955

San Felipe, Baja California del Norte, Mexico

3:00 AM. After a couple of hours of broken rest I got up and drove up to Jim Long’s place and loaded his gear. We drove off to Marineland where we started off in the big truck and were on our way to San Felipe. As we passed Frank Brocato’s house we waved to him and Boots. They were waiting for us with the pick-up truck and the skiffs. The drive to La Jolla was uneventful except that I had a fine conversation with Jim. It is a wonderful way to get to know your staff well to take them on trips such as this. Jim is an interesting and humorous soul and should be a fine trip companion.

At La Jolla we stopped in front of Jon Gnagy’s apartment. He is an artist and writer who plans to do a feature story on our collecting operations. We all piled out and had breakfast as his guests. Mary Jo Gnagy had prepared a real feast—scrambled eggs, coffee, bacon, cinnamon rolls, and fried potatoes.

This trip is being taken expressly to catch specimens of the giant Gulf sea bass, the totuava. They reach lengths of 6 ½ ft. and weights of over 200 lbs. They migrate up the Gulf this time of year and spawn in the mouth of the Colorado River. Reports have it that numbers are being taken at San Felipe. We have reason to think they are tough and will stand the battering of transport. This is in contrast to our own smaller white sea bass, which is too touchy to live through any rough treatment.

At the border we were stopped by Mexicans and, as usual, we didn't know what to expect. This time we were lucky and were waved on after a brief period of knowing head-nodding at our papers.

A little way down the road we stopped for tacos and beer—enjoyed by all. Jim, who is a musician, had his delicate sensibilities assaulted by the Mexican juke box, which was turned on full blast. I think he is approaching this in the wrong manner. While I agree that some of it is hardly music, it is part of the Mexican scene and I thoroughly enjoy it—particularly at full volume.

At San Felipe we found everything essentially the same as when we had left two months ago. There were swarms of tourists, but the St. Francis de San Felipe was empty. This is our vacant concrete building that we use as a camping spot. Tomas Guerrero, the owner, spent so much money building the walls that he has never put a roof on it, so there it sits, open to the stars, and a perfect camp spot out of the sand and wind. The doors were barred with Ocotillo poles, but we rented it from Tomas for one dollar a day. We can pile all our gear into it and leave it during the day. It is wonderful at night to watch the moon, stars, and clouds move by. It is built on the edge of the beach and adjacent to the skiff launching slip so it is perfect for us.

Boots cooked up some macarone with olive oil and onions. Jon had gone surf fishing so I walked off down the beach to call him to dinner. Hiking was pleasant along the sand at dusk. The sea was flat and gleaming and the air was warm. Mullett jumped all along the water's edge. I didn't find Jon but found that he had gone back another way. Aafter dinner we gassed for a while about this and that and then went to bed. Skies were clear and there is no wind.

April 28, 1955

San Felipe, Baja California del Norte, Mexico

We were up at 5:00 AM. We loaded for the day's fishing. The skiffs were hauled down and launched. Then we put the bulky live car in the water. The newest motor would only run on one cylinder. It was shorting out someplace. Finally, after much tinkering we left for the northeast of San Felipe. There we fished for bait. The procedure is to catch bait on hook and line and then put them on very large hooks which are dropped to the bottom. The bait consists of 1-2 lb. croakers. This croaker is *Micropogon ectenes* and is called chano by the Mexicans. Apparently it occurs out in the "channel" but is not often taken close to shore. The croakers bit avidly early until the slack high tide, but as soon as the tide switched they stopped and we began to catch sting rays (*Urotrygon* sp.) and guitarra (*Rhinobatos* sp.). I spent some time tinkering with the motor. Finally, I found that one of the plugs was cracked completely in two. With a little tape and string I put it together and the motor worked for a while until it jiggled loose again.

We had hired an old Mexican friend as a guide. His nickname is Chicho. He is a gentle old white-whiskered soul who was sporting a badly arthritic hand and wrist. I don't see how he could work but he did. Doubtless he didn't have enough money for medical aid. His real name we found was Narciso. He has never mastered my name and calls me "Kelly"—pronounced "kay-lee".

Just after settling down Boots let out a yell. He shortly hauled in a beautiful totuava well over 5 ft. long. We quickly sunk the live car while Jon maneuvered for pictures. We slid the big fish through the side door of the live car and I jumped in and

deflated him with the hypodermic needle. The Mexicans call the needle an ajuga. The fish had come up from 48 ft. and she was badly inflated. After the gas was released she swam around the tank very nicely. No more fish came in. We did not attempt to tow the live car in but anchored it with a 60-lb. anchor and a long anchor line.

On our way back we spotted porpoises, which I think are an undescribed species. They were very small, probably under 5 ft. They were dark brown with a small, rather triangular dorsal fin. Jim saw one quite close aboard and reports that it was blunt-snouted like a Dall's porpoise. The two I saw were wary of the boat and sounded when we came within 100 yards. I suspect they are the harbor porpoise, *Phocoena*, but of an unknown species. They could be heard to exhale and inhale as they swam along.

Several times we ran across schools of Gulf rays (*Rhinoptera steindachneri*) swimming close to the surface. Some of them had their fin tips out of water. They fled immediately when our skiffs cut through their schools. Sometimes they were so numerous as to appear as large brownish patches on the water some distance away.

Back on shore I took Jon around to make arrangements for him to take the bus back to Mexicali. He was bent on culture so we stopped by the local cantina, which has something of an evil reputation. Things were progressing nicely when we arrived. One well-lubricated fellow was doing a sort of solo hat dance to the thunderous music of the juke box. Jon broke out his sketch pad and furtively drew a series of quick impressions of the place and at the same time tried his first tequila and lemon and salt. This, I feel, is really too much culture at once. These potent things should come one at a time. We turned in after getting all our gear ready for the morning.

April 29, 1955

When we arose at 4:30 AM the sun was barely lighting the eastern sky. The tide was very low, exposing wide tidal flats in front of the St. Francis. We had planned to make a set with the beach seine in order to obtain bait quickly, but we could see it was useless under the circumstances so we reverted to the Mexican system and shoved off to fish for bait. The motor had a new plug in it but somehow the cover was shorting the cylinder out so, after some tinkering and much cursing, mostly in Italian, we left without the cover on the motor. As we passed the point we ran into a very large southern swell, apparently from a storm down toward Guaymas. I quickly fell into the clutches of mal de mar.

At the live car, which we found easily using a series of landmarks on shore, we found that someone had tried to gaff our totuava. The gaff was floating in the tank and the fish was swimming nicely around the bottom of the tank. The top had been latched. Frank theorized that the *& had tried to gaff the fish and had hooked him. The fish then jerked the gaff from his hands, later shaking it loose. There must be some good in the toad's soul as he hooked the top and thus prevented it from being washed away by the waves.

We fished and caught a fair number of croakers, but no totuava. The wind began to pick up so Frank and I decided it would be best to begin towing the live car with one boat while the other drifted and fished. We did this. The live car was so heavy that, even after 6 hours of towing we had made about 6 miles of progress. By this time the wind had risen and all boats were making for the harbor. Frank hooked his skiff on ours and we tried using both boats to tow. It speeded things up nicely but constantly brought

water over our bow and gunnels. The blow kept building up so I called a halt and we dropped anchor and started in without the live car. It was thoroughly sloppy going and the coverless motor kept cutting out in the spray. We were still a good two miles off the point when Frank took us in tow and we started in behind him. Long before we reached the point Boots and I were soaked to the skin. Old Jim sat dry and happy in the big skiff laughing his little sardonic heart out at the sight of us. Before long we beached everything and hauled all the gear up to the St. Francis. It feels wonderful to get some honest exercise after answering the phone and writing letters.

Frank and I set out to make arrangements to charter one of the big boats to haul our live car. It is obviously impractical to do it with our skiffs. There are about 5 tons of water inside it. We found the skippers reclining inside an old broken skiff on the beach. We agreed on 30 dollars a day for the boat and crew, which is well worth it to us, seeing as how the wind is still increasing. We are to meet them at the point at 4:30 AM in the morning.

Back at the hotel we had a glorious chapine of totuava meat and various vegetables, potatoes, onions etc. The fish was donated to us by a sportfisherman who is camped nearby. Off to the sack.

April 30, 1955

We were out of the sack at 3:30 AM and loaded by 4:00 AM. After a quick cup of coffee we cruised out into the bay. The swell had switched to the northeast and was as bad as the day before. Before dawn we were at the point and waiting for our boat. It didn't appear so we scouted around the point, getting well sprayed in the process. No boat. We ran from boat to boat but she didn't appear until nearly 7:00 AM and then she had a party of American sportfishermen on board. We were thoroughly disgusted but boarded and found that the boat hired by the fishermen had broken down (a logical thing) and they had bee shifted to our boat. So, we calmed down and went after the live car. Our landmarks took us right to it. Frank and Boots secured it to the stern and we were off. But the choppy sea and the long cable combined to allow the live car to dive. We looked back and it was gone. All we had was a taut cable. I yelled "alto" to Luis, the captain. After we stopped, the old car slowly came to the surface. Frank shortened the cable and off we went. I was mightly glad we had latched the top as we would have lost the fish otherwise.

After catching our bait we sat fishing for a long time, then suddenly my line gave a mighty yank and I dropped it. Luis picked it up and shortly we had a beautiful totuava on the suface. Two others had hooked up at the same time. Frank and I and Boots quickly took our two fish back to the live car. I took off my clothes and jumped in while they struggled with the fish. Acrobatics were required to get the monsters into the car in the heaving sea but in they came and I deflated them as the waves washed over me and the live car. I pulled myself out and dressed. Before long we ran out of bait and couldn't catch any more, so Frank and Boots and a couple of crewmembers went inshore in the skiff to fish for some. After about an hour they returned with a tub full of bait. In the meantime another totuava had been caught. She was hooked by the pectoral fin and gave the fisherman a terrible struggle. It hurt my soul to see the fish gaffed and swatted with a long club.

We distributed the bait around and before long one of the fishermen had a strike and fought a 6-foot totuava to the surface. He told us we could have the beautiful beast so off came my clothes and back into the live car again. It was a wonderful gesture from the fishermen, all of whom turned out to be fine fellows. The three new additions all swam nicely around the live car.

In the afternoon we hauled up our lines and made for harbor. It was a pleasure to watch the live car bucking along behind us at considerably more than one knot. Offshore, in front of the St. Francis, we anchored the live car and went ashore. It was far too rough to think about landing the beasts and the tide was low. We knew we would have to wait out time that evening about 9:00 PM.

After dinner we sat watching the rough surf and wondering what to do next. I rounded up the local Inspector de Pesca and got our papers straightened out. By the time I returned it was 9:00 AM and the surf was murderous. Frank and I and a fine old fellow named Andy Tomlinson made a tour of the beaches to try to find an alternative landing spot. We found one where the surf was low but we couldn't get the truck down to it. I was mightily worried for fear the water fleas (isopods) would kill the big fish as they wallowed in the shallow water near the shore. We had lost fish to these little devils before. They simply chew a trapped animal to death. So it seemed imperative to land the fish somehow. The surf didn't go down, so finally I decided that Boots and I should go and look at the car and the fish and then decide whether we should tow them ashore regardless of breakers or leave them at anchor. We made it through the surf though it was frightening seeing the big swells loom up out of the dark. The water at the car was so dirty I could see nothing in it. Usually the water fleas swarm under a light at the surface and none appeared under my flashlight beam so I felt better on that score. A little poking with a bamboo pole showed that the fish were alive. So Boots and I hauled up the anchor and towed the car out into deeper water. I dropped the anchor what I thought was a safe distance away from a little fishing boat. The darkness muddled my judgment on this. Back through the surf (which is much worse than going out) safely and then to bed, feeling heartened to know that our animals were OK and in deep water. We just hoped the surf would drop for the morning high tide.

May 1, 1955

San Felipe, Baja California del Norte, Mexico

I awoke this morning with the wind blowing a gale into my sleeping bag. It was coming directly from the east. Frank and Boots had been up earlier and were walking around peering at the waves beating on the shore. There were about four lines of breakers. The water was coffee-colored and so dirty that you couldn't see an inch in it. The air smelled of dead fish. The Mexicans toss all the interior workings of their totuava back into the surf after they clean them and there must have been quantities of rotting material on the bottom. Frank and I had a stewing session trying to figure out what to do. We decided to wait until the tide came up a little to see if the surf would drop. Before long the wind began to switch to north east and as the tide rose the outer lines of breakers dropped and disappeared. We went up to another beach to see if we could land there and decided we could so off we went to gather all the gear together. Back at camp the breakers had subsided so much that we decided to try it here. The wind had swung around to the north and the seas were calming. Off Boots and Frank went through the

surf to the live car, which we could see bobbing offshore. I got the truck ready with Jim's good help. Before long they reached the surf. Frank threw out a lot of excess tow line and the skiff came free through the breakers. We beached her in a hurry and began hauling on the live car line. Before long she was wallowing along the water's edge with water running out of her ports. Frank told me that I had put her too close to the boat anchored near her and that the anchor lines had become twisted during the night. Apparently they had swung around each other without doing any damage. Just plain lucky, that's all.

Finally we got the tow line attached to the truck and began putting a strain on it. Frank and I jumped into the live car and began catching the big fish. We put them into a stretcher and handed them out to the fellows outside. We had about 30 American fishermen and some Mexicans helping us. They were run up to the truck and slid into the tank. The waves repeatedly broke over the live car so Frank and I got soaked. The car would lift from the bottom with the waves and bend and creak. After hauling it ashore we found that the keel had been cracked in the process. Finally everything was loaded and we all breathed a mighty sigh of relief. None of us had had too much hope of getting the big fish into the tanks alive. We packed, had a little lunch at Herman's, and left.

The skies were filled with thunderheads as we drove toward the border. Over the coastal mountains we could see great blankets of clouds topped with a halo of cirrus. It reminded me of summer afternoons in New Mexico. Here and there the rain was falling from the clouds in wide columns. I enjoyed this ride a great deal and reminisced about my summers in the New Mexican deserts. All this peacefulness was quite a change to the hectic events just past.

At Olive, Boots and I checked the tanks and found our fish still doing well. We drove into Marineland at 1:15 AM under heavy storm clouds. The fish were hoisted and we all had the final satisfaction of seeing them swimming in the tank. Battered but swimming and with every chance of surviving.

May 3, 1955

White Landing, Santa Catalina Island, California

This trip was to be taken with a photographer who was to take pictures of a soupfin shark fishing trip. At 8:30 Frank came alongside Marineland pier with only Boots aboard. I think they were somewhat relieved that it wasn't going to be what they call a "Charter Party" or a trip with photographers or writers aboard. We launched the live car from the pier and tied it astern. The speed of the *Geronimo* is about twice that of the Mexican boats with which we are used to towing the live car. It swashed and slid from side to side until Boots tied the heavy skiff astern of it and then all was well.

The day was completely cloudy and quite calm. The trip across the channel to Catalina Island was uneventful. No porpoises were noted and only a very few blue sharks. Frank told me that it was just two days past the new moon and that we could expect big tides and currents. This he says, usually means poor fishing, but we shall see.

We made our landfall on Catalina at a point called "Shag's Roost"—named in honor of the hoardes of cormorants which sometimes roost there. One of our tasks was to catch a dozen lobsters for Dr. Bullock at UCLA. He is doing some physiological work on the nerves of these critters. If fishing is good we would like to take back some for the

circular tank. Frank thought the local poachers would probably steal our traps if we left the floats above water so he had Boots tie the float lines so the floats sunk about 3 feet beneath the surface. We placed the traps very close in to the shore at a place Frank said was crawling with lobsters.

Leaving the traps thus submerged we cruised along the shore toward the east end and Church Rock. We passed through some schools of bait which Frank and Boots estimated would sink our boat. As we approached the east end a large swell came up and the water nearshore became a milky-white, like skimmed milk. We hopped in the skiff and rowed until we were just outside the breaker line. The net (9-inch cotton gill-net) was laid parallel to the beach in the murky water. We then commenced running the net by cruising up and down the cork line looking and feeling for places where the corks had sunk or the net was bunched. These signs meant a shark had gilled. We finally found one ear the end of the net. It was a 5-foot male soupfin. This is an unusual occurrence as the males are normally taken in deep water. The poor shark had rolled over and over in the net and was nearly dead when we untangled him. He came to slightly in the boat tank and began swimming slowly around the tank. More sets netted us nothing. I insisted on pulling the whole net myself once just to get my hand in and to earn my dinner.

Gad, what a job. One needs to be in condition for that sort of work. My forearms were tight as drumheads when I got through. Thank goodness the net was no longer.

Rather dejected, we turned for the lee of the island and shelter. I could hear Boots cussing softly in Italian. He takes these little fisherman's setbacks very seriously.

Dusk had begun to settle over us as we got through the calm water enroute to Turquoise Springs. Fog rested on the crest of the island, spilling down the canyons, patches of sky were turning red as we dropped anchor. I quizzed Boots about the various types of anchors. He informed me of the workings of Northhill anchors, Stock anchors, Danforth anchors, and the like. Our anchor, it turned out, was what Frank called a "genuine anchor"—with the accent on anchor. One feels sort of safe not placing his trust in some unknown geezer named Northhill or Danforth, but in a GENUINE anchor. I know it weighs about 30 lbs. and takes a good heave to get it over the side.

We made a set for leopard sharks and while Boots and I were working the net, Frank cooked dinner. We ate up the fare which had been brought along for the photographer and our own too. I took a short row for the exercise of it.

The genuine anchor was hauled up and we cut on up the coast to White's Landing where we tied the boat up to a mooring which was reserved for a yacht named the *Endymion*. I'm sure it's 80 feet long, mahogany throughout, with suave waiters. The *Geronimo* is much more my speed. Anyway, the *Endymion* didn't show up so we rocked at anchor undisturbed for the night. At times the boat was surrounded by swarms of small fish—smelts, sardines, and flying fish.

When we had made our try for leopard sharks I enjoyed the sight of two old bald eagles standing imperiously on their nest which capped a rocky crag about 300 ft. up the face of a cliff. We saw the silhouettes of herds of goats and kids picking their way along the crest of this cliff.

I didn't sleep too well—it was warm in the forecastle and my long johns were too short so I had to sleep in the semi-folded position. I was too sleepy to get up and take them off and not sleepy enough to doze off anyhow. What an impasse. It was finally resolved by the alarm at 4:00 AM.

May 24, 1955

Marineland, California

Up came the genuine anchor, the motor started with a gentle roar. We slid out into the dark water while the Fish and Game patrol boat cruised by, flashing its spotlight on the cliffs. I presume they were looking for poachers.

The tide was low and our floats were at the surface when we got to Shag's Roost. The water was so shallow and the traps so close to shore that Frank had a ticklish job getting in with the *Geronimo* but he did it without a hitch. We hauled up the traps and they contained over 50 nice lobster of all sizes. A few moray eels squirmed in the midst of the flapping lobsters. We put the lobsters in the boat tank and left for Church Rock. On the way Frank told me about some of his fishing exploits. One time he decided to go flying fish fishing. This is done with gill nets which are strung on the surface. One net of specified length is allowed per boat. Frank found he couldn't make a living with one net so he asked the warden about using more—no dice. Frank told the warden he was going to beat the law and the warden said "try". Frank then got two skiffs, gave them each numbers and set a shot of net for each skiff. This made three for him. The warden consulted the State Attorney general and found that Frank was quite legal—so long as he didn't hook the nets together. Ah well.

The surge at Church Rock was big again and our net sets gave us nothing. We fished at a place called "The Palisades", which is a long, 300-500-ft.-high sea cliff carved out of naked rock. It apparently is the result of faulting and earthquakes. In various places one can see old stream canyons which end high on the cliff. They were formed before the uplift and have been cut off too rapidly to cut down to sea level.

I felt a little woozy and went below to take it easy. This is the best cure for me when I feel tis was.

Around the west end we went and into a little cove marked by a barely submerged rock called "Tacoma Rock" in memory of a boat by that name, which ran aground and burned on the rock. We went prospecting for leopard sharks but found none. Frank's bad phase of the moon surely proved true this time. He said the fishing would change in 3 days or so when the quarter was reached.

I hopped ashore and investigated a midden which I could see topping a nearby bluff. It was full of bowl fragments of the island Indians. These were all of steatite or talc. Some slight excavation had been carried out, judging from the holes. Down the cliff I pulled up some succulents (*Dudleya*) for Phylly's forthcoming rock garden. We left for Marineland and about three hours later, arrived at the pier. On the way across we had seen practically no sharks and two Pacific white-sided dolphins.

May 29, 1955

Pushawalla Oasis, Riverside Co., California

We started out from Van Nuys at about 7:30 AM (Bob and I) and met Glen Miller in Corona. The sky was overcast and the air cool. By the time we reached Cabazon in San Gorgonio pass the sun had come out and the air was hot. We could see the hot whiteness of the Coachella Valley below. At Snow Creek we stopped for sand samples

and I found how unused to the heat I had become. The slightest exertion was a vast effort. I was very short of breath—with a sort of oppressive little headache.

Down in the valley we criss-crossed the desert taking sand samples at various places to show the transition from large-grained sands at the upper end to fine sand at the lower terminus of the dune deposits near Indio. We found one series of dunes east of Garnet which apparently have accumulated over seepages from the San Andreas fault which runs through the valley at that point. In another place we found windrows of wind-blown gravel. It was nearly 2 mm. in grain size diameter.

Up we went to the entrance to Pushawalla. At the end of the paved road we stopped and Bob put big 4x4 blocks between the axle and frame of the Chevy sedan we were driving. I let out some air from the hind tires and off we went up the wash—thumping and bumping. The blocks prevent the wheels from chattering but they make the car bang constantly. We bogged down a couple of times but managed to get the car nearly to the lower end of the stream. We made camp and Bob and Glen tried to get the car turned around and freed from the sand. I was too far gone to work in the 110 degrees so I flaked out on my sleeping bag in the shade of a nearby palm tree. Finally the car came out and sat high and dry in the middle of the road, pointing downstream. Little white-throated swifts skimming through the air. They slipped along above the vertical walls of the canyon.

These little birds are about the most graceful of all birds. If I were a bird a swift would be a high choice on the list. Down the canyon the red-tailed hawk's nest was occupied and we could hear the screeching of the parents up and down the canyon. Doves were everywhere. After a wonderful supper—steak, potatoes, and onions, peas, and pineapple—I prepared to start my toad census.

The toads were calling quite well for the first time during my visits this year. I had wonderful results and had too many toads for me to handle. I caught a male *Bufo cognatus*, the first toad of any other species but *B. punctatus* that I have ever seen at the oasis except for the tree toad, *Hylla regilla*. It was taken just below the main oasis. It escaped from its jar during the night. At about 12 midnight I went off to bed under cloudy skies. All around my sack I found toads hopping, even though we were camped 150 yards downstream from the end of the water.

May 30, 1955

Lone Barchan, Imperial County, California

It was showering lightly on us when we got up at 6:30 AM. The skies were full of thunderheads and it was delightfully cool. The big drops stopped after a while. After breakfast we bumped down the canyon, making it easily this time. Our destination for today is Lone Barchan, a single crescentic dune that rests on the floor of the Salton Basin west of the Salton Sea. It is just below the old sea level line. After a little reconnaissance we dropped down into Tule Wash and drove along the hardpan bottom. It was like a paved highway in places. This arroyo is one of several which cut up across the old lake bottom toward the divide between the Salton Sink and the Borrego-Clark Lake area. It is winding, steep, mud-walled and nearly flat-bottomed. At one point we passed a group of tules for which the arroyo is named. They are clustered around a very much mineralized seep in the stream bottom. Up the wash we went about 3-4 miles until we came to the base of the Lone Barchan.

This dune dips one of its cusps into the stream bottom. It is a very interesting dune of the so-called moving-dune type. It is crescent shaped. This one is roughly 700 ft. across the tips of its cusps, and perhaps 40 ft. high at the center. I sampled the dune at various places and scared out an *Uma* and chased him across the arroyo to a rodent hole. I poked in the hole and dug it out. Finally I saw something squirming under the sand. It didn't act like a lizard so I refrained from grabbing it. Shortly a tail poked up out of the sand with a rattle on the end. It was a little sidewinder rattlesnake who had taken to the burrow for shelter during the heat of the day. The snake was bloated and later I found that it had swallowed a very large adult male *Uma m. notata*. We surveyed the dune front and found that it had moved appreciably since our last visit. The southern cusp had whipped back a little and the main drop slope had moved forward a little.

The day got so hot that the numbers on the stadia rod started to jump, and we had to cease operation. We took shelter in the shade of the arroyo wall. There was little shade. I saw a better spot down the creek a little way. It was enticing enough to roust me up in the heat. I carried my tarp down and spread it out in the shade. The others were about to join me when I looked in a crevice about 2 ft. from my nose and there sat a nicely coiled sidewinder peering out at me and the heat. I poked a thermometer under him and found that he was in 29.9 deg. C air and we were in 38.0 deg. C. air. He certainly had the right idea. However comfortable he was I didn't want him 2 ft. from me while I was trying to rest, so we hauled him out and did him in. Glen took his rattles. This place seems to be full of the varmints.

After we had sat in the shade for an hour or so, the wind came up and began to blow our maps and gear around. We stowed everything and sat down again but it got worse and worse and began to whip up the sand. I guess it had gusts up to 30-35 mph at times. It was most unpleasant sitting with the sand and grit whipping all over. We retired to the lee of a clump of *Tamarix* downstream. I set up a tarp to divert some of the sand. We hoped the wind would abate toward evening so we could finish our surveying. Even with our shelter the fine sand sifted onto us like flour. We were all dusted thoroughly and had sand all over us. I walked upstream and to the lee of the dune. I had the excitement of actually seeing the dune move.

In the center of the crescent the air was comparatively still, unlike the gale outside. I looked up toward the crest and could see a sort of sand corona or halo along the crest, where the wind whipped over the top. The top of the ridge could be seen to become fluted and build up until finally it went out of equilibrium and a section of sand began to slip down the drop slope. The little sand slide moved noiselessly toward the bottom and finally piled up there. That portion of the dune had moved forward an eighth of an inch. The crest was now straight and began to flute again. So the cycle went. It was majestic in a way to see the dune actually moving in its own incredibly slow geologic manner across the desert.

After some more sitting in the sand and getting sand on top of our sand, we finally decided the wind was not going to drop enough for us to work so we piled our gear into the car and drove off down the creek. Getting out of the steep-walled arroyo with the car required a little Barney Oldfield driving to make it but, thank goodness, we didn't have to excavate any new roads in all that heat. We bought a little ice and some milk at Westmoreland, after passing across the sand storm in its full fore. The windshield got pitted a little and we were on the verge of turning on our lights. The main sand being

blown passed right along the axis of all the barchan dunes in the valley. The skies were filled with dust everywhere.

Off we went to Split Mountain Canyon, which was the nearest shelter we knew of where we could have a calm and sand free camp. It was beautiful in the canyon with its 700-ft. vertical sandstone cliffs, and I guess much more beautiful than usual because it had not a grain of windblown sand. After a minimum of the usual after-dinner yak yak we went off to bed and all had a nice sleep.

June 1, 1955

Home

Up at 6:30 and after breakfast we drove toward home. At Benson Dry Lake we stopped and hiked up toward an interesting dune mass tucked on the hillside (east slope of the large butte overlooking the lake). As we walked up toward the sand the wind was strong and at our backs. It died down as we approached the dune and when I reached the other side it blew strongly in the other direction. The dune apparently is deposited in this spot because of this wind situation. I saw no *Uma* though there were some tracks. The trip home was uneventful.

July 14, 1955

Catalina Harbor, Santa Catalina Island, California

Frank and Boots and Mac and I shoved off from Fleitz Landing at about 6:30 for Catalina. We are on a general collecting tour—looking in particular for specimens for the jewel tanks and for white sea bass.

We cruised out of the harbor under what Frank and Boots call “albacore weather”—high scattered skeins of cumulus clouds and warm weather.

The seas were quite calm and pleasant so I failed to come down with my usual seasickness. About 8 miles out from the light we came upon a patch of floating kelp (*Macrocystis*) and took a sharp look under it—sure enough a school of blue perch (*Medialuna*) could be seen hovering under the canopy.

The channel water was markedly green and nary a blue shark was seen until we reached the island. No porpoises showed themselves.

It is always exciting to me to round the west end of Catalina Island and cruise along the sheer cliffs and barren coast of the windward side. It has a sinister appearance to me—swells crashing in against the massive cliffs and water dropping off to a deep blue a few feet from the shore.

To add to the scene we saw a great blackish bird flapping along on sepulchral wings, landing on the knife edge of a steep spur, looking down on us. It was an immature bald eagle.

Frank took the *Geronimo* in and out of the precipitous coves at the edge of the kelp. No sea bass showed themselves. We rounded the wave-tossed reef at the entrance to Little Harbor and slid into the calm, opaque green water behind it.

The hook was dropped while we rode at anchor. Frank produced a fine spaghetti for us.

Little Harbor is far different from the western end of the island. The back hills drop gently into winding canyons with broad sandy floors back of the bay. Pretty

beaches rim the harbor and behind these flats clothed with *Juncus* and saltgrass stretch up the canyons. A few small rocky headlands break the landscape. It is calm and beautiful and inviting. Frank tells me there is a fine ranch nearby.

After lunch was finished we pulled the anchor and cruised on down the coast, peering at the kelp beds to no avail. A little farther we saw a group of gulls working along the edge of the water. As we approached Mac called, "Look at the fish." Boots said it was a big "black spot"—a fisherman's term for a heavy school, which appears as a black spot on the surface. The school extended along the beach for perhaps 75 yards and from the low breaker line to about 100 ft. offshore. The fish were nearly solid in the water. Frank said the school went clear to the bottom. "You can always tell this when the top fish are forced clear up to the surface." The two Franks estimated that there were at least 100 tons of anchovies in the school.

We could see the school part miraculously and a big bass would rush up into the void. The edges of the school shifted like rapidly streaming pseudopodia. I noticed that the fish in the parts of the school that were calm, face in all directions and were scattered farther apart. The frightened fish on the periphery were densely packed and reacted in perfect unison.

On down the coast we went until we came to a place where Frank pointed and said, "See that black spot there—there's at least 5 tons of seine leads down there." I asked why and then was told that the black spot was a submerged rock and that fishermen repeatedly set their seines around it, thinking it was a deep school of fish. Frank said there were usually schools of blacksmith and yellowtail around it. Sure enough, we spotted one big old yellowtail which must have weighed well over 20 lbs. He had what looked like a gaff mark on his side. We watched him for a while and then went on down the coast toward Ben Weston Point where Frank said the harbor seals hauled out. We saw a few jiggling themselves down into the water.

We turned around and returned to Catalina Harbor. Mac and Boots and I jumped into the skiff and loaded the diving gear. Near the west side of the entrance we slipped over the side and began searching for specimens in the kelp bed. It is difficult to describe the scene we swam through as there is nothing on land to compare it to. The big kelp (*Macrocystis*) filters the light, casting the scene in rich, bright amber shades. Tall columns of twisted strands of the kelp sweep up from the bottom, bending in the tide, and sweeping back and forth in the surge of the waves. The cliffs above the water tumble into the sea and below the surface the gray and brown rocks are carpeted with a dense feathery matting of many species of algae. There were dark pink tufts of *Gelidium* and coarser light pink and violet *Corallina*. Close to shore the bright yellow brown beds of *Cystoseira* took over. Down deeper the little trees of *Eisenia* were to be seen. These are a beautiful brown in color. Springing from a single stalk they end in a tuft at the top.

In places the rocks were coated with a solid mass of worms (serpulids?). The usual conception of a worm doesn't include the concept of beauty. But that was predominant with these delicate creatures. Each ended in a little rosette of brightly colored tentacles—dark indigo blue, reds, cream yellow, and white. When I touched the worm colony with my hand and when I swam by, their little heads would pop in and disappear. Down deeper, near where the rocks shelved off onto a gently sloping sandy bottom, we found real forests of gorgonian sea fans. They looked yellow to our eyes at 30 ft. beneath the sea but at the surface they were a deep henna color. In the patches of

sand we saw many little gobies (*Coryphopterus*) and captured a few by chasing them into a little nylon diving net.

Other fish we noted were the beautiful young of the garibaldi—bright orange dotted with brilliant iridescent blue, red-striped convict fish, senoritas, various perch, and many others. I found a couple of old whisky bottles which had become encrusted with algae, bright-colored bryozoans and tunicates. They were quite beautiful and I saved them.

Back at the boat with our booty, Mac and I decided to go investigate the wreck of an old abalone tender which juts out of the water on the west bak of the harbor. We climbed around on its sloping decks for a while and found that what Frank had said was true—"That wreck has been salvaged 250 times before you guys got here."

Back at the boat we loaded the beach seine into the skiff and waited for the tide to come in. As the tide tipped at high we set the net in the water at the head of the bay and caught quite a lot of fish—one small white sea bass (20 in.), several species of perches, and two thornbacks. We made two sets and returned to the *Geronimo*. Frank produced a nice dinner. Much gassing about this and that followed and finally we went to bed.

July 15, 1955

Johnson's Landing (Emerald Bay)

Up at dawn. We piled out and loaded the skiff and rowed ashore onto the long, cobbly beach just west of the wreck. There we made a set with the big nylon beach seine. As the net came up toward the beach we could see a big brownish blob in the water. Finally as the net was beached we found the blob was composed of about 30 big bat rays all congregated in the bag. We tied the bag and rowed the whole affair out to the boat with the bag dragging in the water, flapping and squirming. On board we selected out a series of opaleye and a few of the bat rays, put them into the tank and gave the rest their freedom. Mac wanted to inspect the shoreline for young opaleye so we walked the beach finding a very few.

We did find an old anchor chain which was very artistically rusted solid. I demanded that we take it back as a decoration for the oval tank. It had been a mooring chain for an old albacore processing barge which was anchored in the harbor back in the twenties. It was a beastly thing to handle as it was rusted solid and would not coil up but stuck out at odd angles. Beside that it weighed at least 250 lbs. We made it though and lashed it to the deck of the *Geronimo* and were off around the west end into the calm lee waters. At Tacoma Rock we stopped and I made an exploratory dive to see what sort of bottom was to be had. On the way I picked up about 10 abalones (Pinks) with a screwdriver. The bottom was an incredibly dense jungle of all sorts of algae. It was so thick that in most places no real bottom could be seen. I suspect that in 30 or 40 ft. of water it would have been clearer. The surge from the west end must be a factor in producing this luxuriant growth. Beautiful though it was I decided that we would have much difficulty in locating and catching fish in the jungle.

Up with the anchor and down the coast we went toward Arrow Point. There Mac dove around a pretty little rocky reef which was entirely surrounded by a plain of sand. The little underwater island was teeming with life and we caught a few small fishes. I spent most of my time skin diving and shinnying down the kelp columns while holding my breath. At one point I dove down to Mac, who was poking around among the algae at

the bottom. I peered into his faceplate upside down and startled him a little. He led me off and showed me a big kelp fish hidden in the growth. Shortly we climbed into the waiting skiff and returned to the *Geronimo*. There was Frank fishing with a hook and line in the midst of a large murky area of chummed water, a very odd attitude for Frank, who has never owned a fishing pole.

We cruised off toward Emerald Bay. The Cal Fish and Game Boat *Marlin* was there with a group of divers. We pulled up alongside and talked with them. Then Mac and I rowed to the lee of Indian Head Rock and I dove down to look the place over. I dropped beneath the surface and looked into one of the most startlingly beautiful underwater scenes conceivable. Algae were everywhere—the large kelp, the small encrusting species and the busy types—greens, iridescent blues, coral reds, topaz, greys, and yellows. Little avenues of clear sand wandered among the kelp toward the edges of the bed. Whitish rocks loomed up dotted with long-spined bluish-black urchins. Out on the flats I saw dozens and dozens of tube worms poking up from the sand. They ended in a circlet of tentacles about 2 inches across. All my attempts at digging them out failed. Their tentacles were of several hues—reds and buffs mostly.

Fish were everywhere—there were swarms of cigar-shaped senioritas milling among the kelp columns. The perch were there as well—little seven-eleven perch (*Cymatogaster aggregata*) were seen in their breeding color. The males were nearly jet black while females were dark reddish gold with a few scales of bluish caste. Under nearly every rock little white gobies (*Coryphopterus*) could be seen poking their heads out. Their eyes and the tip of their first dorsal fins are jet black and look like little black pebbles until you realize that they are part of a fish. Down in the deeper waters I found the little blue-banded and zebra gobies common. These are two of California's most brilliantly colored fishes and rival anything found on the coral reefs. The blue-banded goby is a bright scarlet orange dashed with vertical bands of iridescent blue. The zebra goby is red and is lined with many vertical lines of dusky blue. Both are small—reaching about one inch. The blue-banded fellows were almost always first seen as they perched on top of the white rocks within inches of the spines of the urchin (*Strongylocentrotus franciscanus*). When disturbed they would skip into the retreat of the urchin spines. The zebras were more often found in closer contact with the urchins. Usually they were hanging upside down at the top of the recess dug in the rock by the occupant urchin. They too retreat into the urchin when danger comes. If the urchin is removed the goby leaves his retreat and skips over the rock surface to another urchin or a nearby crevice. It was terribly frustrating trying to catch these elusive little fellows with a diving net. They had no intentions of going into a white nylon net no matter how hard we tried to persuade them. I did finally catch two.

Mac and I finally rowed back to the *Geronimo*, much exhilarated by the dive and the sights we had seen. There a fine lunch was waiting—abalone chapine cooked to a T. The abalone was the most tender I have ever eaten. Frank had bashed the critters with a 2x4 on the stern of the boat.

The Fish and Game boys were skin diving over toward shore and came up with a bottle containing a peculiar fish. Mac and I rowed over and identified it as a fringehead. It is one of those peculiar blennies which is able to open its mouth to an incredible size during combat. The rear ends of its jaw bones are only loosely attached by means of a membrane. When the fish opens its mouth this membrane is stretched out full—it is

bright yellow inside. The combat of these fish is probably mostly intimidation display though their considerable array of sharp teeth suggest that they may actually make contact on occasion.

Further evidence of this is that when we confined 4 of them in a jar the smallest one was killed shortly. The divers brought up 4 of them, 3 in old encrusted Smucker's imported jam jars. I wonder if there is a social hierarchy favoring the imported jar homes?

I went down later and peered into several dozen bottles and cans and found nary a fringehead. To be sure I found no Smucker's jam jars either. I came up with an old bathing suit, a broken frog spear, some sea urchin shells, a couple of rifle cartridges, a knife and fork, but no fringeheads.

Later Bill and I made another pair of dives out by Indian Head Rock. We both saw moray eels poking their malevolent heads out from among the rocks. I prodded one with my screwdriver and he snapped at it.

We were both thoroughly fagged and dried off and changed clothes. A couple of young boys sailed by in an 8-foot dinghy which had a mast and a nice little sail pushing it. Later we saw them apparently foundering and rowing back. As one boy pushed at different times than the other, and harder, the boat was wiggling around in a most frantic and aimless manner. Bill and I leapt to the rescue in the big skiff. I offered them a tow line. "Drop dead" was the reply. We found that it was their first time out in their own sail boat and no help was even to be thought of. We retreated hastily.

Mac dug succulents for his horticultural wife. I had already dug succulents for my horticultural wife on a previous trip. We were nearly overrun by a herd of passing boy scouts.

Later we took Frank and Boots and rowed ashore to Camp Emerald Bay. I had attended the camp as a young boy scout back in 1938 and it hadn't changed a bit. The same mess hall—the same bunk house where my "putrid polecat patrol" had bedded down. We talked to the 6'5" camp director—a fellow named Mac David—and we found that even the routine was the same. They still fight over the green goddess and still haul certain members off into the hills and make them sleep out all alone. Mac David had been on the island since 1928 and didn't like the mainland. He did a fair amount of moaning though.

We talked about poachers and poachers' methods and Frank knows them all. The Fish and Game is now catching poachers by stationing men high on the hills with cameras and big zoomar telephoto lenses. They also have developed the splendid trick of finding illegal traps, pulling them, tagging the lobsters with inconspicuous tags, and replacing them. Then when lobsters are brought in they can tell easily who was the illegal fisherman.

Back at the boat ate a light supper and went to bed.

July 16, 1955

Home

Up at dawn. An uneventful trip home. No porpoises or blue sharks sighted.

August 6, 1955

Catalina Harbor, Santa Catalina Island, California

The channel was almost red in places near the San Pedro Breakwater. I think we are getting touches of red tide. Salps (*Salpa s.*) were scattered across the channel. Our crossing was calm and uneventful. No porpoises were seen and only one small blue shark was seen.

At Catalina Harbor we dropped anchor close to the *Stella Maris*, a boat about the size and shape of the *Geronimo*. This boat is populated by the Falconi Brothers, more popularly known as “the alcohols”. There are three of them, Paul, Batiste, and Augustin. Paul is called “Goat”, Angie is Angie, and Big Alcohol is Batiste.

After supper we went over for a visit with the Alcohols. Quite a crew. All bachelors and all pool their cash, giving it to their mother who rules them with an iron hand.

April 26, 1956

Guaymas Trip

This trip to Guaymas was planned for several purposes. First, we wanted to see if we could locate a source of small reef fishes to supply our tropical tank and jewel tanks. Secondly, we wanted to test our new transportation gear with a fairly long trip before trying really long distance transport such as carrying fish from Mazatlan, as we will have to do when we make an attempt to collect saw fish and nurse sharks there, later in the year. Third, we wanted to obtain a number of brightly colored fishes for the oval tank. My collecting crew was composed of Frank Brocato, Frank Calandrino, Bill McFarland, and myself from Marineland, and Dick Rosenblatt from UCLA. Dick is an authority on Gulf fishes and a competent collector and diver.

Most of the packing fell to Frank and Boots, as I was plagued with a siege of disease in the tropical tank until the time we jumped aboard the big truck and left. Frank and Boots went on ahead late in the afternoon in the Stake truck and Dick, Mac, and I left about 10:00 PM in the big transport truck. Bill Monahan was on hand to see us off, and while mumbling about the fact that our load had bowed the truck bed slightly, presented us with a bottle of medicinal spirits (Old Crow). This we tucked under the seat and drove off with the pleasant feeling that all emergencies were thus taken care of.

April 27, 1956

Dawn found us crossing the huge Algodones sand hills, east of the Salton Sea. The pale pink morning light heightened the impression that these clean sweeping billows of sand were ocean waves. Bringing us back to the reality of the desert were the fragments of the old plank road along the edge of the new highway. This old road was built of ties attached together with straps of steel. The constantly shifting sands of the dune mass have twisted and ripped it into a thousand upended fragments.

As we crossed into Arizona we were stopped by the Arizona State Highway Patrol and required to buy a temporary Arizona license for the truck. We dove on uneventfully, noting the cultural changes which occur as one leaves California and enters Arizona. Frank Sinatra was largely replaced in the juke boxes by Tex Ritter and Ernest Tub wherever we stopped for coffee. My attempts to convince my companions that this

western cowboy music was really modern folklore and should be treated as cultural, fell on deaf ears, I am afraid.

Late in the afternoon we arrived at Tucumcori Mission, where we found Frank and Boots waiting for us, as we had planned. Ten miles beyond we came to the border. Our permits were not complete so I anticipated a lot of fast Spanish and deep frowns and shuttling from one authority to another up the hierarchy, ending in a call to San Diego, where all would be clarified by a word from the higher resident god there. But no—Frank found what he described as “a genuine dago” in the midst of the officials. This Genuine Dago was named Bonfiglio and was about to have Frank haul out all the gear stowed in his truck. Frank discretely greased his palm with some green salve carried for the purpose, and I did the same with the little Mexican ordering me to unload the big truck. In a miraculous change of heart each official then marked big X’s on each box and off we drove, seven dollars lighter, but free to roam all of Mexico showing off our magic X’s. This is a magic called “mordida” by the Mexicans, and I guess, “cumshaw” by us. At any rate, my expense account shows the entry—“Mordida--\$7.00”.

We had driven for about 20 hours and I was willing to go a way out of town and make camp for the night, but Mac knew of a swell place to eat in Hermosilla. This town, which is the capitol of Sonora, he said was about 100 miles down the road. It proved to be nearer to 200 and we arrived late at night. I drove into the nearest place advertising “Comidas Mexicanas”. We had some of the most miserable tacos I have ever eaten and a skimpy plate of beans and cheese. The beer, however, was delicious as usual, this being one of the few really predictable things in Mexico. After this meager meal we drove south of town and pitched out the sleepig bags amongst the saguaro cactus. With swigs of medicinal spirits warming our interiors we dropped immediately to sleep.

April 28, 1956

About 8:00 AM we were roused out by the sun beating down on our sleeping bags. We returned for a fine breakfast at Mac’s pet restaurant. The town is one of the most beautiful in northern Mexico. It is a mixture of ornate Spanish cathedrals and new buildings of clean modern architecture. The Mexicans have a real feeling for modern architecture and are generally more daring in their approach than Americans, the Oceanarium notwithstanding. The desert climate makes the dense shade of huge Indian beech trees which line the sreetes a real delight in summertime. Unlike most other Mexican towns, Hermosillo sports broad clean paved streets over much of its spread.

Before long, as we drove southward, we could see the twin peaks of “Tetes de Cabra”, a mountain rising near our proposed camp site. We chattered seven miles out over the washboard road toward the peak. The road skirts the broad crescent of Ensenada Bocoibamp (Bocoibampo Bay) and ends at the nearly landlocked lagoon called Estero de San Carlos. We cut off the graded road on a two-rut trail that led down to the shore, just before reaching the lagoon. Frank and Boots were delighted with the camp spot we found. The others of us had visited it several times before and so were not surprised at its beauty.

We had our own private harbor, a little cove between two fingers of rocky land. Our camp was made in a crescentic hollow in the cobble berm about 75 ft. from the shore. The water was crystal clear and perfectly calm. No waves lapped at the shore. Back of us, rocky hills covered with saguaro cactus and a dense growth of euphorbias and

mesquites rose to the main mass of precipitous purple desert mountains. Occasional patches of native desert *Washingtonia* palms could be seen in the washes, where water came near the surface.

While Frank and Boots made camp, Mac and Dick and I drove in toward Guaymas to attempt to make contact with the Inspector de Pesca there. This man has no visible function, except to be official, but he must be catered to. We also wanted to locate Johnny Nash, the photographer who was to record our various photogenic doings for posterity. We found Johnny pounding along the dirt road toward our camp. We gave him directions, and went on into Guaymas, where the Inspector was not to be found.

Back at camp the collectors had strung a big canvas over a little stumpy tree and tied it to the truck. It gave us a nice big hollow of shade. We built platforms in the rocks and lined our gear boxes around under the canvas. Lanterns were hung from the tree and nails pounded in for cup hooks. The boats and live car were launched and anchored. Before dusk we took the skiff around the east point of our harbor (Punta de las Cuevas) and set the seine twice for bait, to no avail. We caught a very few small nondescript fish and returned to camp. After dinner we rigged the fishing poles and put on some salt mackerel and squid. None of us even got so much as a nibble, even though we fished until nearly midnight. One fishing pole inadvertently fell overboard when pushed by an oar. The water was unseasonally cool, a sign which might mean that many migratory species would be absent. To bed a little dismayed. We had seen the patron saint of collecting trips, Dr. VanDenburgh, in Nogales, but he looked peculiarly prim and well kept. His beard was large and white, but neatly trimmed, and he was jauntily carrying a cane. He is usually a jovial slovenly tattered mess with whiskers flowing with the wind.

What all this might mean we were not sure.

April 29, 1956

Up before dawn, and as is Frank and Boots's custom, ate no breakfast. We loaded the skiffs with diving gear and set out to make an underwater reconnaissance. Mac and I pulled on our rubber suits and took turns diving over various areas for 2 or 3 miles along the coast, looking for the best fishing grounds. West of our camp, beyond the entrance to Ensenada Bocochiamp, the water deepens abruptly and we could operate only very close to shore. Nevertheless, we were able to swim up a number of underwater channels and corner numbers of groupers and schools of a striped grunt (*Haemulo sexfasciatum*). A few schools of bright yellow and black sergeant majors were seen. About 5 Gulf sheephead were seen. These are pretty fish with long trailing fins, a species we wanted badly for the oval tank at Marineland. At one place I dove among heavy columns of sargassum weed and was able to swim down and touch the dorsal fin of a 30 lb. grouper which lay nestled in the vegetation. Experiences like these make me wonder where the sport lies for skin divers who spear these docile creatures. Many other species are approachable enough so that one can swim within 3 or 4 ft. without frightening the fish away.

Among the sargassum columns were many knobby calcareous algae castles, protruding up through the foliose algae like so many stalagmites. This particular stretch of bottom was among the most interesting we saw. The wind chop had begun to pick up and we had seen very little of the kinds of fish we wanted so we turned the boats back toward camp and rounded Punta San Antonio at the entrance to Bocochibampo. Just east

of the entrance Mac inspected a little cove and came up announcing that the bottom had many pretty brilliant blue *Pomacentrus rectifraenum*, a species of damselfish.

We entered the mouth of Estero San Carlos and dove along its rocky shore. Mac saw a few nice snappers, including *Lutjanus argentiventris*, a species with a red back and a yellow belly and tail. We had hoped that the warmer water of the Estero would perhaps have attracted various brightly colored species, but this did not seem to have been the case. In one shallow neck of the lagoon Mac and I cruised over the bottom and saw many interesting small fish such as smooth puffers, Trypterygiids, and gobies. These however, are of relatively drab coloration. While the others took the boats back to our harbor, Mac and I walked overland into camp, a distance of about ¼ mile. I had forgotten to get my shoes before the boats left and so had to pick my way slowly among the rocks while Mac smiled superiorly down at me, from his vantage point up on his soles and heels.

Back at camp Frank, Mac, and Dick decided to go to town for some food. I took a hike up the wash in back of camp to get a look at the country, while they were in town. The vegetation is rather typical short tree forest with a strong admixture of desert species. The mesquites were good trees up to 30 ft. high. I saw the white paper barked palo blancos and the yellow scarious hielio trees. The moister spots supported scattered groves of palms, some in flower. On the nearly level alluvial benches bordering the stream bed were many fine specimens of a stubby little tree (*Forchameria watsoni*) with smooth white bark, very heavy, obese limbs, and a dense crown of long, slender, thick green leaves. Nearly every one of these trees had its complement of little lizards clinging to its bark and matching the color perfectly. The lizard was the ornate tree uto, *Urosaurus ornatus*. On the ground I scared up several little gridiron tailed lizards (*Callisaurus draconoides*), which curled their tails over their backs before fleeing.

Down in the hollows I saw a few *Pyrrhuloxia*. This species is a beautiful desert relative of the cardinal. It has a brown back and a dusky red crest.

After about 5 miles of walking I came into camp to find Boots and Johnny a little worried about my long absence. Boots and I decided to try the little gill net and so carried it to the skiff and cruised out into our harbor and set it just at dusk. We caught one small grouper and a Gulf opaleye, neither fish being very desirable. As we pulled the net we could see the lights of the stake truck bouncing along the road toward camp. Our skiff bottom grated on the cobbles of the beach just as the truck pulled to a stop in camp. Shortly Frank had a good dinner ready and Mac had constructed a good cooling drink from rum, ice, and pineapple juice. We relaxed and listened to Johnny's stories about the odd people he has worked with. He wanted to know why I had been collecting lizards, and I think we half convinced him we were going to cook them.

After dinner Frank and Boots baited and set the traps out on the rocky bottom off Punta de las Cuevas. Mac, Dick, and I went fishing. We stoked up the motors and headed for the cove in the lee of Punta San Antonio. We had been anchored for about ten minutes when I hooked up on the bottom and Dick tried to set the hook in an anonymous fish. His rod tip shattered and mine broke at the ferule. Three rods in two days and only one intact one left! Dr. VanDenburgh, why were you looking so dignified?

Fishless, we returned to camp at about 11:00 PM. Frank, who is not a friend of the roving rattlesnake or the crawling creature, had put his cot up on the tailgate about 4 ft. off the ground. He was puffing away, sound asleep when we crawled in.

April 30, 1956

Frank routed us out in the dark at 3:30AM. We stumbled over the loose cobbles and loaded the gill nets into the boats and then waded the bows out into the calm cove and scrambled aboard. In the black starry night of early morning our boats cut through the phosphorescent water. Half an hour later we hove to, outside of Punta San Antonio. In the early morning light Frank and Boots payed the nets over the stern of their skiff under the massive shadow of the 200-ft. vertical lava cliff of Punta San Antonio. This was the spot where Mac and I had seen schools of grunts and sergeant majors. We watched the bobbing corks for half an hour but not a fish was taken. Another couple of sets yielded two fish, one of which was a gulf sheephead. Two net sets in the Estero yielded nothing but a few tortillas (Gulf stingrays) and big diamond sting rays (*Dasyatis* sp.), all of which were thrown back.

All of this was very discouraging. I sat in the stern of the skiff thinking what to do. Frank sat in the bow of his skiff, looking long-faced. We hadn't caught enough good fish to sneeze at, the water was frigid, and we had even seen very little underwater. I finally called the skiffs together and said, "Let's pack up the kit and leave for Mazatlan, where we know there'll be fish." We chucked our two fish over the side and revved the motors up and headed for camp.

Boots stewed up a pot of coffee and Mac cooked us pancakes while we decided what to do next. A look at the map showed that it was 477 miles to Mazatlan. This was considerably farther than I had thought. This would make our run home almost 1,500 miles, and we were already attempting about the longest large-scale saltwater fish transport by truck that had been made. I was confident of our gear, but not that confident. Finally after breakfast was over and everyone was moping around, I said, "It's too far—we'll stick it out here and scratch for our fish. After all, we haven't even tried some of our most potent collecting gear, such as the beach seine." I tried to read Frank's face, to see how he was taking this decision. I couldn't tell, except that he was worried. He knew that we weren't really prepared for Mazatlan, where the surf is apt to be rough and gear has to be hauled over a 200-ft. sand beach, and isolated camp spots where gear can safely be left are non-existent—but I still wanted his valued opinion. Finally I felt that he agreed and we set out to plan our operation.

With Johnny and cameras on board we set out for the cove inside San Antonio Point, where Mac had seen the damselfish. I picked a little inlet and Frank and Boots set the gill net around it. We rigged up the diving apparatus and set out to try out the "slurp gun". This is an invention of Mac's and mine, which consists of a cylinder of plastic and a plunger. When a trigger is pulled the plunger is pulled up in the tube by powerful rubber bands. It was designed to suck up small fish. It worked quite well and before long we had a few small, brilliant blue damsels swimming in the tub. I saw some rudder fish and one fine old snapper wedged under a rock. Frank caught a striped grunt in the gill net.

We transferred operations around the point to a big tidepool. We raced over and set the gill net in the entrance. I jumped in the pool and shortly was rewarded with the sight of one of the most beautiful fish in the Gulf—an angel fish covered with brilliant iridescent blue spots and a bright orange tail. I poked at him and he rushed into the net—as simple as that! We spent the rest of the afternoon trying to chase two *Cirrhitus* into the

same net. These are bass-like fish with electric blue lines and jade green background color. No luck, but Dick did toss out about seven nice lobsters which Frank gathered into the skiff. I poisoned a small pool with rotenone, which Dick had brought along. This is a potent fish poison used by scientific collectors in gathering museum material. I thought if I could dip the fish up quickly enough and put them in tubs of clean water they might revive. I succeeded in catching about two dozen small fish, including some sergeant majors. Mac and Dick found another angel fish in an outside channel but could not dislodge him into Frank and Boot's net. Frank quickly named the angel fish a "Guaymas garibaldi". After a reconnaissance dive at a nearby island we started back to camp. Frank and Boots pulled the traps and brought in a snapper and a very rare species of eel, *Gymnothorax argus*. Our eel was the seventh known specimen, as I recall.

Back at camp Frank fixed the lobsters in a delicious chapino with tomato sauce and pasta. What a superb meal to have at sunset on the beach at Guaymas! We had Galleta biscuits to soak up the juice and a splendid McFarland cocktail (either rum, bourbon, or tequila in lime juice over ice). "This," we said, "beats working."

As everybody was pretty well bushed I called off a proposed night seining in favor of a little bull slinging contest and the good sleeping bag.

May 1, 1956

In view of the success in obtaining little fish by use of the rotenone poison method, I decided to try a deep poisoning, in hopes of capturing some of the deeper water forms. Many of these little fish are quite colorful and would make fine small tank material. I also wanted to carry out a more thorough poisoning of the big tide pool.

In order to catch the low tide, which came in early morning, I asked Frank to rout us at 6:00 AM. He is an excellent human alarm clock in the early morning hours. He didn't fail us and after stumbling out we consumed one of Mac's egg pancake breakfasts, loaded the skiffs, and cruised out into the calm bay. At the shelf surrounding the pool, Dick, Mac, and I put on our rubber suits while Boots and Frank rigged the diving gear and set gill nets at the entrance to a nearby underwater canyon. I started the poisoning while Mac and Dick went underwater in an attempt to drive several big Gulf sargos into the waiting net. They succeeded in capturing two of these pretty bronze fish. I picked up dozens of small fish and ran them through a rinsing tub and into a freshwater tub. The method proved promising as I was able to save many fish, though more died than lived. If I could somehow put the fish into cold water, where the effects of the poison are strongly inhibited, I would get much more success. As the poison constricts the gill capillaries and prevents the fish from absorbing sufficient oxygen, I think an oxygen aerator for the holding tubs would help a great deal. Some fish are so far gone when they are first picked up, however, that nothing would work, I suspect. We have a heavy alcohol which will anaesthetize fish well, but it will not work in open water like rotenone, and requires much more quantity to be effective. I used four double handfuls of rotenone for a pool which held an estimated 4,000 to 5,000 gallons of sea water. Dick picked up three more spiny puffers when we set the fine mesh gill net around an area known to harbor a fine school of sergeant majors. We were all dismayed, particularly Frank and Boots, by the fact that these fish would seldom gill themselves. All of us noticed that nearly every species retreated under rocks when disturbed. I chased a couple of small groupers over the bottom toward the net and had them swimming at a great rate before me. When they

reached the net, which is so fine as to be almost invisible, they abruptly stopped and fled under a nearby boulder. Nighttime would be the time to capture them but the colorful species all sleep under rocks or in the sand at night.

Puffers are a more satisfactory fish. They cannot swim very fast and when one is sighted the diver swims over it and taps it until it inflates and it then becomes helpless. It is then escorted to the nearest boat.

Over on the lee side of Pelican Island we tried a deep water poisoning. We mixed the poison into a doughlike consistency and I donned the Desco diving mask and took the poison cans down to the bottom, spreading great lumps of it in the crevices at the bottom of a 40-ft. underwater cliff, and out over a boulder field beyond. Frank tended the diving gear and Boots cruised the surface in the other skiff, picking up the fish as they flipped to the surface. Mac and Dick swam and dove from the surface, picking up fish in their fine-mesh diving nets. Many more fish stay on the bottom on one of these operations than appear at the surface, so I was very busy indeed picking them up off the bottom.

The bottom at the island is a luxuriant place. Many kinds of short algae species clothe the rocks. Sabellid worms retract their delicate radiating tentacles as one swims by. Some are white, others are reddish brown and of considerable size, the larger specimens having a tentacle spread of three or four inches. Gorgonian sea fans cling to the rocks under nearly every overhang. The venomous little white gorgonians were common. They deal out a rather potent sting to the unwary diver who brushes against them. Another dangerous denizen which I saw in some numbers was an exquisite sea urchin. This particular creature has extremely long, banded, black-and-white spines, which are as thin and sharp as a needle. The body of the urchin is set with five brilliant, iridescent blue specula. One has only to touch this creature and the spines become deeply embedded. They are quite painful and cannot be removed as they fragment when pulled with the forceps.

Many fish were recovered, including some nice specimens, but many more were dead. The poison has to be placed heavily to affect the fish before they can swim away, when a deep poisoning such as this is done.

It was dark when we finished and so we pulled the traps, retrieving a few small octopus, and went ashore. Boots cleaned the octopus by turning their bags inside out and removing the interior workings, including the ink sac. He then boiled the beasts for about 20 minutes, while Johnny looked on in obvious disgust. When the boiling was completed, Boots removed the skin and chopped the beasts up in sections, sucker discs and all. He constructed what he called a "dago salad" out of them. This consisted of the octopus, chopped onion, a little garlic, olive oil, and vinegar. A pot of hot coffee and the salad made up dinner. Johnny bravely chewed away on a couple of sections until our conversation got him and he retreated from the salad to the cold cut department. "Great flavor, this octopus, but Boots, don't you worry when the sucker discs stick to the top of your mouth?"—this was the sort of thing that drove him off.

Actually the octopus has a nice, delicate flavor which is distinctly seafood-ish but very different from everything else except squid. It is very rich however, and one cannot eat much. Tomorrow is a big day—so to the sleeping bag. There to be greeted by ever-increasing hordes of saltwater mosquitoes. These beasts are insidious. They don't buzz but bite like fury.

May 2, 1956

Up at 3:00 AM and into the skiffs quickly. Boots ran the small skiff and Mac the large one. Our goal was Playa de Bocochibampo, 7 miles away. This is a stretch of sandy beach which we wanted to seine for jacks. Our early start was to allow us to hit it at dawn, the best time for seining, as the fish cannot see the net and they are very often in close to shore at that time. At night the phosphorus in the water lights the net like a luminous fence, as it is being pulled ashore.

We watched the sun rise over our bows as we slipped along. At the beach we found the beach very shoaly but set the net anyway. Throwing the seine lines over our shoulders Mac and Dick and I pulled one wing onto the beach while Frank and Boots took the other in their own fashion. Instead of walking with the line they pull it in hand over hand. This puts most of the strain on your back and arms. Our method wears on the legs. At any rate the seine held mullet, numerous stingrays, one Gulf electric ray, a few smooth puffers, and a few small halibut. Not very good.

On our way back we detoured to a dome-shaped rocky island. I hiked over it looking for likely tidepools for our alcohol, while Boots and Frank worked the gill nets. My hike proved fruitless but they caught a few striped grunts and some trigger fish. We found a nice cobble and sand spit extending from the north shore of the island and set the beach net again. This time we came up with a nice series of porgies (*Calamus brachysomus*).

Back at camp by about midday we ate a belated breakfast and took it easy for a while. Mac and I crawled under the big truck where it was cool and breezy. The hour's nap was delicious. Summer came all at once this day as it was well over 90 degrees F. From our jewel of an ice box we produced some cold beers to assist our siesta. These had thoughtfully been provided by Johnny before he left for home, after his camera gave up the ghost.

In the afternoon Boots and Frank worked over their nets. Every set with the gill net produces some holes and snags and these have to be repaired before a new set can be made, so Frank and Boots were seldom idle. Dick and Mac spent a couple of hours observing the behavior of some small fish called Trypterygiids. Dick is writing his doctorate on these beasts and has been probing into their private lives for a couple of years now. I took a swim with the face plate but the water was still frigid and now had turned quite murky so I didn't stay long.

The dinner of broiled mullet was wonderful. This was accomplished over Frank's ice box shelf and a bag of charcoal he bought enroute.

After dark, back to the skiffs. We shoved off into the dark night to try to find our island and its cobble beach. I took the tiller and miscalculated grandly, getting us off our course a mile or so. Finally we slipped into the dove, cutting the motor to keep from frightening the fish. We had seen hundreds of rocket trails left by fish as they shot through the luminous water, away from our bows. Many of these had been made by flying fish and others by big rays. The latter make a great broad flash of cold light when they are startled.

Our set netted a school of bonefish, more porgies and a series of blue-lined grunts (*Microlepidotus inornatus*). The booty was ferried out to the waiting fish tank in the big skiff. With the dripping net and lines aboard we cut directly northward toward a long beach. We knew it harbored masses of algae but wanted another set badly. Frank and

Boots dropped the net into the water far offshore and we began pulling. It came hard and got worse. I estimate it took us forty-five minutes to get the net in. It contained tons of fragmented algae. We couldn't possibly beach it so we began to shovel the debris over the cork line with our hands. One of us saw something flap down in all the soggy pile. A broad tail emerged. It was a splendid adult pargo muleto (*Hoplopagrus guntheri*), a pretty bronze and gold species of snapper. Further search turned up five more of these splendid fish.

It was an hour's work to clean the net and stack it in the stern of the skiff. By this time the moon had risen and everyone was only too glad to hop into the skiffs and push off onto the calm moonlit bay. I took the tiller of the big skiff. All the hills and islands, so familiar by daylight, were distorted out of all recognition. The little cliffs of our Punta de las Cuevas looked like a huge, towering rampart as we approached our cove. The fish were dumped at the live car and the skiffs beached and hauled up above high tide line, the fish tank pumped dry and the usual bailing done. Then we trudged up over the cobble berm and into camp where our coal oil lamp was still faithfully burning. It was after 3:00 AM—just about where we started the day before, so the sleeping bag felt good and we all went to sleep in spite of the bloodthirsty mosquitoes.

May 3, 1956

Those xxx@@@!!! mosquitoes!! They have real discrimination—and it's all against me, as far as I can tell. I hope they drank a toast to my poor departed body as they sucked the last drop of blood from it. Nobody else seems much bitten or disturbed, even though I am sleeping right next to them. Those guys will be sorry when I'm gone—and I'm leaving. Tomorrow night I spend inside the fish tank on the big truck. Even the bug bane we have been using won't stop the beasts from feasting off all my more exposed parts. Enough of this hypochondria (hypochondria I say—I never heard of a psychosomatic mosquito but I suppose there's always time for a first).

Frank and I took the little trawl net and cruised about 3 miles down the coast to the long sandy beach. On our way Frank asked me if I had seen the porpoise. No, I said, where, what porpoise?? I stopped the skiff and we idly rocked in the swell for ten minutes, but the animal did not surface again near us. Frank said he saw it once. It weighed about 80 lbs., was black, blew with a loud "puff" and had a very small low triangular dorsal fin. This description perfectly fits the new species of porpoise which Mac and I have been describing. We suspected it was at Guaymas but did not know.

On down by the beach we plopped the trawl in the water and set the little shear boards. Our hauls were unproductive in general. We picked up a couple of pretty little flatfish (*Pleuronichthys ritteri*), a lot of algae and many specimens of the sharp-spined poisonous urchin. The day had turned steaming hot as we turned for camp.

Frank noted a group of skiffs working off of a low island. They had been in one spot for two days so we investigated and found that they were taking pargo (*Lutjanus peru*) in considerable numbers on hand lines using anchovetas for bait. At last—a source of snappers for us. We found we could buy bait and if the school only stays put until we come back in the morning we will have our snappers.

Mac and Dick had been diving and came back with reports of one crevice under a big boulder at Pelican Island which contained one Guaymas garibaldi and three *Cirrhitus*, the brilliant blue and jade green fish we have been seeking. After breakfast, Mac and I

decided to try to catch these fish. We took a small piece of gill net and rigged heavy fish hooks on the end of a short pole. With Boots tending both of us, we dove down. I swam to the rear entrance of the cave and was greeted by three beautiful *Cirrhitus* staring at me out of the crevice. I could almost hook them but not quite. Meanwhile Mac crept in the cave from the other side and set the gill net across it. I poked vigorously around with the hook with no results. After about half an hour we found that there was a cross channel which was inaccessible. Not so dumb, these cold-blooded vertebrates!

Dick and I dove around Punta de las Cuevas. I was most disappointed by the fragmented algae which filled all the caves and potholes. Dick, however, persevered, and came up with a nice little frog fish (*Antennarius avalonus*).

We dove around the flat island and I set the pole hook in a ice big Gulf sargo, but he struggled free. We did catch some nice spiny puffers.

Back to camp and a nice dinner of broiled mullet, and one of Mac's inimitable concoctions. Mac seems infinitely resourceful when it comes to mixing a drink. He will stop at nothing to find ingredients, it seems. In our case, after a hard day's net hauling, diving, and general boat pushing and gas can toting, they were all creations which knew no peer. Tequila, rum, beer, bourbon (nearly gone now), or pickling alcohol are all grist for Mac's mill. Limes, lemons, pineapple juice, orange juice, papaya juice, mangoes, bananas—it makes no difference as long as the master blesses the mixture.

General gear rigging and preparation for snapper fishing in the morning. I moved my bag up into the truck tank amid all sorts of derision. I suspect they secretly wondered what they were going to do for a decoy when I left.

May 4, 1956

Up with the first red streaks of dawn. Into the skiffs and off to the snapper grounds. We bought two buckets of anchovetas for ten pesos and soon had our lines on the bottom. We fished until about 10:00 AM and put 28 pretty red snappers in the live car, including one *Lutjanus guttatus*, which I hooked.

To the frying pan—with gusto—where Mac decided to make French pancakes. If he had only of had a little flaming brandy . . . ah well, they were good enough.

Frank and I drove into Guaymas to see the Inspector de Pesca, but he proved to be out on a extended siesta, which was calculated to last beyond the Cinco de Mayo until Monday. So we left a little pile of literature for the office help to marvel at and picked up some cigarettes, rum, and bread. The day was scorching hot and the streets dusty and without shade so we were glad to return to our bay and shady camp.

After dinner Mac and I hiked up around the end of the Estero San Carlos and got well chewed by mosquitos for our pains. We had hoped to see our porpoise, which is thought to frequent the lagoon, but were not so fortunate.

A couple of gill net sets at Pelican Island netted nothing. Back to my sanctuary and my residual bites. Like I had predicted, the mosquitoes now turned to another victim—this time it was Boots, poor fellow.

May 5, 1956

Out on the snapper grounds at dawn. Frank and I were in one boat and the other three in the other. Frank had some mysterious formula and caught fish one after another. I caught aout 9 fish and the others just moaned about no bites. We came in with 34

snappers, and I suspect Boots had had his fill of advice from my boat on how to catch snappers by the time we decided to leave.

Mac and I went back to the tide pool. Mac saw a big Gulf sheephead swim in just as we arrived. We netted the entrance and tried to drive the fish out. No success. I saw something under a big rock and poked around with the hook. Finally I came up with a big pargo muleto. This time he didn't get away and I ferried him successfully to the skiff. I was swimming out with my fish when a whole school of big diamond sting rays swam around me, scaring the daylights out of me. Back in the pool I found another fish, and this time, with Mac's help, we pulled out the Gulf sheephead, well hooked.

We made a reconnaissance dive across the bay and caught a long-spined spiny puffer (*Diodon holacanthus*) and found some excellent grounds for a new deep water poisoning I wanted to try.

Back at camp we shaved off our whiskers, except for a little lip foliage and headed for town. This was Cinco de Mayo, Mexico's fourth of July. A nice new place has been built along the main road, called the Guaymas Inn. It caters to the American trade and is careful about lettuce and ice and such things as might give the tender gringo tourist's disease. We settled down around a few ron co-leens (rum collins) and had a fine Mexican dinner. We were entertained by a splendid Mexican trio who called themselves the "Trio Bahia". Mac asked them if they had recorded and they said certainly they had. Finally we found that this had been done on a tape-recorder.

In town we wandered around looking for the celebration, but found that the holiday was to be held on Sunday—tomorrow evening. At the far end of town we found the Atayde Circus, complete with cotton candy and extremely low-fi public address system. Being sports for the evening we bought tickets, at 20 cents each, and walked in. We perched on shop worn bleachers up under the tent edge. The band alone was worth the price of a trip to Guaymas. Little White Lies, played on tuba, valve trombone, bass drum, and other nameless instruments. All instruments virtually independent of one another, and all trying to keep in time, not with each other, but with 20 Mexican girl acrobats hanging from the roof. For the most part we had seen the show on TV, but the sea lions were fine. The trainer, billed as Captain Montoya, or something like that, stepped out, resplendent, even for a seal trainer. He walked on his toes and looked like he wore a corset like Juan Peron. His seals couldn't balance things very well, but one big old boy, named Tarzan, screeched and hollered and bellowed with vast enthusiasm through it all and then did a wonderful Charleston. What a sight! It was great seeing that critter flapping his big flippers, in time with one or two of the accompanying instruments.

After a couple of rounds of cerveza at some of Guaymas's seedier cantinas, we drove back to camp, Dick and I taking in the night air in back as we chattered over the washboard.

May 6, 1956

This morning we planned to try a deep water poisoning among the big boulders of a landslide, which had fallen into a nearby cove. The wind, however, was coming from the south, directly into the cove and causing a big swell. Frank thought it was shifting so we decided to wait a while to see if things would calm down. So we hopped into the stake truck and took a little drive up toward the foothills. In a short distance we found ourselves in a sparse short tree forest. I found several caves which had obviously been

occupied by Indians at some time long past. The mouths of the caves were covered with cracked shells of all descriptions and evidence of fire could be seen in the burned earth of the cave floors. We collected a couple of specimens of *Crotaphytus collaris*, the collared lizard. This must be just about as far south as they go. They were the smallest members of the genus I have ever seen.

Back at camp the wind had shifted and we immediately put out into the bay and the collecting grounds. I had Frank and Boots set both gill nets around the area in a semicircle. Mac dropped the poison in. Schools of California sardines were in evidence and we killed thousands of little ones. We have seen other, larger schools. It seems likely that the Gulf harbors a large population of this enigmatic fish, though it has only been reported from this area once before (Walker, 1951?). We collected many fish and caught some nice ones in the gill nets as they tried to rush out of the poisoned area. These included Gulf sheephead and some nice sergeant majors. Frank and Boots had a real job cleaning the sardines from the meshes of both nets. We left about dusk.

Some nice sierra had become emeshed in the net and as these fish are too delicate to transport we relegated them to the ice box, grill and the dinner table. They were delicious but not so good broiled as deep fried. Tomorrow we will gather gear together, do a poisoning for Dick and the UCLA museum, and have everything ready for the morrow, when we leave.

May 7, 1956

Mac and Dick and I left Frank and Boots working on their nets as we left to do the poisoning we had promised Dick. The water of the bay was virtually opaque. The south swell had brought in shoals of plankton and warm water. It was now fine for diving, in contrast to the temperatures we had had in previous days, but we couldn't see anything. Ah well, you can't have your cake and eat it too. Finally, around Punta San Antonio we found a clear cove which had not yet been invaded by the sea of plankton. We dove for 4 ½ hours and produced a nice collection including 48 species. Some were rather rare fish, but these were not of Oceanarium size, as the largest ran to slightly under one inch in length. The poison drifted into a small school of 4-5 inch sardies and stunned them. Their movements on the surface attracted pelicans and gulls in droves. I estimated that 800 pelicans were feeding in our cove. Frigate birds and boobies came too, though only a few.

May 8, 1956

Up at dawn. Immediately we began to roll sleeping bags, pack boxes, and load the little truck. The big canvas came down, leaving the camp looking awfully barren and hot. The load was balanced by Frank to be sure we didn't develop a list. It was an incredible pile of gear, now that the big truck could no longer take things in its big tank. Frank and the rest of us looked more than once, wondering if it was all going to fit.

Next we went down to the beach and awaited Frank and Boots, who rowed out to the live car and pulled the anchor. When it was close inshore we hooked the anchor line to the winch and slowly dragged it ashore with water gushing out of the side ports. Boots stood on top of the truck wearing gloves, Dick stood by the calibration pipe to take the weight of fish. Mac and I hauled the tubs from the beach up to Boots, and Frank dipped from the live car. It seemed like a vast number of fish came from the live car. We

worked fast and smoothly until all the fish were stowed, including the little specimens in their separate bottles. While the rest of us stowed nets and traps and motors and other items in the empty live car, Mac took the initial chemistry on the water. The sun was blazing by this time and we were all covered with perspiration. Mac came down off the truck shaking his head. “the pH is 7.3. I checked it three times. And the oxygen is low. The temperature was also dangerously high.” I said, “Frank, let’s get the little pump rigged. We have to change water, that’s all there is to it.”

We would have lost the load before reaching the U.S. border if we hadn’t done this. I took off my clothes and toted the suction line out into the bay, while Mac backed the truck onto the cobbles. Frank and Boots rigged the pump and soon we had a nice stream of newly fresh water going into the tank. I began to congeal so I got some twine and tied a rock to the end of the hose and also attached a buoy, so it floated in mid water without moving. We reasoned that leaving the water standing over night had caused the changes in its chemistry, which our aerator had not been able to compensate for.

Finally, we were refilled and loaded, with the pH OK and the temperature down. The poor stake truck was really staggering under its load and steered extremely badly. It was past noon and we hadn’t eaten so I suggested we detour and get a bite at the Guaymas Inn before pushing toward home. We tried but the place was closed, so rather than go clear into Guaymas, we turned and headed for Hermosillo. The day had turned scorching and we were glad to see the sun move lower as afternoon came on. We checked our rig repeatedly and changed the filter bag a couple of times before hitting Hermosillo. Our belated breakfast at about 3:30 PM certainly did hit the spot, though we were all surprisingly unstarved because of the heat.

On toward the border as soon as lunch was over. The water temperature had climbed in the tank and we began to fear that our heater was leaking when it was shut off, and this proved to be the case. Exhaust gas was leaking by the flutter valve and slowly raising the water temperature to dangerous levels. The pH began to drop too. We rigged the auxiliary aeration pump and were delighted to see a nearly immediate rise in pH away from the dangerous level to which it had dropped. The temperature stayed up and we began to lose water because of the wind picking up the aeration streams and blowing them over the side. I tried to top off with fresh water but Mexican line pressures in the gas stations we visited prevented us from borrowing more than a few gallons.

At the border at about 10:00 PM, I uttered the magic words “Paragraph 1677” to the Americans (which is the paragraph giving the rules for admitting fish not for human consumption and thus free of duty). The miserable Mexicans, however, wanted to see what was inside all that stuff on the back of the truck. I tried to stop the auxiliary aerator with my foot and got a jim dandy shock through my wet field boot. We all handed in turista permits, except Mac, who was sleeping in the box on top of the cab. About the time we had dispensed with these papers, Mac emerged, yawning. The Mexicans did a small double take but for some reason more or less ignored the incident. I explained we were Cientificos and Biologos and other impressive things. We didn’t have our paper from the Inspector de Pesca in Guaymas, as he never did show up, so I didn’t want to get involved in a discussion of permits. In this vein, I fumbled with all the wrong wrenches I could find, getting the tank open, splashed water on everyone near and put on a grand show hunting for a flashlight for them to see our fish. When I finally got all this done

only one authority was left and he took a two-second look and waved us on. This was fine, and I was even happier to see our snappers swimming strongly.

Across the border, I topped off the tank a little with fresh water and we rigged a canvas to prevent spray from blowing away. We shortly found that this prevented good gas exchange at the aerator and was dropping the pH dangerously again. We cut strategic holes in the cover and up came the pH. I am amazed at how sensitive this factor is to small outside influences.

We took turns in the box on top of the truck (I named it the “hanging gardens” in honor of my sleeping place in the Honolulu Aquarium). It was comfortable and cool, but no place for a claustrophobic.

On through the night after a brief stop at Tucson to have a cup of coffee with Mac’s father. Filter bag changes, water tests, gassing the engines, and riding in back to check the rig, were the order of the night. Frank and Boots labored on in their weaving truck. I tried to convince them to sleep in a motel, but they would have none of it, and later events proved their decision to be our salvation.

It seemed very odd to see the dawn without ever having gone to bed. Dawn found us at Gila Bend. We all wrapped ourselves around a good breakfast, changed the filters and all the rest, and drove off again. I took the Stake for a while and was rather shocked at how hard it was to drive. We got Frank up in the Hanging Gardens but he came out about two minutes later mumbling that he couldn’t go to sleep in that thing. We shovelled Boots into it and drove on. At Yuma the Highway Patrol wanted to make me buy a license for the stake. I looked glum. Finally he said—“When are you coming back to Arizona with that rig?” “Never,” I replied. He rather morosely waved us on.

The temperature began to climb in the tank as the warmth of the day came on us, so at Winterhaven we put 150 lbs. of ice in the tank and brought it down nicely. Frank went, as he calls it, “snooting around” the big truck and found that we had sheared a lug bolt on one wheel. When they were tightened the garage man said we would have lost the wheel in another hour.

At Westmoreland the truck lost virtually all its power and was making a vast racket. Mac and Dick found that the exhaust line had expanded and cracked loose, thus releasing the vital back pressure on the valves. We had this welded again and drove on. At Indio we added 200 lbs. of crushed ice, ran through our usual routine, and shoved off again.

On into the night—drive, check, gas up, change filters, chemistr, drive, and so on. We felt sure we were going to make it by the time we stopped for dinner at Lawndale. What a seedy looking crew we were when we ordered our food! Then Mac couldn’t find the truck key. What a blow! I had visions of sitting there, 20 miles from the Oceanarium, until all the fish died, looking for the keys, but finally Mac conjured them up, and off we went, pulling in the Oceanarium gate about 10:45 PM. We were greeted by brave wives who kissed us in spite of our facial foliage. What a relief to look in the tank and see our fish swiing happily after their long ride! Every one had become a precious cause by this time and such things are not to be let slip away without a fight. But we won, Ma, and were delighted even through our weariness. It was good to see Bill and Phil Schulyer and the whole place. The fish were hoisted to the flume by a benevolent style Coonie, and we left for home and a bath and a little sleep.

September 17, 1956

Seal Trip

At about 5:30 AM we arrived at the *Geronimo* and loaded all the diving gear aboard. Our party consisted of Frank and Boots, myself, George Barlow, Dick Rosenblatt, and Fred Munz. The latter three are graduate students at UCLA and were along to help us collect seals and to capture certain fishes which they needed in their research programs.

The morning was calm and clear after we left the bank of coastal fog. Frank took us around the east end and we inspected the little pocket beaches along the steep southwest face of the island. Not a harbor seal was seen. Their main rookery is located at Ben Weston Point, on the extreme windward point on the island. As we came upon this area we began to see the seals poking their heads up above the water as we passed. They peer curiously for a few moments and then duck back down among the kelp fronds. Ben Weston Point is a rugged rocky area with little pocket beaches of cobbles and gravel interspersed. An almost constant surf beats upon this shore and safe landing spots are few. Probably this is why the seals congregate at this spot. On one beach we saw four or five seals resting like obese sausages on a little berm, just out of the water. They slid into the water before the boat came within 300 yards of them.

George and I were landed from the skiff through the surf. We had two big nets, a seal box and a couple of apples. We took refuge behind a boulder as big as a small house and dried out our clothes. I crept down close to the beach to look over the situation. A big boulder resting close to the beach afforded fine refuge for us. I set up a little blind of some old drift wood, kelp fronds, and cobbles. This was done from behind so as not to disturb any seals that might be in the vicinity. George and I lay behind this watching the surf. Finally, one seal appeared at the water's edge. It looked nervously around and then slid under the water and disappeared. We watched for three hours and saw two more seals, neither of which came all the way out of the water. All the seals suddenly appeared at the edge of the surf, swimming under water for some distance so that they were unobserved. Each scanned the beach carefully along its whole length and then left. We felt that we had been undetected but that the seals were exceedingly wary. They are hunted by fishermen constantly and this probably accounts for their wariness. After three hours the *Geronimo* returned and we boarded her and left for Catalina Harbor. I felt that the seals were so wary in the daytime that we stood little chance until darkness.

At Catalina Harbor we dropped the anchor for the night. The boys went out for a little diving before dinner. When they returned I took the skiff out for a row. We noticed a big boxer on the beach, barking at some goats. He chased a billy, a kid, and a nanny up onto a big rock at the water's edge. The dog took a nip at the billy and got butted for his pains. He chased the kid but it scrambled away up the rock. Then he took after the nanny and backed her into the water. She launched out into the bay like a leaky rowboat and swam away from the barking dog. Before long she developed a port list and I rowed over to her, taking her by the horns, dragging her into the skiff. What a bedraggled critter! She sat in the skiff peering at me out of her big, frightened eyes, while I rowed to the *Geronimo*. A short conference followed in which we decided that since she was a MOTHER and we didn't really want a goat anyway, I would row her back to the beach. She jumped over the stern onto the rocks and stalked away up the hill shaking herself and

trying to retain her full goat-like dignity. We heard a bleat as the little kid found her mother, up on the fog-covered slopes.

September 18, 1956

At 4:00 AM the alarm woke us and we upped anchor for the beach again. As we cruised along, the moon set and the morning became very dark. Frank spotted the beach somehow and Boots rowed George and I ashore, where we landed on a big rock. Both of us had our nets. We crept along as quietly as possible in the dark. The first light of dawn came as we walked up over the rocks in sight of our beach. I could see some vague black objects far down the berm. We walked as close to the water as possible so as to put the animals away from the sea from us. Suddenly we heard a clatter of cobbles and saw two seals lumber off into the water right next to us. I thought all was lost as the others would hear and go too and they were too far away to catch at that moment, but no, they stayed on the beach, unconcerned. A big wave swept ashore and rattled cobbles as it broke. George and I broke into a run under cover of this noise and in a moment were in the midst of the sleeping herd. There were about 15 animals. They came down the beach like express trains. I picked out one and caught him just as he was entering the surf. What a struggle. Once he was in the net he gave me a terrible time. He looked immense. It was all I could do to haul him above the water. I estimate he weighted in at 250 lbs. George had caught another and neither of us could reach the other. I tied mine in the net and finally dragged him up the beach and gave the handle to George. Then I ran off down the strand and signalled to the *Geronimo* for help with my flashlight. The two of us could do nothing but hold on. Soon Fred Munz came ashore and we tried to figure what to do next. We cut the nets loose from the hoops and dragged one struggling beast down the beach to an open spot where Boots came in with the skiff. I waded in, waiting for the time when the waves were lowest, and threw a line to him. He rowed like mad to keep from getting swamped and towed the struggling seal out to the waiting *Geronimo*. The one I had caught was too big to be dragged across the sand (we were afraid of chafing the net though and hardly had the strength anyway as the animal insisted on snapping at us when we got too close to him). Both animals were exceedingly mean and tried their best to bite sections out of each of us.

Boots landed the porpoise stretcher and we rolled the big boy into it and carried him snarling down the beach. He was launched like the other and dragged out to the *Geronimo*. Frank had to use the block and tackle on him.

George and Fred and I lugged our gear down the beach and loaded it and ourselves into the skiff. Back on board we changed into dry clothes and took a look at our new captives. They snapped and growled but seemed in good shape.

Back at Catalina Harbor I spent a little time trying to pry a timber off of an old sunken Chinese Junk. I was of the impression that it was teak but it turned out to be exceedingly mouldy pine.

On around the West End ad down to Emerald Bay, where we anchored. Some porpoise were noted, including a school of adult *Lagenorhynchus*. I didn't want to catch a porpoise at that time as I would have done the UCLA boys out of one of their major reasons for helping us. They wanted to gather observations on some certain fish species. So we left the poropise for the next day, as they were definitely in the area anyway.

Fred is working on the physiology of the retina of fishes and wanted a series of a small goby for his work (*Coryphopterus*), so we gathered the diving gear together and started catching them for him. I tried out the Slurp Gun with tremendous success. This is the gadget which Bill McFarland and I invented for sucking up small fishes. I caught ten fishes in ten slurps. It needs some improvements but even the pilot model works well.

We caught Fred some sheephead and he retreated down the hatch of the *Geronimo* to process them. He has to excise the retinas in the dark and fix them in a special fixative. He emerged about an hour later about 9/10ths seasick from this delicate work and the rolling ship.

By this time we had so much junk on board that we put the three UCLA boys ashore for the night. They had a fine beach to sleep on.

September 19, 1956

Up late this morning—at 6:00 AM, and off to the channel to look for porpoise. About $\frac{3}{4}$ of the way across the channel, after zig-zagging back and forth for two or three hours, we came upon a very large school of Pacific white-sided dolphins. They were spread over perhaps a square mile of water, about seven miles off Pt. Vicente. Many young were seen in the school, including a number which must have weighed no more than 30 lbs. The young were perfect little replicas of the adults except that their colors were a little duller and their dorsal fins were without the characteristic hook of the adult. The little fellows continually leapt playfully from the water like little tunas. One jumped 14 times in succession. Some were glued to the sides of their parents and swam in perfect unison.

Frank missed his first shot because the net jammed. Then he hit a big animal and shortly we were off in the skiff running down the line. Her fellows stayed with her for a while and they swam off as we neared her.

Shortly we unloaded all the plunder of the trip, getting the seals situated in the porpoise training tank and the porpoise in the circular tank. Off to the dock and home.

January 10, 1957

Tursiops Trip

Frank and Boots and I wet to the *Geronimo* at about noon and soon were out of the harbor, heading for San Diego. Our purpose was to make our third attempt for *Tursiops gilli*, the Pacific bottlenose dolphin. We were anxious to perfect methods of capturing this animal as we expect it to be the mainstay in trained sets for the future Sea Arena.

This time we had a modified net on board with which we hoped to circle the creatures and were equipped with a considerable fund of information on the habits of the species.

The weather was threatening and we planned to pull into Newport Bay for shelter, but when we got there the sea was calm so we decided to make a run for it and kept on course. Below Newport the coast is virtually without shelter of any kind so we hoped the weather would hold for the next eight hours. It did as we pulled into the lee of Pt. Loma at about midnight, dropped the hook, and went to sleep.

January 11, 1957

Up at dawn. We ran up the bay toward the Ferry Channel where the porpoises had been seen before. Before we reached it we saw about 15 animals in all, cruising up the bay toward the channel. We saw one old fellow whose dorsal fin had been sliced along its edge and whose body was marked with a broad white line along its dorsal surface. He probably had been scraped by a ship. We followed them all day long, charting their movements. They spent the morning in the bay around the Ferry and then moved leisurely into the Sea Plane Base area. We stood helplessly by as they cavorted among the sea planes. About every five minutes one of these big planes would come roaring down the channel and take to the air, just over our mast. No chance for a set. About 1:30 they started out into the channel leading toward the entrance. The Navy and Marines were engaged in a big series of war games including landings on the Camp Pendleton beaches. This meant that at least one war ship of some description left or entered the harbor every 15 minutes. As our net would be in the water about half an hour at the very least we could not set it in the channel and expect not to get run over by a destroyer or an aircraft carrier.

About 2:00 PM they began making for the entrance to the bay. We hoped they would leave it and go southward along Coronado Strand where there is no traffic and little tidal effect, but no, they played in the tidewater channel and at dusk, to our dismay, moved back into the harbor again. Our last sight of them was as they were lazily breasting the tide going up the bay.

After dinner we took a turn out in the bay and tried to locate the elusive animals by the lights which edge the bay. None was sighted. We tured into Kettenburgh Boat Works and tied up.

January 12, 1957

Up at dawn and up to the Ferry Crossing. Not a porpoise was seen. I figured they might be clear up in the shallow head of the bay and so we cruised up as far as there was water to float the *Geronimo*. No porpoises. Frank said, "I'll bet you they went out of the Bay last night." We turned and cruised toward the entrance. Even though we kept a sharp lookout no porpoise showed its dorsal to us. There at the entrance Frank spotted a fin clear out at the last buoy. The animal was swimming into the bay from Coronado Strand. Soon we found five animals coming into the Bay, breasting a strong outgoing tidal current. There was no chance to work in the harbor because of the current so we decided to take a look down the Coronado Strand to see if there were any more outside.

About two miles south of the Coronado Hotel we spotted a group of five cruising along just outside the surf line. As we came close with the boat their first reaction was to turn toward us, away from the containing line of the surf. Frank saw this and retreated seaward. The porpoises returned to their course. Frank brought us up about 200 ft. outside the animals and abreast of them. He then started creeping closer. They turned toward us again and Frank edged the boat outward. Finally he called out, "Let'er go" and in an instant Boots had cast off the skiff line and I was watching the net fly off the stern as the boat raced ahead parallel with the cruising porpoises. I brought my skiff inside the net so it could be locked when the circle was complete. Frank made the turn about 200 ft. ahead of the school, which had sounded. He then flew around them on the inside, skirting the surf zone too close for my comfort, and I am sure, for his or Boots, though I

had no fear he would do the wrong thing. As he swept around toward me the porpoises rose in a bunch and blew near the head of the net. Boots leapt into the skiff and we locked the net while Frank brought the *Geronimo* close to the net on the far side.

There he reached over with a boat hook and cleared a tangle in the net where the leads had jumped into the big mesh, thus pulling the bottom lead line off the bottom and leaving a clear route of escape for our captives.

“We’ve got them.” Now we had to make them hit the net and tangle in it. Boots and I rowed into the net and slapped the water with our oars, tossed the pike pole at the animals when they rose to blow, threw rocks at them and just plain yelled. No luck. Then we sank the cork line and let the *Geronimo* into the circle. She cruised around like a motorboat, churning the water to a froth, with her fathometer going full blast. The sound emitted by the fathometer apparently is very frightening to porpoises as they run like rabbits when we switch it on at sea. No luck. Frank stood back in exasperation. “we’ll have to purse-seine it, I guess.” This meant that Boots and I took the skiff and began to gather the corks of the cork line into bunches of 30 or 40 and tie them. This had the effect of cutting the circle of the net in half. Still they surfaced, and we saw that we had ten animals instead of the five we had bargained on. “The \$\$\$%# critters still won’t hit the net, I guess we’ll have to umbrella it. This consisted of tying a line on the cork line, running across and tying it on the other side. Then the two were pulled together. This made the net into a figure eight. All ten came up in one section. Then we divided it into a clover leaf. Still they rose. Finally one of the sections collapsed in the tide. Five animals were in the section. One old fellow saw it close over his head. He rushed at the net and rammed his way to freedom. Another, in fact it was the old fellow with the scarred back, burst over the cork line. The other three hit the net right at a bunch of corks. A tremendous thrashing began with net and porpoise flukes flying. Boots and I rushed over in the skiff. I grabbed the littlest captive, which was a baby of about 150 lbs. or so. I tried to pull it into the skiff but the weight of the others made this almost impossible. Boots struggled with another as the *Geronimo* came skirting around the net. As she came alongside our thrashings filled the skiff with sea water and it sank to the gunnels. Boots leapt aboard the *Geronimo* and I swam alongside the tangle of net trying to pull the big beasts into the skiff to get their heads above water. The little fellow seemed already drowned to me. The biggest animal had ripped through the net until only its tail was held. I tried to pull it into the skiff by its flippers. The old girl objected and opened her mouth and clopped it closed about 6 in. from my nose. The sight of all those rows of teeth caused me to switch my efforts to the posterior segments. Meanwhile Frank and Boots had slipped the stretcher overboard and I tried to work it under her. She was so long that she stuck out both ends a long distance. One lunge and she had broken the spreader board into splinters, scraping the broken wood over one of her eyes.

Frank and Boots began bringing the mass of net and porpoises up on the boom as I climbed aboard to help them. Then the boom snapped. The hook at the mast had broken loose under the extreme strain. We had no choice but to continue hoisting with the boom and hope that it wouldn’t collapse on our backs. Creaking and straining, the animals came on board. We cut the old girl loose from the net and she flopped onto the deck. What a monster. She was 10 ft. 1 in. long and we think she must weigh about 800 to 1,000 lbs. Another porpoise about 500 lbs. in weight was in the net and then the little animal. These two had drowned in spite of our best efforts to save them.

We turned around to find that the remaining five animals were still surfacing in another segment of the net. Afternoon was on us and the wind was picking up. We were disturbingly close to the rising surf. Discretion is the better part of valor so we decided to haul in all the net we could gather so that we could make a quick getaway if we had to. We did this and the animals continued to rise in the remaining net. Finally, as we were about to try to drive them into the mesh, they spotted the opening in the net between the two wings where they were being pulled aboard the ship. Out they went, and joined their old friend "Scarback" who had been waiting for them all the time we had been working on our captives. We had set the net at 11:00 AM and it was 3:30 PM when we finished.

As we had not yet had time for breakfast, I started peeling potatoes and before long had a tasty snack of fried potatoes and onions, bacon and three fried eggs a piece. As for myself, I was hungry and scarfed the food practically without tasting it.

We called Marineland while we were still working on the animals in the net and once in port made preparations to unload the big animal. The truck arrived at about 8:00 PM and we struggled with the huge beast. The tail loader of the truck refused to function so we had to hoist the animal by hand onto the truck bed. We never would have made it if we hadn't commandeered the help of about 10 teenagers who were stading around watching us.

The truck left and Frank decided that the weather and the low fuel tanks of the *Geronimo* made it sensible for us to stay in port and try to run for San Pedro the next day. Off to the welcome sack.

January 13, 1957

The threatening skies made us uncertain that we would be able to venture out of San Diego Bay, but we fueled and listened to weather information and decided to run for it. We expected the seas to be rough but we found nothing but a gentle swell all the way and made fine time under a cloudy moonlit sky. On the way up Frank and Boots and I hashed over the operation a dozen times and decided on new ways of beating some of our problems, particularly those of hoisting the animals aboard once they had become tangled in the net.

I feel that our mission was accomplished with much better success than we could have expected. We can now go out any time of year and have reasonable assurance of making a capture. The net worked perfectly and the animals behaved in a manner that makes them simple to trap in the net. Our discovery of their habit of leaving the harbor to swim along the Coronado Strand allows us to work on them in a calm area with little or no traffic to bother us. We will never try for them in San Diego Bay again. We have reports that they congregate around the garbage dumping grounds off Imperial Beach, a few miles south of the place where we circled our animals. If this proves to be the case, and it sounds logical, we may be able to cruise directly to the animals at any time. I feel that there is now no earthly reason for us to consider further the idea of shipping porpoises by air from Florida.

February 2, 1957

*Field Notes on trips taken for the capture of a pilot whale, Globicephala
scammoni*

For more than a year we had been talking about the possible capture of a pilot whale for Marineland. As the animals were of a small enough size that capture seemed feasible we had begun actual preparations in December of 1956. We knew that the whales congregate in certain localities when squid are spawning and that their presence is predictable with great certainty. After many a session talking about the best method of capture and handling we decided to attempt to get close to the whales by use of the porpoise pulpit or from a skiff towed by the *Geronimo*. We decided on a rubber life raft to transport the animals to Marineland. Our plan was to exhaust the whale until it could be handled alongside the *Geronimo*, slide the raft under the beast, inflate the raft and drydock the whale. Then we would bail the raft dry, or use our portable, gasoline-driven pump for the purpose. Then we would tow the animal to the pier and slide raft and all on a heavy plank platform. This would then be hoisted onto the waiting truck and taken to the holding tank,

Tony Arnoe had obtained the raft for us through Goodyear Rubber Company. The raft measured about 13 ft. in inside length and was calculated to hold 20 men. Frank and Boots spent many hours rigging lines and net protectors on the raft. We had lines for towing, lines for securing the whale in place, extra bridles in case the raft would have to be towed backwards, emergency releases for the CO₂ bottles, and so on. The platform was built of 2x12's, carefully bolted together and sanded and oiled to prevent any damage to the raft. Bill Monahan made sure that "Marineland of the Pacific" was painted on our equipment in enough places that it would be hard to take a photograph without the viewer knowing about us. Everybody was briefed on photography techniques and enough film and cameras to support Eastman Kodak for at least a couple of months were loaded on the *Geronimo*. On board, Frank and Boots had rigged heavy 24 thread lines and special capture snares and nets.

Frank and Boots, Don Hackett, Charlie DeSoria of "The Sea" television show and myself left the dock at 7:00 AM. Our first problem was to bring an animal on board for measurements so that our nets could be built of the proper mesh and so that we could examine various anatomical features such as flipper placement, size of the head, and anything else that would tell us how the animal could be caught alive. Frank brought along his deer rifle and planned to shoot an animal, cut quickly over to it so Boots could harpoon it before it sank and was lost. This procedure sounds cruel and was not pleasant for any of us, but we could rationalize our way out by remembering the works of whalers past and present, and the fact that the animal would die instantly from a shot in the head. This same procedure had been followed prior to our first porpoise capture and had proven its value there.

We made our way toward Catalina Island and met with a large diffuse school of pilot whales off Emerald Bay. In spite of our best efforts we were unable to obtain an animal. The big beasts sounded before we could get very close to them. We left this school and went around the west end of the island. Off Ribbon Rock we met with another group. Frank shot one and it was killed instantly and slid in the water toward the *Geronimo*. Boots stood poised in the pulpit for a shot with the harpoon. Just before the animal came close enough, another larger animal raced over, reared partly out of the water and fell over the blowhole of the stricken beast. This caused the dead animal to sink and disappear a second or so before Boots could drive the harpoon home. We watched the school dive in search of their member. We were in 1,200 ft. of water and the

whales apparently were diving very deeply, though I cannot guess if they were reaching the bottom. One long dive by the group lasted 4 minutes and 50 seconds. After about 40 minutes they dispersed and began to swim up along the coast again.

The squids were spawning in uncountable numbers off Ben Weston Point and dolphins and pilot whales were lazing in the water feeding on them, while dense swirling flocks of birds were everywhere. We were unable to get another animal and had to settle for observations on their schooling behavior. We could make out three major kinds of schooling activity in the pilot whale groups. Feeding animals moved very rapidly and more or less randomly with the animals paying little attention to one another. Travelling schools very often moved as a single front with the animals swimming adjacent to each other. It was possible to harry these schools long enough so that one could get fairly close to them or cause them to stop and backtrack, but as soon as they were left unmolested for a while they would move off again in the same direction as before. In some cases, where the animals were swimming fairly fast (4-5 knots), it seemed almost impossible to disturb the formation, other than to cause the nearest animals to sound. The third group, and the one which looked most promising to us, was the lolling group where a dozen or more animals could be seen lying at the surface, playing and rolling in the water or resting with the tops of their heads and dorsal fins out of water. These groups could be approached quite closely before they would sound.

We anchored in Catalina Harbor and enjoyed a good meal and a night's rest. Because of the shortage of bunks I put my sleeping bag out on the galley floor.

February 3, 1957

Another day spent without obtaining an animal and without getting very close to them. We cruised around the island in an attempt to find the beasts in the calm water of the lee but failed. We anchored in Emerald Bay.

February 4, 1957

Charlie DeSoria had to get back to the mainland so we worked a little in the morning and shot across the channel toward the Palos Verdes Peninsula and down over Dago Bank and Huntington Flats without seeing any animals.

February 5, 1957

Back out to sea, with Frank and Boots, Don Hackett, and myself. We went directly to the west end of Catalina Island and about a mile offshore from Ribbon Rock we came upon a large school of pilot whales. After working with them for a few hours we finally hit a fairly small animal and Boots was able to harpoon it. We brought it alongside and were interested to note a member of the school swimming close to the boat following the dead animal. The larger beast did not come close enough to be netted, however. We hoisted our prey onto the deck and began examining it closely. It was a young male 9½ ft. long. Our measurements showed that our guesses on the size of mesh in the net were fairly good and that we could expect our net to be successful on a larger animal. In Catalina Harbor I worked the animal over carefully. It was marked with a whitish patch between the pectoral flippers. It had a few hair follicles on its lips as is the case with other species of whales, particularly foetal whales. We had killed the animal instantly with two simultaneous shots through the brain case. In its stomach were the

beaks and lenses of quantities of squid. The creature looked much like a great overgrown tadpole with a long grotesque tail.

February 6, 1957

We spent this day trying to maneuver onto the whales with the *Geronimo* and trying to get close from the skiff. We tied a steering oar to the stern of the skiff. I took the oar while Boots attempted to wield our big heavy net. Twelve hundred feet ahead, Frank maneuvered the *Geronimo* around and among the schools of pilot whales (I estimate that there were 500 in the area).

Don tended our line and took pictures of it all. With great skill Frank put our little skiff close to the whales as we both moved along. Boots swung the great cumbersome net around in an attempt to hit the whales as they surfaced near the skiff. I worked the skiff closer with the oar and tried to keep out of entanglement in the swinging net. Twice the whales surfaced within five or six feet of the skiff and Boots lunged at them with the gear. On the first try the apparatus broke and we had to improvise a makeshift splice as we bobbed and slapped along. The second shot slid off the head of the startled whale, which reared up in its fright and throwing its tail free of the water, sounded in an instant.

Frank took our places in the skiff, which was a welcome relief for us, considering the damp blowing fog which surrounded us. Frank got one rather poor shot and had the animal slip out of the collapsing net. As he was mending the net another whale actually swam up behind the skiff and bumped it with its snout. From the *Geronimo* we could see, and almost hear, violent gestures of helpless fury from Frank.

It was obvious that we were too close to the water in the skiff and that our net was not properly designed for the job we were asking of it. So we turned for home. As we rounded the west end of Catalina Island we came upon a small school of pilot whales. Among them was one that seemed to have a large white blotch on its snout. Our first fleeting thought was that it was a killer whale. Soon we were able to make out that it was an adult pilot whale carrying a partially decomposed foetal baby on its snout. We watched the animal for half an hour and could see the little snout and flippers of the dead baby. It was so decomposed that when it was left briefly floating on the surface, the wavelets passed right through it. Its skin had been eroded away and the creature was almost entirely white as a result of the exposure of its underlying blubber. The nose of the adult had been worn until it too was white. Who knows how long this whale had been carrying the little dead animal? It carried the flaccid body down on each dive, bringing it again to the surface.

Frank launched out into the skiff and we were all delighted to see the whales swim directly toward him, their globose heads plowing through the water as they came. We saw Frank strike with all his might. A huge tail and flukes swept out of the water well above Frank's head, crashing spray over the skiff. The animal sounded and was gone. We learned in a few moments that Frank had "scooped" the whale and at the crucial instant the net had collapsed. The whale, presumably a big adult male, had flipped in a tight circle and had actually swum out of the net without touching it.

On the way back we talked over what we had seen and what should come next. Frank and I decided that we should use the skiff, at least a little longer, as it would be easy to rig in the proper manner. If it failed we agreed that we should try a swordfish plank. We would build a net that wouldn't break and that could be handled for quick

shots. Frank devised a platform with a little enclosure which could be mounted on the skiff and in which one could stand.

February 13, 1957

Back we went to sea again. Frank, Boots, Don, Fred Lowe, and I all felt that success was within our grasp. After all, on the last trip we had hit the animals at least five times and had had one run into the skiff. Our gear was in good order and would give us a much better chance than before. About four miles out of port we came upon three California gray whales cruising in the flat, calm water. One 35-foot animal circled the *Geronimo* completely. We could see the beast as it swam on its back under water about five ft. below the surface.

The waters were full of porpoise: Dall's, striped dolphins, and common dolphins. At one point we were accompanied by two striped dolphins who swam in front of the bow for 20 minutes without a break. I had an extraordinary opportunity to observe them. The sea was so calm that every detail could be seen on the animals. In fact I was able to tell the sex of the animals. Both were females. They ran the bow for long periods of time without any movement of their tails. In fact one of them cruised for 47 seconds without a single stroke of her tail. There is now no doubt in my mind that these little cetaceans ride the bows of vessels to hitch a free ride.

Though we looked carefully we could not find a pilot whale until we finally came upon a school travelling up toward Santa Barbara Island. It was moving rapidly and in spite of all our efforts we could not get close to any animal. We harried the school for a long time with utterly no success. We finally left the school and failed to find any more animals. We anchored in Catalina Harbor and contemplated our troubles, trying to figure out why we should be able to approach the animals one time and not the next. No answer.

February 14, 1957

In the early morning hours I heard the wind blowing across the harbor and when we got up we could see a fairly heavy swell running outside. We regretted the disappearance of our beautiful calm weather as our methods were certainly not geared to high seas. All day we worked the skiff among schools of whales, off Ben Weston Point. Many times we approached within 20 ft. of the resting animals but each time the slapping skiff bottom on the waves gave us away and the whales sounded. In these resting groups we saw the creatures do several amazing things. Curious individuals would raise their heads out of water bolt upright, turn their heads, and look at us. They looked for all the world like big brown stumps. The Italian fishermen call the pilot whales "Monico" of monk. The name is certainly fitting in view of this peculiar habit.

The we saw them do just the opposite. Sometimes a whale would point his head directly downward into the water, throwing his tail out into the air. I timed one big old fellow who stayed in this grotesque position with about five ft. of his tail and flukes out of water, for 40 seconds. Many times we watched them swimming on their backs and lolling with their flukes and flippers out of water. One pair was noted mating.

The noises emitted by these interesting little whales were of several kinds. We have heard them whistle a high-pitched whistle that was almost out of the audible range.

Sometimes they chirped much like a baby chicken chirps. We heard one emit a wail like a low pitched siren. The most common sound was a series of repeated popping noises.

From time to time we saw whales breaching—that is leaping completely free of the water. They made a sufficient splash to half empty an oceanarium, when they fell back again.

Coming so close but not close enough became very frustrating after a day's watchful waiting in the cold fog on the bouncing skiff. We finally returned to the *Geronimo* and had a cup of hot coffee and talked it over. Our conclusion was that we would have to seek calmer waters before we could hope to succeed so we set out for the lee of the island and the hope of finding our animals there in calm water.

Although we kept a careful lookout, not a pilot whale was seen. We anchored in Emerald Bay and talked things over. We hashed over every angle and finally decided that we would have little chance of success except for an occasional occurrence, with the skiff, unless it was glassy calm. Glassy calm days are few and far between. The solution was to try for plank shots with a swordfish plank attached to the bow. Next morning we crossed the channel and saw no more pilot whales.

February 25-27, 1957

Frank and Boots had painstakingly mounted the swordfish plank on the bow of the *Geronimo*. It was 26 ft. long (the *Geronimo* is 37 ft. overall) and supported by over 300 ft. of judiciously placed cable. Two thin cables ran along it as guides so that a person could thread his way out to the end as it bucked along. Every movement of the *Geronimo* was magnified several times at the end of the plank so that even a moderate sea caused it to cut up and down 20 ft. or so with each plane of the ship. Although the storm flags were not up, the big swells were crashing over the breakwater as we left port and skies were leaden with low clouds. The sea was at its worst for any of the trips taken during the whale venture. Through it all Mac, who had taken Don Hakett's place, was certain we were going to catch a whale. After all, he said, he was aboard. We made our way toward the west end of Catalina Island in hopes of picking up our resident herds. Not an animal was to be found. We proceeded on down the coast to our old stamping grounds off Ben Weston Point. No whales. We rounded the east end and pulled into Avalon Harbor for the night. The squid had gone and the whales with them. What a feeling. The only moment of the day worth recording was when Mac ventured out onto the plank and dropped his wallet in the water. It was churned under by the *Geronimo*. As we were commiserating with him Boots sighted it off in the water and we retrieved it, not even wet on the inside.

An old fisherman named Pete rowed over alongside of us in the harbor and as he sat and sculled in his little rowboat we learned all the news of Avalon—who had bought the market, what the local poachers were doing, what Fish & Game was doing to the local poachers, and so on. Frank cooked up a stew out of what we claimed was moose meat and we went ashore to take in the off-season sights of Avalon. The big moment came as we were resting on a bench along the waterfront when the local cop almost got into a fist fight with the county sheriff. We sat 20 ft. away as their words became more and more impassioned. They were arguing whether the sheriff should be allowed to park where the local citizens should not. Just before the climax arrived the sheriff raced off in his jeep in a cloud of dust.

We talked to one of the local fishermen, George Voyovitch, who rides the crest road of the island in a jeep every day and can often see the whales. He had seen none after the storm which just preceded us.

Back at the *Geronimo* we decided next morning to go back around the east end and cut out to sea in an attempt to find the animals if they were farther out offshore.

February 26, 1957

It was a glowering foggy day as we pulled out of the harbor. Once we passed out of the lee we came into a big swell that dipped the plank into the water from time to time. We cut back in toward the unseen island after a fruitless search in the rough, foggy waters. At the west end I asked to run toward Santa Barbara Island, in hopes that the whales might be found there. About three miles out we ran into a school of pilot whales travelling rather rapidly. Both Frank and Boots took turns in the pulpit. The big swell sometimes dipped them in the water up to their waists and then rocketed them 30 ft. above the surface.

Every swell brought a sickening drop like that one experiences on a roller coaster. The net flew and more often than not the pulpit stopped abruptly inches from the surface. In this rough sea we had practically no chance at the whales though we did get over them enough to raise our hopes that the plank would work in better weather.

I hoped we would find the whales in the lee of Santa Barbara Island, so we kept our course. As we neared the island the big swells humped up over the shallow shelf that surrounds the island, making conditions worse and worse. We finally turned and went back down the channel toward Santa Catalina Island again. I went out on the pulpit in the relative calm of running with the sea. Mac and Fred did their best to get Boots to turn me into the sea so I would get dunked but Boots, bless him, refused to do it. Anyway, I stayed dry.

We kept our lookout for hours without seeing anything except a few Dall's porpoise and a school of common dolphins. I put in a call to Bill Monahan as we cruised off Avalon in the calm lee waters. "We would be in tomorrow." The plank looked good but the weather had prevented us from using it." About 10 minutes after this conversation Boots spotted a group of pilot whales lazily cruising along. We closed on them and Frank climbed out into the pulpit. Several times we had chances that didn't quite succeed. Finally a huge old male came up under the pulpit. His great black back seemed to well up under the plank. Frank hit him, and believe it or not, the whale's head was so large that Frank couldn't slip the gear over it. From our later experiences we would probably still be fighting him if Frank had succeeded in snaring him. The air was filled with Frank's own particular brand of language and gestures. Frank hit another which took out the line but shook free. We kept trying. I asked Frank to come off the plank for a breather and to steer the boat while Boots worked the plank. Frank asked me if I wanted to go back to port as it was getting dark. I said "No, let's work until dark and see what they do."

Frank would have scalped me if I had said, "Yes, let's go back to port." As it got darker, suddenly it became much easier to cruise over the animals. Boots let fly on one and bounced the gear off its head. A few moments later with great skill Frank put the pulpit over another animal. Boots struck again and this time the net came free and the line began to fly over the side of the *Geronimo*. We did not know how well snared the

animal was so Frank eased the line out carefully, always keeping it taut. We were afraid the animal would turn on its back and shake the snare. Every time the boat came abreast of the line we had to slack off. The first dive of the animal took out about 600 ft. of line. The beast did not go straight down but out at an angle so it is doubtful if she was down more than 400 ft. She stayed submerged for four minutes before coming up with some of her friends alongside.

The light was gone so Fred Lowe just stood by in helpless photographic frustration. Damned inconvenient of us to catch our whale in the dark. Frank snubbed the line and tried to put a strain on the beast by letting the line out slowly. Finally the line went slack. We all feared that the whale had escaped but Mac up on the pulpit could hear blows out ahead. We pulled the line in. Freddy dropped his cameras and started flaking line down as it came in. Before too long it became apparent that the whale was still there and that she was just lying in the water so that she would not exhaust herself pulling the heavy line. When she came close enough to the boat for us to make her out she went down and began taking line over the side at a considerable clip. We had attempted to keep the ship going in the same direction she moved but this time she crossed us and before we could change our course (we had to be very careful not to get the line caught in the screw) she had taken out all but 20 ft. of line. If she took it all she would come up abruptly against the weight of the *Geronimo* and we would have had to test the strength of the snare or the line, whichever proved to be the weakest link. But we stopped her.

Six other whales were travelling with her, making rocket trails in the phosphorescent water, usually swimming just ahead of her. They took us out into the channel and were heading us out of the lee of the island into the rough San Clemente Channel. Nothing we did would seem to change their direction.

I tried to call on the radio but was frustrated by a maddening series of calls from Navy boys calling their girlfriends. We couldn't get a call through until 11:30. Meanwhile the whale just kept swimming with remarkable endurance. Frank developed a method of snubbing the line so that he could regulate the strain on the plunging beast. He kept a heavy tension on her at all times so that she would wear down. Finally she slowed enough so that we heaved her into view. One time we put a spotlight on her as Fred snapped a picture. This frightened her and she sounded briefly, only to be hauled by brute force back to the surface.

We could see that, in addition to her company of pilot whales, she had a retinue of Pacific striped dolphins as well. Another hour and we decided to try to bring her alongside. Mac tried to slip a noose around her tail but did not succeed until several attempts had been made. As she came alongside the *Geronimo* her whale friends left and only the little dolphins remained. Boots and I jumped in the skiff and took the life raft on board. While I tried to keep the skiff from getting caught under the rising and falling rail of the *Geronimo*, Boots tried to slip the raft under the whale as she lay thrashing and blowing. Finally, with an acrobatic maneuver where I pushed the boat off, reached over to the raft and Boots pushed with an oar while the others pulled lines behind the beast, we managed to slip it under the captive. Frank worked the whale in among the maze of lines so that it would not become fouled and gave the command to inflate the bottles. Boots pulled one and I pulled the other and in seconds the whale was drydocked in the high riding raft with only a moderate amount of water around her. Boots jumped in the raft and

began bailing, so her blowhole would be above water. Frank and Mac and I lashed her in place while Freddy sealed rigging and ladders to get his photographs. The whale proved to be in excellent shape and breathed very satisfactorily. She had been very securely netted. The raft was a superb resting place for the animal as it was cushioned by water at all points.

Then as we were about to begin the trip home I came within an ace of falling ingloriously over the stern of the skiff in my excitement. Everybody was exultant. We, by golly, had caught a real, live whale, and were about to bring it in! We didn't think many people had done that before us. We celebrated with a cup of hot coffee. The chase had ended 10 ½ miles out from Avalon, or well on our way home.

As usual I had gotten soaking wet and went below to get into dry clothes while the others secured the raft and headed for Marineland. Frank took the *Geronimo* in close to the Breakwater at San Pedro, in case we should encounter bad weather and have to duck for shelter. The weather was the best we had had on the trip and so we headed on up to Marineland, inspecting our charge once every 15 minutes. Off Marineland at 4:00 AM we tied to a buoy and waited for dawn. By 7:00 AM the beach was lined with cars. The loading platform came down, we slid the raft and whale in it and up she went, as simple as that, onto the waiting truck. Then the whale went up the hill to her holding tank and into the waiting arms of the public relations department.

January 22, 1958

San Felipe Tursiops Trip

Off at 3:00 AM for San Felipe and an attempt at capturing the tonina (*Tursiops gilli*). Frank and Boots and I travelled in our big truck and two photographers, Lee Green and Cy Johnson, drove down in their pick-up. We met at the border. Our attempt to cross on the strength of our permit failed and Boots and I had to purchase Tourista Visas. Frank stood out of the way and didn't buy one—which fact was never detected by the Mexicans. Thus Frank had the pleasure of bilking the Mexicans out of three dollars.

The office of Aduana (customs) was lined with braceros awaiting their papers for crossing. Our man preempted the only typewriter in the office, leaving the braceros waiting while he recorded such deathless information as our job description (both biologists) and the color of our eyes. Finally we finished and gave the typewriter back to the bracero clerk and were on our way. A little lonche in Mexicali and we were on our way down the long desert road to San Felipe. There we found the St. Francis unoccupied as always, and roofless as always. We obtained its dubious rental for a dollar per day from the new proprietor, Carlos Duenas. We learned that the old proprietor had lost it in a poker game. We moved into the empty freeze box for the first time. This is a 12x8 cavern whose door hangs limply from one hinge. Gear was unloaded and we began preparations for the next day. I laid out my sleeping bag in the open air in the main salon of the St. Francis since I didn't like the idea of being cooped up in the confines of the box. This proved a sage maneuver as the night's music could be heard for blocks. Lee took bass and a resonant one it was. Boots supplied the piccolo. Frank and Cy formed the sax section while I slept in quiet cold isolation as a blustering cold wind swept over the beach and the roofless St. Francis.

January 23, 1958

San Felipe

Up early. Frank and Lee and Cy went into town to check with the Cooperativa about a boat. Boots and I decided to take a hike up onto Punta San Felipe to look over the sea for toninas. We walked around the point over the rocky flats and up onto a steep spur of the point. The wind blew so hard that I had to climb down a little from the edge of the ridge to keep my balance. The Gulf was covered in white caps. We could look far out across the Gulf in all directions but could see no toninas.

Back at camp we found that Frank had arranged for a boat the following day, weather permitting. We rounded up gear and got ready for our 8:00 AM start the next day. The two cameramen had an incredible pile of cameras, batteries, tripods, and unidentified but heavy gadgets. We who had to do nothing but catch the porpoise had the lesser pile.

In the afternoon I drove up to a little pocket beach north of town and walked up and down it looking for porpoise skulls. I didn't find any but had a good walk out of it.

The Cooperative Boys were in the midst of a three-day shrimp trip but would take us along while they fished. Actually, they obliquely stated that they would be at our service but for the record would complete their cruise as planned. They assured us that the porpoise came in droves as the drag net was hauled aboard. They then waited around the boat for the trash fish to be throw overboard.

Frank bought two dollars worth of shrimp (about 4 ½ lbs.) and we had a sort of shrimp macarone with tomato sauce plus a huge pile of fried shrimp as a side dish. It was superb and everybody emerged stuffed to the scuppers. After dinner our photoraphers amused us with tales of their many travels around the world.

January 24, 1958

San Felipe

Two trips with the skiffs sufficed to get all our gear on board the Cooperativea boat, *San Fermin*. The *San Fermin* had come originally from San Pedro, having been built somewhere around 1920. She was a mess of frayed wood, tattered lines, and rusty gear. Somehow or other she still stayed afloat. Frank thought that one rough day in San Pedro weather would have done her in. In the calm waters of the Gulf the Mexicans are able to stretch out the lives of their boats without the grace of paint or repair. The *San Fermin* was the last opeative boat the Cooperative has. The other two, the *San Luis* and the *Felipe Angela* lie sun-baked and cracked open in the estero in the middle of downtown San Felipe.

The *San Fermin* turned toward Punta Estrella and soon dropped her shear boards. The net was streamed off the stern and disappeared into the murky water. The silt and mud from the Colorado River keep the upper Gulf constantly brownish with a visibility of at most three ft.

We dragged the net for a couple of hours before some porpoises hove into sight, leaping along. Our hope was to get close enough to them in our skiff to drop the grabber over them. All sorts of combinations were tried but never would the animal surface near the waiting collector.

After this experimentation we crossed San Felipe Bay and set the drag down again north of Punta San Felipe. Once again an hour passed before the porpoises came

again. The *San Fermin* was stopped and the trash fish scooped over the rail. Gulls and pelicans filled the air, arguing frantically with one another over the little fish which floated among them.

The porpoises came in under water. Occasionally we could see them through the murk as they picked up the sinking fish. Many times they blew under water, causing big boils of bubbles to well to the surface. Ever could we get close enough for a shot.

Fortunato Valencia, the skipper, told me somethig of the little harbor porpoise of the Gulf. He said that it was commonly called “vaquita” and that “cocinita” referred to a species which came in great schools to the bow, probably *Delphinus*. He said the vaquita was about four ft. long when adult. The dorsal fin was shaped just like that of the tonina he said. As for color, it was a uniform lead gray which became white on the ventral surfaces. He said there was no black line from eye to mouth as is found in the harbor porpoise of San Francisco Bay and northward.

Fortunato is an observant and sagacious old Yaqui Indian whose word and memory one has a tendency to trust. He told stories of catching the little porpoise in the estero north of San Felipe (15 miles). He stretched his totoava nets across the entrance and snared three of the little animals as the tide dropped. He also mentioned taking one in a drag net while fishing for shrimp. The portion of the gulf near the mouth of the Rio Colorado was the grounds where they often saw the little babies of the vaquita in May and June. The young were described as being two ft. or somewhat less in length.

He mentioned the story of a fisherman who was working near a small estero at Aqua Charlie, near Punta Estrella, south of San Felipe, who came across a mother and her baby stranded by the dropping tide. The gulls had picked one eye from the baby but when both were lifted over the bar they swam rapidly off into the depths. Another fisherman told us that the vaquita was commonly thought to be a “duende”. The translation of this word is loosely something like “a creature inhabited by a supernatural spirit”. This fisherman thought such notions came from the porpoise being so wary that it puffed to the surface once or twice and disappeared from view. All this was most interesting to me as we were speaking about an animal which was completely unknown to science.

We went ashore with all our gear to plot the next day’s operation.

January 25, 1958

San Felipe

This morning we got up before dawn and loaded the skiffs for a try at netting the porpoises with the big net. The air was calm but very near to freezing as we pushed out into the dark. We took a box of food for the Mexican cook, Olayo. Olayo stood adamant against the customs of the norteamericanos and refused to wear shoes even though the weather was cold enough for fur boots. His “Florscheims” as Boots called them, was a tough, brown and horny hide that covered his splayed, almost prehensile toes.

We dropped the trawl overboard and after a decent interval the toninas showed up, waiting for the expected meal. While they gathered around the boat as the catch was dumped on deck, Frank and Boots and I tried to circle them with the net from our two skiffs. Before the net was half out someone gave the alarm and they appeared lazily puffing along outside the cork line. The water was so murky that one couldn’t see three ft. yet they had sensed it and left the danger area.

At lunch Olayo brought out a meal of ham, eggs, potatoes, tortillas, beans, and salad. Lee Green, usually a cavernous eater, sat picking at his food, mumbling something about weighing too much and diets and all. He ate just a couple of tortillas filled with beans. We all noticed this and wondered if he was getting sick. After the meal was over he made it all clear when he told us that he had been peering expectantly into the galley when he spied Olayo trying to cut the tinned ham we had brought along. The galley is a peculiar affair where there is only room for one man, and he has to perch over an open channel that leads directly below into the engine room. This space allows the cook to yank the lanyard for the starting motor of the diesel engine. Anyway, Olayo couldn't keep the ham from sliding while he was cutting it so he used the simple effective expedient of grabbing it with his prehensile toes and soon he was slicing off sections with facility. The sight of this little brown man standing on lunch was too much for Lee, but he claims he didn't tell us as he didn't want to spoil our meal!! The inexorable conclusion is that Lee realized that his problems were all in his mind and that Mexican bacteria were not really involved.

The next try with the net was a beautiful attempt. The porpoises were lured to the bow by a man throwing fish to them. The net had been piled on the stern of the big boat and was now streamed into the water. The circle was only about 2/3 complete when the porpoises took fright and disappeared under the boat to come up, puffing on the other side.

At dark we left the boat and made for shore again. We decided that our next moves would have to be at night as the toninas were reported to be much less wary in the dark and to take bait readily. Fortunato reported that they ran the bow and would surface to blow. The photographers could not work in the darkness so they packed their gear and started homeward. They had been an interesting pair and well accustomed to the rigors of field work so that they were easy company to have along.

January 26, 1958
San Felipe

Frank wanted to get some of his gear ready for the night and we had decided to go equipped with the Indian Salmon Hook apparatus, so that had to be built. While Frank and Boots labored over their gear I took a long hike down the beach toward Punta Estrella. I wanted to see if I could pick up any skulls of the little vaquita. I found a few fragments including one skull in bad condition. On the way back I hopped over the beach dunes to the playa surface behind where hiking was easier than on the soft sand. I got my first view of a peculiar parasitic plant that the Indians used to use for food. They called it "sand food". It is a strange fleshy plant with a large thick watery stem, and a crown of little star-shaped purple flowers. The roots led directly to the roots of two nearby creosote bushes.

After a time I came upon the only giant cardon cactus I have ever seen in the vicinity of San Felipe. It must be one of the most northern plants of its kind. It is a battered old patriarch growing partially out of the dune mass.

At about 1:00 PM I walked out onto what is laughingly called the "Aeropuerto de San Felipe" and there met Frank and Boots who were waiting in the truck. My hike had covered about 14 miles and I was bushed a bit. It was good to ride the rest of the way.

At 4:00 PM we boarded the *San Fermin* and set our net off Punta Estrella. After dark we brought it up and had a big load of bait on deck as a result. Some very interesting fish were in the pile. There were wolf fish—very long silvery critters (*Trichiurus ites*) which the Mexicans called “liston”. There were the fuy little batfish that crawl on their fins over the bottom and which have a fishing lure on their nose (called “cameleon”).

At dark the weather began to turn bitterly cold. The sea remained as flat as a millpond however which proved to be a blessing later on in the night when we came to personal grips with a tonina. There was no place to retreat as the wheel house only held three people and two of the Mexicans were always sleeping and the galley only held Olayo and his Florscheims. So we stayed outside and froze.

Frank tried the bow with the grabber but the porpoise still refused to surface anywhere near him. It was very frustrating to see the big beasts a couple of feet beneath the surface, riding along steady as a rock. In fact Frank could stand it no longer once and took a shot which missed by just a couple of inches.

The skipper stopped the boat before we could get another shot and one of the deck hands, Rafael, began to throw bait over the side. We were literally engulfed in a cloud of gulls and pelicans, even though it was pitch-black night. The toninas came in under water and could be seen picking off the bait beneath the surface. They gave us no chance to use the grabber. Manuel, the head of the Cooperativa, had been rigging a line with a big totoaba hook. He picked out a small corvina and put it on the hook. After a few moments he got a mighty strike and the thin nylon began to whistle through his hands. The line was so small he couldn't get a grip. We jumped into the skiff just in time to see the last of the line streak over the side and disappear. Manuel was burned painfully across his fingers for his effort.

A more sensible rig of manila line was rigged and in a few moments we got another strike and the line began leaping from its basket into the murk. Boots and I jumped into the light skiff. Frank and the two deckhands jumped into the other. Just as we cast loose Manuel leaped into our boat with the line which we made fast under the bow. It was 2:00 AM and the case was on. The porpoise took us off at breakneck speed away from the *San Fermin* while Frank and his boys tried to get close enough with their skiff to put the grabber over the animal. No luck.

Finally Frank and his boys got close enough to us to try to tie up to our skiff. They were puffing and panting. Frank had been cussing us so thoroughly for not turning the porpoise (which we couldn't do) that he had actually run out of breath and all that was left were soundless gestures.

The porpoise pulled us on and on. Finally, Manuel who had hooked the porpoise and who thus considered himself in charge of this particular animal, untied the line to Frank's boat and asked to have the motor turned on. Frank let out a bellow including a variety of unkind words about the kind of knot I had used to tie him up (very unkind, I'd say). With the motor on we retrieved much of the line and finally got within about 30-50 ft. of the animal. We were really racing over the water now. I tried to keep the skiff after the animal by watching the faint line of phosphorescence it made where it cut through the water. A drag boat with its net down loomed up and swept past us with amazed Mexicans watching us as we flashed by. Luckily we didn't get tangled. Finally we met the panting men in the other skiff again and we tied them alongside, using the motor to

drive both skiffs. Sometimes we swept around and around as tightly as the skiff would go, following the plunging animal. Frank lept in our boat and he and Boots and Manuel brought the animal up short until just the leader line was out. As the animal swung around us this line would cut against the nearest man. A cry of “arrea” was given (slack) and the line let out before painful rope burns could result. This mad struggle went on until all of us were dragging. I took my turn on the line but my office-tenderized hands gave out long before my will was used up.

Boots lept in the big skiff and shortly had set a small portion of the porpoise net around the animal and our skiff. The big beast became entangled quickly and while the skiffs were lashed together Frank and I struggled to keep the animal's head above water. He was a monster. Frank could just get his arms around its head and I had no chance of making mine reach around its middle. The beast was probably well in excess of 10 ft. long and 600 lbs. in weight. Even with the skiffs lashed no one could help us for fear of having the skiff capsize. So on we struggled. The hook fell free and Frank noted blood from around the animal's eye where the leader had chafed it. Suddenly with a flip the animal wrenched from our hands and dropped into the muddy water and was gone. Later we found three small pieces of bailing wire tangled in the net which must have held the lead line off the bottom. Anyway it was dawning and we had fought the animal more than four hours and it was gone. Listlessly we rowed back to the *San Fermin* and climbed aboard. We decided that we had had enough for one day and so made for the St. Francis.

January 27, 1958

San Felipe

We took it pretty easy today resting from the all-night ordeal. Most of the time was spent wandering around the downtown shopping district of San Felipe and talking to the Mexicans. All of our crew was involved in a big baile, or ball, which was being given or one of the relatives of the captain. The guest of honor was being feted on her 15th birthday, which is something of an event in Mexico.

January 28, 1958

Up early and on board before the crew arrived. We began to wonder if they would make it after the big baile, but they did and we were off. We wanted a day to give our grabber a real try, and if it failed, to use the salmon hook on the tail stock of the animals. We tried all day and had only one poor shot with the grabber though the porpoises ran the bow many times. We tried to use the hook but we had nary a chance.

We spent half an hour observing the little vaquita. We followed two for a time. They were extremely wary. Their dorsal fins are very unlike those of any other *Phocoena*. They are very high and have a slightly recurved posterior border. The vaquitas always blew only once or twice before a long dive which was presaged by a curving of the tail stock. No flukes showed.

At the day's end Frank and I sat down in conference and decided to call it quits. Our reasons were manifold. We had been reduced to techniques which could just as well be done in San Diego Bay and there we would have a much better chance because we would be working from our own boat and would have a five hour run home instead of a sixteen hour one.

We thought that we would like to try a beach net operation of the type I learned about while in Washington. This method was used during the teens to catch *Tursiops* at Cape Hatteras. It consisted of stretching a fine net parallel to the beach and waiting till the porpoises ran inshore of it, then encircling them. Even though they were perfectly able to penetrate the net the porpoises would mill while a heavier net was set inside the light, maneuverable one. Then we would be able to take our pick of the porpoises and to handle them easily.

The other expedient would be to try the hook. Instead of hitting a heavy muscular area like the head or body muscles, we would aim for the tail stock which is sinewy and cartilaginous. Then, we felt that the process of opening the wound for cleaning was a bad one and may have done much more harm than good in previously hooked animals. The water would immediately contaminate the wound and reinfect it. Instead we would rely on shots of antibiotics in the wound area and intra-muscularly to bring the animal around. Both of these methods seem promising to us as a source for this most difficult of animals. Our resources are not yet exhausted. So we packed our gear and got a little sleep.

January 29, 1958

Home

After a little walk along the beach north of San Felipe we drove home, having no trouble at all with either customs. Frank made his escape without ever getting hit for the three-dollar fee, and is probably still gloating about his success.

Sturgeon Trip: November 1955

Reconnaissance Trip to British Columbia: September 14-27, 1957

Letters from Hawaii: September 1959

Sawfish trip to San Blas, Mexico: February-March 1960

Sturgeon Trip: November 11-16, 1955

November 11, 1955

Never underestimate an Italian or his curses. Both proved their worth on this trip. Dagos, as Frank and Boots prefer to call themselves, have a strong superstition that no new venture should ever start on Friday. Oblivious to all this I scheduled our trip to start Friday night. We were headed for San Francisco Bay to try for sturgeon. These peculiar, archaic fish live in the Sacramento River and in the upper part of San Francisco Bay, or San Pablo Bay. Early in the century they were fished unmercifully until they became practically extinct. In 1921 they were placed under complete protection. Last year they became numerous enough again for them to be fished by sportsmen during a limited season. Dr. Calhoun, Director of Inland Fisheries for California arranged for us to capture a few of these strange fish for display, in exchange for our cooperation in their program of study relating to the biology of the sturgeon.

We loaded our big truck and put aboard a few fish for the Steinhart Aquarium and left Marineland at about 9 PM. It was bitter cold on the Ridge Route. I was worried for fear the temperature in the fish tank would drop so low that the fish would die. They were subtropical grouper and cabrilla and had been living in the uniform environment of our tank for a long time and probably could not stand very low temperatures. I decided that we should shut off the aerator for a while. Most of the heat loss occurs as the water is sprayed through the cold air. Cold fish breathe very little and can go for fairly long periods without aeration. We stopped in the valley below and Boots looked at the fishes and found them doing well. The rest of the drive to San Francisco was uneventful but enlivened by stories about Frank's numerous relatives. He seems to have an inexhaustible supply of Mafia members, pecan farmers, and clothing dummy manufacturers among his family.

We found Steinhart Aquarium at about 11:30 AM and finally unloaded our animals safely into their new homes. We caused quite a stir charging among all the spectators with our stretcher containing a flapping grouper.

I made a brief stop at the Museum of Vertebrate Zoology to check some porpoise skulls important in our forthcoming description of a new species of porpoise from the Gulf of California. Frank and Boots went out for coffee. Dinner and a motel room and some much needed sleep.

November 13, 1955

During the night it had begun to rain and by morning the wind was blowing from the south and the rain fell in a blinding shower. The road took us up along the shore of San Pablo Bay, past the Carquinez Straits where the Sacramento River enters the bay, to Antioch, where Cal. Fish and Game has a field research station. We poked around the

river, looking at all the boats and watching the diehard striped bass fishermen huddled in the rain along the banks. A truck carrying hot soup could have made a fortune for a man on a day like that. Back at Antioch we signed in at a motel and went to a show—something about the south seas and black pearls. I was struck by one sequence where Dennis O’Keefe and Virginia Mayo wrestle with a giant rubber octopus in a freshwater lagoon which guards an underwater cave full of sacred black pearls. All ended well, however, with the hero making off with Virginia and the villain first getting stuck through with a great spear and then getting blown sky high by a lot of black powder.

Back at the motel we squashed the black widows we found lurking by the furniture and then listened to some more of Frank’s relatives and went to sleep.

November 14, 1955

We were up early and down at the field base. Shortly a state car drove up and a swarthy fellow shouted a lot of unintelligible words at us and waved his hands in circles. Another dago! This one was Vince Catagna, the fisherman for Cal. Fish and Game and he was waving to us to come have some coffee. We met the others, John Skinner in charge of the research on sturgeon and striped bass, Bruce Kimsey, another biologist, and a summer assistant. We drove to Carquinez Straits and boarded the little research vessel *Striper*. She was about 27 ft. long and had a big net reel mounted on the stern. I saw Frank and Boots eyeing the trammel net wound around the reel. They picked up the strands of webbing a silently inspected the knots and the twine. Without uttering a word they told me that the net was somehow “no damn good.” It wasn’t either. Before we were through it had ripped in 20 places and the largest fish had gone through.

We pushed out into the river and downstream to the entrance into San Pablo Bay. It was biting cold, windy, and overcast. John Skinner told me a little about the sturgeon. There are two species in the bay—the white sturgeon that reaches over a ton in weight and 19 ft. in length and the green sturgeon which seldom exceeds 300 lbs. The green sturgeon is covered with a series of extremely sharp, hooked plates which make it extremely difficult to handle. It has a long, hooked proboscis in addition. The white sturgeon is much less dramatic except for size. One was recently taken up the Sacramento River that had 350 lbs. of roe. This roe is the basis of the finest caviar and sells for \$3.00 per pound on the hoof. John and his crew had tagged over 1,000 sturgeon in the year past and one had been recovered far up the Oregon coast.

Strangely enough these peculiar, sluggish-looking fishes are far from sluggish and constantly jump out of the water. We saw perhaps 15 fish leap into the air during our few hours on the bay. The power of the sturgeon is great and fishermen fear to bring large ones aboard as ribs have been broken and boats splintered.

We set the nets twice before our fish hit. We could see them thrashing around in the trammel. We reeled the net in and the fish were hauled aboard and tagged. They simply lay stretched out on the deck on the trip back, which took about 45 minutes. This exposure seemed to do them no harm. Boots was down below peering at the hull of the *Striper* and he told me that we had lost the biggest fish as they tore through the old net. “Our net would have held them,” he said, as he poked at a couple of cracks in the stem of the boat.

We loaded the fish into a stretcher and ran them up the dock. They swam off into the depths of the tank as if they had never been out of water. We drove off down the road

and stopped at a big motel in Port Chicago. We rented a palatial suit of rooms for \$7.00 per night and set up a four-hour watch on the pump truck. The little auxiliary banged away evenly until my watch. Then at 1:30 AM it stopped. I rushed out, thinking an irate inhabitant of the motel had shut it off to stop the din. I started it again and it ran very unevenly. Finally I found that a little access plate had come loose and had fallen into the governor, shutting off the engine. This was easily fixed so things went well until morning. After breakfast we started for the Martinez dock, where we were to get striped bass. About five miles away the truck started to make an awful banging. Various theories were advanced but the only concrete thing we knew was that the oil bath had been blown off the top of the carburetor and had spilled oil all over everything. We limped into a nearby gas station, popping and banging. When we were 300 yards away from the station the attendant had our case diagnosed properly. He said a valve wasn't working and that raw gas was blowing back into the carburetor. "Lucky you didn't have a real explosion and a fire," he said. A couple of hours and \$7.50 later and he had it fixed. Boots and I went on down to the dock to find the others out on the *Striper*. We looked over every boat in the bay including a lot that were "built in the dark of the moon with an axe in the backyard"—or so Boots said. Then Boots found a nice little white-haired man waving his hands in the air while talking to a tugboat captain. Sure enough he was a "dago." The rest of the day was spent exchanging uncles and aunts and fishing advice, amid much gesticulating. I enjoyed it all but have not yet mastered all the gestures.

Finally the boat came in with no fish and we jumped in the truck, said our goodbyes to our new friends and started for home. We were all anxious for the welfare of the sturgeon who had been in the tank too long already. Darkness found us on the main highway. The truck traffic on Hwy. 99 is incredible. I counted 298 trucks and semi-trailers in about 45 minutes of driving.

Temperatures were near freezing as we started up the Ridge Route. A long line of creeping trucks wound up the 6% grade. When we were nearly to the summit I noticed that the temperature of the motor had begun to climb. Almost as soon as I noticed it, it was boiling furiously. We stopped amid great clouds of steam, which poured from the exhaust manifold and the muffler. People behind us could not see for the fog. We let it cool for a long time while we shivered in the cab. Boots and I worried about Frank's arm, which troubles him when it gets cold. Finally we filled the radiator with the only water we had—salt. Off we went and made it over the crest two fills later. It was so cold Frank literally could not hold a flashlight on the radiator cap for me to pour in the water. He was shivering too much. Finally we came to Castaic and stopped in a station. We got a cup of coffee and drove down the road to a garage. It was dawn and we had to wait until 9:30 before the mechanic came. He opened up the garage and lighted a big drum stove. We clustered around it, soaking up all the heat given off, like sponges. Our problem was a cracked head he thought. We waited and finally got a new head. It was replaced by about 2 PM. We watched the motor turning over merrily as we breathed sighs of relief, feeling that at last we must be free of the Dago Friday curse. Then I tore a great hole in my pants. He was still with us. Then the truck inexplicably bent a push rod and a valve and stopped with a cough. He was definitely with us. I took one look at the dejected tired faces of my buddies and decided that a picture was in order. I took out the camera and something fell with a clatter. Somehow the slide had broken on the film pack. The old dago monster was going to far. On our way up I had seen the patron saint of collecting

trips twice. His name is Dr. Vandenburg and he is generally an old, wrinkled, white-haired man trudging along the road with a pack on his back and a scraggly beard on his face. If you see him, the collecting is bound to be successful. Our collecting had been good but it wouldn't be unless we got the fish back alive. So, we were having a battle between the Mafia and Dr. VanDenburgh while we stood by watching and got our pants ripped.

Finally at 4 PM the truck was fixed once again and we drove the rest of the way in uneventfully, arriving at Marineland at 6 PM after about 40 hours without sleep. We hoisted the fish into the flume and noted that three out of the seven fish were in poor shape. I guess it was a draw between the good Dr. and the Mafia.

Field Notes—*Tursiops* recon.

June 26, 1956

Frank, Boots, Bill McFarland, Dave, a photographer, Dick Miller, and I left for Ensenada to find out the haunts of the Pacific bottleneose dolphin and, if possible, to try to capture one or two specimens. We went in two trucks. Just north of San Diego the big truck began to clatter and lose power. We feared a broken valve but it was only a tappet which had come unscrewed.

At Imperial Beach we drove down the City Dump road to San Diego Bay. There we were greeted by the sight of a new Buick up to its haunches in the rising bay waters. The most unconcerned owner finally came up in a speed boat. He didn't seem to care whether we pulled him out or not but we did anyway. The guy didn't even steer his own car but stood idly by while Frank and Boots tied the lines and Boots steered his car. He didn't even seem to care that we succeeded. He non-committally took us for a ride in his boat, noting that he had seen porpoise (large, dark-gray ones—obviously *Tursiops*) in the lower bay around anchored navy boats and fairly near to the salt works. This water is 20 to 30 ft. deep at high tide. Frank thinks they can be caught by ringing them with a net of proper mesh size (15-20 in.) and 35-40 ft. hung depth.

We found great shoals of *Fundulus parvipinnins* among the grass and *Salicornia* fringing the water's edge at high tide.

On down to Ensenada where we took a room facing the bay. The room was typically Mexican in that the planning was grandiose but the execution incomplete. The john blocked the passage between the two rooms and the shower with three knobs gave off only cold water. There were three plastered-over doors.

By quizzing local fishermen we found that *Tursiops* often comes up along the coast and into Ensenada harbor where the big animals play among the anchored ships. Generally they come following anchovy schools, it was stated. We were also told *Tursiops* never went into lagoons. This I knew to be false.

We inspected a dead porpoise on the beach about two miles below town. It proved to be a young *Tursiops*.

June 27, 1956

After breakfast we drove to Estero Beach. There we met Johnny Nash and quizzed the local inhabitants who live at the mouth of the Estero de Punta Banda. I suspected these big porpoises go into this lagoon. A few men had seen them in the lagoon once or twice during this spring. The closer we got to the water the better our reports became.

We rented a couple of skiffs and set out to recon. the lagoon. Two large sand bars could be seen from the north end of the lagoon. These were about 300 yards south. We counted 38 harbor seals on one and saw others in the turbulent waters of the entrance. As we cruised up close to them they all jiggled off the bar and disappeared. The Estero waters were clearer at the mouth and became more and more opaque as we went farther up the lagoon. About a half mile down the lagoon we stopped by a little float adjacent to a trailer camp. We asked about porpoise and were referred to Antonio (Tony) Perisky, an old Slav fisherman who had lived on the lagoon for 35 years. He lived in a shack on the sand spit across the lagoon.

Mac had been sitting in the skiff witing for us. He noticed a school of young-of-the-year opal-eye around the floats. They were quite large (about 35 mm). I wonder how many come into the warm lagoon waters? The areas near the lagoon mouth are all sandy. The nearest kelp beds and eel grass beds are 4-5 miles south. But somehow these fish found their way in.

We cruised over and met Tony. He was a gray-haired, weatherbeaten man of 65 or 70, with sparkling blue eyes and a kindly face. He answered our questions carefully in perfect English. I have every confidence that his observations are thoroughly accurate. He told us he often saw porpoise in the lagoon—once or twice a week. Usually they came in at high tide but ocasionaly at other tides. They went clear to the south end of the lagoon on occasion. Groups of two or three to 30 animals had been seen. He could only recall one kind in the lagoon. These, he said, were dark gray and some were very large. He would guess that some dead ones he had seen ran 18 ft. in length—anyway, longer than his 16-ft. skiff. During the war years (1941-1945) he had fished the lagoon for soupfin sharks and had caught tons of this fish in gill nets. Many times porpoise had gotten behind his nets but they had always skirted the nets and swam away. This occurred even though the water was virtually opaque most of the time. His nets were nine in. stretch mesh and tied of heavy cotton twine. He had seen the *Tursiops* harrying the schools of croakers that come into the lagoon and had, several times, seen them toss 2-3 lb. croakers into the air and catch them again as they fed on the fish. He reported that schools of *Tursiops* were even more common along the surf outside the lagoon where they stayed all year. More were noted in summer than in winter, however. He told us that before the war (1916-1941) he had lived at the mouth of the Estero where the motel is now. Many times he had seen killer whales come into the lagoon after the harbor seals. They never came farther than the first sand bar. He recalled seeing an adult with the tall dorsal fin rush after a seal at San Martin Island and strand himself on the rocks as the swell receded. The next wave floated him off.

The old man had fished lobsters all along the Baja coast and had once had a camp on Natividad Island. We left him after inviting him to come to Marineland as our guest. We cruised through the whole lagoon and sounded two of the narrowest parts. In each case the water was about 25 ft. deep. The lagoon is surprisingly narrow and straight

throughout its length. The old man had told us that it had been much wider when he first came in 1916 (from his description about twice as wide). The lagoon is now about 100 yards wide throughout its length, widening at the blind end into a broad shallow bay. A few channels run off the main lagoon on the inshore side and two or three narrow ones on the sandbar side. Tony had told us that the year he first came to the lagoon he had seen a gray whale enter the lagoon mouth and swim down to the first sandbars and turn and leave. He said there was the skeleton of a whale in one of the shallow inlets about half a mile down from the entrance on the inshore side.

It looks obvious to me that alluvial materials from the two large arroyos are tending to narrow the lagoon.

We cruised down to the spit at the entrance and landed there. I found the body of some sort of a cetacean about 16 ft. long. The skin was still on in some places. The flippers looked broadly oval and no pattern could be made out. The skull was buried in the sand. I tried to reconstruct it and put together the basicranium and picked up the ear bones and the bones of the palate. I could not tell what it was.

We went back to town and spent a little time on the pier looking for *Tursiops* but none appeared. That night was spent in Tijuana and the next morning we made a few sets at Imperial Beach for *Fundulus*, taking 2-3 thousand. Then to Marineland and home.

1957 Reconnaissance Trip to British Columbia

September 14, 1957

The first stop was Santa Barbara where we visited the Marine Station and inspected the water system. The water circulating system at Santa Barbara is quite interesting. A sump is set in a hole in the shale which underlies the sand along the beach, the surface of which is about a foot and a half below low tide. This sump extends down about six ft. below this level and is filled with graded gravel and sand. At the bottom is a transite arbor infiltration plate and this connects with a transite pipe which extends from the infiltration gallery up the beach. This transite pipe is cemented in place in this trench cut into the Monterey shale. This pipe extends up to two centrifugal pumps, one being a standby. The system by which the water is sucked out up the infiltration pipe is most interesting. There is a circuit of pipe which extends from the storage tank past the end of the transite pipe leading from the infiltration gallery and back to the storage tank again. The centrifugal pumps are in this line. As the water cycles through this circle it passes a venturi at the end of the transite pipe leading from the infiltration gallery. This serves to suck the water from the sea filter into the system. If 60 gallons of water are recycled through the system the 40 gallons of new water are brought in by the venturi into the storage tank. There are two storage tanks up on a hill above the laboratory. The water comes down to the laboratory by gravity. It is discharged into a lagoon on the other side of the laboratory. Wet benches are used in the laboratory which are coated with a very heavy grade of building paper. This tar paper has been covered with a good many coats of a paint which is known as Gilsonite or Gillicote (Fuller trade name). This gives a hard, resilient black finish to the building paper which seems to make a very nice top for the

water tables. In the back of the marine lab there are two tanks which are made of fibre glass. These are about six in. deep. They have two overflow pipes at the center of each of these tanks. The water comes in from the top and overflows into these center standpipes. These look like very efficient holding tanks for small fish. The air lines running through the laboratory are made of copper and the water transport lines are plastic and have given good service. The plastic was not Uscolite. The air lines were discharged through very small pet cocks, and allowed the use of small diameter rubber tubing to the airstones. This is better than the system we have at Marineland. Most of the tanks which were used were small redwood storage tanks with glass on one or two sides.

Next, we went up the coast to Monterey and made an attempt to get into the Hopkins Marine Station but found no one there. We walked out on the fishermen's pier at Monterey and somewhat to our surprise found an aquarium in operation there. This aquarium was named the Wharf Aquarium and is run by Mr. and Mrs. Nelson Hyler. The aquarium was small but was well lighted and extremely neat. It was, I think, a good show and worth the 35 cents they charged for admission. The most useful piece of information we gained from talking to Mr. Hyler was with regard to small display tanks which he had hung on the walls of the aquarium. These were covered with a sort of a framing set out at an angle from the wall so that the tank appeared to occupy a blister on the wall. This frame could be lifted and was hinged at the top. To service the tank the frame was lifted and the tank exposed. This system used single tanks which were independent of any continuous water supply. They were heated with a submersible thermostat and each had a separate aeration system. This sort of display could be very useful at Marineland for the spaces between the columns and could be adapted to a large number of different sizes of tanks without much trouble. I think it would be a very useful thing for adding to the number of displays at Marineland for a very nominal cost.

He had a seal tank which was made of fibreglassed plywood and had had it for two years. He said that he had had no trouble with it at all. It looked in excellent condition. Amongst the displays were a number of standard freshwater aquarium fishes such as the blind Mexican cave fish, the electric catfish from Africa, neon tetras, etc. Piranhas were there. He also had one electric eel. He had a small bank of saltwater tanks on the other side of the aquarium which were serviced by water pumped from the Monterey Harbor and discharged back into it without any recirculation. These were made of concrete. The concrete was a special lightweight type. It was soft enough so that you could dig your fingernail into it. Each had a metal rim at the top which Mr. Hyler admitted he didn't like. He was using a plastic recirculation through his aquarium. He seemed to think that he was the first one to do this but this is not so, of course. He was contemplating installing a porpoise tank out on the end of his aquarium in a space of about 20 by 30, planning on a tank about five to six ft. deep. He was interested to know if he could obtain a porpoise from us. He had two octopuses which he kept separated in cement tanks which were approximately 4 ½ ft. long, 1 ½ ft. from front to back, and about 3 ft. deep. He said he kept these octopuses on the average of 4 1/2 months. Apparently he never kept them together. His water temperature was at about 60 degrees when we were at the aquarium and he said it did not rise above this. I was impressed that the major part of his display was composed of standard aquarium fishes and yet it was very attractive and certainly was the mainstay of his exhibit. It seems to me that we are missing a good bet at Marineland by not putting in some such material here. He had a

specimen of *Girella nigricans* in one tank and said that about 120 of them had been taken at one time in Monterey Bay by a gill netter. These were the only ones he had seen in his two years on the pier. He is an instructor at San Francisco State College.

September 15, 1957

We started out this morning from Monterey and went directly to Pt. Richmond where we talked to a couple of men who were fishing there. They seemed to be old residents of that area. They mentioned seeing porpoises swimming behind or with the San Rafael ferry. This ferry is no longer operating. Their description of these animals was very sketchy but we did find that the animals were apparently quite large. One man thought they were about 14 ft. long which sounds doubtful and four tons in weight, which sounds even more doubtful, that they probably had pointed noses and that they were probably gray which sounds a good deal like *Tursiops*. They could tell us nothing about *Phocoena* in the Bay but directed us towards the whaling station which is on the north side of Richmond. Before we left they told us that we might be able to obtain pictures of the porpoises that swam with the ferry from the Richmond Independent, a newspaper which apparently has published these pictures in the past. The Whaling Station is on the north side of Richmond at Mapelo Point. The station is a large building with a rampway out in front which extends into the water. The whales are hauled up onto a big vacant floor and there flensed and sawed with big rotary and straight saws. No one was at the plant when we were there so we left. We went across the San Rafael Bridge and stopped at its base and asked some people at the Rod and Gun Club there if they knew anything of these porpoises, and they said they knew nothing of any porpoises in the bay but were familiar with ones outside. We then went down to Stinson Beach via Highway 1 and stopped to talk to people at Bodega Bay. There we talked to a skipper of a fishing boat and he told us that he had never seen any porpoises inside of Bodega Bay but had seen animals a couple of miles outside the entrance. His description sounded very much like *Lagenorhynchus*. We left Bodega Bay and continued north along Highway 1 to Fort Bragg. At Noyo, just south of Fort Bragg we talked with a man who was reputed to know a good deal about fishing conditions. He told us that they were having an extremely warm year. As evidence of this he said that the water outside the entrance of the river was at 60 degrees on the day we were here and is usually somewhere around 42 degrees at this time. He mentioned that there had been two opah taken in this area. He also mentioned the presence of white sea bass which had been taken locally, that blue sharks had been seen in this area. The ling cod which usually come into shallow water around this season had stayed in deep water. He said that there were no anemones locally which would be good for display but suggested that we go to Tillamook Jetty in Oregon where he said there were many beautiful examples of different colors. Once again, there seem to be no *Phocoena* here, but he mentioned seeing animals which sounded like *Lagenorhynchus*. These animals were supposed to be about three miles offshore. He felt that the poor salmon fishing season was connected with warm temperatures. His name was Mr. Reese.

September 16, 1957

We started today from Fort Bragg. We might mention before going any further that while talking to Mr. Reese at Noyo, he said they had seen a sea otter offshore lying on its back and feeding on what they presumed to be an abalone. Apparently the

fisherman had had a good chance to observe as he knew what the creature was. We came up the coast and finally got on a main highway after a long delay and went to Humboldt Bay and Eureka and went to the fish docks there and were unable to get any information of any value to us. We then went on up the coast to Crescent City and went into the Crescent City Aquarium which has many earmarks of a McBride operation. When you go into the entrance of the Crescent City Aquarium you have to enter through the gift shop which is cluttered with all kinds of junk, all sorts of shell lamps, and then you go into the Aquarium itself. The admission charge is 50 cents and the Aquarium consisted of a small room about 40 ft. long and perhaps 20 or 25 ft. wide. The displays were very small wall tanks, I would say not much more than a foot by a foot in some cases, up to larger tanks that were perhaps three ft. long. Under them were tanks into which you looked from the top. These extended out underneath the tanks above so that you could only see into part of them. These were considerably larger than the upper viewing tanks. The most impressive display they had, as far as I was concerned, was an anemone display composed almost entirely of white *Metridium* anemones and a few *Anthopleura* anemones of a lemon-colored shade. They had one harbor seal outside and you could also see him inside. Its name was Bubbles, interestingly enough. They had one sealion. Other displays were of the seatrout or greenling, *Hexagrammis*, a number of rock fish, a few star fish, one small wolf eel, a 20 lb. octopus in one of the horizontal tanks on the floor, one raja maclata, some starry flounders, and an exhibit of small flatfish which was very unimpressive. They had an exhibit of tube dwelling worms which was interesting but badly done. The room was dark and the ceiling was hung with nets. Altogether it was a most unimpressive place to me. I would say that a quarter of the display was made up of anemones and about half of what remained made up of rock fish. A little separate room adjacent to the aquarium room was called the whale room. It contained a pickling vat which had a 12-ft. foetal finback whale in it and also a pickled pilot whale, which they called a killer whale. They had some foetuses of humpback whales and some other mementoes of the whaling industry plus such things as an ice cream machine and some old beat-up typewriters and other things of the sort. They also had some exhibits of pipefish. They called the pipefish a "rare needlefish." There were several things in the aquarium which made me think they had some southern California connections, probably McBride, and the pilot whale was one of them as they're quite uncommon along this coast and of course are very common in our area and the pipefish was another. We went down to the community dock where the fishing boats tie up and talked to three different fishermen and were able to get some information. They have seen no porpoises in the harbor at all though they do see some porpoises offshore, around the St. George's Reef in particular. One of the fishermen had seen some recently. His description fits *Lagenorhynchus* perfectly. We got no reports any place along the coast of any harbor porpoises. We asked about the warm water which is prevalent offshore this year and he said that they had had a tremendous influx of blue sharks which had consistently taken the bait off of their hooks. Also when they'd catch a salmon the sharks would leave them nothing but the head. They mentioned that the salmon fishing had been extremely poor. They had had a very bad season and they blamed this on one of two things—either the warm temperatures or on the fact that the stocking four years ago had been interrupted by a flood and so that it hadn't occurred in that year which would be presumably a part of the catch which would be returning this year. He mentioned pulling in his crab trap and

feeling that they were still warm from having been brought up from the bottom which indicated to him that there was warm water down to the bottom, which sounds reasonable. He mentioned an influx of *Velella*, the “by the wind sailor,” which he, of course, called the Portuguese man o’ war. He mentioned that one man had taken surface temperatures here in an attempt to avoid the areas where he couldn’t catch anything. He had recorded temperatures as high as 69 degrees and this was about a hundred miles offshore. Local sea temperatures are somewhere around 58 to 60 degrees now.

September 17, 1957

We drove across Oregon today and made our only stop at Corvallis. There we visited the laboratory of Peter Doudoroff who works in conjunction with the U.S Public Health Service and the Fish and Wildlife Service and the Oregon State University and the Oregon State Fish and Game Department. He is the head of the Fisheries Dept. at the University. After leaving the laboratory we came to Portland and took a room for the night where we will tomorrow visit the Washington Park Zoo and continue northward to Point Defiance and Seattle.

September 18, 1957

Our first stop today was at the Washington Park Zoo in Portland. This zoo is a small affair on the side of a hill. Some of the buildings are very old and in need of repair—or better still—replacement. However, as a general rule the place was quite neat and the animals looked in good condition. We inquired to find out the status of the Portland Aquarium and found that it had not been built. It had been taken off the budget because of building expense and had been indefinitely postponed. Parts of the new zoo are being built over the hill in a canyon. The bear pits were already practically completed. The impression I got was that they will be bringing in a director for this aquarium section, presumably a Curator at such a time as it is built. We left Portland and continued on towards Tacoma and finally came to the Port Defiance Park, which in my estimation is rather difficult to find. The signs leading to it are small and it would seem rather easy to get lost. The park itself is a very pretty affair set on a point which extends out into the southern end of Puget Sound. It’s all covered with many kinds of trees and is quite beautiful. The aquarium itself sits in a very old frame building which is partially on a pier connected with a boat dock. It’s a two-story building and the aquarium occupies the lower floor. What was in the upper floor I do not know, probably some kind of storage. We toured through the aquarium which has about 40 tanks in it, some of which I would say were about 250 to 400-gallon capacity and the smallest tanks I would say ran somewhere around 40 gallons. The displays were varied and included a large number of very interesting invertebrate animals. We met the director whose name is Cecil Brasseur. He’s a very personable fellow. I would say he was in his forties, obviously a good aquarium man and one who handled his animals well and took considerable care with them.

The saltwater circulation system began at a pipe about six in. diameter which was strapped to one of the pilings at the end of the pier. It extended down into water about 25 ft. deep. It ended about five ft. above the bottom. Water was sucked out of this pipe, I presume to keep the kelp from going over the intake of the pipe itself. There was another pipe extended down into this one of larger diameter. The tidal range is about 12 ft. in the

area and their intake must have been extended below this level. They use direct drive centrifugal pumps. The water was circulated through what looked to me like Uscolite pipe. This extended up to the aquarium, the pumps supplying about 80 gallons per minute, part of which went into a bait tank system in another part of the pier and the remainder into the aquarium. They were getting somewhere around 50 or 60 gallons a minute into the aquarium itself. Then the water went into galvanized pipes which distributed the water over each of the tanks. From the galvanized tanks a T came off, went through a small valve and then dumped into the separate tanks. There was no recirculation at all in any of the tanks except for one tank which held a garibaldi. It was heated with a small aquarium heater. The small valves on the inlet to each tank were for the purpose of allowing the main pipe to be backwashed with hot water to kill the nauplii of barnacles encrusting inside the pipes. He said he did this once every couple of months. His valving was so set up that he could run this hot water into the pipes, close off all the tanks and then release the hot water out to drain. Once the water was in the tanks it spilled over with a conventional overflow into a channel which ran between the tank banks. The channel was coated with a heavy grade of tar paper. The water merely ran by gravity down in this channel and back into the Sound again.

The worker cleaning the tanks walked along a cat walk which was suspended over the top of this channel. The tanks themselves were made largely of glass. They had metal framing and this metal framing was obviously of iron and was in extremely bad shape. The number of invertebrates he kept attested to the fact that he was getting no contamination of any significant amount in the tanks from the galvanized pipe or brass valves. I presume this was because of the large flow which ran through the pipes. I'll go through some of the displays which were in this aquarium. First he had several displays of anemones from the Puget Sound region, including a nice display of *Metridium senile* which is common along our coast as far south as Point Conception. He had some very nice *Tealia* which apparently are relatively common and can be obtained at the lower part of the intertidal zone or just sub-tidally in this area. They didn't cling to the pier pilings but were much more common on the rocks and therefore were a little more difficult to obtain. He had a couple of species of *Cribina anemones*, some of which were extremely beautiful. He had our local form of *Xanthogrammica*, and he also had a species of *Tealia* with a beautiful reddish base and transparent tentacles. It was quite a beautiful thing. Next, the octopus tank. He told us several interesting things about the octopus. He is able to keep octopus as long as two years in his tanks here, his water temperature ranges between about 45 in the winter and up to about 54 degrees in summer. He said that he had difficulty keeping any of the large octopus alive for more than a couple of weeks up to a couple of months. Therefore he didn't even try to keep them. He was able to keep the smaller ones and preferred animals to weigh in around 20 lbs. He stated that he found it much better to keep the octopus in a small tank where they didn't seem to batter themselves. He also found that the ones he had in storage looked better than those in the observation tanks. This is the same sort of thing we've observed. He felt that this was due to the fact that the octopus was kept in constant light in the display tank and was allowed to be kept in the dark in the storage tank. He mentioned that he had tried to provide octopus with shelters made of glass jars into which they could creep and yet in which they could still be seen. I don't recall what success he said he had with this. The octopus are said to disappear here in the month of July. This is the same sort of thing we have in

the south. They seem to be obtainable in as little as five ft. of water and are caught right of the dock at Port Defiance. He had a tank with dog sharks and leopard sharks and a couple of rajids. On the other side had had a series of misc. tanks holding such things as the swimming scallop shells, the purple-hinged scallops, and a series of sea cucumbers. Some of the Echeuroids are beautiful things. They extend tree-like tentacles out one side of their body and actually fish in the water with them, straining out small particles. Periodically they insert one branch into their mouth and withdraw it. Then they insert another one, etc. Some of these animals have bright-red branching tentacles. Then there were sea quills which were bright orange in color. They are fluffy creatures which are phosphorescent at night. These animals are eight to ten inches long. He said they were easily obtainable in the Nisqualli Flats area of Puget Sound at low tide and that he dug them out like clams. He had a number of very interesting small fish—perhaps the most fascinating of all was *Rhamphocottus*, called the sea pig. It is a very peculiar little cottid fish, which actually creeps around on his belly. It's the weirdest little creature I ever saw and immediately attracted the attention of all of us. The fish lived in little bottles. They were the most grotesque fish I have ever seen and would make a wonderful small tank display. He also showed us the sailfin blenny *Blepsius*. There were several other blennies with tremendous quantities of cirri on their heads, of various sizes and shapes, all of which were very interesting display material. He showed us the Irish lord which is a large cottid fish, with mauves and wine red color, whites, and a very very striking creature. Then we saw an *Enophrys bison*, another cottid which is not as pretty but is a striking animal.

The sand launces were in another tank and were very interesting. He had the sable fish and several species of rock fish in various tanks. As a whole his fish display was not too exciting with the exception of the *Blepsius* and the *Rhamphocottus*. He had displays of various mollusks in the area including the geoduck (gooey duck). It was in a tank by itself and was rather an obscene-looking object. It made an interesting display and apparently caused quite a lot of comment because a lot of people didn't believe there was such a thing. There's nothing in his labelling system or in the display methods which is of much value to us because it was all very archaic. Another display which I must mention were Serpulid worms, some of which are very beautiful. One tank was virtually filled with tube-dwelling worms which must have been more than a foot long. The tubes were considerably more than a foot long ending in a plume of purple and greenish gills which are extended and which could be made to retract by tapping the glass. They would retract very quickly and then extend again. These are apparently very common on pilings in this area and I think would make a perfectly fabulous display for Marineland. In one tank he had a display of wolf eels which were impressive. I might mention that in some tanks he had let the glass separators, the glass walls in the tank, the front and back get covered with Bryozoans and also with barnacles. One tank was encrusted with tunicates. These made a very effective display because the barnacles were kicking their legs out of their mouths constantly and making a lot of motion which made a very interesting sort of backdrop for the tank.

Mr. Brasseau told us that they were planning to build a new aquarium at some time in the future as part of a program of expansion of the parks and recreation facilities of Tacoma and that his section of it would amount to \$250,000. He hoped to build an aquarium consisting of a series of tanks around a central tank which would be something

like 60 ft. long and 20 ft. wide in the center of which would be an island. This island was for the purpose of blocking the viewer's vision across the tank so that he would have a continuous view around his island. I think this is a very good idea. The admission charge was 25 cents, and I think it was well worth it. Outside the aquarium he had one Galapagos penguin which he had had there for some time. This was a true Galapagos penguin and not a Humboldt penguin like the ones we have. He said that in the wintertime he had to give it shelter. I thought this was kind of ironic for a penguin. He had the largest harbor seal I've seen. It was a big male that had been in captivity for 19 years. He was really an enormous old beast. He must have weighed 400 to 500 lbs. He also had some smaller ones, including a baby one that he was trying to save from starvation. It had become starved and his method of force-feeding it was quite interesting. He had a syringe with an enema attachment which I'd say was about 15 to 17 in. long. He filled the bulb with milk in which he had dissolved penicillin tablets. He inserted the tube into the little harbor seal's mouth and pushed it clear down into its stomach. Then he slowly forced the milk into the seal's stomach. He said that if he did this too fast the animal would regurgitate it all and that he'd have to start over again. He had had one harbor seal that had begged to have this done to it. He said that he had to make the little seal defecate first before it would keep the milk down. He did this by pushing it into the cold water. After it was finished with its milk he put a herring in its mouth and very gently held the little seal's jaws closed and massaged its throat so that it swallowed the fish. It swallowed three in this manner without any trouble.

I might mention a few things about the boat facilities here which were very interesting. They had put in a new pier which included a large, broad landing area on which they had many skiffs stacked. They had a hoisting device for boats which consisted of a platform which was raised by four cables. A person wanting to lower a boat merely rolled the boat onto this platform and moved his trailer off, then got into his boat, and was lowered into the water and floated out over the platform and rowed out into the Sound. When coming back in, he merely rowed into this garage-like affair and the platform raised up underneath him and lifted him back on top of the pier. It seemed like a wonderful way of doing things. In our particular situation, Frank thinks that the surge would make it unusable. Mr. Brasseur said that he would be glad to help us collect at any time that we wanted to come up this way, and I think he would be a wonderful person to work with because he obviously knows the area well and seems to be a good collector.

We left the aquarium and drove directly to the Woodland Park Zoo in Seattle and there met the director, Dr. Johnson, a very nice fellow. We discussed the sea otters with him at some length. They still have one in captivity. We took a look at it. It's one of the most remarkable beasts I have ever seen. Its skin was as limp as it could possibly be around the animal. He seemed to move around inside of his skin without regard to where the skin was going, constantly preening himself at all times. The animal surprised me by being smaller than I thought it would be, though this animal was apparently a full-grown female weighing about 40 lbs. The hindfeet were very strongly webbed and were used for swimming in a very efficient way and the tail was used as a rudder. When they brought the animal in it was on a feeding schedule of once every four hours. Finally they had got it down to the point where they were feeding it three times a day. It was eating such things as little crabs (which it ate whole, shell and all) and shellfish (which it cracked on the side of its tank) At one time it cracked them on its chest in the manner which had

been described in the literature but finally abandoned this and started cracking the shellfish on the side of the tank. It had actually knocked off a considerable amount of the cement along the edge of its little tank. They had had two sea otters originally, which were flown in from Amchitka but they only had one at this time. The other had died about three weeks after it had been brought in. The living animal seemed very well adjusted in captivity. I was surprised to see its ribs showed through its skin. This indicated to me that it, as Dr. Johnson told us, didn't have any fat layer and apparently for this reason had to eat constantly. However, as I mentioned, they had gotten it down to three feedings a day. It was living in fresh water. In addition to the shellfish, it ate whole herring.

September 19, 1957

We spent the night in Seattle. This morning Frank and Boots took me over to the University of Washington. They left me there and I went into the Department of Zoology while they went over to the north lake and inspected Harry See's boat which is under construction there. After talking for a while with Dr. Snyder, the herpetologist, I left the Zoology Department and went down to the fisheries laboratory which is housed in a new building alongside Lake Washington. The first person I met coming in the door was Dr. Albert W.C.T. Herre, the old gentleman who has been working with bryozoans and fish for a good many years. I spent a little time talking to him about *Amphiprion*-anemone relationship. I left Dr. Herre after he had run me up and down the halls at a great rate of speed and had introduced me to Dr. Field, who was a professor of fisheries and a comparative psychologist from Ohio State. He is using psychological techniques on fishes and seems to be a competent person. He was doing Skinner box training methods on trout and also had done activity studies and was connected with the studies of reaction of trout to light. He mentioned that they had found that fish could be attracted to very low light on very low wattages. A 75-watt bulb which was run down to about 10 watts was apparently quite a strong attraction to fish even through the very murky waters in a glacial-fed stream. They were now trying, instead of producing a light barrier to repel fish towards a fish ladder, to attract them by means of this low light intensity attraction. He seemed to think that this was going to give them much more success than the former method, which is the one that has been publicized in the past. The program apparently has come to an end and various personnel have been let off. The program had been sponsored by the Army Corps of Engineers in connection with their dam-building program. We inspected the apparatus that they used for this purpose and it consisted of a long trough about 20 ft. long and perhaps 7 or 8 ft. wide which was divided in 3 channels and into which an artificial current could be run and the fish manipulated from there. The impression I got was that the fisheries department was spending tremendous quantities of money on these experiments, far greater than any place I visited before, whether their results will warrant this, of course is something else again. We then went in to look at an activity wheel which had been constructed and it was large enough to hold approximately 10 tons of water. It was electronically controlled through a series of cams. The velocity of the rotating wheels could be measured very carefully. He stated that in this wheel they could simulate velocities up to 10 ft. per second or thereabouts and that instead of using cue marks (which is what we plan to do on our experiments) he had used a light barrier through which the fish does not want to pass, behind which were two electrodes

suspended in the water so if the fish did go through the light barrier it was shocked. The fish were brought in in a darkened box and were released in facing upstream ahead of the light barrier and would go around the activity wheel to the opposite side away from the light barrier trying to get into the darkest parts of the tank and apparently good readings were obtained in this way. Dr. Fields seemed to think that this apparatus was not satisfactory as a straight channel apparatus into which the fish could be put and through which the water could be flowed at a given rate. Once laminar flow was obtained he thought the apparatus represented a much more natural situation and that the fish reacted better. It was also a more portable apparatus for field work. The channel and the wheel gave final results which were quite similar. Exactly why he didn't like the idea of using a visual cue, I'm not sure. We then went outside and looked at the raceway through which salmon come on their upstream migration directly into the fisheries hatchery which is part of this building. The salmon are brought into a large long trough and allowed to sit here until they are stripped. The eggs are put in the adjacent hatchery and hatched and released there so that the fish go out to sea and four years later come home again to the original hatchery.

We saw Dr. Donelson's trout which he had been breeding for several different characters. The ones that we saw were ones which had been selectively raised for large size. Some of his fish which were three years old ran somewhere around from six to eight lbs. They looked to me like they were notably much more obese than a normal trout. Their body proportions seem somewhat different. Dr. Field stated that he had been able to train trout to do things normal for them in one trial on some occasions, and that the farther he got from the natural sort of thing for a trout the more training it took before this was achieved. Then we met Dr. DeLacey and he took us around the aquarium section. They have a saltwater system there which holds something like between 6 and 8,000 gallons of water. I don't remember the exact figure. The aquarium room consisted of a series of small tanks which were of no particular interest to us. I didn't think that there was anything unique about it. The water was transported mostly through rubber-lined iron pipe and most other equipment was rubber-lined iron. They seem to find this quite satisfactory though I'm not sure that it is as good as other materials in some ways. In one room we saw a doughnut tank which was designed by Dr. Chapman. In it was the adult skill fish which had been obtained far out at sea. The fish was doing very well. It came up and snapped at me when I put my hand in the tank. You could crawl into the center of this tank to view schooling movements or swimming movements. Temperatures available in the aquarium room ranged from about 40 degrees F. up to 85 or 90 deg. The water quality in the system apparently is variable and dropped from relatively high levels to down to a pH of 7 before the water was refreshed. They were bringing in a couple of large loads a year from the outside and they were pirating water from a nearby oceanographic station in the interim. We then went down to the Sand Point Naval Air Base and met Dr. Victor Sheffer and Karl Kenyon, the Fish and Wildlife mammalogists. We had lunch with them there, talking over many things. We talked about the local killer whale population. Dr. Sheffer seemed to think that there was a resident population in Puget Sound which had a regular track in which it moved so that it passed a given point with considerable regularity. He thought that they were probably reasonably difficult to approach and that they could be found most places in the bay. He suggested that we should contact the Washington State Department of Wildlife if we were planning to catch these animals as

their crews could monitor them from the air as a part of their regular program and let us know where the killer whales were located. We asked about the harbor porpoises. Dr. Sheffer told us that they were relatively common throughout the area and that they could be obtained in some of the lower parts of the Puget Sound, around Steilacomb, Willapa Bay and the Nisqualli River area, and he said that they sometimes come in shoal water but that near these areas there was water 20 fathoms or so. He mentioned a man named Phil Putnam who is a collector and aquarist and who occasionally caught a *Phocoena* for the Biological Supply houses. He mentioned a Lawrence Carver who works at Moss Landing who was supposed to know about *Phocoena* in that area. We talked about sea otters at some length and about the problems of transporting them, etc. Apparently it's a matter of time, a matter of the animal's fur becoming covered with filth and becoming wetted clear through, whereupon the sea otters die. It would seem that this problem could be treatable by a lot of different methods than they were using. They were required to feed the sea otters about once every four hours and were using the greenling, *Lexagrammus*, for this purpose, which were caught at Amchitka and carried along on the plane when the otters were being transported. Both of them seemed to think that the California sea otters were no longer under Federal jurisdiction but were now under the State Department of Fish and Game since the last treaty had been signed which omitted the herds from the California area. This would mean that if we were to obtain them that we would have to do it through our own Fish and Game Dept. This might be a very good situation. Kenyon was going back to Amchitka to continue his studies of the sea otter and was having troubles with his budgets. The Fish and Wildlife Service had cut off some of his funds. Dr. Sheffer said that the pilot whale apparently gets up to Washington only exceedingly rarely and that they had had just one specimen of this species taken from Washington waters. That was a dead animal which had been washed up on the beach along the southern coast of Washington. Other reports of this animal probably referred to *Pseudorca*, the false killer whale, or to the killer whale itself, which is called the black fish in these waters. I forgot to note that the Port Defiance Aquarium kept a beautiful species of jellyfish alive, reportedly for as long as two to three months. Cecil Brasseau said that the jellyfish would die if they were left swimming free in the tank. They apparently bump themselves against the walls and die very shortly. He had done something which I thought was quite clever. He ran a string on the end of a needle and tied a button to the end of it, ran the needle up through the center of the jellyfish, actually piercing it, and pulled the button up underneath the tentacles, then tied this thread above the tank so it couldn't be seen from below. The jellyfish was effectively suspended in the center of the tank where it couldn't hit the walls and the wound apparently didn't hurt it any. It could be fed by introducing material into the tanks that would adhere to the tentacles. We may be able to do this with our big purple *Pelagia*, which I'd like to try sometime.

September 20, 1957

We came this day from Bellingham and drove directly to the Stanley Park Zoo and Aquarium. It is set on a peninsula which extends in Burrard Inlet, a beautiful stretch of saltwater lying north of Vancouver. The aquarium building is built in the midst of a beautiful grove of trees and directly adjacent to the zoo. It consists of 40 tanks, one of which is a very large tank about 30 ft. long. In addition to these there are many small

freshwater tropical tanks of the standard home aquarium sizes. The building of the aquarium itself is very modern and very attractive. It is not too easy to find the aquarium. One enters through a central lobby, passes a ticket stand and a book counter. The book counter is one of the most attractive that I have seen and includes a wide variety of books, many of which we do not have at Marineland. Behind the book counter is an open grotto of freshwater tropical plants growing from a little tank containing turtles and alligators. The tank displays themselves were not particularly exceptional. They did have a fine display of the humpback salmon in spawning condition. They are most unusual-looking animals because of their odd secondary sexual characteristics. They have a very beautiful display of anemones of very delicate shades of pink and orange. The large tank was used solely for holding the dog sharks and was not a particularly startling display, though the tank itself was an excellent one and could be used to much greater effect. The lighting over the tanks was often fairly dim and not as good as one might expect. There were a fair number of reptiles exhibited in rather inconspicuous ways—alligators, caymans, and several species of turtle. The freshwater tropical display was quite good and I particularly noticed their backgrounds which were made of reed matting of different colors. They had such small species as the electric catfish, the knifefish, Discus, various other more common critters, a few of the freshwater sport fish, such as the yellow perch and pumpkinseed and so on. One of the most unusual displays they had was of the horseshoe crab which had been sent from the east coast. These animals are very unusual and interesting. The tank decorations were not particularly good in my estimation and many times sands were used on the bottom of the tanks which could be seen to be accumulating hydrogen sulfide bacteria beneath their surface.

The water system of the aquarium is a very interesting one. It is very much more modern than some, yet it still has its faults. It is run by a pump man who also installed the system under contract as the aquarium was being built. Briefly the water system consists of an intake sump which is set out offshore a considerable distance. At this time of year it becomes covered with a bed of *Nereocystis* kelp much to their dismay. The water comes in by gravity through a transite pipe in an unfiltered condition, the only thing being strained out were pieces of kelp which are kept out by a screen. It enters a sump made of circular concrete pipe and is sucked from the sump by a pump which delivers about 250 gallons a minute. This is then forced uphill, all the time going through transite. The pump itself is a rubber-lined centrifugal pump and according to them is giving them excellent service thus far. I was interested to note that the transite which was being used was obtained in a number of different fittings. These fittings were iron on the outside, transite on the inside and led to all transite pipes. They had elbows and tees, forty-fives, etc. The water then passed up the hill and into a storage tank holding forty thousand gallons as I recall, which was under the floor of the pump room in the main building. This is completely in the dark. It is a large cement tank, the top of which forms the floor of the pump building. The water is then sucked up through another centrifugal pump. First it goes through the filter beds and then is sucked up from the sump and circulated about the system. There are three pumps, going to three different banks of the system and they theoretically can be divided off, but at present this is not done and they all go to the same sump. In effect the whole system is run from a single supply. The filter beds were a regular sand-gravel type and were completely inadequate in size to handle the volume of water in the system. They probably have something like half the square footage for the

same amount of water in our system. Much of the distribution system is through plastic pipe of the kind which is held together by hose couplings—sort of a limp plastic pipe which is not threaded. Jerry told us that it was very flammable and that this had been a problem, but that it had been quite satisfactory otherwise. At no place in the system does the water touch metal, the valves being rubber or neoprene diaphragm valves of very large size. They were installing a diatomaceous earth filter for the freshwater supply system. The few warmed seawater tanks they had in the system were warmed within the tanks themselves or within a small supply system which strangely enough had no heating elements supplied to it. They were being warmed by a freshwater garden hose which ran into the sump and then discharging this water back into the freshwater system again. In other words they made a bypass in the hotwater line which passed through the tank and effectively heated it. The heat exchange must have been very poor and must have taken considerable length of time to bring the supply of water up to temperature. The freshwater tropical tanks were heated by heating the room in which they were placed and were kept at a temperature of about 75 deg. The temperature fluctuation in the water of the aquarium was relatively extreme, going as high as about 60 deg. in the summer which was marginal for the survival of the anemones and some of the other creatures on display. The labeling system left much to be desired. The labels were not lighted and since the corridors were reasonably dark it was quite difficult to see them. We had to stand very close to see what the labels had to say. The admission was 25 cents. Murray said that they would bring in something like 1,500 or 1,600 dollars on a good day during the summer season and that in the winter they were lucky to make 300 or 400 dollars. His whole operation is apparently operated on finances derived from this income, though he doesn't have to pay for his building, that being taken care of by the city. On the whole, the aquarium was a very attractive place and had a nice series of displays, but one felt that it could have been more imaginatively done as far as backdrops were concerned, the tanks all made of concrete and decorated only with rocks, etc., which had been placed into the tanks loosely without being cemented into place or any attempt to do final rockwork.

This morning we went to the University of British Columbia. Murray Newman took us around the campus. The first place we visited was the biology building and there we met Dr. Hoar who showed us some of the apparatus which he was using and which his students were using. We then went to see Dr. Ian McTaggart Cowan, mammalogist of the department. We talked to him for quite some time about killer whales. He mentioned that the killer whales were sometimes extremely common around this area. They sometimes occurred in as many as 2,000 animals to a school. These schools were scattered over the sea in smaller groups. They occurred primarily when the salmon were running into the rivers (which is taken place now and continues on a little bit later). He mentioned that the place where they seemed to congregate most often and most regularly was at the mouth of the Campbell River which flows down toward the north end of Victoria Island. Here is a place called "The Pond" where they come into rather shallow water in pursuit of the salmon. He mentioned that the stomach contents of the killer whales which had been inspected in this area showed that they had been feeding largely on lingcod and not on the salmon but they certainly must feed on salmon too. He mentioned the presence of a white killer whale whose course had been charted around the island. It had been seen many times. It apparently had given birth to a partial albino fairly recently. They had seen this other animal and were also able to trace its movements around the

island. He mentioned that one fisherman in the Campbell Bay got angry at killer whales and had charged them with his skiff and had run into them. This would seem to indicate that you can get relatively close to them. Cowan considered this to be a rather foolhardy undertaking. He mentioned that there was a fairly good airport in Victoria from which the animals presumably could be flown if they were caught in this vicinity. From Campbell they would have to be brought down the coast about 100 miles. This would mean, of course, that we would have to work from a large vessel. He mentioned that they occasionally saw the young which were still in the yellow condition like the one that we saw out of San Diego. I asked him if he had any records or information on anyone having been killed by the killer whale and he said that he knew of no one on the Pacific Coast. He mentioned that the blackfish was often seen by the sperm whalers far off shore traveling in large schools, presumably they were coming northward in the warm water along with the sperm whales. The whaling station north of here at Cold Harbor was supposed to have taken about 600 animals last year, but even so to be just making ends meet. He mentioned that we might try the use of a compound called nicotine salicylate which has been used to sedate deer when they are trying to catch, transport, and tag them. A corporation called the Palmer Chemical Co. manufactures pellets of this compound which can be shot with an air rifle into a deer. They are also starting to manufacture a hypodermic harpoon with which larger quantities of the material can be shot into an animal. The effect is to cause the motor nerves to be blocked off so that the animal fails to have any muscular movement. Apparently it doesn't have any effect on the respiratory system. If this works with cetaceans it would be very valuable for us. The effects apparently wear off in quite a short time, within 15 minutes. He seemed quite interested in preparing a television show of Marineland, including work on board the *Geronimo* with pictures of our local cetaceans. His show is broadcast by the Canadian Television Network and apparently goes clear across Canada, so it should be a good advertising for us. He also said that it was being purchased by an American Company. the name of the show was "The Living Sea" and he narrates himself.

September 22, 1957

We went out on the beach and dug clams and ate 'em raw.

September 23, 1957

We visited the Nanaimo Marine Station today. Dr. Brett took me through his laboratory spaces and I learned several things there concerning my experimental gear. He showed us the saltwater system. There is no filtration except through a series of nylon cloths, which served to remove large particles and there is an intricate mixing system using hard rubber pipes and hard rubber valves, which they found quite satisfactory. He was using much larger valves than we have used at Marineland. A student from Australia was there measuring the effect of different salinities upon the lethal temperature relations of herring and Dr. Brett was in the process of planning a new program using adult salmon and was establishing tank space for them. The only major innovation he mentioned in his holding tanks and transport system was a so-called upwelling flow. The water came in from the bottom and forced its way to the surface and it was believed that this would cause the salmon to be more calm than if the water was sprayed in from the top or otherwise. He was going to impart a rotational flow to the water in addition to this and in

his transport tanks planned to use oxygen which was introduced under low pressure into the circulating system. He was planning to use a canvas brailer bucket system like the anchovy boats use in San Diego Bay to handle his fish so that none of the slime would be lost on the animals. They would then be carried into the tank system on an overhead rail which lifted the whole transport tank up and set it into the holding tank. A sluice system with dropping doors fore 'n' aft was going to be used to separate out the fish they wanted to handle. Then, a false botom was removed below the gate and the fish fell down into a tank below and was removed and therefore was never handled by a net prior to being used for experimental purposes. They had some aluminum tanks which were very nice and light and which were lined with fiberglass. These were being used as holding tanks in the laboratory and like all their holding tanks had a circular flow and central drain. We went over the entire hierarchy in the institution and found out much about their program.

We then spent some time talking with Gordon Pike, the whale authority, and he told us a good many things about the whales and dolphins of the area. He said that the killer whales were very common in the Alert Bay-Discovery Pass region which is towards the north end of Vancouver Island. They had been charting the white whale around the Island. He said that the young apparently were born in the spring of the year. The animals were here all year round but were more common during the time of the salmon run than any other. There is an airport which is capable of taking four engine planes near the north end of the island and could presumably take a plane used to haul such an animal from there and directly to the states. The airport was located adjacent to an old lumber pier which had a large boom used for lifting logs and a road running out onto the pier so that if animals were brought in on board a ship they could be lifted directly from the ship onto a truck and taken directly to the airport a short distance away. He also mentioned that the baby of the white killer whale was mottled in color and had been traced around the island with the adult. He stated that pilot whales were quite common but were a long ways offshore, one having been taken recently about a thousand miles offshore, apparently occupying the warmer water there. These were seen in conjunction with the whaling activities of the Cold Habor station. This station is taking finbacks, blues, humpacks. One right whale was taken this year puls many sei whales. He showed me an inlet towards the middle of the inside passage on Vancouver which had, according to him, quite a concentration of harbor porpoises. He said, however, that they were quite wary of boats and that they never seemed to go into very shallow water. He recommended, once again, that we talk to G. Clifford Carl of the Victoria Provincial Museum which we shall do day after tomorrow.

September 24, 1957

We started out this morning from Victoria and went to Port Sydney, got on the ferry and went out to San Juan Island. It was a most beautiful trip. At an island called Orcas we waited for several hours before we could get a transfer ferry to take us to Friday Harbor. We arrived at Friday Harbr in the late afternoon and went immediately to the marine laboratory of the University of Washington. There we met Harold Barnes from the Millport Lab of Scotland whom I have met earlier, and a couple of graduate students from the University of Washington. We asked a great many questions about the fauna from the students. They mentioned the following forms: they said that there were numerous sponges in the area but the sponges were very difficult to keep in captivity and

for some reason or other tended to break down after a while. There are a number of jelly fish which occur in the area, but most of these apparently are quite delicate and difficult to keep. The species which was being kept at Point Defiance Aquarium apparently is not very common. There is a species of sea anemone which occurs here (*Anthopleura* sp.), which is a large green form with pink-tipped tentacles and apparently quite common. Also the various forms of *Metridium* are common and supposed to be very hardy. There are some forms of the sand anemones which are available by dredging and apparently come up in considerable numbers. One of these is *Cerianthus* which can be obtained in this way and then there is also the true sand anemone. The sea pens are quite common and apparently keep very well according to the students. One fellow told us that the sea pens would live even though they were left lying on their sides for quite a long time. Normally they are in an upright position of part of their body buried in a mud burrow. There are a large number of different kinds of starfish available here, including our own *Pisaster* and some other ones which would be of no interest. Apparently the 21-ray star is very common here but this, of course, is of little interest because we can obtain it in Avila. The sea cucumber fauna is most interesting and apparently has a large number of forms which keep very well and some of which have very beautiful tentacles which they extend and leave extended most of the time. Some of these are bright red in color and others are bluish, etc. There are a large number of worms in this locality some of which apparently would make fine display material. This one species of *Nereus* (*N. brunius*) reaches a length of about four ft. and apparently will live for months at a time in the tanks here at Friday Harbor. There are polyclad flatworms living in this area, some of which reach six in. in length which would make an interesting display because of their mobility. The tubeworms apparently do very well and if the tubes are injured during the course of taking the animal they apparently regenerate these quickly. There are several species of these but the most showy is the one which is being shown at Pt. Defiance Aquarium. There are large numbers of nudibranchs available, but these apparently would be of little use to us because they are annuals and die off during the winter so that we would at best get half the season out of them. It seems like not enough considering the distance we are from home.

There is a very large crab fauna in this area and an equally large prawn fauna. The prawns apparently would be of little display use as most of them are very small. The crabs on the other hand include a species which would make fine display material; large decorator crabs, hermit crabs, and some of the large spider crabs in this area are quite brilliantly colored. Most of them are quite hardy in the aquarium. They apparently are able to keep octopus virtually indefinitely in the tanks. They keep them in a rather shallow tank not more than 10 in. deep and covered with a wooden cover so that the octopus can't get out. The octopus is virtually in the dark all the time. They obtain these intertidally by use of bluestone in the holes in which the octopus lives and they report large adults grow to 50 or 60 lbs. The smaller ones are preferred. There are several species of tunicates which might be interesting material. The sea lemon and the sea squirt and a transparent tunicate which clings to the walls of the tank are quite common. We took a tour around the salt water system of the station and found that it was set up very much like that of Pt. Defiance Aquarium. The water was sucked up through a pipe which was strapped to a pier piling. The difference between the two systems was that a large part of the Friday Harbor system is pyrex glass which has been painted with aluminum

paint to keep the algae from growing inside of it. There are sections of this system which are made of polyethelene tubing. There are two intakes, one of which comes in from the end of the Cantilever Pier. The water is sucked up inside of a rectangular tube that extends down into the water which rapidly becomes extremely deep in this particular location. The water is then run for about 200 yads to the aquariums in the laboratories. It is the only source in the laboratory used for chemical embryology. The other pumping system supplies some of the other laboratories used for animals which are not so sensitive. The valving of the system is accomplished by large-scale stopcocks just like the smaller laboratory kind. In places the pipe is run through a metal sheathing but for the most part is exposed completely. The joints—where there are joints—are couplings which are fitted with rubber gaskets. We did see some *Phocoenoides* on the way over—travelling very close to one of the islands off the San Juan (not the Shaw) group there. They were travelling very close along shore and we found out that this was apparently something of an unusual record; probably unusual only because people haven't looked.

September 25, 1957

We travelled from Friday Harbor to Victoria where we saw Dr. G. Clifford Carl, the Director of the Provincial Museum. We talked to Dr. Carl for some time about killer whales, trying to find out as much as he could tell us about these animals. We got rather a little information from him that we didn't already know. We found that the animals were very abundant and that they were abundant around Vancouver, but probably more so in the north though Dr. Carl didn't seem to know whether this was so or not. He told us that he had reports of the white killer whale all the way around the island and that he'd had one dubious report of its being accompanied by a smaller white offspring. He doubted it because he considered the whiteness to be recessive albinism, but of course it may not be, it might be merely a white pigmentation and not true albinism at all and therefore perhaps a dominant characteristic.

One bit of information we did get that seems valuable to me is that the young are born when they are somewhere around eight ft. long and thus we would have to prepare for catching an animal at least ten ft. and probably twelve ft. would be closer to the minimum size that we could expect to handle. He told us that the killer whale sometimes passed very close to shore at certain locations along the southern part of the peninsula, as a matter of fact near Sydney Harbor. They had been seen close enough to shore so that he thought a person could actually throw a net over the. This seems like pretty much of an off chance to me however and something that you could hardly wait for. He felt that if a person were to wait for the animals in a specific spot around the island that he could be pretty well assured of seeing them within a week. He felt that the best season of the year was during the summer and he didn't commit himself but he seemed to intimate that this was probably connected with the salmon runs around this time of year. He didn't know anything about the Campbell River locality and didn't have much to say about the northern localities such as Alert Bay and Discovery Passage. He said that he had had no records at all of killer whales having killed anyone any place in the world though there was rather a dubious record in China of a whaleboat having been apparently destroyed by the killer whales. One of the members thereafter disappeared, though nobody saw the killer whale take him. The museum itself had a lot of interesting material in it. However a good deal of it was falling into disrepair. Some of the animals were a little bit motley in

places, toes falling off grizzly bears. They had some rather badly done things on some of the fishes though we found much of interest to see there. I think that was about all we gathered from Dr. Carl. Unfortunately we missed Cleve Vandersluys at Friday Harbor, the skipper who collects for the Friday Harbor lab in the summer time and is a commercial fisherman during the rest of the year. He probably would have been a good source for us. Unfortunately he was out rescuing a couple of purse seiners at the time and we couldn't see him. We left the Provincial Museum and came across the straits of Juan de Fuca to Port Angelus.

September 26, 1957

We travelled from Port Angelus to Astoria and stopped—visited the fish cannery there. Other than that we accomplished nothing but traveling.

September 27, 1957

Leaving Astoria we quickly traveled to the Seaside Aquarium at Seaside, Oregon, which was run by Mr. Enser and his wife. Mr. Enser seems to know his business quite well and runs a rather nice little aquarium. It's located on the beach and sucks its water from the sand. For the most part it is on open circulation. However, when bad conditions set in, he can go on internal circulation. Most of his system is galvanized pipe but is being replaced with plastic pipe as pieces wear out. One of the major displays in the aquarium was the anemone exhibit which is the best by far that we have seen. The aquarium itself consists of a gift shop which is off to the side of the ticket booth and entrance to the aquarium. In other words you go past the ticket booth directly into the main aquarium room or to your right into the gift shop or to your left into the seal room. The main aquarium room itself is square and contains about 20 exhibits, including a couple of exhibits in the floor which were not particularly impressive to me. They were lighted by underwater light shining through a port.

One of the first exhibits that we saw was a small exhibit of sticklebacks in eelgrass. This was set in a small tank—I would say 10 gallons—which was viewed through a brass porthole which gave quite a nice effect. The metal was painted black but if it had been polished brass it would have been even more effective. The tanks around the walls were not especially large, I would say 400 or 500 gallons of water. He had a nice display of the wolf eels, including several adults which were pretty nasty looking. He had two octopus displays—a couple—one in the floor and one in the wall. He stated that he could never keep the octopus for any great length of time and he felt that they were sensitive to minor temperature changes both in the tank and during capture. He preferred capturing his octopus in his doghouses as he calls them, which are wooden boxes similar to our own, because he felt that the animals were less battered than they were in traps. The boxes were raised to the surface (they are about three ft. long as opposed to our four ft.) and they were dumped directly into a burlap sack which had been previously wetted and fit directly over the end of the box. If he had trouble getting an octopus out of the box he merely inserted the leg off of a 21-arm starfish into the box and the octopus soon vacated. Apparently they do not like to occupy the same box with the starfish. He mentioned that he caught most of his in a hundred feet of water or less and he also mentioned that during the summer when the surface water is warm to about 60 to 65 degrees that the octopus were very difficult to obtain and apparently had moved out of the area in which he was

used to trapping. While I think about it he mentioned that during the summer season when they had an unusually warm year, the water reaching about 65 deg. F., two or three examples of the white sea bass were obtained locally. He called them sea bass and from his description they sounded like white sea bass. The anemone display was mostly concentrated in one large corner tank which held about 400 gallons of water. The floor of the tank was covered with a nice rockwork foundation which went up as a series of shelves back up to the sides of the tank and into the corner, almost reaching the surface. On this were set perhaps 200 anemones of both *Metridium* and *Cribrina*, including both the colored *Metridium* and the white one. The tank was very brightly lit and each of the anemones was fed individually on pices of fish or crab, three times a week. He stated that they were fed individually from the end of a stick. He stated that the display was much better the next day after feeding. He fed his anemones in the evening. They opened up to their fullest extent on the following day. He felt that his display when we saw it was not fully expanded but that it would be the next day, but it looked pretty good to me the way it was. Other than these displays he had a few interesting small animals, some of which were misidentified, blenny eels and cottids of one kind and another, *Sebastodes*, etc. He had a very fine tank full of the 21-armed starfish which was made into a good display by the mere fact that he had probably 15 of these starfish in a single tank. In most of his tanks he had carefully put *Phyllospadix* plants which gave a very nice effect. One felt that he had tended his displays quite carefully and had tried to keep up the artistic side of it. I felt also, for a person who was presumably untrained, that his biology was about as good as any of the small aquariums that I'd run across. The seal display consisted of about six harbor seals, some of which were quite large. All of these harbor seals were trained to do various tricks, in order to entice a little food from you. For 15 cents you could get a bag of Columbia River smelt which held quite a fair amount of chopped fish. It wasn't messy. It didn't get too slimy on your hands and there was a dispenser for towels nearby so that you could wipe your hands off when you were done. There was a receptacle for the bag.

The little seals all did tricks of one sort or another for their food, and I thought put on a wonderful display. It was something that we could well do at Marineland. They raised such a ruckus when they were putting this display on that it was impossible not to laugh at them. Some of them would jump up and down on their stomachs on boards, making a tremendous racket as they slapped back down on the boards; others would clap their flippers or slap their sides. Some of the seals made a tremendous lot of racket by a sort of a constant braying noise. All in all, it was a very amusing exhibit and was itself worth the price of admission, I think. (The admssion was 50 cents for adults.)

Inside the aquarium space there was a tank which was I believe five- or six-sided. It had straight panes of glass and was made out of cement. In the center of this was a sort of rockwork pinnacle. At the time we looked at it, it had a series of dogfish swimming around in it. It seemed like it would be obviously a good sort of display tank for octopus for our second floor and as Frank suggested, would be fine if it were divided in two by a plate of glass so that two octopus could be kept and people could see them from all sides. I think we could design a fine tank along these lines. The gift shop was reasonably small, but seemed to hav a large selection of the usual junk that you find in gift shops. I felt that they were doing a good job. The Ensers seemed like very nice people to me and I think they will be visiting us soon. They had prepared a nice little guidebook for the aquarium which they sold for 35 cents. The color work was done on a three-color process and left

something to be desired but the layout of the book was simple and I thought quite effective. For the most part the information given in it was straightforward with no falsification at all. They had a nice series of postcards on the postcard rack, many of which were taken from pictures used in the guide book. These postcards were very attractive and I imagine would be good saleable items. They cost a nickel each.

Some of their harbor seals had given birth in the squarium. They had a display on the wall showing all the pennies and pieces of metal and keyrings, etc. that had been taken from the stomach of one of their animals that had died. This was, I think, kind of effective to keep people from throwing things in the tank. There were at least a hundred articles on this board.

We traveled down the coast from Seaside and as we went through DeLake, which is just south of Oceano Beach, we passed a thing called "The Oceanarium." It was closed. There were signs saying "whale" and "octopus." It looked about the size of the Seaside aquarium. Then we went on down the coast further in a fine wind storm. At Depoe Bay we stopped and went in the aquarium there. This aquarium is run by Mrs. Palmer and was in rather sad shape. She had a sign up outside saying that over a million people had gone through it. Probably a million people had been cheated out of their 35 cents admission. The aquarium itself consisted of a series of 20 small tanks most of which were viewed through circular glasses. A good many of the animals were dead. The place was extremely dark and there was no worthwhile display in the whole place as far as I could see. The water was extremely dirty in some of the tanks. There was a central section. One walked through a single corridor around the central section, which also had tanks in it. Their anemone tank was very cloudy but if it had been clear it would have been a good display, but not as good as that at Seaside. One tank which might be of some utility to us was a tank in which you could look on top of the water. There was a hole in the wall which extended back into sort of a cavern and you could look as if you were looking into the top of a tidepool. It appears to me that such a design might be useful to us if you could also look underneath the water at the same time, in other words, have part of the front of this tank made of glass so that you would have the effect of looking at the top of the tidepool and also seeing a cross-section of it at the same time. From there we continued on our way and are now at Roseberg, Oregon. Tomorrow we hope to make a stop and jump to Steinhart Aquarium and home.

Letters from Hawaii

1959

Dear Phylly,

I miss you and wish you all could be with me. I'm sitting in the dockside installation of the U.S. Fish and Wildlife Service at Kewalo Basin in Honolulu. Our unit is perking along nicely just outside the door. A little three-year-old Japanese girl named Diane has been helping me type. She is the daughter of one of the staff. She doesn't type very well but likes it a lot.

The trip over was pretty uneventful. We could feel the weather getting warmer, day by day as we cruised along. The California current was pretty evident by water

temperature alone and by the swell and wind. Once outside it the water began to warm and finally reached 81 degrees. The fish came through fine, after an initial loss of most of the last load we took to Puddingstone. The ship scarcely rolled at all and I never had the slightest touch of seasickness. We ate with the passengers and Captain and all that. The food was endlessly plentiful and very good. I am afraid that we usually did little more than read, sleep, peer at the fish, and eat.

Once we began to enter the central Pacific water mass we came into the thunderheads and squalls of the tropic seas. There was virtually no life at all to see, except a few flying fish. Boots and I made friends with the mess cooks and listened to the ball games in their room. We got clued in on the sailors' viewpoint. Just as in the Navy they lead an incredibly tedious life.

We came to the islands in the dark and passed Diamond Head just after dawn. We shut the water off and went in with the tank on internal circulation to keep out the harbor water. It didn't take too long to get the containers off the deck (they are big semi-trailers that come off their wheels) and then us. We boarded an incredibly beat-up semi-trailer and towed the critter to Kewalo Basin, where I am now. It is a nice corrugated iron laboratory set on a coral fill peninsula.

We have the open ocean on one side and the basin filled with trap boats and skipjack boats on the other. The boats come right past the door into the cannery. There is a wonderful little hole-in-the-wall restaurant about 200 yards away that serves about a square foot of rib steak for \$1.50 with soup and salad and all the fixings. We are temporarily holed up on board the Fish and Game vessel *Makua*, in nice bunks with the water lapping at the hull. We spent one night at the Princess Kaiulani and moved out post-haste. It was too fancy for fishermen and we felt like crumbs crossing the lobby in our dirty clothes. I'm not sure where we will finally end up, perhaps on the lab floor. So far there has been little time for sightseeing. Boots and I did wander around in the main drag of Waikiki wishing we had wives along. We peered at the sands of Waikiki pondering whether or not to take a handful up to put in Frank's bed, but we desisted. We wandered around in the gardens along the edge of the Royal Hawaiian and Moana hotels. Absolutely beautiful with dense thickets of Ti plants and phyllodendrons and god knows what else. There were big coconut palms and banyan trees with aerial roots as big around as a man.

Our plans for the coming days are pretty hectic. We will probably finish fresh-water acclimation of the shad tomorrow and start planting on Monday on Oahu. We will take the critters to three localities here. Then we load shad onto the *Makua* and set out at dark for Maui (Kahalui harbor) and reach the island at dawn. We will then plant there and return to Molokai to fish. We will probably use hand lines and such for our specimens. Then we will come in and work the trap boats for a while.

We might even get a Hoki-Lau thrown for us. This is a communal event in which the natives tie palm fronds to a line and go way out over the reefs and come in, driving the fish before them. Apparently this is thought of as great sport and the natives do it just for fun.

Our return date is up in the air now. We probably will not get aboard the *Hawaiian Rancher* which leaves here on the 13th and gets in about the 21st, but will probabl come in on the 28th on the *Hawaiian Builder*. This is because we got a bum steer from Matson in Wilmington and didn't get on the roster soon enough. At any rate the

boat will hit either Kauai or Maui on the return trip, plus Hilo on the Big Island. We will not have much time in either port but enough to say we have been there anyway.

You know Phylly, I take a look up at the hills now and then, and think, if only my family were here I would take a little time out and just look at it, but when you're along, or with a couple of guys, you just go on working. There is a dense mass of clouds that hangs over the high peaks and must rain almost constantly on them. These mountains are precipitous and covered with a dense jungle of vines and trees. The trees are beautiful everywhere. It distinguishes the place. Mimosas, monkey pods, koas, and so on. It really is a very lovely place and everybody dresses most casually. It is hard to tell a pregnant woman from everybody else since most are wearing muumuus. These grow on you and I now think they look pretty nice (in contrast to my former attitude that they were absolutely awful).

Well, I guess that is about all. I will walk down the dock and go aboard the *Makua* and crawl into the bunk. It is too warm to get covered up. I hope all goes well with all of you. Susie, Nancy, Barbara, and Little Dickie, you and Mom. Please give them all a kiss for me. Tell them I saw a big lion today in the store window but that I didn't buy him because I have some other things picked out.

I hope Bets got off OK . . .

I love you very very much Phylly and wish I could give you a great big hug and a kiss right now.

Ken

1959

Dear Pop,

I'm sitting in the U.S. Fish and Wildlife Dockside laboratory after a hard day of sightseeing. Our tank is set up outside on a decrepit old semi-trailer and the shad are cruising happily within. We have lost very few since a rather severe loss on the first day while we were still tied to the Wilmington dock. I guess we still have 2,500-3,000 fish in the tank, which should be plenty to stock the islands. The initial plant in the Colorado River was 55 fish and the species is widespread now.

Frank and Boots and I went swimming on Waikiki today (warm, very salty, and the bottom covered with coral hunks but still very nice), drove around past Diamond Head after looking at the Aquarium and on around the rugged volcanic coast to Kaneohe Bay and the over the Nuau Pali and back to the station. We had a nice Chinese dinner at Wo Fat's and came back again.

On Monday we begin our planting on Oahu Island. We will make two, one in a big, shallow lake and the other in a reservoir up in the hills. Then we load the Fish and Game vessel *Makua* with fish and sail for Maui. We will arrive after about a 12-hour run and take the fish up the island to some lake or other. Then we turn around and head for Molokai where we will fish for specimens, using handlines mostly, I believe. After that, things are pretty uncertain but I think we will not leave until the 18th of September.

The weather is a bit muggy but far from oppressive. We get a few showers but nobody pays any attention to them. The top of the mountain seems always cloud-shrouded however and I think it must be pouring down up there almost all the time.

The Mafia are having a fine time. They have poked into the construction of all the Hawaiian boats and criticized the fishing methods and unloading techniques plus the

general sloth of our associates (they do this everywhere) . . . All in all they are having a fine time and soaking up culture with every pore.

We have peered at many of the fish they get here. There are some really nice kinds that should pep up the Marineland display a lot I think. I just hope that John Prescott can sell the management on giving us a new wreck for the tank to provide refuges. If not we will undoubtedly lose a lot of them.

I hope everything is going well with you and with the Portuguese Bend contingent. Phylly will miss having Bets around to help with the kids. Mom should take up some of the slack but I hope she doesn't try to do too much.

Drop me a line if you get around to it. Oh, by the way, the first mate on the ship coming across was an old timer at Catalina and knew Holder and Jimmie Jump and worked with Farnsworth and the others. Quite a fascinating guy.

See you about the end of September,
Ken

September 1, 1959

Dear Mom,

I guess you will get this a couple of days after your birthday, but at any rate I am typing it on September 1. I hope you have a proper birthday celebration. It is really worth having them just to watch the kids. They seem to have as good a time on other people's birthdays as on their own. I have a goody picked out for you but you will have to wait until I come home.

Tomorrow is the big day here. We plant our first shad in the ponds of Oahu. This of course is the culmination of the whole effort on the way out. Thus far the fish seem to be in fine shape and I am confident that we will do a successful job. Then, in the afternoon we will load the Fish & Game vessel with fish and leave for Maui. The trip will take about 12 hours. We land at Kahalui and take the fish up the mountain to a couple of other lakes. Then we come down and leave for Molokai. The boat will stop while all hands fish for us. We hope to gather a good amount of various kinds of large fish for our tank.

Today we went out to the Waikiki Aquarium and looked around while we waited for the director. He didn't show up so we went over to the zoo to look up my friend Paul Breese. Paul and his wife took us out in Kaneohe Bay in their boat for a dive and swim over his own private reef. When I say private, it is just a spot he knows and frequents. The bay is a really spectacularly beautiful spot. Fluted, almost vertical cliffs rise to a knife-edge ridge back of the bay. All are covered by green trees, vines, mosses, and ferns. The bay is large and almost enclosed by islands and reefs. We wound around through channels in the reef past some beautiful houses set right at the water's edge and out into open water. We crossed over to a verdant paradise of an island called "Coconut Island." It is the site of the University of Hawaii marine lab. It is a low island covered with palms and trees. We entered a narrows out through the trees and entered a long, perfectly calm lagoon. The station is arranged along one bank, with a little dock, machine shop, labs, eating halls, and animal houses. All the buildings are low, white-frame construction with wide verandas and half-screen walls. Tanks of marine animals are set up along a boardwalk in front under the shade, while others are held in screen boxes hung along a float. We cruised up the lagoon looking at the little minnows being chased by barracudas.

Back out in the bay we circled the island and beat up wind into a choppy sea to a shallow reef that comes just out of water at low tide. We dove there. I had never really looked at a live reef before. The color of this particular reef was rather drab—browns, whites, and an occasional spot of color. But the animals are spectacular. I saw at least 40 species of tropical fish, many of brilliant colors—moorish idols, damselfish, angel fish, wrasses, and so on. The invertebrates were just as interesting. Delicate feather-like hydroids took the places of algae. Strange sea cucumbers were very common. They were red or pink and filled with water. If you lifted them out of water they drained down just to water level and refilled if you lowered them. Their body walls were transparent and they had a feathery plume of tentacles at one end. Another species exudes a string of sticky material when annoyed. These strings are so adhesive that they literally pull your skin up when you try to remove them. Mushroom corals were everywhere. The water was about 80 degrees, I would guess.

Well, we are packing up now for the voyage so I will sign off for the time, wish you a happy birthday, and get to work. My love to all of you gals (and Richard). I miss you and will certainly be glad to see you.

Love,
Ken

Dear Phylly,

Just a quick note before we go out to sea. We are leaving in a few minutes for the fabled islands of Kauai and Niihau. The latter is the island which everybody is forbidden to land upon. We will fish there as it is reputed to be the best fishing in all the islands. Our collection grows but in halting jumps. We get a load and then lose a lot of them. I hope we will make it for good this time as we are now using a big receiver which we just lowered in the bay.

Your letters are wonderful but I suspect some of them have been sent back to you inadvertently since they got a new mail clerk here and she stopped all our mail for a while.

All my love to you, sweetie. It will be wonderful to get home and see all my family again. I have lots to tell by now.

Love,
Ken

September 5, 1959

Dear Phylly,

We have just come in from a four-day trip on board the Fish and Game vessel *Makua*. The trip was a wonderful one and quite successful from the fish standpoint. We caught 230 fish—all on hook and line. This amount included a lot of very pretty critters. There were several kinds of triggers, wahoos, jacks, wrasses, and so on. Probably the most brilliant are the moanas or goatfish that are really gaudy.

I guess I will just start with a day-by-day account of my doings since I last wrote. We were scheduled to leave for Maui with the shad in the *Makua*'s bait well, having talked the powers that be out of sending the whole unit over on a barge. The boat left on Monday evening, but I had been invited over to some friends of Paul Breese's for dinner, so I planned to stay and fly to Maui and meet the boat. Frank and Boots accompanied the

fish. This proved to be a sage maneuver as things turned out, since it was a horribly rough trip with water crashing over the railings and the ship rolling and bucking for several hours. The channels between the island are very rough as a usual thing, I think because the land funnels the wind and speeds it up. I went out to Kaneohe Bay with Paul (the zoo director and an old crony of Charlie Shaw's). His friend, who is a shark authority, lives way out in the sticks, down a dirt road, past two taro fields and a couple of caraboos [sp?] and right at the water's edge. He has a grass-plaited luau house and a modern frame house. It is quite a place, with no apparent neighbors and only the lapping waters of the bay and the trees and stars to keep you company. About half a mile behind the place the huge, fluted cliffs of the Koolau range rise.

When we arrived, dinner was spread out on a plaited matting in the grass house on Ti leaves. We had a lot of exotic goodies that I can scarcely remember, such as Lomi Lomi salmon and such—all eaten with the hands, and very good too. The company consisted of some students from nearby Coconut Island, the host and hostess (she is Philip Wylie's daughter), and a wonderful old Hawaiian lady who knew nearly every song written including both Hawaiian, Tahitian, Cowboy, and so on. We had quite a song fest. I wished many times that you could have been with me. The affair didn't last too long. We peered at the geckos crawling around the house, plus the tame Hawaiian owl.

Paul and wife and I went up to their house and thence to bed. I didn't sleep much though because it was hot and the mosquitos were thick and the combination kept me thoroughly uncomfortable. Paul took me to the airport at 7:00 and I boarded an Aloha Airlines plane that cruised out over Oahu and dropped down on Molokai to a little field. Molokai is largely uninhabited or farmed. There are only about 5,000 people on it all told. Much is rugged volcanic mountains ending at precipitous cliffs. We cruised along over the sea just out from these cliffs and directly over the leper colony there. It is a little settlement nestled on a fan-like lava flow which spreads out from the base of these cliffs into the sea. The peninsula is backed by vertical walls nearly everywhere. We could see a burro trail descending the cliff in a series of switchbacks. There is a little hospital, churches, houses, a small landing field, a couple of roads, and a lighthouse in the colony. Beyond the colony the coast is even more rugged. Great steep-walled canyons lead up to abrupt faces that usually had waterfalls pouring over them.

We then came to Maui. This island is composed of two very high, rugged mountains separated by a saddle-shaped plain. One of the mountains is Haleakela, a great 10,000-foot volcanic peak that is part of Hawaii National Park. We cruised over the checkerboard of farms and landed at Kahalui Airport, where we were met by a Fish & Game truck and taken to the dock, where the *Makua* was waiting. Frank and Boots were absolutely shot from having been up all night tending the shad. The fish were in excellent shape and we began preparations for the planting.

A nice fellow who was in charge of heavy equipment for the C&H Sugar plantation escorted us up to the planting site at a reservoir on the plantation grounds. On the way he gave us a lot of information about the art of sugar raising. The plantation is one of the largest in the world, encompassing 640,000 acres. They have their own schools, shops, stores, foundries, and so on. He had 135 pieces of heavy equipment to care for. This included such things as 65-ton carry-alls that are packed full of cane and driven to the refinery. The sugar is brought down to what we would call brown sugar and then shipped to Crockett, California for the final processing. They even run their power

plant on the stalks that remain after pressing and have enough power to supply all of Maui during the refining season. It is hard to picture the huge size of this operation. They even have their own railway.

We drove up through the plantation onto the side of Haleakela to a nice pond all set about with trees that looked like mesquite. They run large numbers of black angus cattle above the cane fields and these were milling around. We put the fish in with little trouble and lost about 6 out of 1,500. The only plant that has been poor to date was not made by us but by Fish & Game by air to Kauai. The threadfin operation has been highly successful and are we glad that it is over. The only trouble is that it is supplanted by hauling live aquarium fish back, which is worse in many ways.

Once we finished the plant we went back to the ship and Pete Wilson plopped us all in his car and we drove off to see Haleakela. It is about 25 miles to the top. First you pass through cane fields, and then grassland dotted with groves of eucalyptus and then up into lava floes heavily vegetated with low bushes and finally out onto the crest at 10,000 ft. The crater is immense. A 1,000-ft. cinder cone looks like an anthill inside the crater. There are several of these cinder cones down deep inside the main crater. In two places the lava poured through the crater wall and ran like a vast glob of molasses down to the sea. The crater of course is dead now, but you can imagine what it once was.

We could look out over the sea and look at the surrounding islands. Mostly they were covered with cloudbanks. We drove back down peering at pheasants and chukkar partridges along the road. Back at the boat we watched an aku boat unload (skipjack tuna). It is a most primitive operation by our standards but the fish are in A-1 shape.

Pete wanted to take a run over to a village called Lahina, on the other side of the saddle. Boots and I jumped at the chance, fagged as we were by this time. We arrived just at dusk, giving us time to wander around a little. It is a charming place. Once it was the capital of the islands when it was a whaling port. Evidences of whaling activity could be seen in the form of old rendering pots and other such gear. They had a grand old hotel called the Pioneer, complete with veranda, swinging doors, and a fine old-fashioned bar with wicker furniture . . . completely charming. We'll have to stay there when you come to the islands with me. We were looking for the crew of a tuna boat and wandered across town. The center of town is occupied by one huge banyan tree. The single tree covers a city block. Dozens of aerial roots descend into the ground to support the spreading limbs. Some of these roots are as big around as a man, or more. We met a couple of ex-patriate divers who were eking out a living diving for the black coral that our Carmel artist was using for his jewelry. Pete decided to stay on the boat and left us with the car (which he had borrowed) to get back to Kahalui as best we could in the dark. We made it but not without a few deviations in the dark.

Next morning we left port at about 2:00 A.M. for Molokai and our fishing attempts. It was bright dawn when we passed the end of the island and up along the cliffed coast. One canyon in particular seemed unbelievably beautiful to me. It was a U-shaped gorge ending about a mile inland at a 1,000-ft. sheer cliff. The canyon was choked with trees, and taro patches and such, and up over the cliff plugged a waterfall as large as Yosemite Falls. Fabulous . . .

We finally began our fishing activity in earnest at Kalaupapa (the leper colony). What a lonely and isolated spot it is. The sheer cliffs lock it behind and the rugged lava coast against the sea. The tradewind-whipped seas crash in relentlessly sending plumes of

spray up into the wind. We drifted in what lee there was, droplining with considerable success. We caught lots of goatfish and wrasses and such. Most everything had to be punctured with the needle to deflate the gas pressure that builds up when the fish are hoisted from deep water.

The men on board, Georges Gilbert (the skipper), Sam, Carl, and Richard, were wonderful fun. Georges is an islander who has never left the islands. He is a smart and happy man who is always singing something. In some ways he is an unsophisticated childlike man, which is greatly refreshing. For instance he thought nothing of singing us a little song about canning pineapples that he had written in his grammar school class.

The others were biologists with the territorial Fish & Game or crewmen. Sam, the crewman, is a peppery little Japanese man. He is an oldtimer in the tuna long-line industry. Carl, a very intelligent Japanese biologist with Fish & Game, and Richard, a rather sleepy Japanese working on the tilapia project (a fish they are also trying to develop for tuna bait).

We caught some Kona crabs on funny square-mesh crab traps. It is undoubtedly the most delicious crab I have ever eaten. Sweet, wonderfully textured flesh.

Next morning we cruised down along Molokai to the west end. We made an attempt to catch ulua, which are big jacks, but failed. We also set the gill nets and I went ashore with Georges to try for seargent majors. We landed on a beautiful lava reef. The pools are superb and filled with all kinds of wonderful critters. I saw many little 1-2 in. butterfly fishes that normally cost \$10 each in our stores. I had a little bamboo pole with a length of leader and a single hook. The trick was to drop the bait into the swirling water as it poured over the boulders white and foamy. It was great sport catching all kinds of strange critters while creeping over the rocks. I got thoroughly soaked with one wave that crashed on the rocks in front of me.

After staying in this cove for the night, we crossed the channel and made for Oahu. Flying fish were everywhere—ones with pink wings and ones with clear wings and little ones like bumblebees. We saw a few porpoises that are much like our common dolphins and then entered the harbor. Frank and Boots and I then worked like demons until almost midnight getting the fish off and into the storage tank. It was back-breaking work carrying all the fish in big buckets and garbage cans.

That's about where we are now . . . the fish are piling up from trap fishermen and our catch and other sources. I think we will have a nice load without too violent an effort. One thing about this fish transporting stuff . . . there is never really a time when you can really take it easy.

Well, this letter is being written in pieces and hunks here and there. We just returned from having dinner up at Tinker's house. It was fun. He has a nice house with pandanus (hala) trees in the backyard, plus frangipani and mango trees too. I had a couple of rousing pingpong games.

Your letters were wonderful, Phylly. I could see our little daughter all covered with beet juice and hear Richard howling. Oh my, it must grate on your nerves but it carries all the sounds of home to me and seems very wonderful. There is nothing like being busy to combat loneliness, but sometimes it breaks through pretty hard anyway—usually when I am doing something I would like to share with you. I love you awfully much and want to be with you and the whole clan. I imagine it will get pretty hard to take

about two days out to sea. Right now I can swat mosquitos and wait stoically to go home, but it is far enough off so I unconsciously take it in stride for the moment.

All my love to you sweetie and give the whole crew a kiss from Daddy and tell them where it came from.

Ken

Save my letters Phylly, I want to compose field notes from them.

September 14,

1959

Dearest Phylly,

We just came in from Niihau and I was greeted by a fine lot of letters. Most appreciated too. It is great to hear all the little goings on at home. I wish I could have witnessed the first day at school for Susie. She must be pretty darned grown up, and I can imagine how you felt with her traipsing off into her own private school world. Well, it will be fun to sit back and see what happens now.

I will know definitely tomorrow, but it looks now as if we will be boarding the *Rancher* on Saturday the 19th and coming directly home, instead of the later *Builder*. There were some cancellations and we may get aboard. This will be wonderful as the *Builder* has been delayed a couple of more days and I want to get this show on the road and get home to my family and to get the critters off my hands and into the tanks.

I guess I should give you a day-by-day chronicle of the Niihau trip. It was an interesting one. We left the basin at noon and cruised out into the channel. Kauai is nearly 100 miles up the line and could not be seen for a long time. We had a following sea and thus a pretty smooth ride. Sometime early in the morning we changed course away from Kauai for Niihau. When I went on watch at 4 AM we were cruising down the high cliffs of the windward shore of this "forbidden" island. As you may know, it is owned by one man, a Mr. Robertson. He also owns about half of Kauai. He is a very religious person and has sought to protect the natives of Niihau from the corruption of the outside world. If a native leaves without permission he may not return, and no outsider is supposed to land.

About dawn we rounded the cape of the island, past a big cinder cone, and started up the leeward side. We set our crab nets out in deep water offshore. These are discs of netting in which the crabs become tangled when they try to walk over to the bait secured in the middle. Once this was done we went in closer to shore and began hook and line fishing. Georges emptied a catsup bottle and used it as a float for an ulua line. This is a big jack that we wanted very badly to catch. He baited a most venomous looking hook with a live goatfish and tossed it out. During the course of the trip we took six ulua with the gear. They are among our nicest fish. Our hook and lining produced a fair number of nice fish, mostly the same kinds we had taken earlier at Molokai. The boys loaded the skiff with nets and tanks to make a set inshore for large reef fish. The net was set in a semi-circle with the ends against the shoreline. The men then dove and chased the fish toward the net. A few would get entangled and then be taken out by a diver and handed up into the boat. Georges, the Hawaiian, French, and Irish skipper, was hit by the tail spines of a big kala (unicorn fish) and was ripped on one finger almost to the bone. The hand was patched up while I went into help retrieve the net. I wore my face plate while

Fuji, a taciturn but wonderfully efficient Japanese fellow, dove with the aqualung. I hovered above him to untangle the net from the diving rig as the surge swept it back and forth. Inches at a time the net came in. It had to be untangled from each piece of coral in this fashion. I guess it took us three hours on the single set.

We were anchored off Nonopapa, which is a cattle loading station with a big barn set under large aljiroba trees. These look like big mesquites and cover the island. The island is marked by a large row of volcanic cliffs that slope down to a rolling grassy prairie that supports a couple of large brackish ponds and finally ends at the other extreme of the island in the cinder cone we had rounded the day earlier. Niihau is largely a cattle ranch, but they also run sheep and goats and raise some food plants of one kind or another. It is lower and more arid than the other islands, except for rocky, barren Kahoolawe.

After a wonderful meal cooked by the abrupt little first mate, Sam, we went back to hook-and-lining for night fish. We caught a lot of mempaches and little cardinal fish. In the evening, after the fishing had slackened, Georges hauled out his ukulele and sang Hawaiian songs. He has a fine tenor voice and knows and can translate many of the local songs. It was great fun and we ended up with an orchestra of pots and pans and stove lids, plus the uke.

September 10, 1959

We were up early and inspected the crab traps for the second time. This time we brought up a dozen and a half of the wonderful critters. On our way we were accompanied by a school of 15 or so big *Tursiops*. They ran the bow wonderfully well, and as well as we could determine, were identical with our California species. Then, later in the day, we saw some small, slender porpoises in close to shore. Much to our surprise they started jumping into the air. We saw tiny ones of no more than 25 lbs., up to adults of 125-150 lbs., leap into the air and spin like tops before hitting the surface again. One even did a one-and-a-half flip while spinning on his long axis. They look like a small *Delphinus* but are slimmer with a longer snout, are smaller and swim slower and much closer to shore than our *D. bairdi*.

We had talked with some other fishermen in a sampan and they told us to go up to the end of the island for our netting and hook and line. So we started up along the coast, past long coral beaches as clean and vacant as if no one had ever walked them. All through our journeys along the coast we were followed by a rickety old stake truck or by horsemen racing through the grassy fields watching us. Finally, after an hour's run we reached a little rocky cove near Lehua Island. The truck on shore was there to greet us and we could see the natives beckoning us ashore. Fuji, Frank, Boots, and I decided to make a set at this place and rowed in. Fuji and I put on our diving gear and plowed ashore. The natives had nothing particular to say but just wanted to talk to strangers. They were dark skinned and all but one had the dark hair of the Polynesians. The one was red haired. All were childlike in their simplicity and knowledge of the outside world. They were dressed in jeans and dusty shirts and hats. One that looked a little like a dusky Milton Berle knew a little English. He didn't know what "cow" meant but understood when Fuji called cows "Pipi," which is the Hawaiian word. They didn't know what I meant by California, but vaguely understood "Cahlifornie." Of course they didn't know what an aquarium was. Milton Berle had a transistor radio under his arm and was

miraculously and incongruously listening to the Dow-Jones Stock Quotations. He was probably Niihau's industrialist. We found that there are 21 registered voters on the island and they vote absolutely solid Republican, all other parties being sinful I should imagine.

We pushed off through the surf and cruised over the bottom. I picked up a sea cucumber and tossed it to the laughing natives on the shore.

The undersea shelf was rifted with deep canyons studded with corals. All kinds of beautiful fishes cruised about. We saw big kalas with their vicious spined tails, pretty black-and-red tangs, butterflys, and many pretty wrasses. We set the net across one of these rocky flats and began chasing the fish into it as best we could. We sought the fish out and actively herded them toward the net. Most of our catch was tangled where the net had been hooked up against a rocky reef. Amongst other fish, we took one big, beautiful, jade-green-and-pink parrot fish of about 15 lbs. Frank and Boots took our catch back to the boat with the outboard while Fuji and I tried to drive more fish in. Then came the tedious task of bringing the net up. The bottom was criss-crossed with channels like those of a maze, dug by sea urchins. The net caught on the ridges and tangled in the coral. By the time it was up we were both puffing a little, though Fuji much less than I.

At the boat we found Sam fishing away. He is Japanese, about five ft. tall, and full of pepper, but great fun. He loves to come up and say, "Hey you, give me you line, I'll show you how to catch fish." And then he proves it. One time Fuji was sleeping in the galley and Sam went up to him and shook him. Fuji mumbled something incoherent and Sam shouted "Shut-a-up you," and then walked off laughing. Sam had caught about 12 humu humu ele eles (black black trigger fish). I tried and caught 3 in a couple of hours while he caught 12 more. Finally he showed me his gear with little leaders and hooks and I began to catch then too.

The others went out to make some more sets. Georges had encased his finger in the halves of a bamboo pole split lengthwise. There was not room for everyone in the skiff so I stayed on the boat and fished. The boys made three sets and got virtually nothing for their pains but extreme fatigue. I loaded the tank with humu humu ele eles.

That evening we cruised up to Lehua Island. It is a tall cinder cone that juts up from the sea a short distance offshore from the main island. We tried to anchor but the anchor dragged free and fell into deep water while we drifted. So Georges turned the ship down the coast again and we dropped anchor again off Nonopapa.

September 11:

Up at dawn and off for the crab traps. This time they were not to be found. Fresh trade winds had come up and the sea was a mass of white caps. We took our bearings and could not find the buoys. Finally we gave up and shortly came upon the floating line and one buoy. The evidence suggested that sharks had taken the traps and line, clipping the latter loose and stealing the crabs.

We went back in to Nonopapa and made another set in a tiny little protected cove. After much effort, in which I put an aqualung on to retrieve the net, we caught a few nice kalas and other fish. What is tantalizing was to see the myriads of beautiful fish that we could not take. After the set I beached myself and picked up a piece of Niihau rock to put in my garden, along with rocks from other islands we have visited. We picked up a load of slate pencil urchin sand went back to the ship.

The ship then turned up the coast and made for Kauai, flight after flight of flying fish spraying away from the bow as we cut along.

We reached Kauai a little after noon. Georges called a friend of his, Hoppy O'Neil, and borrowed a car while the ship put on water. We were to take a brief trip up to the high mountains of central Kauai. We cut up through cane fields and into the Aljiroba forests and then into eucalyptus groves and finally into the native forest itself. It is composed mostly of chia trees, which bear the flower called lehua. If you pick the lehua blossom it is supposed to cause a storm to come. We didn't pick any but could see the devastation wrought by Hurricane Dot where she passed through the forest. The other common tree is the koa, with long, sickle-shaped leaves. Soon we came out into a pretty series of meadows set amongst the forest trees. At 4,000 ft. it was cool and quiet. We saw wild pigs rooting in the grass at the edges of the clearings, jungle fowl called here and there, and quail and pheasants were common. This was Kokee, a vacation spot for islanders, and a lovely one too. On up we went and finally came to a promontory that overlooked one of the most beautiful places I have ever seen. It is called the Kalalau Valley and is a great amphitheatre of fluted and carved palis dropping from 4,000 ft. down to the sea, almost in a single leap. Here and there, knife-edge ridges stand up a thousand or more ft. that are so thin, even at their bases that they looked like one could poke a hole in them with a stick. It would be utterly impossible to climb them and there would be no place to stand if you did scale to the top. The valley below was choked with verdure—trees and vines and palms. Off across the valley a white waterfall plunged 2,000 ft. or more in two leaps. One man lives in the valley. He is an ascetic negro physician, who a la Thoreau is living off the land and writing a philosophical book there. He lives in a cave and can be reached only by a tortuous trail that winds up from the sea, through the jungle and under the waterfall to his cave. He lives on guavas, passionfruits, papayas, taro, and fish and goats when he can get them.

Back down the slope we visited the beautiful and majestic Waimea Valley—the so-called Grand Canyon of Hawaii. It looks much like the Grand Canyon though it is probably only a third as deep. Then we wandered in the forest and Georges picked some of the vines and plants used in making leis. The vines are carefully picked and stripped. The species used to have the finest woodsy smell. The forest was full of plants that we see only in our greenhouses. Ti plants, tall hala or pandanus trees, and so on.

We drove on down the valley to Hanapepe where we ate dinner and thence back to the ship after dark. It had been a memorable trip to a really sainted spot.

September 12:

Next morning we weighed anchor from Port Allen and made for Oahu, this time into the sea. The weather forecast said we were to have moderate to fresh trades. This means winds up to 30 knots and great spume-capped rollers. The boat pitched and bucked along at a snail's pace of about 6 knots. Sometimes we took spray and whitewater clear over the superstructure, but amazingly enough I didn't get seasick. In fact I haven't been sick the entire jaunt for some inexplicable reason.

Halfway across the channel we came upon a floating board and caught two dolphins. We made port at 9PM and secured everything and went to bed.

Well, Phylly, after that we unloaded and checked our fish and worried over the things that had happened in our absence. We had lost a lot of fish and pumps had jammed and people hadn't taken enough care. I guess it is too much to expect anyone to supply the vigilance it takes to bring these critters back except us.

We now have a lot of fish in the big tank being treated for bugs. It is a touchy time as they have to go on internal circulation for a couple of days.

Tomorrow I try to make arrangements for the homecoming plus the final fish round-up from various sources. We will all be glad when it is over and we can put our unit on the boat and come home. I want to see my family all . . . proud little Susy, Pixie Nancy, and sweet little Barby, plus squally Richard, and long suffering patient Mom . . . but you I want to hug and kiss more than anyone sweetie. I miss you all very much.

All my love,
Ken

Sawfish Trip
February 23-March 12, 1960

February 23

Don Hackett and I roused ourselves at 3:00 AM, and my wife Phyl drove us down to Marineland. With little ado, we climbed into the big 5-ton truck and started off in search of sawfish, which we planned to catch some 1,700 miles away in San Blas, Nayarit, Mexico. At San Pedro we found the other two members of our party, Frank Brocato and Frank Calandrino, waiting in their pick-up as we lumbered up. Then off through the night. Neither Don nor I had ever driven a rig such as we were doing now. In fact, I had recently been driving a little Volkswagen, and there was some difference, to say the least. The truck had 15 speeds forward and three in reverse, so we drove with exceeding caution, feeling out the braking and learning how much space we needed to turn and pass. The big 2,000-gallon tank on the bed put quite a load on the truck but she took it well. Once we were on the open road we found we could cruise along at 45 without much effort, and providing we gave ourselves plenty of room to stop, it was safe enough. Certainly we felt impressive sitting up in the cab looking down at everybody below. Volkswagens were positively things to be scorned as it was obvious that the truck could roll right over one and crack it like an egg.

Dawn broke as we started into the San Geronio Pass and we rolled along without event to Yuma. There we found we had to license the big truck to pass through Arizona, at a cost of \$15.50. Toward afternoon Don and I began to feel like "rig pushers" except that we clashed an occasional gear here and there. The other truck drivers recognized our exalted status by waving a nonchalant hand at us as we went by. By the time we stopped at Gila Bend the cold night air of the desert closed in and we were glad to park our gear and take a nice comfortable room for the night.

February 24, 1960

An uneventful day's driving to Tucson. We visited the Arizona-Sonora Desert Museum briefly to look at their new small tank displays. They have done a marvelous job with fiberglass, producing simulated granite, sandstone, and porphyry that is indistinguishable from the real thing. My only complaint—the tanks lack color.

February 25, 1960

Left Tucson early and rolled into Nogales before noon to begin battle with the border officials. Little did we know what a battle it was to be. These border towns are not only unsavory places for the most part but also centers of the red tape industry as well as the mordida or greased-palm industry. Whole fleets of Mexicans survive on what they can con out of the American tourists. Our passage through American customs was brief and easy. We were advised to handle our Mexican problems through a broker and I sought out a Mr. Carlos Miller Ojeda, who had been recommended as an honest man, which he certainly proved to be. He ushered me through several departments and we were soon on our way to the southern check point just south of Nogales. There all was going well with swarms of inspectors crawling over our baggage looking for ways of menacing us into thinking we would never get through unless a few bills were appropriately passed.

Then one particularly official gentleman in military clothes sporting a sign "Celador" asked how big our truck was. "Five tons," I replied. He arched his brows and shambled in to phone the Chief of Customs, a Mr. Sanchez. Since we were classed as tourists Mr. Sanchez thought it a little odd that we should be driving a 5-ton truck. We agreed, but we explained that their own Mexican consulate in Los Angeles had advised on going as tourists. No avail. We must go back. After endless conferences in rapid Spanish, with Mr. Miller waving his hands in frustration at the perfidy of his own countrymen, we found that our permit stated that we were allowed to take in personnel and equipment, but that it was not possible to construe equipment as including a 5-ton truck, even if it was the only way we could ever hope to bring back live sawfish. The permit would have to be changed.

That evening I called the Mexican fish commission from our motel on the American side and requested an emergency change be made. Alas, it could only come from Mexico City, and this sometimes took weeks (which we very well knew from past experience). The man in San Pedro said he would try and mark it "urgente." So we relapsed in our rooms muttering and plotting new ways to stir up Mexican officialdom.

Our frustrations were just beginning, though we didn't know it.

February 26, 1960

Up this morning and right into a nice day's battle with regulation books. Mr. Miller escorted me to the Mexican consulate and the consul (a nice, wispy little woman) said she would be glad to issue me a commercial visa but that she saw no way else to go in if our permit was not changed. Hurray, I said, let's get a commercial visa. Aha, she said, where is your passport? None existed. I will get one, I said. Once again we thought we might be on our way until I found that this passport required a physical exam and took two weeks. The best thing they said was to fly to Los Angeles where I personally could hurry up recalcitrant officials. Off to the American consulate on the Mexican side. The

fine gentleman there told me that we were in a pickle. We agreed. He said he would call his embassy in Mexico City and attempt to have our fishing permit expedited or have the Mexican minister of transport give us a special permit for our truck. While he was stirring things the consul called Mr. Sanchez and badgered him a little, but the rule books held firm. He called the Mexican consul too and found that we might cross if one of us obtained "industrial clearance." "Let's get industrial clearance!" I shouted, clapping my care-worn hands. If you do it that way, he said, you might be through tomorrow morning." So, off I went to get industrial clearance, but this turned out to require a passport, too, so we were back in the soup again. If we only had one commercial visa all would have been well.

The real meat of our problem was that trucking in Mexico has been organized and no American drives a truck in Mexico for commercial purposes. Semis come up to the border and the American unhooks the trailer and a Mexican hooks on.

Well, maybe tomorrow our telegram would come.

February 27, 1960

It didn't. We called San Pedro and he hadn't heard either. He explained that telegrams sometimes took five days to get through official channels. Would he phone at our expense? He would, but how could we arrange the bookkeeping and all that? "Oh, good god man, forget the red tape and get us across the border!" No chance today because they only work half a day on Saturday and even under the best of circumstances inspection takes that long. Another poke at Sanchez and one at the American consul and our time was up. The latter gentleman was sure, however, that something would pop on Monday and maybe then we would get through on Tuesday.

With all the parlors closed where we might poke officials we relapsed and decided to take a drive into the surrounding country for the afternoon to ease our wounded souls a little. We piled in the pick-up and drove out west of Nogales to an old camp spot of mine in Alamo Canyon. This beautiful place was the site of an Apache massacre in Geronimo's time. The old adobe of a settler named Yak Bartless who was killed by these ferocious Indians stands there today in ruins.

We walked among them wondering what it must have been like during the time when it was in use, and what it must have been like to live in the midst of such savages as the Apaches. We hiked down the canyon under huge sycamores, alders, and willows, into the deep gorge of the main canyon. Great, precariously balanced spires of rock reach up from the canyon floor, some as high as 250 ft. Boots looked up at the wild scenery and opined, "If this whole thing was just under water it would be a damned fine octopus ground." It takes all kinds.

On our way back we stopped in at a place called "Pete Kitchen's Museum." It was run by a retired Army Colonel named Gill Proctor. The old adobe was the original farm house of Pete Kitchen and had seen the scars of Apache sieges for decades. It was full of a marvelous collection of Indian and early Spanish relics plus many things from the old west.

February 28, 1960

To keep from stewing over our troubles this Sunday, we decided on another ride. This time we headed east and drove to famous old Tombstone. It was a cold ride in the

back of the pick-up but interesting to see the tall, snow-capped mountains and the broad, grassy prairie between. Gradually the scenery changed to desert as we neared Tombstone. The town is a rather down-at-the-heels affair. We looked in at the OK Corral and decided they needed a little showmanship. First we decided, they should toss out all the old Model T Ford parts, spruce up the grounds a little, install a live horse or two, and stage the Earp-Clanton fight on the hour. Also, they needed Safady's touch in the gift shop. The Bird Cage Theatre was a little better but a few electrographed labels and a little classy announcing and gate keeping would have helped, not to mention some enlightened maintenance. As a final thought for pepping up the show at Tombstone we thought a snack bar would go over big, selling "Earp Burgers." Really, it was a shame to waste our talent.

February 29, 1960

After a call told us that our telegram hadn't arrived in Nogales, we called Bill Monahan and poured out the whole ghastly tale of woe. He went right to work on it by prodding numerous officials in Los Angeles and soon called back to say that the Mexican Fish Commission in San Pedro had received word of our permission. We learned however that telegrams sometimes take five times as long inside Mexico as outside and that there was no assurance that ours had gotten to Nogales. Phone calls were flying, including a long-distance one from Mexico City to Mr. Sanchez. We learned with great glee that it had been necessary to shut off all other phone service in Nogales when this call came in. The Monahan-poked Los Angeles Mexican Consul had also called, as had other people. Before the day was over Mr. Miller had occasion to call Sanchez and ask, "Do you remember Mr. Norris and his party who are trying to fish at San Blas?" Mr. Sanchez snorted: "Do I remember Mr. Norris? Ha! I not only remember Mr. Norris, I *dream* Mr. Norris." It looked like we were winning.

March 1, 1960

A call from Mr. Monahan at Marineland had informed us that our telegrams should be in the hands of the Mexican Fish Commission official in Nogales, a man we didn't know existed. Boots and I sought him out and found him up an unmarked flight of stairs in an unmarked office over a liquor store. Yes he had our telegram, in fact had had it late Saturday. Our impulse was not to leave him unmarked but we calmed ourselves and waited while he typed up a new permit and gave it to his secretary to type six more copies. Then we raced back to Mr. Miller and bonded our truck and gear. For all his work he charged us the princely sum of 8 dollars and would not take more. We were then inspected in several different planes and shooed across the border with moments to spare since the truck gate closes at 2 PM. We wound our way unbelievably through Nogales and out to the check station. We were so well known by this time and had so many official stamps and signatures that mordida was not even required. In minutes we roared out of the station and onto the open oad, unblocked by official Mexico. Diego Hoffa be damned!!

Several hours and a half dozen check stations later we reached the pretty town of Hermosillo, the capital of Sonora. There we holed up in a plush motel charging \$6 a night, complete with tile floors, floor show, and swimming pool.

March 2, 1960

We drove on toward Guaymas through a scrubby desert whose floor was carpeted with a veritable sea of orange mallow flowers. At Guaymas Frank and I inspected the harbor for the best spot to refresh our water supply on the way back. We found satisfactory water but it was so cold (66 degrees F.) that we doubted that we could hope to use very much for fear of killing our animals by temperature shock. On we went, passing through vast farms in the river deltas. Dams that have recently been constructed have converted thorn forest into wonderfully productive farms for grains, cotton, flax, vegetables, tobacco, and other crops.

We stopped for the night at a motel in the midst of the thorn forest just north of the Sinaloa border. The weather had begun to warm compared to the chill of Nogales. Boots and I took a little hike out into the thorn scrub, marveling at this spiny jungle which is so dense a man on horseback could not ride through it in many places. Some of the mesquites sport thorns more than two inches long and needle-sharp.

March 3, 1960

We pushed on over the reasonably good paved road toward Mazatlan. From time to time the road dipped into the foothills and we saw the thorn forest give way into the the short-tree forest composed of tangled vines and peculiar papery-barked trees, many covered with colorful flowers. By the time we had reached Culiacan we had begun to pass through groves of Sabal palms and the Mexican houses usually had thatched roofs very reminiscent of Africa. We saw our first parrots flying over in their peculiar direct flight, with wings beating rapidly in shallow strokes. After lunch at Culiacan, one of the oldest cities in North America, we climbed the mountains and rolled toward Mazatlan.

Our truck has three fuel tanks and one went dry on this grade so we switched over to a new one. Before long the truck began to sputter and lose power. However, once darkness fell it picked up and we cruised into Mazatlan and took a couple of rooms in a rather nice looking motel. A little ferret-faced, blue-eyed Mexican, who looked like he didn't like daylight, showed us to our rooms. We unloaded and went into town for dinner and a look around. Mazatlan is a picturesque place of narrow cobble streets, grated windows, doors ajar to reveal lush patios filled with palms and vines in sharp contrast to the dusty streets outside, Mexican rancheria music pouring from cantinas, idle men loitering under street lamps, plush tourist districts shunned by the working populace of the town, and a broad harbor filled with boats of all sorts.

Back at the motel Hackett and I went to sleep in spite of the mosquitos but Frank and Boots kept awake by the same beasts watched while the opposite bank of rooms from ours came to life about 11 PM with taxis shunting in and out and men and girls shuttling back and forth, laughing and drinking. Vice like poverty is accepted in this land as part of the scene.

March 4, 1960

Frank was up before dawn pacing around and waiting for one or two of us to stir so that he would have an excuse to rout out the rest of us. We were on the road early and plunged nearly at once into the foothills. The scenery became rapidly more tropical. Sixty-five miles south of Mazatlan we rumbled down the main street of a sleepy little sub-tropical town called Esquinapa. Palms were everywhere in evidence, and big, three-

foot iguanas became a common sight, crawling over the rocky walls lining fields. Many of the sabal palms were seen in the throttling grasp of vines that clung so tight that they dug into the palm trunk. Fig trees did the same and it was common to see the many-rooted trunks of figs with the crowns of all-but-hidden palms appearing among the fig leaves. The vulture population became at least equal to the human population. We noted three kinds—the common California vulture, Audubon's caracara, and the smaller black vulture. We suspected that these fleets of macabre birds made their livelihood from the dead livestock that dots the road edges. The stock runs free and is probably the biggest hazard to navigation that an American driver encounters. Donkeys, cattle, and horses all had fallen prey to cars and trucks, though the cows seemed the most vulnerable. The fleet-footed goats emerged with a record of 100% escape so far as we could tell from our sketchy roadside census. At any rate the carrion supply was in good shape and the vultures were all smiling as we passed.

The hills became more rugged as we reached a little hamlet called Rosario. This town boasted the ruins of a 300-year-old church standing on its hillside. Behind the town to the east we could see ridge after ridge of hills rising to the scarp of the Sierra Madre itself.

Not long after this the truck began to puff and wheeze again. We crept up grades in the lowest gears available with the engine popping and sputtering. Objecting all the way, it finally brought us to a turnoff which announced that San Blas was 26 miles off to the southwest. The road was paved and we weaved and wound our way down toward the coastal plain below. As the flats came nearer we dropped into a true jungle of tall, leafy trees, vines, and palms. Banana groves covered the hills in places, and were called "oro verde" by the Mexicans because of the value of the crop. Once we reached the plain we crossed a mangrove swamp and then a broad tidal inlet and entered San Blas. It is a true tropical town set in the midst of coconut palm groves, huge mango and papaya trees. The houses vary from calsomined adobes of every conceivable color to woven thatched houses to ancient adobe ruins from the days of San Blas's earlier glory as western North America's first seaport. We looked into one of these—the old customs house—its roof gone with figs growing and taking their very nourishment from the walls, ancient staircases circling upward to a floor that no longer existed, graceful arches and paved floors. Palms grew in the anteroom, and bougainvillea vines crawled across the second story porch.

We took rooms in a place called "Bungalows San Blas" for 20 pesos a day (\$1.70) and got our gear arranged. It was a nice two-story apartment with a central courtyard shaded by a 100-ft. mango tree. Our beds were a bit resistant and the shower fell directly onto the toilet but these were minor things, since we were in San Blas, our destination.

Then we scouted the beaches to find what we could about the sawfish situation. Our general plan in such ventures such as this is to ask innumerable questions and make no commitments for a day or so, meet what fishermen it seems wise to seek out, and generally learn the score. Then we make our decision and arrange for boats and so on. This avoids the sometimes fatal mistake of falling in with the wrong people at the outset and then having to leave them and cause bitterness. It isn't hard to find the best man for the job by this means as he will be recommended from various sources. The con artist will not. He will be recommended only by his cronies.

We learned that the sawfish were present and fished to some extent for livers and meat, the latter being esteemed in Mexico City and other inland towns. We learned that boats were few and mostly dugouts. Some of these were very large though, holding four or five tons loaded. Some were masterpieces of craftsmanship. To our delight, there was rather little surf to contend with, but a considerable shallow bar across the lagoon entrance.

Just before we left, the tiny gnats called "Cayenes" emerged and began to chew happily on the flavorful hides of newly imported touristas (us.) We decided we could stand their chewing if the bites didn't swell up later.

In the evening Hackett and I took a walk around town, listening to the juke boxes blaring rancheria music, chickens squawking, pigs squealing, dogs barking, and Mexican men whistling in the dark. Everywhere I have gone in Mexico this nighttime whistling is part of every village scene. Why, I don't know. Maybe they don't have enough money for a trumpet. Think what it would be like if they did.

We stopped in for a Corona (Mexican beer at its best) at what must rank as about the dirtiest bar I have ever entered. Then back to the rooms for the night. During the night, in spite of bug-bane which we applied liberally to our exposed but still delectable hides, hundreds of tiny soundless mosquitos came to feast upon the new turista harvest. They were so small that they passed readily through the screened windows. The Cayenes were no serious problem but these little monsters caused me to swell up in one continuous mass of bites on arms and legs. The others were not too affected but their time was to come later when the bugs found my scar tissue too tough to penetrate.

March 5, 1960

This day we made the rounds of the fish landings again and Frank and Boots (both getting pretty fluent with their Spanish) extracted much valuable information. I am a little more reticent and lack the backlog of Italian words to be thrown in in a pinch, but even my language is becoming pretty serviceable. Hackett was mum as he didn't want to act like a paunchy tourist in a loud shirt and dark glasses saying "Si, Si, Senor" in what he thought was Spanish.

Our path led to the Inspector de Pesca, one Senor Pepe Padilla. He spoke English well and directed us to one Luis Garcia Lopez. Mr. Garcia turned out to be our man, which was evident in a few minutes. He was the innovator in the port and had introduced nets for shark fishing and knew a great deal about sawfish, having a long, dotted series of scars across his chest and along one arm to prove it. His respect for the fish was great. He owned one of the best boats, a 18-20 ft. inboard with a small Gray gasoline engine. With little further ado we hired him along with a taciturn crew man named Caligsto Gamio-Chipe for about 15 dollars a day, including gas. We arranged to meet them at Matanchen, an open roadstead about two miles down the coast, where the sawfish were said to be common.

Having settled this we went back to our rooms and began to gather our gear. Frank and Boots and Don began assembling the big wire mesh vivederos, or live boxes, which we planned to use to hold the live sawfish.

We were fortunate in meeting two Americans at our bungalows who were most helpful. In fact these two men simply could not do enough for us. Both had given us the name of our Mexican fishermen and so had the Inspector de Pesca. One of the men, Paul

Brunell, promised to photograph our capture efforts and later send us a graphic record of the attempt. The other, Mr. I. W. Allen, helped with his fine cruiser which accompanied us and helped with some of the maneuvers. It is wonderful to meet such men in foreign lands if for no other reason than to know that they give Americans a good name in these countries.

With our pick-up loaded we relaxed and wandered down the cobble streets to a little restaurant called the Beachcomber. They offered filet mignon for 10 pesos, and a meal for four including beer all around and soup usually ran about 4-5 dollars. The filet was of variable quality and sometimes reflected the hard life of the cow that supplied it, but for the price the name alone was enough.

Frank stayed in the bungalow shooting the breeze with our American friends while Don and Boots and I went out on the town. We watched a fine baile, or dance, in the city square, where young girls danced shyly while their dueñas watched from the sidelines. An incredible orchestra sporting ancient valve trombones and tubas and maracas beat out the songs. The night was warm and we weren't sleepy so we dropped in at the pool hall for a couple of games. Boots allowed as how he didn't know the rules very well, but then proceeded to clean off the last ten balls without a miss. Four games cost 2 pesos, or 24 cents. Off to bed for tomorrow the sawfish collection was to begin.

March 6, 1960

We hustled ourselves out early and drove to Matanchen to meet Luis. It was an eerie, foggy morning. In the mist we watched two roseate spoonbills rise from the mangrove swamp and disappear—the first of this species I have ever seen. Before we reached the beach we drove through a dense mangrove forest with gloomy canals of drab green water flowing completely covered by the arcing limbs of mangroves. We could see snappers cruising along under the road bridge where it crossed these channels.

At the beach no Luis was in sight. While we waited we watched some skimmers feeding. These are big tern-like birds with large red bills. They were cruising along the water's edge within 20-30 yards of us. At the point where the water was swashing back and forth over the sand they would cruise in, lower their beaks until the tip was about a half inch below the surface, fly 30 or 40 yards in this position, and leave a perfect V-shaped wake. Their beaks were just slightly opened during this maneuver. They were attempting to catch some small killifish-like creatures that were schooling.

Finally, an hour overdue, Luis and his man appeared on the beach. They had mistaken our request and had waited for us at the bungalows. The delay was of no importance however, as it was too foggy to work since Luis could not see his landmarks. A cup of hot Mexican coffee and a little conversation and finally we jumped in the dugout canoa and paddled out to the little cruiser anchored offshore. Soon we were underway across the broad bight of Matanchen.

For five or six miles it is edged with a broad white-sand beach, finally ending on the south in a series of abrupt rocky cliffs. Offshore two or three miles is a shallow reef beyond which is the open clear sea. We heard reports of many fine reef fishes here. Such things as squirrel fish and Moorish idols were reportedly common. The bight itself has a muddy or sandy bottom and is very murky. It was a flat calm day with no indication of a swell. We saw many eagle rays flipping the tips of their wings above the surface, a few mobulas, or small mantas, and our American friends reported two 10-12-ft. whale sharks.

About two miles offshore we simply payed out the net and left it. Back at San Blas, Don and I left Frank and Boots and took a walk up to some ancient ruins that top a nearby volcanic bluff. The noontime heat was upon us, sapping much of our energy. We walked down the palm-bordered back streets of San Blas watching the iguanas slip off the rock walls as we passed. We then climbed up a dusty trail between shacks of saplings, into dense banana groves and finally out onto the bluff top. We were soon in the roofless ruins of an old fort. It was a massive structure and from its front parapet one commanded a view of the entire coastline. Old rusting cannons were still in place, pointing out over the coconut palms. We left the fort and wandered down a dirt road which shortly led us to the impressive ruin of an old church. Scattered on the grassy area in front of it were several old crypts, some half gone with age, and others intact. Inside the church we entered a massive room with a great vaulted ceiling whose roof was missing. The sunlight streaming in fell upon vines and palms growing near the place where the altar once stood. Two old beams still spanned the roof, though they were a lace-work of holes from boring insects. Outside, some of the outbuildings could still be seen though they were locked in the grasp of hundreds of roots from giant fig trees that grew over them. The roots were literally tearing the ruin to pieces.

San Blas is the oldest port of the west coast of North America, having been established in Cortez's time, about 1535. It was the major stopping place for the Manilla galleons, upon their return across the Pacific. Here crews stopped for water and fresh fruit to cure the ever-present scurvy. I doubt that these ruins date nearly this far back but they were doubtless quite old.

We returned to Matanchen at 5 PM, boarded the boat and made for the net. After a minor bit of engine trouble we reached it and found the corks down in a couple of places. The first thing we pulled up was a drowned green turtle, then a live one, and then up out of the murk Frank and Boots pulled a great thrashing sawfish. Luis cautioned us to stand back. He stripped to his shorts and leaped into the ocean with a piece of rope in hand. Gingerly he slipped a noose around the bill of the fish, being very careful to stay well out of reach of the blade. The saw of these fishes is edged with equal rows of triangular blades more than an inch in length. One swipe would sink them to the hilt in an unwary person.

Then Luis climbed on board and while still dripping water he and Frank and Boots secured the tail of the big fish. It was then cut free by the flying knives of our collectors and left astern on the tether. Don tended the ropes attached to it while the boys went on down the net so see what else was in store. We found two more big sawfish—one about 15 ft. long, or three ft. longer than the tank. We towed them all in very slowly and anchored them out in the bay with buoys and head and tail ropes secured to anchors.

It was something of a puzzle how we were to handle these extremely dangerous and powerful animals. We left this for discussions over dinner to solve and made our way ashore, elated at the easy success in capturing our quarry. Such luck as this very seldom occurs in fish collecting. Usually there is much learning to be done before capture is successful. Don and I figured it was because Dr. VanDenburgh had been taking good care of us. We had seen him in Los Angeles when we were getting visas and once again in Mazatlan. This latter encounter was second to none in my memory. He was old and wrinkled as he should be, with a cane, a long white beard, trifocals, a stalkers cap, and leather and canvas jodhpurs. We watched him for a block as he pottered along, spreading

benevolence on all collectors. How Frank and Boots explain it, I don't know. I rather think they don't take too much stock in Dr. VanDenburgh.

March 7, 1960

Frank and Boots planned to set the net again today while Don and I went into Tepic to obtain a few small items plus a permit for the big truck to pass on the roads. In the course of our trip down we had learned that it is fine to operate a truck in town with an ordinary license but on the open road one is required to have a thing called "permiso carretera."

So off we went up the long road to the junction with the main highway and then up farther and farther from sea. We passed through a forest of leafless trees with big yellow blossoms. From a distance they looked like hundreds of lighted candles amid the foliage. Before Tepic is reached the road leads up into the oak belt. Most people don't suspect that Mexico is the motherland of the oaks of the world since there are scores of species living on the flanks of the Sierra Madres. Tepic itself is a hot, dusty town with rutted, rocky streets teeming with cars, carts, horses, people on foot and assorted animals. Aside from being on the main road it has little contact with the tourist flow in Mexico, since it has little to offer them.

We obtained our permit with ease, and what's more, no cost, at the Ministerio de Transportes office, and returned to San Blas. The net was in the water when we arrived and so we began packing gear and rearranging for the long trip home in the event that we should be lucky enough to catch some new fish. Our plan was to use the freshest fish we could catch for the trip home and to use those on the tether only if necessary.

Boots gave us another pool lesson and we went to bed.

March 8, 1960

Frank and Boots were up early and off with Luis while Don and I gassed the big truck and took her down to the Matanchen Beach and began loading water. Don stood out in the water and held the inlet hose while I rigged the pump ashore and started it up. At best this bay water is murky, but it is good fresh sea water even so, and a little filtration should bring it around.

The collecting crew appeared with another sawfish, and bless them, a nice 6- or 7-ft. nurses shark in tow. The sawfish had been taken from the very end of the net, after hope of success had all but been given up. They had also taken one huge old bruiser of a sawfish that could never be transported because of his size. I had calculated weights and in terms of our water volume about the best we could hope to haul would be a thousand pounds of fish (the equivalent of a heavy bait tank load with constant fresh seawater) and even this was putting a lot of faith in the efficiency of our gear. We would have to do better than anyone had ever done to haul this weight successfully for nearly 1,700 miles over the uncertain roads of Mexico. This meant that our load would be limited to two 12-ft. sawfish and the nurse shark, and even this would probably slightly exceed 1,000 lbs. of fish.

We began loading shortly. Luis and Caligsto cut saplings and wiggled them into the sand just outside the surf. One pair of poles was placed 8 in. apart and the other about 15 ft. back. The fish was then maneuvered until his saw protruded between the poles in front and his tail was tied to the rear pole. Then we slipped the rubber innertubes over his

saw and secured them lightly in place. Then a pole was tied lengthwise on his huge body, fore and aft. With this we lifted the animal onto the canvas stretcher. The pole was then released and we walked the beast up the beach. After a difficult struggle we hauled and lifted the beast onto the tank (I fell in) and slid him into the murky interior. This was repeated with the other two animals and the diesel generator started, circulation pumps turned on and filters started.

Then we left the rig standing alongside the dirt road while the fish calmed a bit. After two hours Boots and I discharged about 2/3 of the water while Frank and Don loaded up back at San Blas. We then refilled the tank with new water. This was done to eliminate early waste products from the fish that might have been given off in their early thrashings and excitement. Then, we said our goodbyes, over a couple of Coronas and left our friends. The truck drove better than we had hoped under full load. In fact there was rather little difference between it fully loaded and just carrying the tank unit empty.

We were soon on the road and winding our way up toward the main highway. It was frightening to say the least, going around banked turns with this load of water as the truck leaned ominously on each one. After about 15 miles our old sputtering trouble returned again, much to our horror. We thought we had solved it but we hadn't. Finally Frank sat on the running board and adjusted the carburetor while I drove. The truck picked up at once and began running pretty well again with a richer mixture. We were just sitting back congratulating ourselves when a loud bang startled us both. Frank said, "Blowout," and sure enough he was right—only there were two instead of just one. Both tires on one side of the floating rear axle had gone. We stopped in dismay thinking that this might scotch any chance we had of getting our charges home alive. After a brief conference we decided to leave Boots and Don at the truck to put on the spare while Frank and I drove to Tepic with the two bad tires. After a little searching in Tepic we found the main Goodyear dealer and asked about tires. We soon learned that Tepic had no such tires and that our only chance was Guadalajara. More conferences. Finally we placed a rush order for two tires of our size at a cost of nearly 400 American dollars. They would be delivered by 1 PM the next day, we were told. So, we ruefully left, bought some food for dinner, and drove back to our truck. There the boys had finally gotten the tire on after a terrible struggle. I was a distinct candidate for execution when I told them it would have to come off again as we couldn't put a new tire with an old one.

We munched our dinner, drank our coffee, and set up cots alongside the road and were soon asleep in spite of the passage of trucks and cars a few feet from our ears. Thank goodness we were off the main road or it really would have been bad. The mosquitos came, but this time they ignored me and all but swallowed Boots in one gulp.

March 9, 1960

About 9:00 AM, Frank and Don and I left for Tepic to pick up our tires. Boots stayed with the truck, with the diesel faithfully banging away in his ear. In town we fidgeted and squirmed and walked the town waiting for the tires. Finally about 2:30 they came, and tragedy—they were the wrong size. I sank into despair but Frank soon saw that the size was only very slightly larger and that we would be able to use them. So we hoisted them into the pick-up and left for the big rig.

With the size so close to the other tires we simply put a new one alongside the spare, which was a new retread, battened everything down, and broke camp about 5 PM.

The fish were still doing well and our filter was able to keep the debris down in the water to a satisfactory level.

Off we went, but our travail was not over by a long way. The engine of the big rig was only lulling us a little by running on the richer mixture and soon began to sputter and pop. All night long we drove it and it got worse and worse. Eventually it became so bad that if one shifted slightly in the seat while driving, the slight movement of the foot on the accelerator would cause it to cut out and die. We tried a dozen theories and nothing worked.

Finally, 12 hours later and 150 miles up the road, I pulled over onto the side of the road and said, "No more—we'll take the coil off and drive to Mazatlan in the pick-up for a spare." The coil was the reigning theory of the moment, since a mechanic we had roused in the middle of the night in a place called Acaponeta, said it wasn't working right.

March 10, 1960

So, Frank and I drove off again, coil in hand. Mazatlan was about 30 miles down the road. Nowhere in all Mazatlan had they seen a coil like ours. We found one that looked just like it but it was 6 volts and not 12. Finally we bought a light duty 12-volt coil and returned. It was installed, the rig started, and it sputtered inside of 200 yards. Despair settling once again. How long the sawfish could take it we didn't know, but they had better be plenty tough. Frank and I sat on the fender and I said, "Once more, let's just take off the sight glass and see if it's dirty." We did this and I blew a lot of rust out of the filter, getting a nice mouthful of Mexican low octane for my pains. Boots and Frank then said, "Let's open the screen port on the carburetor, too." Frank did this and a ghastly mixture of rust and gas poured out over the engine. With these things in place the truck bounded away, carrying its 45,000 lbs. in wonderful style. WHAT a relief!!! We picked up about four hours sleep at Mazatlan and a little breakfast and drove on. We drove and drove, happily now that we had a chance for success. At Guaymas we called another halt and parked the rig in a big lot next to the gas station. Out came the cots again and four hours more sleep put us in good shape.

March 11, 1960

Back in the rigs again and up the road. Don and I took turns curling up in the cab while the other drove. I found by taking my shoes off that I could coil up, cocoon-style, against the door, with my feet locked in the windwing and my head on the Spanish dictionary, more or less upside-down, and get a few minutes precious sleep. When one is as tired as we were, it doesn't make much difference what position you are in.

Somewhere along the road we stopped at one of our numerous truck stops to show our papers. I summoned up my finest colloquial Spanish and announced to the guard (as we later translated it), "I came a sawfish." He twitched his hairline mustache slightly. I quickly followed with, "You are alive." He rolled his eyes and fingered his .45, jerked his thumb down the road, and walked back into his guard shack. We left.

On through Hermosillo, and over dozens of torn-up strips of road, dozens of filter changes, occasional bits of food here and there, to Santa Ana. Here we planned to take a new road to the west that would take us over the flat desert and cut our journey by nearly a hundred miles. The road began as a long detour and with no end in sight we turned back

and onto the Nogales road. We arrived there in the afternoon to find the red tape waiting. We also found Mr. Miller, bless him, waiting. It was a weekend and we could not get the bonding officer down unless we paid him and three other men time and a half. One of the men to be paid was our old friend Sanchez. I met Miller and he drove me to Sanchez's house. He literally tore said Sanchez apart for this perfidy and finally Sanchez called the border guards. By the time we returned the inspection was over and we had five minutes to get through the truck gate before it closed (2 PM). I leaped into the rig and roared through the gate onto blessed American soil, free from the clawing fingers of Mexican officialdom. We were soon on the road again, having cleared American customs in a few minutes. On we drove, checking from time to time to inspect the animals and the filter and the other gear. A crack had developed in a pipe above the main pump, but it looked like it might hold till we got home.

At Sentinel, Arizona, I called a halt again and we got another four hours by our noisy diesel generator, which bothered us not at all.

March 12, 1960

Up at dawn and onto the road. I called in at Yuma, miscalculating our distance from home by 100 miles, so he had to call in again at Indio for a reappraisal. Then, in the San Gorgonio Pass we ran head on into a head-to-tail traffic jam that extended more or less solidly clear to Corona. We didn't want to stop to call again, and were sorry to find on arrival that our lateness had caused much concern. We finally saw the lights of Marineland and drove in about 8 PM, with fish and personnel intact and the unit banging away. An auxiliary line was rigged and the diesel shut off for the first time since San Blas. The silence that ensued was almost a shock to us after having lived in a din of truck and generator motors for 1,700 miles. Mr. Harris and Mr. Monahan and all the rest of the Marineland crew welcomed us in. We were motley and dirty and tired but the fish were alive and seemed in good condition, and that is just about all that counted.

March 24, 1961

Papago Tanks, Sonora, Mexico

Mark Buchanan, Jim and Maxine Heath, and I left about noon from UCLA, drove down the coast under cloudy cold skies to Hwy 80 and across the crest of the ridge. Long after dark we made the crossing at Mexicali and drove on across the river. All the regulations had changed as usual but we were freed after a few words.

Camp was made on the desert about 10 miles east of San Luis.

March 25, 1961

Papago Tanks, Sonora, Mexico

Up at 8:30 or so to a breezy, cloudy day. Mark got his VW stuck in the sand but we were soon out and off.

No animals except adult *Citeller tereticaudus* [?]. We drove past the cut-off road to Papago Tanks and had breakfast at Los Vidrios six miles beyond. There we met Julian Hayden an amateur archaeologist, and an old Mexican who had been Lumholtz's guide when he visited the Sierra Priate near the turn of the century. We backtracked and turned off on a fair dirt road to the south of a conspicuous granite peak capped with lava. Some eight to ten miles south we stopped at a lava rise to the right of the road and walked up to look into MacDougall Crater—it is between 250-300 yards across with raised edges all around and with no obvious flows resulting from it. It looks more like a meteor crater than a lava crater. The bottom is sand filled and about 100-120 ft. below level of surrounding desert. We saw three other craters that similarly had no obvious flows.

We drove through scattered lava flows and washes to Papago Tanks. It is set in a low broken lava flow and consists of a series of pools set in water-worn lava. To the west is a wash choked with palo verdes, ironwoods, and other shrubs.

Many birds were seen. Ravens had set up stations along the banks of the creek and had spattered the rocks with white. Gambel's sparrows, swallows, broad-tail hummers, and doves were seen.

The only lizard seen was *Uta stansburiana*. It was seen only in sandy areas or at the edge of lava flows. None were conspicuously dark though reddish buff is a predominant dorso-lateral color. Much of the lava hereabouts is red. I think we are seeing intergrades.

March 26, 1961,

Papago Tanks, Sonora, Mexico

Last night was cold, not too far above freezing, but the day dawned clear and calm. Bill Woodin, Joseph Krutsch, Mero Larso and wives and kids left for home before noon, leaving us with Julian Hayden the archaeologist and the old fellow who had guided Carl Lumholtz back about 1910, Don Alberto Celaya.

I started off about noon, hiking northeast toward Sykes Crater. The Papago tanks are set in a lava ravine and consist, at this time, of only two pools 15-20 ft. long and 2-4 ft. deep. The water is green and scummy and buzzing with bees and covered with water striders. The rocks in the canyon bottom are iron gray in color and marked with water lines several feet up their walls. These rocks are mostly smoothed and sculptured by water erosion. Plants in the arroyo are *Hyptis*, mesquites, *Olneya*, *Baccharis*, bunchgrass, *Cercidium floridianum*, and many annuals including *Sphaeralcea*.

I cut off from the tanks and up on top a lava bench covered mostly with small lava chunks. Utas were fairly common on the lava, particularly where the rocks were several ft. high. The animals were quite dark and matched well to the rocks. Both have a rusty red cast. The breeding male utas are beautiful animals covered with bright bluish punctuations (of one or two scales) on the rufous background turning bright red on the lateral abdomen.

I scared a male *Uta* into the territory of a smaller snake who had been hiding under a flake of lava. The small snake rushed out at the intruder and assumed a rather grotesque posture with body curved and laterally flattened. The little lizard sidled toward the larger male in this posture and the large animal avoided him. There was no contact. The posture of the small animal had the effect of showing its axillary side blotch to the large male. [Drawing]

I walked on up on a broad lava flat following a trail that leads from the tanques toward Syke's Crater. Here I scared up *Callisaurus* whose back was a dark chocolate brown, matching the surface perfectly. I shot the animal and continued on toward the crater which loomed up ahead like a broad 300-400 ft. sloping earth-filled dam. I cut down a broad wash at the base of the crater and toward camp. Soon I found my first whiptail lizard of the season and a umber of utas, plus the still-smoking campfire of some Mexican woodcutters who had come into camp last night, and turned around and left.

On the way back I picked up a small horned lizard whose head is as black as coal and whose body is blotched with black.

The palo verdes are in bloom and the hummingbirds are migrating through. Mark took three species (rufous, broadtail, and Costa's). Their bills are yellow with pollen when taken. Outside now I can hear the poorwills calling and can see Julian's campfire blazing under a huge old palo verde so I think I will go talk to him and the old man for a while.

March 27 1961

Papago Tanks, Sonora, Mexico

Up about 8:00 A.M. Maxine cooked up a fine breakfast of bacon, eggs, and orange juice while we talked to Julian about early Arizona culture. Soon Julian and the old man picked up their gear and left for Sonoita. We packed a little lunch in the jeep and set off for Indian Camp. This is a locality 16 miles south on Papago Tanks.

The road leads along the west slopes of the Sierra Pinacate. About three miles S. of camp we passed a rugged new lava flow and continued along its west side down the lava slope. Off to the west we could see the great expanse of the Gran Desierto, which is covered with sand hills.

The Hormiday Range could be seen out amongst the mass of dunes as a saw-toothed granite ridge half buried in sand.

The road led us into deep sand in a little flat area covered with lush creosote and palo verde thickets and thence up onto a lava bench. The rough, jouncy road then took us down off the bench to a gently sloping valley directly behind the dunes and near a pair of cinder cones. We stopped under a palo verde and hiked out onto the dunes where we caught a few beautiful, buff-colored umas on the dunes and some *Callisaurus*. On the hike back we shot a rufous crowned warbler (*Vermivora ruficapilla*) and wandered among the bushes looking for bush utas.

It had warmed to about 90 degrees F. and we were glad to rest for lunch in the shade of our palo verde.

Later we drove to Indian Camp proper, about ½ a mile back up the road away from the dunes. We found a large broken olla and hiked around over the valley floor.

On the drive back we came upon a huge covey of desert quail of which Mark obtained a few for his collection.

The sun dropped low over the Gran Desierto to the west and the shadows made the sea of dunes stand out in relief like a billowing [?]. Far beyond we could see the crest of La Providencia on the mainland of Baja California. In the dune mass flat-topped lava buttes rose up, black against the white sand.

Back at camp we cooked dinner, set a mist net over the waterhole and talked, mostly about Mark's experiences with various naturalists.

So off to the sack.

August 3, 1961

Bahia Los Angeles, Baja California del Norte

After spending the night at George Lindsay's house, Tom Poulson and I were chauffeured by John Sloan to the airport where we picked up Bill Dawson and headed for Tijuana and the airport. There we found Sr. Munoz, the pilot, waiting for us. We loaded our plunder into the Beechcraft (or I should say, it was loaded for us) and took off for Los Angeles Bay.

The flight took us diagonally south over the backbone of the peninsula toward our bay. I was interested to look at the gently rising west slope of the Sierra Juarez and to see the criss-crossing of fault lines over its face. Many streams have followed these lines and deeply dissected the terrain. A number of streams appeared to follow courses not related either to formations or faulting.

As we neared the crest the canyons became deeper and pines appeared below us.

Before long we cruised over La Encantada (I believe), the highest of the upland meadows of the San Pedro Martir. In the center of the meadow were two small shining ponds, which I am told, harbor the endemic *Salmo gairdneri nelsoni* of these mountains. We passed over a number of other clearings and meadows among the pines as we flew along. Sr. Munoz called me to the pilot's cabin and pointed out La Providencia, the highest peak in Baja, which rises about 10,000 ft. It is a rugged pyramid of exfoliating granite boulders slightly separated from the main spine of the mountains toward the desert to the east.

As we passed over the crest of the Martir we could look down the long north-south trending alluvial valley east of the scarp. It is desolate desert. I saw water in a large streambed passing around the south end of the Martir and a dirt road hugging the base of the scarp. The valley looks easily navigable with four-wheel drive.

Farther SE we cut over desolate lava flow desert cut by meandering washes and occasionally lined with double rows of *Washingtonia* palms, one row per bank. We began to see the black spikes of cardon cactus, which became abundant by the time we reached the bay. Before long we reached the gulf coast and began to follow it southward. The Ancantadas Islands hove into view—Muerto, Coloradito, San Luis, etc. I could see the landlocked lagoon at the north end of San Luis. Angel de la Guarda too came into

view as we flew over the Punta Final area and finally we swooped down onto Los Angeles Bay, crossed the field, banked out over the Bay and directly in toward the enormous rugged mountain, finally banking around and down onto the bumpy field by the beach.

The village of probably two dozen adobes and wood and stone houses is scattered haphazardly against the base of the mountain around a spring which supplies the village's water. We checked in at Casa Diaz, the town's central theme and *raison d'être*. It is a store, pleasant restaurant, patio with *Jatropha* and *Bougainvillea* trained on trellises and houses sprawled about. Cerveza and cold pop is to be had and cottages can be rented. We will eat our meals there.

Then we ran down to the station and began to get ourselves organized. The station is huge old gold mine headquarters just off the end of the airstrip. It faces right out on the bay. There is a fine big cement verandah, showers, john (which flushes), power plant, fireplace (which we scarcely need in August), work tables, beds and cots, kitchen, and much other gear.

Water is good, coming from the spring on the hill. We unloaded and went for a hike north along the beach. Low hummock dunes line the shore, most topped by *Allenrolfia* bushes. *Callisaurus d. carminensis* was very common and we sometimes had five in flight at once. The sand-flat tidal area widened as we walked, finally spreading into an extensive flat traversed by meandering channels, perhaps 400 yards wide.

The flat was honeycombed with Sally lightfoot crab (*Uca* sp.) burrows. Each burrow was surrounded by a bare circle of sand and then a circle of cast sand pellets thrown up from the central burrow. The crabs stood near their burrows with large claw raised and waving up and down at a regular period. The effect of 10,000 such crabs waving white claws clear across the flat was unique. Each gave a dull flash of white as it moved.

Farther out on the flat we came upon ucas with red claws and finally field upon field of lavender-rose colored ucas of an entirely different species. They may not have been ucas for all we know.

We saw many birds—ospreys, blue-footed boobied circling high in the air, yellow-footed Western gulls, reddish egrets, Belding's plover?, brown pelicans in great v-shaped echelons very high in the sky, and we even saw what I take to be finback whales far out in the channel. Their tall spouts were visible for several miles. John Sloan met us in the station carry all and gave us a welcome ride back.

We dropped in for dinner and a beer at Diaz and were served California lobster (caught locally), great big platter-sized tortillas and beans and a great meal.

We took a walk up to the spring and found a croaking chorus of *Hyla arenicolor* at work. Date and *Washingtonia* palms are scattered near the water, which is divided into two pools, one for animals which runs sluggishly out of a cut in the hill and the other which is in a [?] cut but damned off by a cement wall to prevent entry by the animals.

The place is calm and peaceful. Everybody is in bed by 9:00 P.M. and I'd better stop now and do the same.

I should mention that we have come up with two thermographs (one hygro) and no ink to run the miserable critters. I spent hours cussing my research assistant who promised to take care of the ink, and tryig to devise a substitute. No luck thus far though. Curses!!

It started raining in the afternoon up the broad alluvial valley to the south of us. Huge thunderheads gathered there obscuring the mountain-tops; and also over the crest of Angel de la Guarda.

After we went to bed the first rain in three years began to fall and continued for several hours during the night.

August 4, 1961

Los Angeles Bay, Mexico

Up this morning about 8:00 A.M. and up to a breakfast at Diaz's. Bacon, eggs, and coffee and then off to visit Smith Island. Our boatman, Felix, led us down to the station boat which we hauled down to the water's edge and loaded. Soon we were cruising out past the sand spit and I among the complex of barren islands just beyond. Finback whales were everywhere in evidence, usually in pairs, spouting their tall plumes of vapor and rolling slowly up as they slid through the water. Many of the sightings were of a pair or larger group, though we did see some singles. In one case I saw what appeared to be a mother and a half-grown. Sometimes we saw the animals within 100-200 yards off island shores.

Before long we headed into a deep calm cove near the north end of Ventana Island where we beached the skiff and jumped ashore. It was about 9:30 A.M. or so and we walked up the steep canyons before the day's heat had closed in.

Bill and Tom and I went up one steep branch canyon. The rocks were gneiss and did not provide really adequate shelter for chuckwallas. We shot several utas and I collected a peculiar velvety red spider under a rock.

Tom collected a baby chuckwalla and before long we started back, since so little was in evidence and our subject the chuckwalla, was very little in evidence. I stopped at an osprey nest and found it to be peppered with shells—murex, turbans, etc. Whether they represent food or ornamentation, I cannot say. Most of the rest was of ocotillo poles, some 1-1½ in. through and 5½ to 6 ft. long, and algae. There were no scats or animal bones.

Back at the boat we shoved off for Smith Island again, crossing a channel which had already grow choppy. More whales and many birds (boobies, terns, gulls, herons) later and we came upon the entrance to Smith (Schmidt?) Lagoon on Smith Island. We wound through a channel 50 yards wide with a rocky bluff on one side—a *Allenrolfia*-covered barrier bar on the other and into a beautiful landlocked lagoon surrounded on two sides by steep, rocky, very barren hills. We beached the boat on the far bar and hopped out. I climbed up a rocky draw, seeing no animals but a few utas. But over the crest I could see down into a starkly barren valley in one end of which the tide entered over a shallow flat. All around the water were mangroves dipping their feet in the water. I hiked down and watched schools of tiny fish pouring in and out of the lagoon mouth, hiked back up and over the ridge and back to the boat.

There we had lunch, a dip in the lagoon, and had just about readied ourselves to go when Tom and Bill spied a peculiar bird in the *Allenrolfia* thicket. It proved to be a black-headed grosbeak female (*Pheucticus melanocephalus*), which is far out of normal habitat which is transition-upper Sonoran.

No chuckwalla so off we went down the coast looking for granite outcrops. Finally we found one area where a band of granite 400-500 yards wide made up the

island from sea level to the crest of the island 1500 ft. above. There were many exfoliating boulders and steep canyons choked with boulders. It had grown very hot and the sun beat down on us unmercifully as we trudged upward boxed in the stifling still air of the cayon. Bill spotted a chuck on the skyline so we scrambled wearily up after it but even though we got a good view—could not find it when we arrived at the site.

Down far below us rocks from our efforts tumbled into the perfectly clear still greenish water, startling a flock of blue-footed boobies from their perches.

I went on up and finally could look down at the base of a huge cinder cone that forms the north end of the island. A most unique lagoonlet has been found there almost exactly in the shape of a circle cut off from the sea by a narrow bar of stones [drawing]. I can't imagine how it was formed. I clambered over granite rocks and down another steep ridge on my way back. About halfway down I saw a huge old chuck on a great granite boulder oriented so as to present its back 90 degrees to the sun. His body was notably inflated and fat. I watched the animal for a time and then attempted to get a temperature record but could not pry it out of its crevice. There were no sticks or poles around.

Half an hour later I reached the beach, hot and pooped. We climbed aboard, drank ½ gallon of water and started for home. The clouds shrouded the valley south of L.A. Bay again and the veils of rain were falling by the time the boat was beached and gear stored.

A turtle dinner later, notes and off to bed in 90% humidity.

August 5, 1961

Los Angeles Bay, Baja California del Norte, Mexico

Up this morning early (John spent much time raving about the red sunrise which the others of us missed). Our plan was to run over to Mission San Borjas some 36 miles into the back country. We loaded the International[?] 4X carryall, picked up John's wife's uncle, a fellow named Jarvis Waldo Dennison (everyone calls him "Denny"). He is a recently retired Airforce Colonel and ex adventurer-in-the-tropics. Interesting fellow.

We drove south along the airport and shortly cut back into a prominent canyon, where walls are made largely of a deep reddish rock. Cardons, elephant trees, limber bush, *Asclepias*, and what we took to be a peculiar euphorb were common. Creosote bush is also common though seldom lush. Shortly the road took us up out of the canyon and onto some broad mesa land. I began looking for *Dipsosaurus* whereupon Bill Dawson announced that they wouldn't be out for an hour. No sooner had he finished this pronouncement than I saw one and whooped for us to stop. It was apparently the central Baja form, just seven miles from L.A. Bay.

I was about to shoot it [?] when it ran under an ocotillo bush. I began to dig out its burrow and unwisely did not use a stick. I hadn't gone more than a few inches when I felt something move under my fingers. Fortunately I didn't grab but recoiled since it proved to be a Baja California rattlesnake as about 6 in. of its body poked out of the sand. Apparently I had prodded it near its head!! A lesson learned, I hope. We handed it out with a snake stick and it was about two ft. long, and quite fat. We didn't retrieve the lizard after this but drove on. Much too close for comfort.

Before long (14 miles from L.A. Bay) we came to the cut-off to San Borjas and turned SW on it. It lead through a broad sandy valley containing one of the finest stands of cirios I have ever seen. Most were in bloom with their tiny ridiculous tuft of waxy

white flowers spraying from atop the stack of the plant. The road eventually turned south onto rugged volcanic country clothed by a dense forest of cardons, cirios, agaves, and smaller brush. The carry-all gave us a terrible jouncing although John is one of the more skillfull desert drivers I have met.

Finally long after noon we pounded our way around the apron of a huge lava mesa and could see San Borjas below. It sits like a [?] of bright green against the drab dun and olive of the desert vegetation and the brick red of the hills.

Soon we entered the village of half a dozen huts, which surround but are dominated by the sturdy old mission. The mission itself is L-shaped with the main chapel along the front and other rooms on the other wing—probably priests' quarters etc. Behind the L are numerous weathering adobes that once formed the tanneries, storage rooms, Indian quarters, bakeries, and the like. The mission itself is made of a very soft whitish conglomerate which I think was quarried from the hill north of town where we could see a prominent scar.

The Mission has two old bronze bells whose inscriptions I could not read. They hang from a bell tower on the east face of the church. In the church itself a statue of the Virgin Mary stood at the end of the empty church with small red candles burning beneath it. Overhead the arched roof of the church stood intact, made of ingeniously morticed pieces of stone. Outside we could see that fieldstone had been piled over the top of the roof and this had been plastered with adobe or lime.

The belfry is reached by a tight steep spiral staircase, each riser made of a single cut stone shaped like the outline sketched here [drawing]. From the belfry one can look out over the peaceful green of palms, figs, sapotes, dates, and adobes, or one can look into the cavernous stillness of the church.

We picked up our lunch and cameras and trudged up toward the springs of the valley. They are noted as having the best water in Baja and I believe it. It is sparkling and sweet as it bubbles from the base of a lava mesa onto the broad sandy arroyo of San Borgas Valley. To this day, however, it is still one of the most remote corners of Christendom, as it was at its founding.

We plunked down next to a big cement water tank under a huge old sapote tree, whose shade was complete. A few filched grapes from some vines nearby, cool water, crackers, cheese, salami, and a prone position on a bed of dried sapote leaves made for a complete peaceful lunch. Purple martins and violet green swallows swooping over the tank contributed to the scene.

We bestirred ourselves, trudged back to the car, filled our canteens, and rolled off down the dusty road, leaving this peaceful spot behind regretfully.

The long bumpy road back was uneventful. We all beame drowsy with the jouncy ride and poor John drove on in silence for many a mile. We arrived hot, dusty, and thirsty, at Los Angeles Bay. Beer and dinner rounded out the day—tomorrow we are off for Angel de la Guarda. We packed our gear and moved our cots out onto the front veranda. It was still and hot and almost saturated with humidity (90-95%). Dennie came over and told us of his experiences barnstorming in South America with Johny Angel and after he left we went to sleep.

August 6, 1961
Puerto Refugio, Angel de la Guarda Island

Up at 4:30 A.M. as Bill woke and routed us out. We quickly dressed and put our gear in the trunk and drove down to the beach. In a few minutes a skiff from the 80 ft. sutchaser[?] *St. Augustine I* came ashore and picked us up. Before 6:00 we were steaming out of the bay and threading our way among the islands at the entrance. Finback whales were once again everywhere. I counted five spouts in the air at once. The animals impress me as small (40-50 ft.).

We grew drowsy after our short night's sleep and flaked out on the deck.

After five hours cruising we reached the north end of the island and entered Puerto Refugio. There are several islands, one of which blocks off a perfect harbor, safe from about every conceivable storm wind. The mountains are rugged, sculptured and fluted by erosion and of reds, whites, and buffs. The water is crystal clear and emerald, and still as a mill pond.

Both islands and the mainland mass are dotted with big cardon cactus. The effect is of great beauty, arid and austere but with a beautiful beckoning sea.

After anchoring we jumped in the skiff and landed on the main west island. We readied ourselves for collecting and hiked up the boulder-strewn wash at 11:00 A.M. It was already very hot and we considered ourselves lucky to find chuckwallas still active. Two great burly fellows were found on rocks, facing into the sun. They retreated to absurdly inadequate crevices and we hauled them out easily.

About noon we found another pair in the shade. The day had grown torrid and near saturation with humidity so we called it quits and walked back to the beach, where we all stripped off our salty steaming clothes and waded into the warm, clear water. It was delicious!! We paddled around for a while and soon the boat came to pick us up for lunch. As we dressed, clouds of mosquitoes descended on us from the shaded crevices, and we were glad to dress and leave.

After lunch on board we sat out the heat of the afternoon under the afterdeck tarp. About 5:00 we went back ashore to look for afternoon emergence in the chuckwallas. We landed in a fog of mosquitoes and swatted our way up the still-baking alluvial fan. Not a chuckwalla in sight. Apparently they had stayed in. We hiked up a steep knife-edge ridge of granite boulders and cardon cactus. About 500 ft. up Bill shouted that he saw a peculiar lizard with a collar of black around its neck. I clambered over and it proved to be a little known rock uta, *Streptosaurus repens*. Before long I had a nice series of these big rock-dwellers. All were clinging to rocks in the shade. Their agility at running over rock surfaces is amazing since they can actually run hanging upside-down on overhangs.

The view from the ridge was a striking one, reminding me of what I conceive the Galapagos to look like—emerald inlets, clear, still water, varicolored barren islands and white beaches, cactus, and other sparse, low vegetation.

Back on board the heat closed around us like a sweaty cloak and it stayed that way all night, except when the breeze came blissfully upon us. As the wind [?], the mosquitoes closed in and tormented us unmercifully. It was too hot to cover up or to go below and too hot to dress so we relied on bug bane and the breeze—neither did a great deal of good and we all spent a fitful night punctuated by low curses and slapping noises.

August 7, 1961
Los Angeles Bay

Up at dawn and up anchor for Isla Granito on the east limb of Puerto Refugio. The skiff boy took us ashore at a granite sand beach in the middle of the island. Steep granite boulder slopes rose on either side of us, dotted with cardons. Blissfully not a mosquito showed its miserable buzzing head. Soon we spotted chuckwallas emerging from their rock crevices in the shade. Their saurian heads poked out here and there far up the slope. With them were many downy gray young pelicans, just about ready to fly. Bill and I hiked to the top of the island up over loose boulders and sliding gravel and obtained several lizards.

Far below us on the granite cobble beach were dozens of gulf sea lions and other little babies. Later we approached within a few feet of them while their parents yelped offshore, and finally they reluctantly slipped like little brown sausages, into the sea.

We hiked along the beach eastward and finally came out at the sand spit at the far end. As I rounded the last point I could see three or four chuckwallas clambering off the beach and up the rocks into a boulder-filled swale. We caught three or four and I decided this was the place for an observation station. There are many animals and they should be easy to observe.

On down at the sand spit I saw a big old chuck lumbering for the rocks across the sand. I raced him and won just before he reached the rocks. With an armful of sea lion skulls for Art Kelly I began the trek back over the boulder beach in the baking sun. Both Bill and I were fagged and steaming hot as we arrived. Quickly we all went for a dip and then returned to the boat. I told the skipper we were through and we upped anchor and returned uneventfully to L.A. Bay, where we arrived at 4:30 P.M.

August 7, 1961

Los Angeles Bay

Not much today but a collecting trip south of the station which produced among other things, a *Dipsosaurus* intergrade between the Colorado Desert form and the Baja form.

We had burro meat for lunch and lobster for dinner and are rotting in the tropics.

After returning to the station we sat on the veranda in the heat of the still evening watching the lightning across Angel. Before long it began to move closer and flashed so often it looked like a pinball machine in full spate. I bet that it would not reach us and about ten minutes later a breeze hit us and the clouds began to blot out the sky overhead. Ten minutes more and the sea had become all white with breaking waves and scudding spume. The wind slammed doors in the station and blew gear boxes over and carried spume up across the veranda and into the sleeping room. Headlights flashed on from the beach and revealed boats heaving at anchor. One washed ashore and we could see figures on the San Antonio II pacing back and forth as she got underway and battled forward away from shore against the sea. We thought of her disabled engine and wondered if she would make it. It was a wild scene.

The wind began to shift toward the south and soon came from offshore and it was all over. Very exciting while it lasted and now the rains began to fall in earnest and we went to sleep with it tapping on the veranda and roof.

August 8, 1961

Los Angeles Bay

This day spent collecting south of the village along the bay edge and on some isolated lava mountains near the bay. We collected a number of interesting animals and returned in the heat of midday for beer and sociability. John and I went out again in the evening and I spent some time watching chuckwallas in the bedroom (they apparently are drinking salt water).

We arranged gear and caught up on notes in the evening.

August 9, 1961

More collecting near town and down by the saltmarsh south of the town. I ate a sour pitahaya and found it delicious—a little like watermelon.

August 10, 1961

About noon we had packed and were loaded aboard the plane. I sat in the co-pilot's seat (to balance the weight aft). I enjoyed the view of the peninsula as we flew between towering thunderheads. George Lindsay and Wes Farmer met us at the airport and escorted us across the border. Home at about 12 midnight.

January 25, 1962

Enroute to Ensenada, B.C.

After a day's delay with assorted Mexican paperwork we boarded the Lockheed Research Vessel *Sea Quest* at 9:00 P.M. and steamed out of San Diego harbor under drizzly skies. Weather reports predicted a mild storm which did not materialize. Our trip is planned in order to study the sound emissions of gray whales and is sponsored by the oceanographic division of Lockheed.

On board are two of her scientists—Bob Eberhardt and Bill Evans, the Captain Harold Moody and Engineer Wendell Tripp. The *Sea Quest* is a 50-ft. converted salmon trawler and very well fitted out for acoustic studies as well as other oceanographic work. I am more or less a supercargo along as an observer.

I turned in just as we picked up the light on S. Coronado Island.

January 26, 1962

At sea enroute to Scammon's Lagoon

Near dawn we turned into Todos Santos Bay and slipped behind the new breakwater. A few minutes after anchoring a decrepit water taxi showed up and offered to take us ashore.

Ashore we looked for and finally found Pedro Mercado, Director of the Universidad Autonoma de Baja California, School of Oceanographia. He proved to be a very pleasant young fellow who we expected to go with us, but he didn't have orders to do so. Finally we found that we were to take the exec. of a Pc [?], Jorge Lagos Knutze. Once he arrived on board we pulled anchor and left for Scammon's Lagoon. We were well down along the coast when night fell—the seas fairly calm and the ship putting along at a sturdy 7 knots. We passed San Geronimo Island and before the sun set we were in sight of Cedros Island, though many miles to the north.

Enroute we spent our time on deck watching seabirds—murrelets, loons, cormorants, shearwaters, etc. We also noted schools of *Delphinus bairdi*,

Lagenorhynchus obliquidens, and one lone humpback whale. This animal blew 75 yards ahead of us and threw its very broad flukes three times for us. I noted the very narrow peduncle and the funny ridged back that is almost but not quite a dorsal fin.

In the evening, as we entered Sebastian Vizcaino Bay, schools of both *Lagenorhynchus* and *Delphinus* came to our bow and rode, outlined in phosphorescence. One could easily see the turbulence patterns around the animals. Some seemed always present back of the pectoral flippers, though it was greatly reduced when they were brought in close to the body. A streamer trailed from the dorsal fin tip and a broad swath from the trailing edge of the flukes. Elsewhere the flow clung closely to the body, notably tucking in over the peduncle. A most dramatic demonstration of flow patterns over these sleek animals and possibly due to a powerful experimental method.

Later at night the wind and swell picked up astern and we began to pitch strongly. Then the swell changed direction until it was coming from dead ahead. The bucking ship became quite uncomfortable. I lay wedged in my foreward bunk and got up from time to time in desperation.

January 27, 1962

Scammon's Lagoon, Baja California

Up at dawn to find our ship approaching the sea buoy off Black Warrior Lagoon. We hove to and waited until the skipper of a big barge operating in the channel to the lagoon came out to give us instructions on Scammon's. Capt Tielit looked German but spoke with a slight Aussie accent. He told us about the outside bar, cautioning us to go in only on incoming tides and out the same way. He told us we would find Erle Stanley Gardiner camp just inside and perhaps a turtle fishing camp but no more human habitation. We left before 9:00 AM and headed for the entrance. The sea had fallen calm and almost glassy and the sun was bright and warm. The sculptured sand hills were white along the shore. Whales became more and more numerous as we approached the entrance from the east-northeast.

I suppose we saw 30 before crossing the bar at 18 ft. beneath the keel. In the entrance itself we passed a number of whales and a large school of *Tursiops gilli*—I would guess 25 animals. The whales were going in both directions and many threw their flukes and a few spy-hopped. One individual outside the bar jumped repeatedly, almost clear of the water.

The sea fell absolutely calm inside as we skirted along the west edge of the lagoon past Conchos Island. Precipitous interconnected barchan dunes covered the west shore interspersed here and there with weed flats dotted with shore birds and brants. Whales passed to and fro and several were seen poking their heads high out of the water and some seen rolling in pairs at the surface, presumably mating or nursing. An afterbirth was passed to starboard—its attendant gulls rising as we bore down.

One sound drifting station adjacent to Cardiac Island produced nothing but snapping shrimp and croakers even though whales passed close above. We attempted to reach Isla Piedras (Gilmore Island) but had to turn back because of shoal water—a new channel was tried and finally we hove to near this low rocky island. Just after anchoring we put over a fishing line and shortly had a buckful of nice bass of three species. Whales cruised close aboard from time to time.

After a nice ham dinner Jorge serenaded on the guitar and after my 8-12 watch off to bed. Tomorrow we proceed up to the nursery.

January 28, 1962

Ballenitas Channel, Scammon's Lagoon, Baja California, Mexico

Up this morning quite early and after breakfast the dinghy was lowered into the water aft and we piled aboard and rode on to nearby Gilmore Island. The island is low-lying, being perhaps +10 ft. at the highest, and is covered with a sparse cover of pickleweed, and *Fouquieria peninsularis*. The latter bushes are the largest on the island. Some were in bloom and all were draped with a heavy growth of epiphytic *Tillandsia*.

I struck out northward, hiking mostly close to shore. Heavy mats of dried sea grass lined most of the shore, burying the rocks a foot or so in many places. Sea birds were everywhere—willetts, dowitchers?, godwits, oystercatchers, surf birds, black-billed plovers, eared grebes, great blue herons, terns, gulls, and brants were some that I remember. Toward the south tip of the island I spotted a flock of brants and stalked up on them, creeping the last 100 yards on my belly. At the shore I pushed my rifle barrel through the pickleweed and sighted in as well as I could (no front sight) on one bird and much to my amazement, hit it and saw it trail behind the flock and settle on the water 100 yards offshore. It soon died and I took off my shoes and pants and waded out to it, finding it in waist-deep water.

Bill Evans and I hiked back down the island and stopped for a time to listen to the sounds. By sitting quietly on a rock we could hear the gabble of geese—there being a huge flock of several thousand birds just to the north along Brosas Island—but mainly the breathing of whales. This was so constant that often 2 blew at once. Most did not seem to be accompanied by spouts, though some were. The hollow cavernous exhalations could be heard for more than a mile, and usually could be divided into 2 parts—the heavy exhalation followed by a less evident inhalation. Occasionally a gurgle or a snore was heard and once or twice of loud volume. May of the whales involved were resting nearby passively at the surface with just a portion of their backs exposed. Some were obviously paired, young and mother, and some were thrashing about and leaping part-way from the water and may have been mating.

We poked in the tide pools and soon joined Bob Eberhardt who was doing likewise. We found some interesting worms, tunicates, gastropods and the like. After a while we walked over to an old turtle fishermen's camp and poked around. I caught 2 brown-shouldered lizards (*Uta stansburiana*) under turtle shells and the others picked up shells and whale earbones as trophies.

We met the captain and went back aboard where we found Jorge and the captain had been losing hooks and line to huge groupers.

Soon we hauled up the anchor and proceeded farther into the lagoon toward the nursery grounds. Off the south end of Gilmore Island we noticed a small whale floundering in the water on a shoal area and could see a grill walking up and down its body and pecking at something. The little whale rolled on its side and slapped its flukes and flippers at the bird as if annoyed by it. Bob said—"Let's go see what's going on there." I quickly seconded the motion, so we anchored and lowered the skiff and set out to see what was going on. Soon the skiff grounded so I jumped out and hauled it along by the painter. Before long we were alongside the animal and found it barely able to

move in the shallow water. It had obviously been trapped by the tide away from its mother. We could see a crusty old adult in the nearby channel, poking her head up out of the water from time to time. I presume she was the mother, though of course we don't really know.

The little whale's back had been terribly pecked by the gulls and was bleeding over a large area (seeping blood) of the mid-dorsal region and upper flanks. Peck marks were evident over most of the back and one could see where the sharp gulls' bills had been driven in and an attendant piece of gray skin and blubber removed. Other than this painful state of affairs and fright, the animal seemed in good condition. I leaped into the waist-deep water and held the whale's head up. Its snout in front of the eyes was quilted like a comforter, with hair follicles, 56 to each side above the upper jaw and from the center of each grew a long white hair. His eyes were covered by prominent eyelids which caused protruberances on each side of the head. Her tiny ear canals likewise were on top of prominent mounds. Once I saw his eyes and they were the same brown color as a pilot whale's, though I saw no operculum. Over the undamaged portions of the skin were occasional white flecks and patches among the otherwise uniform gray.

In the prominent fetal folds and other body crevices were already thriving populations of whale lice, but no barnacles. I lifted the animal's head and could see the lower lip where it overlaps the upper jaw and the short white baleen within. At the symphysis of the lower jaw I could see a round white dot like that of newborn pygmy finback whales and could see the peculiar highly modular tongue. The animal was a male 14 ft. 9 in. straight-line length and the 6 in. of the umbilicus still trailed from the abdomen.

The frightened little animal usually rose up to blow but occasionally burred beneath the water. When I placed my hand in its mouth at its apex, he grasped it firmly with the bow of the lower jaw and enveloped it with his lips above and below. It would be efficient at nursing and the thin head should slip easily into the mammary folds of the mother. The animal was plump and the rubbery skin and flesh turgid.

We tried to steer it into deep water by hand at first and once deeper water was reached, by skiff. Cap found that the outboard would turn the creature if roared on one side and thence followed an hour or so of whale herding in which we attempted to steer the young animal toward his presumed mother. Just when he was going at a good clip he would attempt to sound by rolling on one side and diving, inevitably bumping his snout on the bottom.

Finally we left him in 4 or 5 ft. of water since we were afraid to venture too close to mother and it was getting late.

Back at the Goat we upped anchor and proceeded into the deepest part of the lagoon, where the nursery channel is located. The lagoon is a vast expanse of water and here deep in its recesses were dozens of whales, some spy-hopping, some just cruising and blowing, and some with calves at their sides.

We felt our way through the various channels, in water that varied from 15 to 30 ft. deep, and anchored at the mouth of the nursery channel. On the west it is bounded by a low sand hummocked shore and low bluffs on the east. Whales were all about and we were delighted to find that our radar easily picks them up. I'm now on the mid watch and must go check the wind, heading, and temperature.

January 29, 1962

Ballanitas Chanel, Scammon's Lagoon

Up this morning a bit drowsy after the 12-2 watch. After breakfast the skiff was unlimbered for some plankton tows and I hitched a ride ashore. I landed on a long sand bar and walked back by a broad pickleweed flat bisected here and there with winding salt water channels and pools. Shore birds were everywhere—I saw 2 new species—black-necked stilt and black-crowned night heron. After reaching shore I hiked for an hour over some hummock beach dunes—only *Uta* was active. The dunes were carpeted with evening primroses and a small yellow composite and were soaked with rainwater.

I met the skiff and returned aboard for lunch and afterward we moved the *Sea Quest* into another channel that seemed more frequented by whales. We anchored fore and aft and silenced the ship's engines. The skipper, engineer, and Jorge went ashore to poke around while we listened for whale noises.

Even though whales played and splashed, mated, and cruised near us we heard nothing from them—only the crackle of the ubiquitous snapping shrimp. Then 2 *Tursiops gilli* cruised up and we could hear the slow popping of their echolocation signals with occasional rusty hinge noises. They turned 150 yards away and cruised off away from us.

We now think gray whales may just be good listeners—finding their way by sight and hearing but not generating any special echolocation signals.

The skiff returned near dusk and Bill and I took a turn in it attempting to get another goose or 2, but no luck.

I fished most of the evening for smelt—caught a few—wrote notes, stood the 10-12 watch, and off to the sack.

January 30, 1962

Ballenitas Channel, Scammon's Lagoon

Up this morning at a relatively decent hour to be greeted by Capt. Moody cooking pancakes and bacon for us all. Once they were engulfed we set about rigging and launching a pole fence. This fence is to block one channel leading up Ballenitas with the hope that whales will turn from it and when they detect it, emit characteristic sounds. Ballenitas has a Y of channels leading into it. We occupy one with the *Sea Quest* and the other will be blocked by poles. These poles are 15-ft. aluminum tubes closed at the bottom and weighted with pieces of chain. They were lashed together at 50- and 25-ft. intervals with heavy nylon cord. Once lashed together they were simply towed into place and anchored on each end. The deepest part of the channel is about 15 ft. deep and we were able to bridge it about 2/3 across with poles. I spent much of my time photographing and finally in rigging the last set of poles.

After lunch Jorge and I went ashore on a hunting expedition. Jorge is a bit of a city boy and not privy to much natural history, though he and his countrymen know much more than the average American about things of nature. We walked back inland, traversing an ancient shell-covered beach and entering an ocotillo forest draped with *Tillandsia*. I spotted a jack rabbit and took a shot which missed. Off went the jack inland and I followed. We went about 2 miles in all over very open country dotted with tiny shrubs. I didn't get my jack and I was just as happy.

I circled down to the beach dune where Jorge had gone with the shot gun. I saw some geese out near the edge of the lagoon and decided to try a stalk. I would guess 300 yards as the distance I covered crouched down (now I know what a “duck walk” is named after). It was mucky whitish almost plaster-like mud that I squished and slid through. Finally I crept up to a grass borderland and found myself in real soup. It squished down with each step and irate fiddler crabs waved from their holes at me. Then I came down a winding channel of tidal water deep in black muck and had to stop 20 yards short of the geese (black brant). Ah well—I didn’t really want a goose anyway. What I really wanted to do was to wear off some energy stored up from sitting on the boat, and that I was accomplishing nicely.

As we wandered back down to the beach I saw a whale steaming toward the picket fence of poles. Jorge and I stopped and sat down to watch. The 40-ft. hulk slid along with a long low expanse of black back just above the water, blowing now and then. He steamed right into the poles with a great clatter, turned over with a pole in his mouth, turned back and went back toward the sea at flank speed, puffing in fright. Later we found that the whole sequence had been picked up on tape and the animal made no noise other than breathing and that it had broken the nylon line. We feel relatively sure now that these huge hulks do not have sonar as such, but are probably just “good listeners”. A couple of other whales went through while we watched. We now suspect through the gap produced by the first animal.

Back on board Bob decided to take a run up Ballenitas in the skiff and I tagged along with Bill as the other passenger. Just above the net we came upon a crusty old barnacle-covered mother whale and calf. Soon we realized the mother had a badly deformed tail stock, bearing a deep indentation along its upper border. Somehow she seemed to swim well enough and to bear a calf.

We came upon 4 or 5 other whales including calves as we cruised along in calm waters between low barren bluffs. The sun was setting as we returned, the clouds turned pink, and the hills dark blue while the vast lagoon shone like silver in the fading light. Here and there the tall plumes of spray marked a whale’s presence. The trim little *Sea Quest* lay quietly anchored in the middle.

On board we had a magnificent dinner of steak, peas, salad, red wine, and pie. Afterward Bill and I stood on the fantail listening to the whales blow all around us. The ship was silent as Wendell was fixing a fuel line and had shut off the generator. We thought one of these animals might even run into us, but none did.

Their blows have the deep hollow sound of air rushing from a deep cavern.

Shortly I went below to get enough sleep for my 4-6 watch (on which these notes are being written).

January 31, 1962

Channel between Isla Piedra and mainland, Scammon’s Lagoon

Whales are blowing close aboard on all sides of our anchored ship and it is 1 AM as I write these notes. I’m on anchor watch and pretty sleepy. This morning we ran a sound station and Bill picked up some strange, deeply resonant bubbling as a whale passed close above his distant hydrophone. He also caught a couple of snores attributed to the whale. I spent much of my day reading about our incredible navy debacle at Savo Bay.

Around 2 PM we brought in the pole barrier, stowed it aboard, and heaved up both and headed for a supposed calving grounds across the lagoon to the southwest. We simply couldn't find the entrance channel and finally abandoned the attempt and entered the broad channel between Isla Piedras and the mainland to the east. It proved to be full of whales, many seemed to be passing us by in either direction.

We beat up it to near the south end of the island and anchored fore and aft in a stiff current just at sunset. After dinner we went on silent ship and began listening to the whales. We recorded a whole series of deep resonant bubbling and burbling sounds, snores, and irregular series of sharp ragged plosive noises which as Bill so picturesquely puts it sound like "a poor man's *Tursiops*".

We listened and recorded for nearly 2 hours and were seldom without some noises being produced. All is quiet on board now except for the puffing and splashing of the passing whales, many of which pass within 50 yards or so—one is about 40 ft. out right now.

February 1, 1962

Up this morning at 7 AM and after breakfast and various machinations with the fence which was set to the left of us, Bob, Jorge, and I went ashore for a recon trip looking for the small whale which we thought we could see on the beach. When we came close our sighting proved to be a rock but we set out to do a little exploring. I set out with the shot gun on the mile-long sand bar to the south of the island. It is a mosaic of mud flat, *Zostera* beds, and dotted with shore birds of several kinds—long-billed curlews, willets, dowitchers, marbled godwits, etc. Black brant gabbled in large flocks and tip upped in the *Zostera* beds. As I walked out whales spy-hopped in the channels only a little way offshore—so close that it seems impossible that a 35-45 ft. beast could be in deep enough water to float.

In the pools flat fish and rays skittered in front of me as I sloshed along and I could see a number of interesting invertebrates and red tunicates, tectibranch egg masses, and the like. Then I returned to the island and set out looking for stranded whales. I found ours near the north tip of the island, very dead, and very bloated.

After hiking on around the island on the mud flat I met Bob and Jorge and I told them about the whale. Jorge had seen it and Bob at once decided to get measurements. We pulled the skiff out over the flats and beat up the channel, having a soggy ride of it into the wind.

We finished measuring as the light faded and soon we jumped aboard and headed for the *Sea Quest*. We dodged among "whale footprints"—the tail beat slicks. We reached the ship in pitch-blackness to find Bill chortling over some nice recordings he had taken of *Tursiops* around the poles. When they saw the poles they squeaked and whistled in a most satisfying way.

A little dinner, some listening, and off to bed.

February 2, 1962

The skipper, Bill, and Wendell set forth for the mainland shore after breakfast and walked up and down the beach, finding very little but an old TV tube for their pains. I took a batch in a bucket on board and fished, catching an [?] (*Paralabrax auroguttatus*).

After the boys returned we upped anchor and pulled in the fence and headed up the channel toward Las Brosas Island. Bob decided that he and I would put ashore and camp overnight, looking for stranded whales and cetoliths while the others went over to pick up Bill Kielhorn whose plane circled us and landed at Black Warrior.

By about 3 PM we were abreast of Las Brosas Island and we shortly piled in and anchored off the middle of this long sandy island.

Bob and I loaded our gear into the skiff and Capt. Moody ferried us ashore. We landed on a rocky headland and soon had our gear above high water next to a little sand-rimmed embayment filled with dried *Zostera*. Pickleweed flats spread out shoreward gradually giving way to monotonous sandy flat terrain, punctuated here and there with 8-10 ft. sand hummocks.

Very shortly we set out to reconnaissance the coast for whale remains. I went south along the west shore while Bob went north. My walk took me past a juvenile whale a couple of hundred yards from our camp. We named him Bradford and Bradford was in a bloated condition and was feeling very poorly and smelling worse. On down the coast I passed many mud flats and sandy bays and finally the island became lower and lower until it consisted of a sand bar backed by pickleweed flats. All kinds of shore birds marched along probing the mud with their bills, or simply standing on the beach.

Finally at the very southernmost tip I could look across a great 3-mile *Zostera* flat to Piedras Island. A bar and tiny island rose a few feet at the middle. I rested for a few momets and began hiking up the east coast and soon came upon another whale far out on the flat. He was covered with seagulls standing on his back. I took off my shoes and paddled out to him through the pools. It proved to be another male, also a newborn, but a bit fresher than the last. We named him Cedric. The sun was getting low and I wanted to find camp in the light so I hurried off up the beach barefoot—fording various run-off channels from the interior pickleweed flats. About halfway up I put on my shoes and set out overland to cross the island toward what I hoped would be camp and came up to it just as it became quite dark. No Bob—so I gathered driftwood and soon had a beacon fire blazing. I swung the battery lamp around in arcs across the island and shortly heard a shout—from the wrong direction. It proved to be Bob all right and he soon strode into camp. We both flopped down by the fire and soon began broiling pieces of spam on driftwood sticks in the blaze. Gad—did it taste good. Crackers and fruit juice topped it off and we soon crawled in the old sleeping bags on our mattresses of dried *Zostera* and drifted off to the gagging of geese (brant), the yapping of coyotes, and the breathing of whales.

February 4, 1962

Isla Las Brosas, Scammon's Lagoon

When I woke this morning at dawn there were about 10 brants cruising up and down in front of camp, dabbling in the eel grass. I tried to reach the shotgun and thought better of it, wondering what it would be like to have a 12-gauge blast at 20 ft. wake you up. The geese flew in minutes and I dressed quietly, grabbed the gun, and crawled about 150 ft. on my stomach up to some pickleweed lining the edge of the shore, poked the barrel through, and [?] up on some geese 75 yards away. I fired, they rose and flew effortlessly off. Since I was firing buck shot from a prone position I can't fathom it. I set off for a before-breakfast hike and crossed the island to the NE. One of the first things I

found was another whale stranded on the bar. It was a female and became christened Alice. An hour or so later I returned to camp where Bob announced that corned beef was to be breakfast. I cut open a juice can, made a flat sheet of metal by cutting out the ends, and then folded it into a frying pan, which Bob used to fry our beef. After this and a little fruit juice we set out for Alice across the island. About in the middle of the island we came into some patches of a peculiar looking *Opuntia*. Its stems were unusually knobbly and its fruit a rather dirty tan. I tasted it and it had a rather astringent quince-like flavor, not very sweet, but quite edible.

Two other kinds of cactus were to be found—a *Mammillaria* and an *Echinocactus* or *Ferrocactus*.

At Alice we set about measuring and finished in fairly rapid order. We found that we could lift out the entire baleen plate row for a ramus of the jaw by prying on it lightly. This greatly facilitated us in counting the plates. Alice had been attacked by sharks. Her tail was bitten down to tendons and bone and her flukes were missing some arcuate pieces.

Off to Cedric. He was a long way off at the south end so we hiked partly up on the dry center of the island where the going was easier. We reached the flat where I thought Cedric should be, but no Cedric. We walked clear to the south tip and still no Cedric. Finally we saw him out on the flat about $\frac{1}{2}$ way to Piedras Island, covered with a fleet of gulls. We pondered for a while but the way was too far (perhaps a mile) and our time too short, so we turned toward camp. It was a long, long walk (8 miles), much in soft sand or mud. Finally at about 2:30 PM we made it—cooked and ate our spam for lunch and went to work on Bradford. I tried unsuccessfully to extract an ear bone assemblage but was thwarted by rotten flesh and the hidden position of the bone.

Before the *Sea Quest* returned for us I spotted some geese nearby and decided to try a difficult stalk to see if I could get a shot—it entailed crawling across about 80 yards of wet sand and mud to a rocky ledge on my belly. When I was $\frac{3}{4}$ there, afraid to lift my head, I heard the brant rush from the water chattering and quacking. I looked up and there was the cause—a hawk was clutching a dowitcher, having swooped on it right in the midst of the geese.

Meanwhile the *Sea Quest* had arrived with Bill Kielhorn and Ray Ells on board—they had landed at Black Warrior in their plane. We went aboard and had a beer and set out in the skiff for Cedric on the mudflat. 30 minutes later we found we would have to hike $\frac{1}{4}$ mile across the flat and did so, hoping to get our measuring done before the tide rose. We measured him quickly and started to hike back, exploring a little sandy island on the way. When we returned it was sunset and I was getting cold in my thin shirt. A kapok life jacket helped this some and we cruised out into the channel toward the *Sea Quest* anchored near Piedras Island.

Bat rays, guitar fish, dozens of round stingrays, and one huge diamond stingray rocketed from our bow. We ran repeatedly aground and finally found a channel leading down near the *Sea Quest* only to find ourselves separated from it by a shallow bar.

We pushed with oars for what seemed like $\frac{1}{2}$ a mile before reaching deep water astern of the *Sea Quest*. Shortly we were on board engulfing a big dinner.

I am now reclining in my sack writing and resting my weary bones.

February 5, 1962

Mulege, Baja California Sur, Mexico

Little did I think that this day would end up in a plush sky motel at Mulege, some 150 miles from Scammon's Lagoon. First thing in the morning we hauled up the anchor and set out into the deep westernmost channel heading toward the entrance. Our goal was to anchor near the dunes by the entrance. As we cruised up the lagoon we spotted a new stranded whale on Cardiac Island, clouds of gulls swarming over it at the edge of the water. Bob decided we should measure it and we named it Douglas. I concurred heartily since we were both anxious to get as much data on newborn animals as possible. Soon the anchor was down and Bob and I were ashore with notebooks, tapes, and measurement sheets. Before we had made our landfall Bill Kielhorn had spotted a floating object which turned out to be another whale—very newly dead—in fact it was apparently still warm. We towed it in by one flipper and beached it and named it Evangeline. Just as we had gotten ourselves organized the ship's whistle let out a loud R in morse code. Bob instantly recognized this as "rescue". I would have listened to R for a week and not connected it with rescue. At any rate, before we could do more than get total lengths the skiff cut toward us as fast as it could go, and sure enough, it came to us because a plane was reported down up the bay, and two of the fliers were reported seriously injured and two had walked overnight into the Black Warrior salt works for help. Back on board we heard the measured tones of Capt. Tillit on the radio telling us that if we could make a rescue attempt and bring our pilot over to the entrance to the Nursery (White's Waters) we would be doing a jolly good service. So up came the anchor and we were soon threading our way down the bay again. After about an hour and a half or so we pulled into the narrow channel of the Nursery and came to anchor. About that time we could just make out figures walking up and down the beach below the east bluff. Soon we sent a skiff over and landed. Much to our surprise we found the two supposedly injured parties standing on the beach with pants legs rolled up, entirely intact, surrounded by a crowd of people from the salt works. The manager, a grizzled old man named Cutting, was there and soon loaded us all into his jeep pick-up and headed for the salt works. The plane, an Apache, was across the channel on her back. Her nose wheel had dug into the sand on the landing and flipped her.

One of the fellows in the plane was a land developer from Phoenix—his name was Paul something or other, another owned a couple of cement plants near Nogales, and the other two I didn't meet. They were fishing and just fooling around, having decided to leave only the day before in Phoenix. They seemed not at all concerned about the plane, and I doubt that they plan to try to flip it over and salvage it, though they say it isn't badly damaged.

We drove across a flower-dotted desert to the upper head of Scammon's which served as a reservoir of partially evaporated water for the salt works. This saline water is drawn off into Black Warrior, spread among salt pans and finally brought to crystallization. The works is a fantastic operation. They make as much salt in 180 days as the Leslie works in San Francisco does in 5 years, and all because of the desert sun which beats down almost always. The salt is scraped up by big motorized machines which dump it into 100-ton carryalls. It is quite pure when lifted from the flats. Most goes to various chemical plants—much to Japan, a fair share to British Columbia.

We crossed some of the flats and finally reached the company village—a soulless assemblage of flat-topped houses set in lines on the flat desert adjacent to the ponds. Mr.

Cutting put us up in two of these—nicely equipped with showers, stoves, ice, etc. A rather remarkable state of affairs in this remote desert. The water comes from 4 wells about 6 miles out of town on the alluvial fan. We learned that there was a little satellite village about 3 miles out of town where there were bars, cantina music and where the “girls” held forth. In a place such as this the “girls” are accepted as a sort of service function, like water and power, and it must seem strange to the Mexican folk to find them barred into an exterior community.

A few minutes after we arrived, Bill Kielhorn came in in another jeep and shortly we decided to fly over the lagoon and see where the *Sea Quest* was, take some photos of the channelways, and to see if we could see the downed plane. Up we went with no doors on, so that photography would be easy. From the air we could see dozens of whales in the lagoon, many very far up it, even a couple of miles beyond the nursery. We saw the plane in the middle of a long stripe of windblown sand that a novice could have mistaken for a strip of hard soil, and we flew over the *Sea Quest* making her way back toward Cardiac. On the way back Bill flew low over the dunes trying to scare up a coyote, but no luck.

Shortly after landing Bill asked if we would like to spend the night at Mulege across the peninsula, and we all said OK, let's go. Into the plane once more, after our goodbyes were said, off down the runway and into the air again. Our course took us across the Vizcaino Desert which is lined with very regular and very elongate parallel humps of land that must represent old sea level lines. They extend all the way up to the foothills, and trend roughly north and south. Before too long we crossed over the great arroyo of San Ignacio, and could see it winding out over the plain to San Ignacio Lagoon. It was gleaming with water, like a line of mercury shining in the afternoon sun. I could see the plaza and the old Jesuit church and the sea of date palms in the arroyo. What memories it stirred to see that wonderful sequestered spot again after 12 years, even if from the air.

Shortly we headed right into the rugged Sierra Santa Lucia range. It is a jumbled mass of volcanic bluffs and cliffs, deep dark canyons, and unknown arroyos. On its peaks are some of the few examples of short tree forest in Baja California. It is a refugium that has been examined only by botanists as far as I know, yet it is likely to hold the key to the animal history of Baja since it was once an island and dominated the entire center of the peninsula. I will have to pack in some summer and explore it firsthand, that is for sure.

Before long we dropped down over the Gulf and over Mulege. It is a beautiful place. The freshwater stream pours down and meets the sea, banded on both sides by mangroves and cultivated gardens filled with sapotes, avocados, dates, grapes, and citrus fruits. The field is something else than regal however. It is tucked behind a hill and is very short. Bill expertly banked in past the hill, slipped in, and set down without a hitch. To our left was a nice “Airtel” or hotel where mostly pilots and their passengers put up. The accommodations were very nice though we found when we left that the prices were a bit steep.

February 6, 1962

About 8 we crept out of the sack and after breakfast took a walk up town. The dusty road passed along the lagoon edge, up into town and then along the stream amid

groves of palms. Shortly we came to the old mission. It had been one of the first in Baja, being a visita of the initial one at Loreto. I would guess it had been established around 1700. We walked around it and finally slipped into the main room, where the altar surprised us with its statuary and encrustations of gold leaf. Some of the very old paintings of saints and Christ were hung around the walls and the ceiling was painted blue with gold stars scattered about, peeling in many places. On the walls were some quaint old kerosene lamps with a long curved neck and a globe-like oil reservoir. It was obviously still in use though we saw no one in residence.

We left the church and walked down to the dam which retains fresh water for the town. While we were walking across it we noticed a great whirling mill of frigate birds swooping on the water of the stream above the dam. We watched closely to see what the birds were doing. I would guess there were between 50 and 75 of these sepulchral, thin-winged birds milling around. Each one would swoop down on the water and glide in awkwardly with his head up, splash into the water without losing headway and take off again, fly up into the air perhaps 50-75 ft., shake his wings, and then shiver his whole body like a belly dancer. This so destroyed his aerodynamic soundness that he then fell several feet before flapping and picking up speed again. Obviously they were bathing and not drinking. We watched for a long time to confirm this and did so without much question.

We returned, packed, paid our astronomical bill, and took off grumbling about tourist traps. Those thoughts left us soon enough as we flew up the coast and saw school after school of large fish, porpoise and finally 4 huge finback whales swimming southward in echelon just off a hamlet named San Lucas, 80 miles or so south of Los Angeles Bay. We circled low and could see the white chins and even saw what looked like white markings on the pectoral flippers. The critters looked much thinner and much longer than the chunky gray whales.

We cruised down the backbone of Angel de la Guarda Island looking for palm trees which I had heard were in some of the canyons. Except at the extreme northern end we saw nothing that looked like a palm or water, and even there what we saw was equivocal—some greenery tucked down in a curve in a narrow stream. We flew over Isla Granito and it looked very barren and austere.

We hopped over the San Pedro Martir range and could look down on snow-covered meadows and could even see deer tracks up the smooth white slopes in places. After a short stop at Tijuana we landed at San Diego. I was poked for small pox, my certificate having run out, and our fine trip was over.

April 2, 1963

San Esteban Island, B.C.

Left L.A. Bay at 7 AM on board the *St. Augustine I* for San Esteban Island. Our crew consists of myself as FL (Fearless Leader), Phyl Norris, Sue Norris, "Kelly" Klain, Jim Heath, Dick Lockwood, and Karen Fall.

The trip took the day until about 4 PM. On the way we passed along the mouth of San Rafael Bay, around the south end of Angel de la Guarda Island, south of Isla

Cardeosa (Partida) and past Isla Raza. Partida is composed of 2 peaks and seems very barren. Raza is very low and seems completely barren.

We were far enough away so that it was difficult to tell if birds were nesting or not. Before we reached these islands about ½ a dozen common dolphins came to our bow. They seemed identical to our California form. Before long we passed north of San Lorenzo Island. Its east coast is obviously a scarp as faceted ridges drop abruptly into the sea. Between San Lorenzo and San Esteban we spotted several finback whales and watched them blow and surface. We rounded the island and cruised toward the SE corner. Before this we had seen at last 3 Heerman's gulls with double white primary patches.

Finally we hove to a open cove, bounded on the S. by an isolated rocky knob harboring its inevitable osprey nest and an alluvial buff to the north. Between, the main arroyo of the island curves down from the mountains. The island is not high anywhere, reaching perhaps 1,200 ft.

We made camp against the alluvial bluff—hauling gear up over the rough cobble beach. Darkness set in soon after dinner and we settled in for the evening. The night was cold and windy—perhaps dropping to 45 deg. F. The channel had whipped up and when the skipper (Leopoldo) and his crewman (Nayo), came ashore to leave us some reserve water (we have 70 gallons for 7 days) plus their 13, they told us that a storm (NW) was upon us and might last 3 days or so. The temp. is low enough that any animal activity is doubtless cut down. When I got up at about 7 AM Kelly was coming in from a hike and had spotted 2 *Ctenosaura conspicua* under a rock. Before long we had spotted a couple of *Sauromalus barius*.

The entire arroyo bottom is covered with tracks of these lizards. Everywhere there are boulders with shallow burrows under them. The arroyo is densely vegetated with a large cardons, several kinds of opuntia, dense patches of pitahaya, *Simmondsia*, *Hyptis* (in bloom) and various lower shrubs. The arroyo walls are a jumble of desert varnish-covered boulders rising to old crumbling flows at the tops of peaks.

I prepared to go out on a hike from camp and in the bush next to our tent I captured a racer (*Masticophis bilineatus*). It was in mottled shade. Its head was considerably warmer than its cloaca. Later Jim caught a large one and saw another.

In the afternoon I walked up on the bluff N of camp and came upon a very large *S. varius*. I walked closer, bent down and picked the animal up by its tail, and only then did it begin to struggle. I took its temp. I set it back on its rock and it ran into a pitahaya. I walked over and picked it up again—remarkably docile. Of the *S. varius* we took today I took fluid from the lateral sacs.

The slopes are pocketed with burrows, probably mostly of *S. varius*. Some were large—10-15 ft. in width and leading off in 2 or 3 burrows, probably running back as far as 15 ft. or so. *Ctenosaura* was also seen in the smaller sorts of similar burrows (and under rocks).

All in all, the weather has been too cool for extensive activity. Chucks were only seen at the entrances to burrows, in the early stages of warming, or under rocks. No feeding apparently took place. Tomorrow we will go up the canyon in hopes that the narrow situation there might produce warmer temps. in localized pockets.

The evening was spent [?]menting a big chuck and recording from her. Finally, Kelly attached an extra antenna and we were able to get a clear range of 150 ft. The night was blustery and cool and an ominous cloud blanket covered the stars.

April 3, 1963

San Esteban Island

I got up this morning very stiff and a little sleepy as Kelly and I monitored the chuckwalla a couple of times during the night. The signal came in loud and clear. I stretched a bit to break the kinks loose and took off up the canyon. I found a nice chuck under a rock in the canyon bottom.

Back at the camp the girls had whipped up a good pancake breakfast. After we were thoroughly stoked Phyl and I set off up the canyon. We followed the main wash probably $\frac{3}{4}$ across the island. The canyon is rather densely vegetated with a variety of plants such as palo verde, ironwood, *Hyptis* in bloom, milkweed, *Simmondsia*, a plant that looks like *Simmondsia* but has round purple berries, and beautiful cardons and patches of pitahaya cactus.

We picked up 12 chuckwallas and a couple of spiny tailed iguanas. The chucks were all in completely inadequate burrows, either in the canyon bottom under boulders or along the rocky banks of the arroyos. One gets the idea that these lizards have a deep commodious communal burrow usually in the canyon bank and a wide series of temporary shelters under boulders varying from totally inadequate to cover the whole animal to nearly impregnable fortresses under big boulders. Nearly all in which I caught lizards faced SE or S and the animals were all docile and could be pulled free with little trouble. Phyl and I stumbled back under our burdens, plopping down wearily.

Kelly and Jim returned a while later shouting and clutching 8 lizards that they had hauled from a single rock $2\frac{1}{2}$ ft. long and 18 in. thick in the midst of a pitahaya and mesquite. There were 4 chucks and 2 spring-tailed iguanas.

Later in the afternoon several of us went up to an osprey nest that Karen had found just north of camp on a vertical bluff. The mother screeched over our heads but did not stomp[?] on us. Father, so we assume, stayed away and was clutching a fish in his claws. There were 2 nearly naked gray babies in the nest, lying quietly on their precarious perch. Mother soared and swooped in the stiff breeze that is whipping the channel and keeping our temperatures low.

Dick is a bit under the weather—we hope it is fatigue.

April 4, 1963

The wind has abated somewhat. Kelly and I instrumented a large male chuck and placed him under the rock from which I captured him, about 400 ft. from camp in the middle of the wash. The animal raced off with his pack on his back, broadcasting his cloaca temp. We took a couple of readings as the morning progressed.

Dick had gone off for an early morning hike up the creek and did not return by 10 AM. We began to worry as he had been sick the day before and we didn't expect him to be gone so long. At 10:30 I organized a search. Kelly, Jim, and I took separate ridges while I sent the girls up the creek. I hadn't gotten beyond the top of the ridge when Sue yelled up at me and Dick appeared. I called Kelly and Jim off the ridge.

I clambered back down to camp and was surprised to find Phyl and Karen missing still. So, after taking a drink of water and tossing a couple of bags of raisins in a sack, Sue and I set off after them. We hiked and hiked and called and called but could not catch them. We went past the bat cave, up to the place where the canyon widens. We looked for tracks and could find what looked like faint ones, but we couldn't be sure. At last we turned back and finally arrived hot and panting—no Phyl and Karen. They came trudging wearily in about 2 PM, thirsty and tired.

Our lizard had been resting under the same rock and his temperature went up and up. Finally he disappeared and we could pick up nothing.

Just before dusk a plane came over that we were pretty sure housed Charlie Lowe, Dick Felger and pilot Ike Russell. The plane circled and a small parachute fell loose dangling a small package. It drifted over the sea and sank. The plane circled and circled and finally another parachute bust loose and drifted stopping just into the surf. I sauntered over and picked it up. It read: "Ken, if you get this, we will land on Tiburon and hike to the beach and make a fire. Can you come over and pick us up tomorrow." Obviously Charlie. With our boat out of commission (the starter spring is broken) we have no chance of going out to pick him up. After dusk we watched ruefully as a blaze appeared along the Tiburon coast.

Later, everyone but Phyl and Dick piled in the boat and went langosta hunting. The water was clear and we saw many and took some nice ones with our "Revenilon[?] Grabber". There was much shouting and splashing and order-giving and we finally came back to camp and hit the sack in the calm moonlit night.

Up this morning with plans to do a fish poisoning station off the rocky point of the bay. While I was changing my clothes I noticed a pair of boats coming towards us from Tiburon and almost before I could get back to camp they had materialized into two swift power boats. Sue peered through the telescope and shortly Charlie became obvious, standing in the bow in a bright red coat and Mexican sombrero, smiling like a six-foot-four chipmunk. In a few moments we were wading in water alongside the boats greeting Charlie and Dick Felger. They had flashed the boats down with a mirror from the beach. The fishermen were a sullen crew, unhappy at being dragged out of their way and away from their fishing. Finally Charlie jumped ashore and before long we were up looking for rattlesnakes. There is a single form on this island—a pygmy black-tailed rattlesnake of which only 2 specimens have been taken. Charlie, Sue, and I took off up the left-hand draw poking in among the rocky outcrops. We took some *Cnemidophorus*, a baby *Ctenosaura* and some utas.

As we climbed up the steep talus slope we began to see baby chucks sunning themselves on the rocks. There were scarcely any adults to be seen. The young animals were wary and not unlike chucks on the mainland. We took a series of animals varying from young-of-the-year to ½ grown. We saw only 2 adults. It seemed obvious that the young were relegated to the slopes while the adults were concentrated in the heavily vegetated washes below. Probably there is slim pickings for the adults on the relatively barren slopes.

Far up the north-facing slope of a talus-filled canyon, about 50 yards from the crest, I was rolling some boulders looking for a baby chuck when a flake fell off and there was a black *Phyllodactylus xanti*. After a chase the little beast ran into my shoe and we captured it. We think it is the second record for the species—the first having been

made early in the century. We drank the canteen dry and slipped our prize inside. We hiked on back down the ridge and finally into camp hot and foot weary. After lunch Charlie's boats returned and he left to Kino Bay and home. Dick stayed with us to collect plants and will return to Los Angeles Bay with us.

After dinner we went out after lobsters again and caught 6.

Kelly and I instrumented another chuck and put her out in the middle of the wash.

April 6, 1963

Kelly and I spent the morning recording from the instrumented lizard. She moved 265 ft. and came to rest under a bush. We recorded her as it sunned and then as it controlled its temp. and retreated to the shade. Dick Felger reported seeing the most chucks at the heads of canyons where draws dropped down into them. These are places of dense vegetation. He also saw one in cholla (whose name he will supply), apparently eating flowers. The chollas are covered with greenish yellow blossoms. Not long after Dick returned from his hike we saw a big Guaymas shrimp trawler in the distance toward Isla Turners. It came closer and closer and finally Sue said "There's Charlie on board". We told her she had a Charlie fixation—but the ship kept coming and before long we all could see the big red-coated figure in the bow, smiling out from under his hat. Before long he jumped into the skiff and came ashore. He had hitch-hiked a ride at Kino Bay and they were to take Charlie and Dick and gear to "Ensenada Blanca" on the W side of Tiburon. After some palaver the men took Dick Lockwood out to see a sick man while Charlie got his gear together. Goodbye once again—this time with instructions that if Charlie was picked up on a schedule by his pilot the plane would make 2 figure 8's over our camp. If we didn't see this we would go to Ensenada Blanca on Monday and pick them up. OK—so off steamed Charlie and Dick with an emergency supply of our food in case they got stuck.

In the afternoon we did a fish poisoning at the south limb of our cove. The bottom was covered with cobbles and larger boulders and the water cold. I spread emulsifiable rotenone around by hand in a dense white cloud. Dick and Karen patrolled the deeper water in the skiff while the rest of us worked the shallower parts on foot, wading up to our waists. The collection was not a large one, mostly Trypterygid clivids, clingfish, blennies, and gobies, and *Ogilibra* of at least 2 species.

Lobsters began to come up and swim around having been driven from their crevices by the rotenone. We caught 15 or so and assured ourselves of a good supper. Everyoe collected as long as the cold would allow and then turned back. Phylly and I stayed longest and walked back along the cobbly beach together. Phyl showed me some bright red mites crawling over the sub-tidal boulders. One wonders what they do at high tide.

Back at camp I ate my portion of an apple pie that Sue had whipped up. Jim stoked our campfire and struck up a few good songs. I hauled up the beer buoy out of the cold bag and we boiled up the lobsters. What a feast under the bright desert moonlight with the flat calm gulf shining offshore.

April 7, 1963

Our last full day on the island. I wanted to get a size series of chucks and so Phyl, Jim, Sue, and Kelly, and I took off up a rocky talus slope to the west of camp. Our

previous surmise seemed to prove correct. Adults are in areas of heaviest vegetation while young and juveniles are in areas of lesser cover and food supplies. We caught quite a few in the course of climbing to the top of the mountain. It was hot and we were dry and tired by the time we sat down under a gnarled ironwood tree for a drink. Many of the chucks have their faces and chests smeared with an amber-colored gum of the *Jatropha* bushes. I suspect they are eating the leaves.

As we walked down the wash on the way back to camp, Kelly spotted a big *Ctenosaura* running on a boulder. We sneaked up on it and I got some good photographs before he took off through the ironwoods. Finally Kelly and I cornered him up an ironwood and I grabbed him. Later he bit Kelly rather severely on the hands.

We have quite a pile of lizards building up. The cave under our tent is a squirming mass of bags.

Kelly, Jim, Dick, and I decided to photograph the osprey's nest at the tip of the point at the south limb of our cove. The nest is on the very tip of a rocky vertical-walled bluff. Mother osprey and one baby were in the nest. While she swooped overhead giving her piercing repetitive cry, Jim crept out and took the temperature of the panting baby bird (41 deg. C). The mother bird swooped and wheeled overhead, twice going down to the sea surface and dragging her feet in the water. Presumably she may have normally used this water to cool her babies. Her wheeling circling flight, her tacks in the wind, her instinctive adjustments of wing and tail to the vagaries of the air currents made a beautiful picture.

After dinner (the girls have been providing superb food) we decided to go out after geckos. Sue and Phyl and I went up an arroyo SW of camp. As we wound around in the rocky walled canyon in the moonlight, peering in the crevices and on the bark of trees not a gecko was to be found. Finally we spotted one and caught him on a large cleft rock. On up the canyon we went through the large ironwoods and mesquite. Finally we returned to camp and began to pack some gear for our departure on the morrow.

April 8, 1963

Los Angeles Bay, Baja California

From 7 until 10 AM we packed camp and moved our gear down to the beach. At 10:30 the *San Augustine* I came around the south point and we began to load. Kelly and I took a quick bath in the ample fresh water we had left (almost 40 gallons). With the gear stowed below we hauled up the anchor and started around the island. At the NE end we stopped dead in the water and Leopoldo and Juan (Nayo was on a three-day drunk and not feeling well) went below and did mysterious things until the engine started again. We passed through a series of very turbulent tidal rips until we cleared the island. Between San Lorenzo and Raza we saw the tiny fin and great dark back of a finback whale and later a school of 75 common dolphins.

We passed to the north of Isla Raza, close aboard. It is low and rocky and has a shallow bay in its north side that can harbor skiffs and small boats. About 10 men were on shore gathering tern eggs. As nearly as I could tell only Heerman's gulls and terns were using the island when we passed.

Amazon Trip
March 15, 1967

Phylly drove me to the airport where I first learned that my bags weighed in at 125 lbs., and then boarded a jet to Miami. The overweight is no problem in the USA, but will become so out of the country. Two hernias later we got the bags on board a Varig flight for Belem. The last light of day faded as we crossed the SE corner of Cuba. We landed at Caracas—hilly country with warm humid tropical air. In a few moments we were back aboard and on our way to Belem at the mouth of the Amazon. It was 3:30 AM as we landed and prospects were that my flight up river wouldn't get off until 12:30 PM. I commiserated about all this with a fine Tucson couple and the skipper of a Norwegian tanker. They were all going to Fortaleza or Recife. Much to my delight I was able to transfer to a flight leaving at 6:30 AM on a fine old DC-3. The two beers I had at the airport, courtesy my friends, weighed heavily indeed and I was caught between the desire for sleep and a desire to look at the countryside. I did some of both. The delta region of the Amazon is an intricate maze of rivers and selva-covered islands. From the air one can see a few familiar trees amongst the forest, but mostly it is a mat of green. The river is coffee-colored and probably nearly opaque. It also is flowing fast enough to produce current rips in many places. I saw many rafts of floating vegetation moving along. The plane stopped five times at little tile-roofed villages, usually sitting on the highest ground available. One such was Monte Alegre, a village built on a rounded hill perhaps 100 ft. above the river level. It centers around a great gracious old church with red tile roof and pastel belltower. Here the vegetation and soil were poor—iron concretions and sand. The vegetation reminds me of the short-tree forest of Mexico.

Finally we dropped down at Manaus and circled it. I saw the boat at the pier and the float plane tied down just off the runway. My meager Spanish was absolutely useless and I had to resort to drawing to get my taxi driver to take me to the ship. The driver played his horn like a strad, giving an impression of great speed and determination, and shortly we were in town. It is a somewhat battered tropical latin town on hilly terrain filled with free-style drivers, old battered buses, trucks full of produce, and people. The Portuguese influence is great here; thin aquiline features and few really shapely girls to watch. At the river boats brought in all sorts of produce—bananas, etc.

Our husbanding company, Booth Line, was a great help. They had two or three English-speaking employees and I was able to get tickets arranged, gear toted on board, and so forth.

The *Alpha Helix* is a dream. A white ship about 120 ft. long, sleeping 22 including a scientific crew of 12. She is magnificently equipped with laboratory equipment, machine tools, launches, animal cages, wardroom, fine bridge, excellent quarters, cooking and food storage facilities, and so on. All in all, just about the most posh floating laboratory imaginable—all air conditioned. I bunk with Ted Bullock, the Chief Scientist, in a nice topside cabin. Other scientists are Dr. Sawaya of Sao Paulo, Don Lindsley (physiological psychologist), Peter Hartline (a young neurophysiologist),

Bob Piddington (same), a chap from Harvard working on neurohumors, and some others I haven't as yet met.

I arrived just in time for a big reception of all the local bigwigs from Amazonas State. Everyone who was anyone was on board eating catered food and drinking a variety of drinks. The mayor's representative, the archbishop, the governor of Amazonas State, a gaggle of generals all resplendent in stars, endless people's wives all dressed to the teeth, a variety of scientists and educators including the rector of the local university, two young American English teachers on their way down the river, probably to Sao Paulo and south, and a young local girl named Sonja, who teaches English and Portuguese here.

The governor, when he found I was a student of porpoises, got a gleam in his eye and wanted to know if maybe I couldn't solve a recent and vexing problem for him. Seems a ballot box was missing from a recent election and the story was it was stolen by a porpoise. Could a porpoise do such a thing? Well, sure, if properly trained. I suggested to him that he should be sure that his party had its trained porpoises, too, to even things up, but this may not have passed the translation barrier. I later learned that it is widely accepted that when a local girl becomes pregnant, she has but to say "a porpoise came and did her dirt during the night" and all is forgiven and forgotten. Handy beasts, these porpoises! Up this way they seem related to goats—scapegoats, at least.

Tomorrow we cast off and cruise about 100 miles up the Rio Negro into an area where all that surrounds us are a thousand miles of forest and the rising river. Several missions are then above us, and then just indians and forest alone. This country is peculiarly deficient in some kind of nutrient balance and does not produce for farming.

The river rises about 6 in. a day now, and will flood over the forest floor for hundreds of miles in places. With it go the aquatic creatures, porpoises and manatees included. It will peak about June and then recedes to its low level around October. Afternoon rains are the rule—skies are dark with thunderheads and I am surprised how cool it stays. I walked for a couple of miles around town with no fatigue—a welcome respite after all my traveling. There is very little evidence of tourists here—certainly few stores feature much to attract their money. Instead it is heavy equipment, pumps, barbed wire, tractors, and automobile parts with the emphasis on 4-wheel drive.

(The travel minister, who was at our reception, says his people work for 4 months, night and day, and then lay off)—clothing and furniture stores, street vendors selling all manner of odd fruit, long bean pods (4 ft), cherimoyas, rose hips, papayas, mangoes, bananas, cylindrical cheeses, sacks of manioc, beans, corn, a variety of milled grains and so on. I was not struck by poverty so much as by the brawling roughness of a frontier and a harsh one at that, difficult to push back, but none the less, being pushed back in a hundred directions. Beggars variously maimed and blindmen were common. Most people bore some mark of the harshness of life in a jungle 2 degrees south of the Equator—smallpox scars, and many were the tough wiry individuals, without fat, arms sinewy and tough. Few over-muscled people but most 5 ft. 5 in. or less.

The seemingly endless forest is their resource, but with its flooding from the rains of a subcontinent, it fights back and progress into it is slow. The rivers are the highways though planes are increasingly important, particularly the old DC-3 and the Catalina flying boat for the back country. For me to drop out of the sky on my short stay points up the schism in life here. Most people are locked to the ecosystem here—the river, the

timber crop, the soil minerals; but some of us come and go on an entirely different basis—based upon the technological necessity of underlying industry with the esoterica of pure science. We are an elite but a peculiar, incomprehensible sacred cow elite making use of unbridled curiosity as its grist. Those of us who are truly curious and not just playing the game sift ourselves out and become the mobile ones, the ones whose curiosity is ultimately supported.

March 16, 1967

Well, we're still at Manaus at the dock waiting for approval for our float plane to fly. Permission is tangled somewhere in officialdom. We loaded fuel today and had not the plane tied us up the fuel would have, as it was stopped for a long time by a broken pump. I spent the day rigging my gear and getting ready for whatever animals we can get. Things are in pretty good shape now. We are building a sort of hypodermic to place the hydrophone. I rigged harpoon lines and checked the gun over.

I took a couple of walks today; one to buy a float for the hydrophone and one to visit the indian museum. This museum is run by nuns, Silesian sect, who operate schools and missions up the Rio Negro. The exhibits were interesting, particularly the basketry and pottery. Much pottery has what looks like stone polishing and scraffito—little simple light-colored patterns across the bowls. I bought a fine blowgun and sole palm darts, and made for the ship.

A tuxuci (*Sotalia*) came up astern of us, but listening was impossible because of noises from passing ships.

After dinner a little more gear-rigging and off to bed—very sleepy in the warmth.

March 18, 1967

After a grand night's rest I awoke more refreshed than I have been for days—a good thing because it has been a full day. About 7 AM the engines of the *Alpha Helix* turned on for the first time since I came aboard, a welcome sound for us all. The float plane still has not been released, but hopes are that it will be free soon. It is greatly needed both for biological reconnaissance and for communication with Manaus. The boat turned up channel in the Rio Negro (the Amazon becomes confluent just below Manaus), and quickly out into the center of the mile-broad channel. As we cut through the dark tea-colored water, I talked with Willy Schwartz, our collector. He is a stocky German of about 55 years who has spent most of his life in South America and the last 20-25 years on the Amazon. He carries on a fish- and animal-export business and owns several boats, rafts, and a variety of collecting gear. He has traveled all over South America, much of it by canoe in the rivers. A fascinating man. I asked if he planned to write his experiences. "No," he said, "I'm still living them. Only if you are unfamiliar and thus a tourist are you amazed enough at the commonplaces of a place like the Amazon to write." Thus, the real experts seldom record their experiences. He pointed out a big leper colony on the south bank; it looked like a New Orleans mansion set amid palms and scattered jungle trees.

We saw several tuxuci (*Sotalia*). They surfaced briefly in mid-channel and disappeared. Their shyness reminds me of *Phocoena*, the harbor porpoise. They stay to channels, Schwartz said, while *Inia*, the boto, will enter very shallow waters.

Parrots flew over with their peculiar low rapid wing beats and flights of the black vulture cruised by, taking 4-5 wing beats followed by a glide. Soon the river began to close in around us and the gallery forest grew denser and taller. Now all communication is by boat or occasional visits from the Catalina flying boat.

At the river's edge it is a mass of different kinds of trees, usually heavily laden with lianas and vines so that one cannot look back among the trees. One could see buttressed trunks standing in water, the feathery crowns of palms and the silvery bottomed leaves of the *Cecropia* tree. This tree, by the way, is the favorite food of the sloths (we have two species on board). From time to time we passed either little frame houses or thatched shelters set on the river banks. Around each area a clearing given over to raising manioc, the staple for flour in the region as it keeps, unlike wheat flour. Usually a scattering of brown naked children scurried down to look at our big white ship, while momma looked up from her work or papa peered out from his hammock. A dugout, or sometimes a houseboat, was tied to the steep reddish bank.

The river itself moves fast and is usually braided out into several channels or paranas, with jungle-covered islands in between. It is rather uniformly about 50 ft. deep in the channel and 200 yards width in our channel.

Several hours upstream we stopped to look at Willy's houseboat which is being considered for a shore camp in the jungle. I thought it would have been excellent—3 big rooms and a half 2nd story, all set on huge logs. But T. Bullock and R. Livingston seem to want something more "jungly", or at least they feel P. Scholander will. Pete, by the way, is due in soon (20th).

Out on the water the air was much hotter than on board and for the first time I mildly felt the heat. I cannot get over my surprise at how comfortable the climate is, especially when it is overcast.

I spent most of the day happily trying to set up my sound transmission gear, fiddling with oscilloscope dials and trying to damp resonant waves in my tank. I failed, and finally at about 10:30 PM tore it down and decided I must work in the river. So tomorrow I build a new gadget to hold an animal in the water. I'll also set up gear on the stern under cover.

After a grand steak dinner and a Dean Martin movie, I spent some time cogitating my experiment and looking at Ted Bullock's emerald tree boa and then to bed.

We are anchored perhaps 50 miles above Manaus, 250 yards offshore with the sweet heavy smells of the jungle wafting around us. It seems very hard to believe we are here somehow, surrounded by comforts such as air conditioning, water fountains, three excellent meals a day, hot and cold water, and labs filled with the most sophisticated gear.

March 19, 1967

Rio Negro at entrance of Rio Braueos, Brazil. We are now at or near the station where the permanent shore camp will be established. We hoisted anchor at dawn and steamed up the river between green walls of vegetation. The clothing of vines and foliage grows so dense along the river's edge that one can seldom see into the forest, except where it has been cut or cleared. The forest is a bewildering array of different types, sizes and forms of trees. Feathery palms are common, occasional rubber trees appear—podocarps, silk oaks, and many, many that I cannot even guess at. Vines are

everywhere and are unbelievably strong. It was all I could do to break one about $\frac{1}{4}$ in. through.

Several *boutu rosada* (*Inia*) flashed in the tea-colored water and I saw an occasional shy tuxuci. A good many birds flew along the banks as we passed. Little kingfishers, herons, egrets, terns (surprisingly), parrots, and several ospreys. Thatched houses lined the banks periodically, most were on stilts in ragged clearings and had a half-dozen little brown children peering out the front glassless window as we passed. May came down to the water as our big boat passed, only to watch our wake roll in against the bank and scurry for high ground. One young boy raced down to his dugout and snatched out a precious furred umbrella before the wave hit. He scrambled triumphantly up the bank. One family of mostly girls squealed with delight as we went by. Tall feathery manioc filled most clearings, though bananas were also common enough.

I pressed the carpenters into service and they built me a fine porpoise holding trough that I will suspend over the side when we get animals for the sound transmission tests. Tomorrow I will, at least, test the gear in the river.

At about 3 PM we came into a broad area of the river just above the entrance of the Rio Branco and dropped anchor off a bright white beach topped by a shack that seemed abandoned. Soon we were all ashore exploring. It was much like coming ashore in a new island full of unknown wonders. The house proved to be in pretty fair shape—tile roof, adzed hardwood floors and only a modicum of holes for the rain to enter. Of course, there were no windows; nobody seems to bother with them. We learned it belonged to the local tax collector and that local people thought we were tax collectors at first. Around the house were rubber trees, mangoes, cherimoyas, guavas, and behind a tree-filled swamp of tea-colored water. We walked down the beautiful shining beach and could see the marks of past receding water levels. At highest water it reached about 8 ft. below the house and left it on a 50-yard island. At this stage there was 50 yards or more of beach extending downslope to the water.

Surprisingly, several very large granite boulders rose up from the water's edge—some 10 ft. high. As we hiked down the strand we noted glass palms with needles protruding from both stems and leaves, brazil nut trees with 1 lb. fruit half ripe, great termite nests plastered high in the big trees, oropendulas, big oriole-like birds, a sandpiper, a creature like a surf bird with a striking black-and-white body and red legs. He was chased viciously by a peculiar purplish bird that looked like a cross between a purple martin and a hawk.

Right at our landing the inias came in. There were two or three and they came into the half-submerged bushes, blowing noisily and raising their snouts out of the water. One gray one jumped completely into the air. They seemed to be grubbing around in the muck and were moving very slowly. Finally, a lone tuxuci came in briefly. Unfortunately, before I could get my recording gear together, they were gone.

At the boat I put my gear into the skiff and piloted by Bob Piddington and M. Ruez of the Brazilian Navy, we started off to record. It was falling dusk and the river turned to black glass. Over the feathery outline of the trees the sky grew coral. Piddington took the whaler up a couple of absolutely still back waters where the reflections of trees fell in the water with perfect fidelity. It became almost impossible to see the shoreline. The smooth flight of the boat seemed to be in air. It was eerie and

beautiful. Bats began to dip in the midst of this airy curtain, making silver rings spread around them.

After supper I tied the skiff astern and listened to the underwater noises of the river. It was quiet except for some chirps and repetitive dull smashing sounds. I thought I could hear the faraway slow repetition rate cruising calls of porpoises, but could not be sure. One thing for sure, our boat can be heard. Auxiliary motors, clanging hatches, people stamping their feet.

After a bout with the tape recorder (successful), I'm off to bed.

March 20 1967

Up at dawn and off by myself with whaler to look for porpoises. It wasn't long till I came upon a school of *Sotalia* milling and diving about 50-100 yards offshore in a still backwater. Try as I did to creep upon them, I could not get closer than about 35 yards. They were clicking in low repetition rate trains of very intense little clicks. I recorded for a while and finally turned back to the ship. The school was composed of about six animals including some half-grown young. At its biggest the tuxuci is small, perhaps 5 ft., with a prominent snout and melon—lead gray and white. One jumped clear once, but for the most part they stayed submerged. When frightened they bunched together just as a good porpoise school should, and plunged off in unison.

On board I spent the day rigging the apparatus over the side for the transmission test—wow, what a lot of practical electronics I am learning! Then we spent some time analyzing the tuxuci pulses I recorded. They are very brief, 0.6 m/sec. or less, but my tape proved to be overloaded pretty badly, so I will have to record them again.

After dinner (wow, the quantity and quality of food in this ship is the best I have encountered—I'll gain 20 lbs. 'ere I'm home. Alan Berliner and I took a ride in Scwhartz's boat across the river to a backwater area where *Inia* was supposed to be common. We pulled up in front of a picturesque little village of thatched shacks on silts and Valdovino the harpooner left us in his dugout while we drifted and listened to underwater noises. In air we could hear frogs calling, but underwater, it was a madhouse. Frog calls of the sap cururu (*Leptodactylus* sp.) echoed back and forth; a vegetarian relative of the piranha croaked, things stroked balloons, creaks issued from the banks, and across it all came sporadic porpoise clicks. Then when the hydrophone, unbeknownst to us, began to bang against the hull, producing a dreadful row, it was too much. Valdovino threw his harpon and it bounced off of an *Inia*, and finally we packed up and went home.

Back at the *Alpha Helix* we found that the captain had not returned on the launch *Serendip* and is somewhere upstream, most likely broken down. On that anxious note I go to sleep.

March 21, 1967

Up this morning early. Captain Perez and I put my recording gear in the whaler and went upstream. As we cruised along, we stopped periodically and put the hydrophone in the water. In midstream we stopped to record some tuxuci clicks, but the animals were gone. Later on we approached a small island in midstream and saw the peculiar lump snouts of the boutu rosada poking up in the rip of the downstream end of the island. We pursued them at last into a tiny still cove on the upstream edge of the island. I guessed that there were six animals in all, some small ones and a couple of old

horses. All were bright pink with a fading of gray dorsally. The skiff was stopped and we drifted along silently in among them. I canned a magnificent recording from the encounter and happily turned back to the ship.

After breakfast I completed preparations for the transmission equipment and in the afternoon, I went ashore to watch Don Lindsley and Bob Livingstone try maze learning tests with a group of sloths. I helped them string up a horizontal framework of limbs inside the tax collector's shack, almost backing into a wasp nest in the bargain. Once it was strung the sloth was hung on the framework and asked to creep his way down the only route that would let him escape out the door. There were three or four blind alleys which he could creep that ended in mid-air. The first sloth on the schedule was Pedro, whom I called Jimmy Cagney, as his hair was parted in the middle and he looked for all the world like a pug-nosed Irishman, except that sloths are evident in having no guile. Even though Pedro had understood this same maze in Belem, he turned every wrong corner and climbed wires.

Sloths have a very thick, coarse reddish-gray and white hair. Males have a distinctive pattern on their mid-backs of short, yellowish-orange hair with a central longitudinal blue band. Females are undecorated. I suppose this helps sloths tell whose back they are climbing on. They are long limbed, lightly muscled animals that have a surprisingly tight grip as they hold their claws back against their long black palms.

The next sloth was Bernard Baruch and he was no better. Learning studies on sloths are difficult work for human experimenters. At one point I looked over and found data taker Livingstone snoozing at the helm, notebook crooked in limp fingers. It could happen to anyone.

I left the sloth scientists for a walk in the forest and was able to spot the big emerald green teiids that had been leaving tracks all over the beach. They were all back in the grassy areas of the forest and raced off by bipedal locomotion, I believe. I think I saw a tiny microteiid, too.

Back on board I made ready to go out porpoise hunting with Valdovino, one of Schwartz's boys, and Captain Perez, who has attached himself to my work. I find him a miserably bossy field companion who must give many orders. I have generally ignored him and on a couple of occasions told him "no", but I don't like to do this if I can avoid it. Time is short and his goodwill is important to the trip.

Anyway, with Valdovino's canoa in tow, we set off across the river to remansa (backwater), where porpoises are supposed to play all day and evening. We had treated Valdovino's little daughter, Maria, for malaria this morning and he was all cooperation. Maria is a beautiful little child of two with big brown eyes and long curling lashes. She is ill with intermittent fevers and damaged spleen, and also serious anemia. When all the strange white folks looked so serious, she looked up with wide eyes and burst into tears. Valdovino and wife and another girl and four children live in two canoas. One is a long, low, thatched affair in which they cook. He offered, but I did not accept, some noxious-looking boiled meat served on what looked like crushed dog biscuits. Valdovino is a supple barefoot man of 30-35 with scraggly, eroded, blackened teeth from decay, not betel, a thatch of unruly black hair and an engaging kindly face.

The river is wide and I had to husband our gas supply. Three quarters across we came upon a rapidly moving school of tuxucis who were out of range before we could get

our gear in the water. Down the coast to the remansa we went. Sure enough, there we found both a dozen or more boutu rosada and small schools of tuxuci.

We set Valdovino free and watched as he sliced the water delicately with his broad, spade-shaped paddle held in one hand with long wooden harpoon held in the other, resting on his shoulder. Silently he slid toward the milling boutu. One surfaced ahead of him, bright pink in the afternoon light. He stood up and threw his harpoon, away late and well behind the slow-moving boutu. He did not throw again all afternoon and soon indicated that it was hopeless. I recall thinking as I saw him throw, "Either he knows something I don't, or he cannot even hit his hat." And what fisherman on the River Amazon can't throw a harpoon?

Later I learned from Dr. Sawaya that he probably was superstitious about the boutu, thinking they bear the spirits of the dead relatives. At any rate, it is obvious that I can't rely on Valdovino for boutu.

As we drifted at the mouth of the remansa, a sight such as one sees at sea took place. A school of bait fish was being harried by a slender, gray-and-white tern-like bird from above and from below by a 1-2 ft. silvery fish called apapa. Around the periphery of the melee cruised the porpoises of both species.

Back on board we worked on experiments and I finally gave a seminar on the sperm whale and finally to bed.

March 22, 1967

Up this morning at 5:05 AM, to go with Sam Crouse to hunt for porpoises. It was pitch black and we finally decided against going because Sam had to begin work in the galley at 6:30. So back to sleep and I didn't make it out again till 9. I fiddled with gear until noon and then cruised up to the little island and was put ashore. My plan was to climb a great *Bursera* tree that overhangs the water about 40 ft., and to wait until a boutu swims by and blast him with the harpoon gun. With a convenient machete I hacked a trail through the lianas and trees to the base of the *Bursera*. By sawing some lianas from it, I made a set of ropes to help me climb up into it. Then I took the harpoon line and shock cord up and finally out on an overhanging limb where I tied it down. Returning for the harpoon gun, I took that up too, and finally secured it well and flaked the lines over a nearby branch. Once all was in order, I clambered back up past the mossy place where the ants lived to my liana pathway along the trail to the landing spot. By this time I was absolutely saturated with sweat. The humidity and still air combine to reduce one to the siesta schedule, which no right thinking Anglo Saxon can take without a struggle.

I had no more than settled down to listen through the hydrophone than I saw a pair of *Inia* cruising into my little bay through some partly submerged vegetation at the end. I listened for a few moments and then raced for the tree. I had negotiated most of the tree and had one hand on the harpoon gun when they surfaced directly beneath me and were gone in the deep amber water. They surfaced again near the outer rocks of the bay and then I could hear their snorting breaths out in the river. No other chance came today.

I watched, listened and waited, and perhaps a dozen porpoises, both *Inia* and *Sotalia*, went by, but none came in the cove. I read, wrote notes, washed my shirt, and listened to the jungle. Doves have the most prominent voices though some unidentified

avian screaming was louder. My terns of yesterday flew over, gray wings with diagonal white on dorsal body and inner primaries.

Epiphytes are common, bromeliads, orchids, and a variety of unidentified flowering plants. Begoniaceous plants are common as trees with large showy flowers.

About 5 a crewman picked me up (too early, I thought) and we returned to the *Alpha Helix* for a magnificent roast beef dinner with Yorkshire pudding.

After dinner B. J. O'Brien, a big Aussie from Cairns, and I cruised out to test out a harpoon he had made. We drifted quietly among puffing tuxucis and boutus, but to no avail since they never came near.

Tomorrow I try the tree again. This time early in the morning till noon.

March 23, 1967

Up at 6 AM and off to the cove. I cruised into the little pebbly embayment where I moored the boat to a tree and set up recording gear. One odd fish (?) was banging away and making such a racket that I wasn't at all sure we could hear a porpoise recorded anyway near him. But later on he subsided enough so that I could work. I no more than had my gear in the water than a boutu rosada broke the surface near the cove entrance. I dropped everything and raced up through the grassy patch, back of the landing, through dense jungle where I had hacked my trail, scaled the tree with help of the liana hand-rails, and finally out onto my perch. Nothing came up, so after many minutes I carefully stirred myself on my somewhat precarious perch, leaned the harpoon gun against a tree limb, clambered over the branches being careful for the slick spots, avoiding the ants and thorny little vines, and made my way back down to the beach. It was hot and still and my clothes were wringing wet from the exertion. As I sat listening in the skiff, it began to rain, so there was a flurry of activity while I stowed my precious tape recorder and other gear, and then sat hunched under my raincoat watching the forest and the river in the rain.

A slow, chugging sound began to increase from in back of the island downstream, and before long an archaic old paddlewheel steamer slid into view. She was all of 100 ft. long, laden with barrels and boxes, her tall stack fitfully belching smoke from the wood-fueled boiler (stacks of cut wood stood on deck to feed it). She cut diagonally across the Negro to the far bank and curved up the river almost hidden to the eye against the green wall of the forest.

Before long the rain subsided and once again I saw a boutu enter the far end of the backwater. I snapped on the tape recorder hurriedly and ran for the tree. Once again I sat and saw nothing surface.

Finally, near noon I hopped into the skiff and returned toward the boat, testing the walkie talkie enroute. It would pick up the ship only when in direct line of sight, and even then only when less than half a mile or so away.

I asked and received permission to go on down toward the remansa to hunt for boutu. This took me into one of the paranas or channels away from the main river; this one 450 yards across or so, more overhang with tall trees and quieter than the river itself. A few wary tuxucis were all that greeted me until I emerged once again at the main river about one mile upstream from the remansa. There I encountered a group of about six boutu rosada, all small and all gray in color. There were two very small babies in the group, the smallest about three ft. or a little less in length. They were puttering along the edge of a hedge of semisubmerged vegetation and occasionally even went past way into

the branches. The babies often swam many yards away from the larger animals, but when I frightened an animal, they rushed close to the side of an adult. The largest animal in the group might have been six ft. long.

I am impressed that the gray color and pink color of *Inia* does not represent two species at all, but simply two color phases based upon age. I have seen several animals that were intermediate. Usually the beak, the anterior melon and the posterior tip of the dorsal fin. The melon is often mottled gray and pink in these animals. All the more or less uniformly pink animals I have seen were large. The color is enhanced by the tea-colored water.

All attempts to catch one of these animals failed. They dive for too long, 2-3 minutes, and follow no predictable path underwater, and are exquisitely sensitive to the presence of a boat, even a quietly drifting one.

At the remansa entrance I lowered my hydrophone over the side and sat, earphones on, listening to the voices of the Amazon—toads, fish, and porpoises. The boat drifted along in the current just at dusk, past a village on the bank. One man, thinking my motor had broken, rowed out in his canoa. I explained as best I could and finally called him over and clapped the earphones on him. He broke into a broad grin, “Ah, sap cururu,” he said laughing—the toad calls. He explained that the insistent rapping noise was the call of the apapa. I didn’t learn what the apapa was. Then to prove my motor worked, which he insisted I do, I revved it up and soon was headed back to the ship, skimming at full speed over the glassy water. This river has different faces several times a day. If the wind picks up against the current, it can get very choppy, particularly where two currents come together.

Back on board we had our usual fine meal. Joe the Guamanian cook, outdoes himself each night with some new delight.

Then Ted Bullock, who couldn’t have been nicer to me in many ways, asked if I wanted to try hammock sleeping over in the tax collector’s house. There our two large-size hammocks strung up, covered with a fine cheesecloth bug deflector. I was tired and so was Ted (who had been up all night doing an experiment). “Whoever goes to sleep first will whistle,” he said, and promptly drifted off with no sound but heavy breathing. For my part I had to experiment with the hammock to find out how to cope with it. My hammock was for a couple, but I couldn’t see how. I found that by lying diagonally one could be almost flat. Slight movements allowed one to support this or that part and by a delicate equilibrium one could support most of one’s corpus, and being careful all the while not to press against the mosquito bar and thus allow easy access to your red corpuscles. Insects are few though and mosquitoes at a minimum. In fact some soil factor makes the whole Rio Negro region impoverished as jungles go, and it is remarkably free of diseases—malaria is sparse, shistosomiasis absent, filariasis absent, and so on.

Other than the piercing cries of the captive sloths, nothing disturbed my rest.

March 24, 1967

This morning Peter Hartline and I went together to my island. Peter is a young neurophysiologist who has been teaching me how to run various instruments. He is an exceptionally bright and personable young man who already can handle his field with considerable skill, and who has the best command of electronics of anyone aboard.

We came into the cove via the upstream approach, but no boutu were there to be disturbed anyway. I set Pete up manning the listening post while I scaled the tree. More or less continuously (with time out twice while I stood and climbed up and down a few branches to get the kinks out), I sat for 3 hours on my branch, harpoon gun within reach, and lines and shock cord flaked over another nearby branch. No boutus.

Finally, I commented to Pete that we had given it the old college try. Twenty minutes more, says I. Twenty minutes later and still no boutu, so I called Pete over in the boat after test firing the harpoon gun and lowered all my gear to him. The gun, by the way, goes off with a helluva bang and kicks like a horse. This accomplished, we went back to pick up the listening gear and were just about to leave when, sure enough, exactly according to the libretto, into the cove came a boutu, big as life. I thrashed around frantically to get the harpoon and lines organized and decided to rush off in the drifting skiff in hopes of getting a shot. Finally, I decided that this might frighten him and so came ashore again, only then to find that I had tied down the wrong line. The harpoon line was unsecured and would have gone over the side like a shot.

Next I set up a post on the high-cut bank at the base of my *Bursera* tree. The boutu came in and surfaced within easy shot of the limb station, but too far from me on the bank. Finally he left the cove and was gone.

Back at the ship we had lunch and I made preparations for another hunt. This time B. O'Brien, the shore camp cook, went with me. He is a big burly Aussie from Cairns. He had fashioned an aboriginal prong spear out of nails and tape which he wanted to try. It was built like this [drawing]. These sorts of spears are reported to hold dugongs weighing as much as 2,000 lbs. Anyway, pushing off from the ship we made our way across the river and quickly encountered several boutu feeding along the opposite bank. Try as we did we were not fast enough to catch one. They surface abruptly from the opaque water and seldom in range. Finally we headed up the remansa. Glassy calm water floods into the forest on both sides leaving an overhanging mass of vines, limbs and tall trees as the borders. A heavy sweetish smell of the jungle pervaded the air. Ahead of us, bright rings spread where boutu surfaced and submerged again after their brief breath. Occasionally the skittish tuxuci surfaced and plunged away.

We drifted and watched. Rapidly moving trails of bubbles, like those from a diver's hose, cut around us and we finally concluded that they came from the boutu rooting in the muddy bottom 25-30 ft. below us. But each time the bubble trails came near, they cut away again and stopped. A few moments later a boutu surfaced at some unexpected point, just out of range. They blow explosively and rise to the surface with the tip of their long snout first, then the bulbous forehead and blowhole. Their eye usually stays just below water. Dusk came and we turned reluctantly for the ship, gliding along into a magnificent sunset, tiers of clouds lighted up in color and finally the sky itself became rosy and faded to amber, and finally the lighted blue of early night.

After dinner Peter Hartline helped me to use a scope camera to photograph boutu clicks. Mastery of an instrument such as this provides a very pleasant feeling. I am beginning to become more a master of my own house in which I can interpret and study my data without having to rely upon others so completely. I must extend this more and more.

March 25, 1967

Up this morning early and with Bob Livingstone cruised off with a ship's rifle (British 303) to see if we could shoot a boutu. We headed for the remansa as I wanted Bob to see it. He is a tall rawboned guy who can charm you out of your shoes. He constantly seeks to thank and compliment people for things they do. He is also a tireless, careful worker of a very considerable note in brain studies. He is a sailor and thus good company for a cruise of this sort.

Knowing my own meager skill as a rifle shot, I gave Bob the gun and steered him in among the boutus. Even to obtain a rifle shot proved very difficult. There just isn't time to swing around, aim and fire as they surface, blow and dive under again.

Finally Bob did squeeze off a shot that missed, the bullet skipping over the water in a ricochet. After a time we entered the remansa (or iguape), passing the thatched houses and on up into uninhabited jungle. At the junction of two channels, I dropped anchor and we waited while I listened. The boutus were all clicking away at a relatively slow rate. When they were somewhat over 100 yards away the clicks dropped to such low levels that I could no longer hear them. Once again Bob fired a shot that seemed to hit a boutu and shock it sideways in the black water, though we couldn't be sure. The clicking became a little more insistent, it seemed, but that was all. No cries or whistles. The boutus moved away from us a little, but seemed very calm about the affair. Soon we hauled in the little anchor and continued upstream, soon coming upon a group of perhaps 15 tuxucis. They moved very warily, as usual. We circled and chased them at high speed and could easily outrun them, but like the boutu we could never tell where they would come up, and even though they did so in a typical delphinid school in unison, I was never fast enough to shoot.

The channel led on into the jungle into a broad lake dotted with islands of drowned vegetation whose tops just protruded above the water. Much of the forest is drowned in this way at high water which may be 30-50 ft. higher than the lowest stage. How plants survive and grow tall enough to reach above the water is a mystery to me. Certainly it becomes unpenetrable when the water floods out and one meets tangles of foliage, vines, and limbs. Some trees are simply encrusted with epiphytes, some dangling long red flower stalks, others sprouting showy white blossoms. Giant phyllodendrons climb many trees, and pod-bearers are everywhere—yellow bean-like pods, ones curved like pears, and the heavy flat cups of Brazil nuts.

As we sat quietly drifting, I was impressed again at the noises in the jungle. It seems that someone is always dropping something. Things go "plop" at the water's edge, cicadas hum in certain trees and the chirring call of howler monkeys could be heard. A woodpecker whacks out a deep resonant staccato that echoes through the forest. Boutus blow explosively.

In the lake we frightened several interesting birds including a pair of macaws with their metallic blue backs and burnt umber yellow undersides. Gas was getting a little low, so we turned and headed back for the boat, somewhat chastened on the problem of obtaining a boutu, but nonetheless pleased for our trip down the water jungle waterway. Even though I had rather little hope by this time, I set out again after lunch to try again, this time with the mess boy, Sam Crouse, and Alan Berlind, a student from Harvard working on neurosecretion. I came close to firing at a tiny little tuxuci that couldn't have been more than 2 ½ ft. long but he proved to be elusive. The sun had come out in full mid-day force so we all covered up as best we could. I wrapped a towel around my

exposed dome and it helped. Soon, however, we headed back to the boat as Sam had to work on dinner starting at 3:30. He is a nice young fellow who has an MA in biology and wants to go on. This was his way of going on the expedition but he has rather little free time from his kitchen duties to look around.

Just before dinner, a big old boutu surfaced near the *Alpha Helix*, so a group of us jumped in a skiff to see if we could get a shot. Finally, I did fire a desperation shot that hit low and caromed over his back.

Back on board, the evening was spent using the scope camera on boutu clicks and in developing nearly 300 ft. of film I took. I finished by about 2 AM and hit the sack, exhausted. The recordings I have made are ample reward, even though I did not obtain animals for my transmission tests. They are the first from the Amazon and are of excellent quality that will allow a thorough analysis of the signals of the two species.

March 26, 1967

Manaus

I packed, disassembled and stored, said goodbyes, and about 1 PM went ashore to climb in the float plane with Diego, the pilot. He is a rough and ready bush pilot, who had been in photoreconnaissance in the Second World War and in Korea, who has spotted for tuna boats, worked the Andes for geologists, and who was one of the first of our craft in the air out of Hickam Field on Oahu after the Pearl Harbor attack. He neither drinks nor smokes, takes no guff from anyone, and flies his plane like the professional he is. As we boarded, just for spite an old boutu surfaced within 20 yards of the plane, puffed a few times, and was off, and so were we.

The flight to Manaus was interesting. Away from the river there is almost nothing except trees and water. Where the water does not flood the forest is untouched for hundreds of miles in every direction. The Rio Negro from the air is black as obsidian. One can see where its meanderings have left families of oxbow channels in the forest. Usually the trees there are smaller and of a more uniform kind than the untouched forest.

We spent the night at the Amazonas Hotel, a nice new hotel with the calcimine paint peeling off the ceiling and the john not flushing. We walked around town and I soon learned that Diego has spotted every pretty girl in town and had done his best to strike up friendships in every case. He knew which mamas shouted at him and which ones he could approach by playing with the little children.

After our promenade, we had dinner in the hotel restaurant. I had arapaima filet—one of the largest freshwater fish in the world. It was good but overcooked. The arapaima, or pirarucu, is a primitive osteoglossid fish living only in the Amazon Basin (Orinoco?). I saw it everywhere in the markets.

We had a chance to see Manaus a bit more than before. It is, indeed, filled with faded elegance. Most houses have tiled roofs that are mottled with blackish moss from the rains. Buildings from the golden era around the turn of the century show ornate facades, intricate grill work, and mosaics here and there. The bandstand and statuary are strictly out of Victorian England. We looked more closely at the opera house where Caruso and Galli-Curci sang. It has a great Port Cochere there for the arrival of Victorian carriages and is reportedly elegant inside. All along the streets young girls stood just outside the iron gates talking with their boyfriends while inside the open door sat the

duena keeping a watchful eye on the proceedings. Many walls are spiked or covered with broken bottles set in cement.

A few elegant houses built in the aseptic modern latin fashion had been built cheek by jowl with the run-down houses of yesterday. Graceful spiral staircases, elegant tilework and stained glass windows were typical.

Back at the hotel I quickly went to sleep awaiting my 5 o'clock call—after bashing a few eager mosquitoes.

March 27, 1967

Up at 5 AM and after a complementary breakfast (papaya, some fine tropical conserve, coffee, and toast), on to the airport. First, I retrieved my blowgun off the float plane where we had tied it, then to the airline desk. After due complications with officials, I got on board a fine old DC3 and we took off (at about 7 AM) for Leticia and points in between.

I had utterly no idea of the vastness of the forest until this flight which took me across the entire upper Amazon basin. It is immense and almost unbroken by human habitation—a carpet of tree tops, mostly dark green but with a scattering of white limbed species, or a spreading tree with light apple-green foliage.

Flowering trees are scattered through it everywhere and feathery palms thrust up through the canopy with much regularity. The scattered nature of each species in the forest is very evident when one looks closely—as if some ecologic force keeps spacing in existence—perhaps some ancient plant inhibitor evolutionary warfare. Here and there along rivers which wind tortuously through the forest, thatched houses show up surrounded by a little clearing and a manioc patch.

We landed at Tefe, a little town on the Solimoes (the upper Amazon), where a nun among our passengers was greeted with shouts of joy from a large group of young girls who had assembled at the dirt field to greet her. She was spirited off by jeep with six giggling girls clinging to the bumper. Gas was pumped into the plane from drums by hand pump through a big funnel filter. Soon we were bumping along the field and back in the air again. The forest became even less inhabited—an unbroken stretch as far as I could see in either direction. Only a winding river here and there broke the monotony. Finally, we sat down on the muddy field at the little village of Carauri on the Turua River, south of the Solimoes. The thatched airport building and stacks of gas drums made up the physical scene. The town had turned out to greet the plane which arrives weekly and is their major contact with the outside world. I saw a European fellow ride up on a bicycle and soon found that he was a Dutchman, a father in a Catholic mission here and had been in the village for 19 years. He told me it had taken six days by boat from the Solimoes when he first came and that he arrived in the middle of a typhus epidemic. Nine years ago the plane field was built (he wasn't sure, but he thinks with foreign aid money from USA). His town is terribly poor and his mission and its one doctor serve an area twice that of the Netherlands—20,000 people in the forest. The village itself is about 1,500 in population, a tiny mote in the sea of green. He told me the soil was not poor and that he had planted one hectare of rice this year and had harvested about 2,000 kilos from it. Now, he wanted to try soya beans but couldn't get them from his headquarters in the Netherlands. I gave him my address and will try to help him when he writes.

Up again over the green sea. The forest looks denser and taller and what houses we see are largely built on water on stilts. At one point, we descended under heavy clouds and over a forest that was about half fan palms—about the only unmixed forest I have seen. In places the forest streams. Vapor rises in hundreds of columns like smoke across the forest. I cannot see what causes this even though we flew directly over a few in landing. At Labaturga, on the Solimoes, a short distance from Leticia, Columbia, it seems to be a military camp judging from the number of sergeants that got off.

The plane swooped up and as quickly landed at Leticia, Columbia, on, believe it or not, a paved strip. I ambled off the plane and was met by the Booth Line Representative and saw a gaunt Greek-looking gent in a “Tarpon Zoo” sweatshirt whom I judged to be the animal collector, Mike Tsalickis. Indeed it was and soon the Booth Line man had surrendered me to Mike. Quite a surrender it proved to be. I was whisked through customs and into Mike’s Chevy carry-all for a bouncy ride into Leticia. Leticia sports about 5,000 people and Mike knows each one individually including talents and foibles. Mike, I found, is more than just an animal dealer. He is an American consul and used to schedule all four airlines in and out, runs a hotel, and is building a new one, is constructing a monkey colony on a 1,000-acre island he owns, exports indian artifacts, has supplied the hospital with all its furnishings via the U.S. Navy, and a whole lot more. It took ten minutes to be put up at his nice little hotel (cottage). We toured his animal-holding facilities which are quite sizeable and then I (oops, Leticia’s lights quit—the Swedish power plant bought so I am told, because the Governor married a Swedish girl) went into the dining room for lunch. Then began an amazing tour of official life in Leticia. Mike had to settle some affairs for a man named Deakin. Deakin, it turns out, runs a nudist camp north of Miami and comes to Leticia to get servant girls. Whether they too become nudists I don’t know. Mike was helping him negotiate for the 17-year-old daughter of a local family. The girl, named Maria, was a shy, pretty, thin-faced girl quivering with excitement over what was happening to her. I hope she isn’t disillusioned by the experience. Papers had to be filled out, the Governor’s signature was needed. She had to have a yellow-fever shot. I need a visa, and why Booth Line in Manaus didn’t take care of this I don’t understand. Anyway, they didn’t so we had to tend to this too. Then, I had to get a refund on an overweight baggage allowance. We hopped in the car, picked up Maria, dickered with the family for a little three-year-old girl, were turned down because she had a twin who would be lonesome, shot over to the Policia about my visa. It needed a two-peso tax stamp. We went to Fiscal and bought two—one for Maria and one for me. I needed two pictures and so Mike took me to the local photographer who was found under a tree in the Plaza. The picture he took registers my amazement at his methods. His shutter was full of long black-and-gray mold, so he sat me down while two people held a black cloth behind me, lifted the lens cap off his 2.8 Schneider lens and quickly replaced it 1/25 second later. Then, he removed and developed the film all in the bag at the back of the camera. We left to take Maria to the Governor, and met a Baptist missionary, the Peruvian Counsul, and the Brazilian Consul on the way, plus six people of lesser stature. Then we went to Aduana to try to get a release for Mike’s latest shipment of canned goods (he is a wholesale dealer). They weren’t quite released but in a few minutes they would be. We whipped over to Cruzero do Sul and got my refund of piles and piles of Cruzeros—156,000 to be exact.

Then, back to the photographer who was thrashing my prints around in a bucket. (Where did he get prints? I still don't know.) Five pesos there (17 p/1\$) and off we went. Aduana released the canned goods and it started to rain. Never mind, back to the animal farm for help. Me and five others to the customs warehouse where 5,000 pesos worth of food was stacked. We slipped and slid down the ramp to the truck with raisins, canned peaches, whole canned chickens, chicken and rice soup, pears, tomato sauce, and on and on. Three loads later, with my shirt and pants soaked with a combination of sweat and rain, we were done. Then to the Policia with my pictures and my visa was done. On to the hospital with Maria for yellow-fever shots.

They needed ten people before they would open a vial of serum so Mike collared his driver, his driver's daughter, tried to collar me, and three nurses. Finally enough people came in and the shots were duly given. Mike took me proudly through the hospital (40 beds) and well he might be proud too. It is clean and quite nicely appointed.

Then, back to my room to clean up and go to dinner. Amongst other things they served me fried yucca root and it was very much like potatoes, a little more fillous[?] and a tiny bit sweet, but very good.

Later, while writing these notes, three girls from around the corner knocked. Mike sent them to check on the state of the water in my bathroom (there isn't any till morning) but their tone and looks told me that their concern wasn't really the state of my water supply. I thanked them, said buenos noches, and they turned away into the night with their duty done. Good old Mike thinks of everything. I don't suppose it's in a consular agent's creed to be so thoughtful but then I don't really know.

Oh yes, a couple of other notes. Deakin I find is writing a book on nudism among South American natives. He has found his favorite tribe—a group living about 500 miles south of Manaus who are both perfectly hairless (the value of this escapes me) and perfectly nude. Then, he proceeded to describe these perfect creatures further—they were, it seems, killing themselves off. Any malformed baby is killed he said as if this explains their decline from 5,000 to 500. Deakin is a freckled, puffy-faced nervous type who exudes unreliability to me.

Mike on the other hand, exudes tremendous energy, charisma, guile, and yes, even a rake off now and then, but on balance is effective, useful, and works in the best interest of our country. He told me about the puberty rites of the local tribes for girls. With the first menstruation, they are locked in a cage and kept out of sight of all males and only released at night for a time under careful guard. Then the family saves to give a party—smoked monkey and other delicacies and finally, a party is given in which everyone including the girl drinks to stupefaction. Then, the tribe elders pull all the girl's hair out and the ceremony is over and she is an adult.

March 28, 1967

After a flurry of packing pots and other goodies, I climbed aboard a Saterra Airline's plane with a dozen other passengers and great bales and bags of freight where the seats had been folded out of the way. For once, there was a good place to stow my blowgun and newly acquired Ticuna indian arrows. The jungle goes on and on. I am staggered by its immensity. After some hours on the plane, we still are over jungle with muddy oxbow rivers here and there. Finally, the jungle began to break here and there with a high ground savannah making its appearance. The jungle then became restricted

to watercourses. With the savannah came roads and I saw two or three cars moving along like bugs. The rivers up this far were at low water. Big sand bars showed tan at every river bend.

We flew through a couple of clouds that tossed us around and flapped our wings ominously (to me anyway—I never like my airplane wings to flap).

Finally, after flying blind, we burst through the clouds to see the Andes all around us, the steep slopes either clothed in dense rainforest or apparently bare. The tiniest usable plot of land of less than 30 degrees was walled with rock with . . .

(Note: The plane landed at Bogota where I stayed overnight, came down with Montezuma's revenge, staggered through customs, got on board a Varig flight to Miami, slept through most of it, and barely made it through customs in Miami with the blowgun and other paraphernalia, got on a flight to L.A. and landed feeling much better.—KSN, November 3, 1971)

September 2, 1971

Northwestern Hawaiian Island Trip

Midway Island

This trip is being taken as a routine survey by the U.S. Bureau of Sport Fisheries and Wildlife, under Gene Kridler, the Wildlife Administrator for the Hawaiian Island National Wildlife Refuge. I was invited to go along as an observer and to take a look at the marine mammals. Eric Laysan Schlemmer is along. He was born on Laysan Island in 1903 and hasn't been back since 1923. He will place crosses on the graves of a brother and a young Japanese girl. He was on the island off and on from 1903 to 1915, and then returned with the Tanager Expedition. John Sincock, the ornithologist of the Bureau who spends much of his time studying the native Hawaiian birds on Kauai, and Erwin Bauer, an adventure and wildlife writer from Columbus, Ohio, make up the rest of the party. I drove to Gene's house at 4 AM, we loaded gear on his station wagon, and picked up the others along the way to the military field (Hickham Field). We had a nice 2 ½ hr. flight in a jet plane of Saturn Airways to the Midway field. Along the way the plane passed over Necker Island, a rugged little curved necklace of rocky promontories that surrounds a little bight of water called Shark Bay like an old Hawaiian fishhook. As we flew over I read from K. Emory's paper on the archaeology of the island. It is covered with marae or stone platforms which have upright slabs of stone along the perimeter. Stone idols of a very characteristic type and stone bowls, one of which was found by Queen Liliokulani, were also taken. Emory hypothesizes that these temples were older than most remains on the main islands. I suppose Necker is ½ to ¾ mile long and perhaps 300-400 ft. wide (actually it's quite a lot wider than this).

I sat with Eric. He is a spare, gray-haired gentleman of 68 with a twinkle in his eye and dozens of stories about Laysan. He told of going there in a sailboat named the *Helena* and encountering a storm that sprung the deck house and caused water to flood in. The pump wasn't working because a bottle had fallen into it and broken. He fished the pieces of glass out and looked at the leather flap valve, finding it badly cut. His father instructed him to cut leather from a shoe. Eric wanted to know if they should turn for the safety of Kauai but father remained firm that they were going to Laysan and that was that. With the pump fixed they pumped constantly, the storm finally abating and they

made it into the channel of the island. The boat was moored to an underwater shot of chain stretched between two large anchors. Somehow it broke free and when they discovered it the vessel was far at sea, drifting away. Eric's father gave the son a box of matches and said: "Do the best you can if I can't get back."

Then he set off in the skiff to try to catch the drifting craft before their entire contact with the outside world was lost. He made it back. Eric was one of 17 children borne by his mother and the family was operating the guano industry on the island. They hauled the guano on a railroad car pulled by mules. Eric, in later years became the maintenance superintendent of the Hawaiian Electric Company in Honolulu.

His trip on the Tanager Expedition was to help with the local terrain and to advise on landings, etc. Alexander Wetmore was along as were other well-known scientists, and Eric acted as his personal assistant. The trip took him to the northwest Hawaiian Islands and then to Wake and Johnston Island.

Birds were everywhere. Especially abundant is the ethereal fairy tern. This delicate little bird is pure white except for black legs, beak, and eyes. It is flying in pairs and hundreds rest up in the ironwood trees. These little birds gleam like shining alabaster jewels as the sun shines through their feathers or glints off their backs and heads. They are bold little birds and once in a while we would rouse the ire of a pair that had been wheeling together high in the blue sky. They descended on us and swooped and fluttered about our heads, hovering with a torrent of chirring tern cusswords, often inches from our faces. I tried in vain to photograph this but always had the wrong lens or one that was out of focus. To see them swooping against the dark grayish green backdrop of the casuarinas lit by the sun is something of constant beauty. Erwin and I manfully tried to catch it for hours on film. He may have succeeded. These little terns lay eggs on limbs or in crotches of trees, the babies hatch out, sans nest and simply perch immobile in these precarious places as they grow. I crept up on a mother and young on the dead limb of a *Casuarina*, but I needn't have bothered. I finally came within inches. I wanted the mother to raise her pretty white wings and so I waved my hand a foot or so from her. Instead her fuzzy little chick raised his downy wings in anticipated flight, but he was two or three weeks too early.

Noddy and Sooty terns are common, especially the former who flit amongst the trees or gather on the wires emitting their raspy, almost crowlike croaks. CPO Cunningham took us to the nests of several red-tailed tropic birds. Deep in the tangled glossy green leaves of the naupaka jungle one could hear the threatening squawks of these birds when one blundered near, crashing through the brush. The pretty black and white checkered babies, as big as momma, sat immobile on the sand looking apprehensively at one. Sometimes they ruffled up their feathers, spreading and tilting their wings toward the intruder and pointing their sharp black beaks at one. Fearsome enough, I suppose, but they couldn't hold the pose for long, but deflated back to normal size again. Parent birds, glossy white with a long thin red wire of a tail and with a Chinese red, almost lacquered bill, sometimes sat immobile too, allowing me to photograph them from inches away. By poking my camera in first I could protect myself from possible jabs of their powerful appearing beaks. Ken Balcomb says they return to the same nesting spot year after year. He has been banding a lot of them.

We flew over Pearl and Hermes Reef, a turquoise and white jewel set in the midst of the azure deep sea. It is a true atoll, one of two in any U.S. state. The other is French Frigate Shoals. That is to say it has a circlet of reef border that forms small islands at various places with a large central lagoon connecting to the open sea by “passes or channels”. The fringing reef is dissected into channels and coral fins, the channels being deep clear blue and the coral brown and tan. In the lagoon one could see vast areas of sandy reef flat, reflecting nearly white through the crystal water. From place to place the water would deepen into green or greenish blue. One could see domes and heads of coral rising from the depths.

I slept as we passed Laysan but Eric was happy to see it shining out toward the horizon, the sun glinting off the central salt lagoon. Not long after we circled Midway, a two-square-mile low island, surrounded on the north by a broad lagoon. There are two islands. ? Island where most of the 2,100 people live and where the airfield is located, and Eastern Island which has only a few people operating some kind of station—loran, I think. The field is a right-angle affair and runs along two entire sides of the main island. It is clearly capable of handling the largest aircraft. The island is rather heavily vegetated mostly with *Casuarina* trees, though there is much naupaka (*Scaevola*) along the shore dunes, and kamani trees are scattered through the forest. They had had quite a lot of rain recently and the soil was grassy and green nearly everywhere. It is a Navy base, operating a loran station, a radio center, sonar and listening and some secret activities, in addition to the airfield. The channel between the two islands has been dredged and seems capable of handling rather large ships. Our craft, the Coast Guard ship *Buttonwood*, was in awaiting our boarding on the 4th.

We were met by Navy authorities who quickly checked us through and took us to the BOQ. We are in spare quarters, but adequate. I called Ken Balcomb, who is Operations Officer on some secret project—acoustic I believe—and before long he came over and we made arrangements for dinner at his house nearby. In the meantime Chief Petty Officer John Cuninghame took us on a tour of the island. We passed the waterworks, which uses the airfield as an catchment basin for rainwater. They also use the brackish lens water, mostly for sanitary purposes. The CPO took us on around to the seaward edge of the runway where we invaded the naupaka thicket

Midway is a little tranquil paradise, and like all paradises, it takes some getting used to. The streets are shady winding lanes, bordered by tall casuarinas, with birds swooping and going about their business everywhere. There are few cars and most everyone rides bicycles. They all know each other and a stranger is spotted immediately, being the object of much curiosity—especially I am told, non-military types. These folks are all doing something interesting or they wouldn't be here. The usual Navy arrangements pertain—CPO clubs, Officers' mess, BOQ's, nice but spare married officer housing, the senior officers with metal signs hanging from pipe posts out in their front lawn—names stencilled on, indicating the impermanence of any military assignment. There are lovely swimming beaches and one can rent a sunfish for 25 cents an hour. The girls are all tanned within an inch of their lives. Everyone's wife has a job, in the PX, the company store, in the Post Office, or whatnot.

Julie Balcomb, Ken's wife, loved the place but said she had missed some of the amenities at first but then everyone was so friendly and had parties going all the time that soon she didn't care and shortly after that she didn't want to leave.

We looked at our future home—the Coast Guard ship *Buttonwood*, a 185-ft. buoy tender—well deck amidships, bridge aft, 11 knots wide open, round hull adapted to light ice breaking (protruberances under water get caught in the ice and if one gets frozen the ship will not be squeezed free like a watermelon seed between the fingers). She was anchored in the little enclosed harbor of Midway waiting our arrival on the morning of the 4th. After a nice dinner at the local palace of culture—the Steak House, we headed for Ken's house and thence back to the BOQ to sleep.

September 3, 1971

I met John Sincock and Eric in the room last night and they were both sipping straight gin. I sipped a little too and then crawled in the sack for a nice snooze. Today was spent getting supplies at the PX—very cheap—got in a little more exploring and had a very interesting morning at Kure Island. We boarded a big Navy helicopter and took off for Kure, with us strapped in amidst piles of supplies for the Loran station there. Gene and John sat in the door to view the monk seals and to try for a count.

The chopper lifted us across the 65 miles of choppy blue water to this little atoll. There are two motes of land, the main one, Green Island, of about 10 acres or so, mostly taken up by the Loran tower and associated buildings plus a little strip. We skirted the other—a sand spit on which we saw about 20 monk seals sunning themselves.

The chopper returned and settled down in front of the main building. There we met the CO—a Lt. J. G., Joel Greenberg—nice but quiet—all the other islanders were notably absent, almost as if they shunned company. We, however, ignored this and went about our business of making a survey of the seals. I talked to Lt. Greenberg and he told me of seeing a school of 20-30 porpoises enter the lagoon through a channel on the far side. He described them spinning without prompting from me, include saying that they spun 4-5 times on their longitudinal axis. He said he had not seen them before. He had been on the island since April and said he walked the beaches every day.

I walked the strand to the north, along a shining coral beach backed by dense naupaka. At many places I could see the shallow troughs where monk seals had hauled up on the beach and into the naupaka. In one such trail I found the culprit—an adult female lying on her back snoozing in the partial shade. Her blubber jiggled as she breathed and rolled loosely about her. She fidgeted with one flipper scratching desultorily. She uttered a very low frequency pulse moan of low intensity as she slept, no doubt dreaming of some monkish exploit.

On down the beach I went, with noddy terns rising in flocks ahead of me and swooping about my head. Frigate birds flapped into the air from the naupaka and croaked in unhappiness as I came too near for comfort. Out on the extreme sand spit I came across three more seals—two adults in the water and one pup (tagged with two stainless flipper tags numbered, I think, 167). One of the adults had a grievous wound in its chest—a lunate cut clear through the blubber, perhaps by a shark with a gape of a foot or so. It was so fresh the animal clouded the water with blood as he rolled away, actually turning over and over on his longitudinal axis as he moved into deeper water.

I pressed hard to get back in time, plunging through the naupaka and disrupting about 20 nesting sooty terns in the process. They objected but I made it in time. On the way back we set down on the sand spit and looked for tags among the seals.

On the way back we circled Midway lagoon looking for a porpoise school that had been seen the last few days there. It was reported to enter by Wells Channel on the north shore and leave through the dredged channel on the south. The school was supposed to have 30-40 animals and to come in the late morning and to leave in mid afternoon. They were reported to go into quite shallow water. One person reported spinning. We found them over against the drop-off from the shallow reef flat north of Eastern Island. They skirted right along the shallows and I estimated 35 animals. They were clearly spinners and I photographed them several times. After being frightened by the helicopter with several passes they dove and one could see their dark shapes down near the bottom in the gin-clear water.

Not much else happened—dinner at the Balcs—very nice and good slides and such—to bed in preparation for leaving tomorrow morning.

September 4, 1951

At sea over Salmon Banks enroute to Lisianski Island

We piled all the gear into the back of a station wagon, pried John out of his sack (he actually miraculously emerged in time without us prying him, but we thought about it). It didn't take long to load the gear, ascend the gang plank, meet the Captain (Lt. Commander Smith—a pleasant, athletic-looking fellow who seems most accommodating), and to find our quarters. Erwin and I are stashed foreward with the crew while the others are in "Officer's Country" astern.

Before long we pushed off into the channel and began checking some buoys on the way out. I looked back to see if I could see the "green cloud effect" again. I had noticed it yesterday. It consists of clouds over atolls and lagoons turning faint emerald green on their undersides because of the hue of reflected light from the sea. A moderate depth of water over white coral sand produces green water, and if it is clear, a lot of reflection results. Under the right circumstances a cloud mass apparently colors up quite strikingly. I first saw some puffs of cloud drifting over the *Casuarina* trees and wondered if there was some sort of chemical fire near. To be honest the effect was probably heightened for me because I wore polaroid glasses, but it's there for unaided vision too. Polynesian navigators in open boats were supposed to have used the effect to locate lagoons over the horizon. I can see how it would work. I can also see how swell patterns could be used once you studied them. We passed about 20 miles south of Pearl and Hermes Reef today, a broad shallow atoll, and I could see marked changes in the swell patterns. Before we reached the atoll area the swells had become regular southeast rollers with no evident cross swell. By the time we were abeam of the Atoll the swells had become complicated by a cross swell, and finally before dusk it became even more complicated still, perhaps from some of the sea mounts nearby, like Neva shoals, or Salmon Banks. Anyway, with practice I'll bet one could learn a lot from them.

My day was spent on the bridge with only short breaks for food and an occasional break to rest my eyes, and especially my aching feet. Not a marine mammal was sighted. The sea was, in fact, remarkably dead, with only a scattering of little Bonin petrels to keep us company. These little fellows look like junior-grade wedge-tailed shearwaters, and one wonders if they aren't sized to compensate for the low productivity of the sea in which they operate. There were quite a lot of flying fish, however, and one oceanic white-tipped shark, but that's all, to compensate for the wind and sunburn I contracted.

Eric and the watch kept me company much of the time, telling me stories of this and that—typical past time conversation that always goes on on watches—what kind of car the lookout is going to get and why, if the finance company comes through, stories of Eric's days before the mast on the four-master *John Ena*, in which he sailed from Hawaii to Alaska to New Zealand. She made 22 knots top speed Eric said, and at 13 he was required to set the royals and stitch on new buntlines aloft underway. It's amazing how many of the crew and officers have taken a crack at being oceanographers, or who want to try. I get the impression that these are exceptionally capable seamen. Their boat has received several awards for excellence, more in fact I am told, than any other Coast Guard vessel.

After supper, very tired. I tried to sleep below but had trouble dropping off, mostly I suspect because it was new and I worried about poking Erwin's rear with my elbows when I rolled over. He, however, was so dead to the world he couldn't have cared less.

September 5, 1971

Lisianski Island, Northwestern Hawaiian Islands

I awoke this morning to look out the porthole and see the ocean light-apple green. Then I noticed that the engines had slowed. We were at Lisianski and were moving into our anchorage. I shook away the sleep, grabbed a cup of coffee and went on deck. Lisianski lay low against the water, a line of white where the coral sand beach lay, a broader stripe of green marking the naupaka and other beach plants, and an occasional larger lump of green made by the three or four *Casuarina* trees on the island. Lisianski is about 3 miles around, tops out at about 15 ft. above sea level, is generally higher toward the center but with some depressions where I am told one could dig for water of the lens. There is a lone palm and one stump. Around it on all sides is an extensive dissected reef. Ahead of us and astern of us now, for instance, we can see the water hump up and break over large coral heads.

Before the anchor was down the crew had lines over the stern and before the anchor was set two or three men were hooked up to large fish. These soon came flapping over the stern—20-40 lbs. ulua (big jacks) and you could see each struggling fish was followed by three or four unhooked brethren.

Gene had us ready our gear last night so we were quickly loaded into the whale boat (the two diesel work boats double as life boats—sturdy craft with much styrofoam flotation so that they can hold many men). We grabbed the knotted ropes as the boat was lowered away. The davits were not swung out but simply extended on a hand operated screw device with a ratchet that gave quick and positive lowering capability without the mess of swinging davits and getting rope falls tangled, etc. A crisp command as the boat hit water cut away the aft block and this was quickly followed by the roar of the engine, and then the foreward block was released (once again a fine strong handle-operated release simplified this often dangerous task). Once again I was impressed with the crew and they waited for the radio to be brought, and the first-aid kit. Drill to be sure, but well-executed and all of it crucial in any kind of sea state (which we did not have as it was nearly flat calm).

We were perhaps 2,000 yards offshore, maybe double that, and the boat soon reached the strand, nosing up onto the slightly tan but gleaming coral beach. We piled

over the bow, all of us passing gear up the beach. Soon this was done and we readied ourselves for the trek around the island. It was about 9AM by the time we picked what we would and would not carry. We toted gear to handle monk seals, and we left lunch and swimming gear. We will use those things when we make the circuit of the island.

Scattered along the entire perimeter of the island were monk seals. We counted 119 in all, including about 20 pups. Some of these we tagged with double stainless tags clamped through the webbing of the hind flippers. This required something of a gymnastic event. John Sincock was the "head" man, and he pinned the seal down with a pair of giant tongs that allowed him to grip the seal around its throat and to press the tong tips into the sand, thus holding that end. Then Gene and I (when I wasn't off photographing something) tended to the stern. We grabbed the hind feet and kept the animal from squirming loose. Gene then clamped the stainless clip in place with a pair of stout pliers built for the purpose. It didn't seem to cause the animals excessive pain, in fact their struggles seemed not especially involved with the actual act of tagging but instead with general restraint. They can snap and Gene says they have a vise-like grip. Their teeth are quite small, however, so I suspect they can't do the damage some seals can. Like as not, after the tags were placed the seal might snort indignantly and settle down in the sand again, not bothering to hump himself down the beach into the nearby sea. Many did, however, and some swam along a little faster than we were walking to come onto the beach again and to be disturbed again. One literally moved in front of us off several hundred yards, seeming not to have enough sense to avoid us.

I was impressed that these monk seals seem not to form meaningful aggregations. The groups were generally small and seemed to be very loosely constructed. One often saw 6-8 in a given area, and often there were pups involved. Dimorphism is slight and there seems no dominance involved at all. At night many seem to move up into the naupaka, forming the long chute-like trails I mentioned seeing on Kure.

As for temperature, before coming here I wondered how a seal could survive on the open beaches of the central Pacific where the relentless sun beat down. Well, it doesn't. These islands are quite far north (26 deg. N Lat.) and only subtropical at best. The water is tepid (78 deg. F), and the trade winds very constant and quite cooling. For instance, today, which was a good warm day, the maximum was 85 deg. F. To be sure it would be hotter on the beach, but not excessively so. The seals make depressions in the sand, like shallow rabbit forms. You can often see where a seal has moved toward the water and along the way has stopped to dig a depression. These are usually about 6-8 in. deep, and have a margin of sand piled around their edge. The animal's head is also in a depression that usually comes up about to his lower jaw. The body depression does not even reach his plimsol line. Some seals have sand scattered over their backs and heads as a result of digging and this must help protect them from the heat. Mostly, I suspect, they simply soak up the heat while resting and thus producing little heat beyond that needed for maintenance metabolism. The wet sand below, the breeze, and the sand serve to keep their body temperatures within bounds.

I should mention that perhaps 10% of the seals we saw were in the process of moult. In this process they become the most ragged looking creatures imaginable—tatters and tags of old skin hanging off everywhere with the glossy dark brown fur showing beneath. I doubt this is significant thermally, since so few animals in the population show the feature at any one time.

Once again, we saw wounded animals. The competition between seals and sharks must be a constant one.

Walking down the beach was to experience a constantly changing panorama of living things, of a remote strand covered with the floating flotsam of the sea. Birds rose from the shore bushes, nestlings craned and looked scared as we passed. Mother blue-faced boobies cussed us out if we came too near to their downy young, a few of which were still on the nest. Fleets of great black seplulchral frigate birds rose flapping from the beach heliotrope to soar effortlessly above us. Brown boobies zeroed in on us at about eye level and flew straight for us with their powerful flight, to veer above us, or hover, as they came near. Fairy terns lifiting like airy feathers from nearby bushes to swoop and hover about our heads, their spotless white plumage illuminated by the sun behind them. Bristle-thighed curlews strode along the beach whistling their plaintive two-noted call. I lay in the sand and tossed pebbles to one. His attention was instantly taken by this and flight turned to curiosity. He came near and only flew when I disrupted the mood by changing lenses on my camera.

Red-footed boobies were very common, especially the nearly grown grayish young whose feet were just turning pink. They sat in groups of dozens per bush eyeing us with more equanimity than most of the birds. Gene told me that the back of the strand was honeycombed with the burrows of wedge-tailed shearwaters and Bonin petrels. To walk there was to crash into some beast's living room with each step, and to risk the chance of cracking an ankle in the process.

Flotsam. Glorious flotsam. The beach was littered with it, and it became a good ruminating point to figure how one could use the stuff to make a living cast up on this island. The glass balls, which were present by the hundreds around the island could serve as burning glasses, where the glass blower cracked off his long blowing tube and left a convex surface. I felt sure I could start a good campfire this way. I will probably try it on Laysan. Then, the heavy net back in which some of the balls were encased could be unravelled for twine. Tattered hausers appeared in some places, partly buried in the sand, and they could be used to make fish nets and to tie rafters and the like. Several fine planks and long mast-like timbers were passed and they could help build a house or a boat. Some pieces of piling could do the same. Endless bottles, some gallon size and some graceful blue sake bottles would make nice utensils. The same could be said of the big plastic floats that could be cut in half and hot stove cookery practiced. I thought a seal or two would provide leather, steeped in bird droppings to tan it, the sinews would work for thread as would some of the roots we saw. The coral boulders would make excellent plaster, and one might even make a house whose walls were largely glass balls stuck together with the stuff. A well would reach the water lens, somewhere near the island middle, or even just in back of the beach.

A short net would provide a constant fare of fish. We noted big schools of mullet, 10-14 in. long in the shallows along many parts of the island. Moi were common, flitting like white ghosts over the coral sand on shallow beaches. Blanched aholholes nibbled at us when we swam in two-foot water next to the beach. Big uluas—20 lbs. or so—cut into water so shallow their fins broke water, trying to get at the rich shoals of fish in shallower than they could go. Any kind of hook with bird feathers would probably get them. Certainly a stouter hook baited with seal meat or a bird or two would lure sharks in. The deck of the *Buttonwod* was littered with them when we returned.

The rusted TV set, its tube still intact, seemed more valuable as a decoration, or a tie to civilization, than for a real utility, though some of its wiring would probably be useful. The two big steel drums would be so useful it would be difficult to figure out which use was best. Probably one would serve as a big foot preparation pot—to render oil from seals, or from turtle eggs (the reserve managers are cringing at all this imaginary slaughter of their precious (and mine) animals, I know, but we can excuse it in me since I am stranded and without food).

The lone coconut tree probably wouldn't help much but it might provide enough nuts, or other nuts might wash up, that a grove could be started. Then, in a few years it would be a staple. But by that time I guss I'd have to figure I'd be rescued. Its sennet would be useful as would its fronds.

By this time the flies began to assemble forces. They came in droves, in fleets, in echelons, in swarms, and clouds. All of us were coated with hundreds of them, attracted to our sweating skins and soaked shirts. Fortunately they were benign flies and didn't bite. They just sat, and swarmed and walked and tickled one and flew in your mouth when you talked. John solved the problem by suggesting that they were the tresses of a gorgeous blond who hovered over us from every angle. That did it, for a time, but after all, one can only take so much hovering from a gorgeous blond before such static activity (if there is such a thing) palls and you want to move on to something more rewarding. John didn't solve that.

Finally we made it around and retreated to the fly-filled space beneath one of the ironwoods with our lunch. We ate happily, considering the company, and plotted a swim, which we soon took in the milky water of the strand edge. It was delicious, just the right temperature and we felt vastly refreshed when it was over.

The shore boat came in, loaded with the ship's crew and they rapidly deployed out along the strand with yelps of joy at each trove of glass balls. In an hour or so they came back burdened down with great bags of them.

Back at the ship we ate dinner, and caught some sharks. I can't identify them—gray above, rather small teeth [drawing], white below, teeth subtriangular to pointed. The fin is large and subconcave posteriorly. They were up to about 8 ft. long and the boys caught them on ulua scraps.

We'll up anchor and head for Laysan—12 hrs. away.

September 6, 1971

Laysan Island, Northwestern Hawaiian Islands

There are so many things to tell it's hard to know where to start. I guess I'll start with dawn like mostly. When I got up it was still dark and the ship was surging along, its engines thrumming as if no island was yet near. Erwin, who sleeps above me, was up rearranging his gear preparatory to landing at Laysan. The ship's complement had decided to drop us and go to French Frigate Shoals to place some buoys, and then to return for us, rather than to wait. I view this with mixed emotions. On the one hand I like the idea of being left here with no support vessel, but I would also like to be able to debark at French Frigate and fly home—there is so much to do before we leave for Rome in October. This now seems unlikely as we will probably bypass French Frigate and there is no other place where I might catch a plane home.

Anyway, we couldn't see Laysan even though we were supposed to be only 15 miles distant. The sun rose through a towering mass of cumulus right over the supposed island. It wasn't until half an hour later that we sighted the island—a thin disc of gray against the horizon, soon punctuated by texture, formed of groups of coconut palms (a very few), scraggly ironwoods, and finally the wreck of a Japanese long liner, cast up on the south shore.

The whale boat was loaded with a great pile of gear, mostly of undetermined nature since it was in dozens of army green bags. We loaded the boat and Eric, John, and I jumped in—Erwin and Gene will come along in the next load. We headed in toward the reef, spotting a break in it where a nice little small boat cove rimmed with coral reefs but with a 50-yard-wide channel some 20-25 ft. deep leads in. Our expert coxswain guided his boat through nicely, cast out a stern anchor and nosed in against the arcing strand of rather steep coral beach. Gear was passed onto the sand making a massive pile, especially when we knew we would have to tote it all up to the crest of the hill some 30 ft. above through the naupaka. John, who has camped here a number of times before, trudged up the sandy slope and found the nice level spot with tent pipes already in place and marked out the approximate dimensions of our tent. Then we began the job of hauling gear. I guess, in aggregate, it must have taken 30 trips to get the stuff up the hill. It was hot and but for the blessed trade wind breeze it would have been well nigh intolerable. Finally after Gene and crew had brought in the final footlockers and the big rubber boat, we made it, stopping now and then for a warm beer. The tent went up, and then another one. I occupy the smaller one in regal splendor, with the other four in the big tent.

The island is quite a lot larger than Lisianski, and has a beautiful lagoon in the center, all streaked with rose red where it has evaporated to sufficient salinity to support red salt-loving algae. In its center the lagoon is blue and it is backed by a swelling white dune, and then, from our vantage point, the sea and sky beyond—cumulus, swirling cirrus clouds above, and no human but ourselves. Our camp is high enough that we can look around the entire perimeter of the island seeing sea beyond. It is a varied little kingdom and the people of Honolulu were right in calling Maximillian Schlemmer, Eric's father, "King Max". I told Eric he was a lineal descendant and we should by all rights call him Eric the First.

Offshore the *Buttonwood* hauled her anchor, let out a long blast, and soon all we could see of her was the tip of her mast bobbing along above the distant northern dunes, and then not that.

Eric and I decided to take a hike, tired as we were. My intention was to go along the beach but Eric wanted to trace out some of the scenes of his youth. So I started out without shoes, thinking it was going to be sand all the way but soon ended up looking for house foundations of Eric's house. We are camped directly above the anchorage cove and that is where the houses and lighthouse used to stand. They ran along the brow of the hill, the guano shed some distance off to the south. All we could find were some squared coral blocks from the foundation. All the rest was sand and clumps of bunchgrass (*Eragrostis variabilis*) and sooty terns. The young skittered along the trails between grass clumps, giving us the old broken wing bit and tumbling head over heels in their attempts to escape us. The larger bushes often supported a dozen or so young frigate birds (*Fregata minor*). Most sported a modified afro hairdo of saffron-colored fuzz

feathers. They looked frightened at our approach but would not abandon their posts. The adults, however, swooped overhead. Eric said that the sooty terns were saying “Eric’s back, Eric’s back” and I think they might have. Next we descended toward the lagoon and finally crossed the old railroad where Eric as a boy had loaded guano for moving it off to the little pier that once stood out in the southern end of the small boat harbor. The ties were redwood, and nearly all eaten and perforated where the spikes had pierced them. We found spikes, all flaky with rust and mostly gone into decay.

It is sobering to realize the near completeness with which all traces of Eric’s life and the many artifacts involved in it have been erased in the time between 1915 and now—56 years. We found rails—little thin ones—miniatures of narrow gauge, and then we came upon a pile of bones and Eric asked if they were mule bones. “Why,” I asked? “Well,” Eric said, “we had an electric storm and the mule that pulled the railroad car was struck. My father said, ‘Son, take out your knife and put it in the bush yonder until the storm is over. Otherwise the lightning may hit you.’” Eric said he followed instructions but never found the knife again. I was sure the bones were from a large domestic animal and almost certainly from Eric’s mule. Then we found an old violet-colored bottle, colored by years of the sun. It was of the old wine bottle kind and Eric said they had carried water in them. Father said, “Drink slow, that’s all there is till you get back to the house.” The tracks led around the perimeter of the lagoon nearly to the south end of the island. There stood the most lasting thing from Eric’s tenure on the island—a large pile of guano of low grade left by the buyers. The guano is found in sheets or sometimes layers as much as 8 ft. thick. It is hard and rocklike and has to be taken out with a pick. It seems to be formed by the solution of the bird droppings over many years, its percolation into the sand and hardening there. New layers of sand accumulate over the hard pan below and are in turn solidified.

They had called his father “King Max” during his years here, and later when the World War came they called him and his family squareheads, Eric said, since they were Germans. It was one reason Eric went to sea. The Navy wouldn’t take him—he was too young (13) so he turned to the square rigger. He describes getting up the mast and slipping and then being grabbed by a big Russian whose only comment was, “Boy, you get on up there”.

When Roosevelt declared the islands sanctuaries in 1909 it finally evolved that Max and family would have to leave even though he had leases on Lisianski, Laysan, and Johnston Island. He offered to manage these islands, kill the rabbits and so forth, but no luck. By 1915 he was off and the rabbits ran riot, and by 1923 the rail was extinct, the honeycreeper and the millerbird were gone. The moonflower on which the honeycreeper fed was decimated but survived. The island was nearly denuded of vegetation—the rabbits ate everything and then began dying themselves. They were then poisoned out in 1922.

Thus a far-sighted conservation effort became lost in the wilds of bureaucracy and the animals were lost. The organized protection of today has saved what was left and is doing so magnificently.

Islands like these are ecological vacuums. New plants arrive, their seeds stuck in the feathers of the birds, or on the boots or clothing of human visitors. The expanses of clean sand invite them in. The rains water the sand so it is damp an inch down and the interstitial air between the grains is probably saturated. These are hothouse conditions.

And then there is no organized competition. The weed thrives. Like as not it spreads like wildfire and forces old familiar plants into some restricted corner. Thus the puncture vine has spread. The *Portulaca*, the common weed of everyone's garden in the southwest, is unbelievably lush here and everywhere. Eric tells me that the soil is so rich in places that they were able to raise huge sweet potatoes, several pounds in weight.

We walked along the salt flat. Brine shrimp abounded in the inch-deep water. The bottom was red with algae. Brine flies swarmed in tiny clouds over the surface. Up above the margins of the water was a gooney nesting ground, dotted with the big oval white eggs, the infertile ones, and the bodies of birds that died. The grounds are jammed with hundreds of birds in nesting time—really many thousands. The birds like the open area to take off. Heavy vegetation prevents these 8-footers from becoming airborne. The gooneys come in around the first of November and before long their enormous chicks, all covered with down, stand in droves over the surface. There are other nesting grounds for these birds—two species—the blackfooted and the Laysan albatrosses—up on the hills above. Now these grounds are preempted by the raucous sooty terns.

Over by the guano pile Eric looked for an old fresh water pond, now choked with *Ipomea*, the beach morning glory. What looked like devil grass had also grown in this area, forming a very pretty warren—the green grass below and the seed stalks showing velvety brown above. I enjoyed walking in it in my bare feet too. I had planned to walk the beach and hence had brought no shoes, but Eric misled me. So, together we picked trails through the *Tribulus* (puncture vine). Mostly I escaped but occasionally one of the nasty spined pyramidal seeds would nail me. Eric was an expert at spotting them, having run the island barefooted as a youth.

We walked up through the thickets of naupaka and at the very south end of the salt lake scared up two little Laysan teal, and away they flew, rather heavily, I thought, as if not used to flight. Perhaps they had been nesting in the deep bushes, as I understand they do. Their numbers are low—only an estimated 50 birds lived here last year. However, later at camp John and Gene spotted over 120 coming out along the salt pond margins just at dusk. They reacted with visible relief since previous evidence had indicated some unexplained decline. The best count in recent years is a bit over 200 birds. They are compact brown ducks with a very marked whitish patch on the side of the face, and while not flightless, they seem unwilling to make long aerial traverses.

We reached the beach along the booming surf of the south shore. Here the protecting reef is absent and one can look out past the narrow shoal into the deep Pacific. The swells roll in and crash against the headland and beach. Right where we emerged was the wreck of a Japanese long liner. She plowed into Laysan doing 8 knots, in 1970. The beach is strewn with bales of line, of floats and flotsam, of old boxes bearing Japanese labels. The boat stands against the constant pounding of the surf, which squirts up through the scuppers and over the well deck.

I was fagged out by this time and took five on the top of a slab of consolidated coral rock, doing what Eric calls “putting her on the slow bell”. Soon enough we rose and slogged through the sand again. Here the shore is margined by slablike headlands of this same coral rock, making a most un-central Pacific-like scene. Most rock here is volcanic and seldom does one see such angular shapes standing against the sea. To the north, this formation cut into the sea and behind it was an enormous long tide pool. The water poured in at the south and literally ran as a stream northward. It cascaded and

tumbled over rocks in the most approved stream fashion and if you didn't know it was seawater you would swear you were walking in a fresh water creek. Finally, it poured into a big boiling pool in which one could see the surge of the sea. The swells outside the 15-ft. rock wall came in through a crack and at the same time I could see plumes of spray above.

We skirted the shore. I found a dead monk seal high on the strand and took what I could of his skull. I hope to send it to Professor Chapsky of Leningrad, a world seal authority who said his museum had none.

Monk seals were common on this shore—I counted 65 between the wreck and camp. All were sleeping blissfully in the sand. One beach they occupied was made of rounded and polished shell bits. The polish was high enough that the beach gleamed in the afternoon sun. The opercula of snails were common and highly polished as were fragments of many other kinds of shells.

I stopped for a dip in the harbor—blissful swishing back and forth in the cool water, washing away the sweat and grime of the hike. Then I walked naked to camp, letting the air dry me off. Erwin berated me for my lack of modesty and I gave him a blast about his decadent white protestant moral structure. By that time the sun had dried me and I put my clothes on anyway.

At dusk we had a toast to Eric. Gene hauled out a chilled bottle of champagne and we toasted the return of Eric, as the sooty terns had done earlier.

Later, as dusk fell the air began to swarm with returning Bonin petrels and wedge-tailed shearwaters. Intermixed with them were sooty terns, who probably didn't want to miss any of the action. I suspect they are that kind of bird. The air swirled with them over the entire island, planing close to the tops of the vegetation and skimming past our heads. Later I walked away from camp and lay down on the white sand amid the bunchgrass clumps to watch them. Often they skimmed in pairs, commenting raucously to each other as they flew. I heard perhaps 8 different kinds of calls, most, I suspect, from the Bonin petrels. One landed a foot-and-a-half from my face. He came in fluttering and crashlanded, tipping over on his beak with a little bump and then looked foolishly around as if to say—"I hope nobody noticed that lousy technique." Then he extended his neck, making him long and thin and waddled off, his body close to the ground. Others landed near. They were feisty with latecomers, greeting them with long, wheezy growls until one bird fluttered into the air and skimmed away. I doubt that they seek a special place to land, except the petrels which go down burrows, for later I found them sleeping in the open, with their necks bent and heads under wings. The light of day was fading into the last rose flush on the horizon and on the towering cumulus. Bunchgrass fronds waved in the sea breeze, dark silhouettes against the sky. Amidst this skimming birds flew two or three ft. above my recumbent head, hundreds of thousands of them. The bird maelstrom dissipated as evening fell, though many continued to fly all night.

A word about Laysan finches. They are everywhere. John estimates 8-10,000 on the island. These little birds look startlingly like the medium-billed geospizid finches of the Galapagos Islands. They are neither geospizids or finches, but honeycreepers—family Drepanidae. The same group that underwent the adaptive radiation on the main Hawaiian Islands, these little fellows are curious and if one sits still they will hop over and even climb on your legs. They seldom fly but mostly hop in amongst the underbrush

inspecting this and that and picking at tiny bits of food too small for me to see. Their bills are heavy and the upper bends over the lower as a fine sharp point. The adults have a lemon yellow flush over their upper body and head and variegated brown and tan plumage elsewhere. The patter is very reminiscent of the house finch, substituting yellow for rose. One cannot help but be amazed at the specificity of evolution in producing these forms in relation to very specific aspects of the environment. I think this specificity is even more precise than most biologists tend to believe, extending to precise body forms and feather patterns, the minute details of food getting, and likely also of physiology. In other words what have sometimes been called orthogenetic trends in evolution are strong. Given reasonably similar material evolutionary process will mold remarkably similar forms even to features like calling pattern, in similar ecological circumstances. This reflects back and makes one realize the pervading precision of adaptation in which feather patterns and all the rest have meaning within the adaptive norm we call an organism.

To bed. Nice rains shower tonight, near dawn, thrumming on the tent and getting my walking shorts outside saturated. Washed my towel too.

September 7, 1971

Laysan Island

The work for today consists of three tasks—first we have to plant the crosses to Eric's brother and another nameless person, and next we have to circle the island to make a seal count (I'll check the beaches for whale and porpoise bones), and finally we will make some sort of count on the Laysan Teal in the evening. We started out well enough, going northward to the bench above the tide where Eric's brother and the nameless woman were buried. Eric bore a cross, like Jesus, across the flats ahead of me. He had located the graves the day before by memory and by use of some photographs which showed the position of the reefs. He found them quickly enough—the old gravestone of one was still standing in spite of the high tides and storm waves of 1969 washing around it. The second stone was missing. We placed the crosses, Eric put a few net floats and one nice dark green wine bottle reverently in the form of a cross over Adam's grave. "Adam Schlemmer" it said, "1896". The other cross was for a nameless Japanese girl who died in childbirth. I objected that they weren't burying the crosses deeply enough to withstand the tides. But they went on oblivious to this so I provided heavy rocks to stack around the cross shafts. Then I thought, "If the railway and all its ties can nearly disappear in 45 years isn't it obvious that all we provide with such a cross is the commemoration of a life beyond its time, and in a way that increasingly becomes remote with time. Adam Schlemmer, who was he?" Well, in actuality he was nobody, only a tiny mote of life too young to have entered the stream of life as more than a mere blip. Today no one knows, not even Eric, of his smiles, his disposition, the love his mother felt, or the searing sorrow at his passing. Adam Schlemmer, one twentieth of what he was, painted on a cross that may be downed by the next tide. What's different elsewhere?

So, why bury the crosses deeper? The major meaning was achieved at the moment we buried them, the moment Eric, in his partly understanding way, commemorated the flow of life, and its end, by placing his pretty green wine bottle over where he supposed the grave to be.

We walked back, I, up the hill, stirring up the sooty terns who cursed me as I disturbed their children. The children, in their turn, used every wile on me, broken wings tumbling, getting tangled in the bunchgrass, but I plowed obliviously on in my giant way with only the remotest feel for the fabric of their lives.

Then came plan component No. 2—the hike around the island. It would use up much of my supply of vitality for the day. It's six miles, slogging through the slipping soft beach sand, in the glaring sun, and I was glad it wasn't seven. Interesting though, and I'm glad I tried. We started out to the south. John and Gene plowing ahead with their notebooks and the stretcher with which they subdued seals. They tossed it over the apprehensive seal, or often enough, a sleeping one who awoke with a start surrounded with fabric darkness and fright. Their modus was then to expose a flipper, or better, two, from under the canvas while John rode around grasping the throat of the snapping jaws. Gene pulled a flipper from under the canvas and snapped a stainless tag in place. It bore a number keyed to date and place of tagging. The snorting indignant seal then shuffled off for the water, rolling his eyes and humping over the coral ledges. It was even more arduous when a yearling was found with a tag in place. Then he had to be corralled and the tag read but in the intervening year he had gained greatly in size and strength. Thus these encounters were often fencing bouts with the seal being forced into partial quiescence while one of us snuck around the rear and tried to read the tag. Often enough any touch of the flippers elicited a throaty roar and a rearing of the animal with mouth open and teeth ready. No one was bitten, however, and 245 seals were counted and inspected.

I watched them phonate on shore. The roar was overt with the mouth open, but often enough a "glunk glunk" sound was made with a swallowing movement with nostrils closed and the larynx being pulled backward in evident muscular movement concurrent with the sound production. I guess that they produce this same sound underwater and that no air is lost.

We walked south along the route followed the night before. Past the river of salt water, and past the Japanese long liner, and then to a magnificent shoreline where a reef of tabular rocks juts into the sea, a lagoon behind full of crystal water. Each wave crashes over the rocks, swirling over them and pouring in cascades into the lagoon behind. Some of the rocks have been etched into grotesque shapes that stand in the lagoon—fluted fingers of stone standing from the crystal water. I noted rudder fish and sergeant major's cruising along, as well as maninis. The two seal taggers were far ahead by this time. I was bothered by a *Tribulus* spine that had pierced my rubber wading shoe and poked my foot with any heavy step.

Later we rounded the southeastern tip and came upon the great sandy beach that forms most of the eastern shore. It must be the home of thousands of gooneys in season. Their eggs are scattered about as are innumerable glass floats and other flotsam. I looked in vain for cetacean bones. It came to me that this island is one of bird shadows. You walk along alone and then shadows of terns and frigate birds streak silently over the sand around you. You know that not far above you the birds circle and swoop. Very often one tends to have a retinue of such curious onlookers, often screaming their heads off.

The beach broadened into a great sheet of undulating sand perhaps 300 yards wide in places. It must be shoulder-to-shoulder with gooneys in season. Even now, when the birds are gone one can see the depressions made by the birds lying next to one

another like the cells of a honeycomb—each 2½-3 ft. across. I zigzagged back and forth across this flat looking for marine mammal bones and nary a one did I find though it looked ideal for them. The waters around these islands must have very few, though I know some of the oceanic species must visit. I came upon a group of fairy terns resting on a big coquina boulder and true to form they fluttered up from their rock and hovered over me, sometimes within 6 in. or so, always making their twanging rubber band noises. They are like peanuts or popcorn or potato chips . . . they're addictive and one can never take just one. If you have a camera the sight of these immaculate birds fluttering so near will induce you to shoot pictures again and again.

The sun beat down hard by this time and but for the sea breeze the hike would have been quite uncomfortable. We were all tired from slogging in the sand—its two steps for one on solid ground, I figure, in terms of effort expended. Gene and John were sweat covered from their continual bouts with the seals, which lay scattered completely around the island—there is no rookery. The only choice seems to relate to the nearness of a sandy slope up which they can climb at night, often into the *Scaevola* bushes. The very broad beach was not so attractive.

We slogged on—around the northern shore where when I stopped for a rest a beautiful green and blue parrot fish came in the shallow water almost to my feet.

Back at camp I dropped my pack and a monk seal skull I'd found and headed for the cove and a cooling dip. Pure delight.

In the evening just before darkness came, Gene, John, and I started out for the central lagoon to count Laysan teal. Erwin has been having leg cramps and so stayed behind and Eric was doing some fishing with a feather jig. The three of us, with flashlights and notebooks, slogged down through the shearwater and tern nesting ground to the lagoon. The ducks come out of the heavy vegetation at dusk and feed on the lagoon borders. We encountered a pair right at the water's edge. They are chunky little birds with orange-red legs, a brown body, a dull-green wing speculum, and a variably expressed white patch on the cheek surrounding the eye. One of the birds was feeding on brine flies, which must be one of their staple diets. The duck walked along, its neck outstretched, its bill chattering, as it engulfed the clouds of flies hovering just above the salt-laden algae.

Gene left me and I hiked southward along the edge of the salt flat in the gathering dusk. Darkness comes quickly here. I hadn't walked more than 1/3 the length of the lagoon before it was dark enough that I could only see ducks by their silhouettes. All I saw were at the water's edge and most swam nervously away from me, especially later when I shone a flashlight on them, or rose from the water a few flew a dozen yards. One got the impression that they would not expend enough effort to fly to the other side of the salt lagoon. The numbers increased as I approached the south end. There the morning glory, *Ipomea*, is densely tangled over a variety of kinds of bushes, and in them the teal spend their days, emerging at night to walk along the edge of the salt flat.

My count ran into the 40s, and was larger when I returned in the dark, making the count wholly by starlight, the moon not yet being above the horizon.

At one point my hat flew off in the wind and began rolling away from me. I thought it would flop flat and I could walk leisurely over to it. But no. It rolled on and on, like the gingerbread man. Since it was precious to me in this sunny, I took chase and was soon running about as fast as I could go with the hat bounding along in front of me.

I gained though. Finally, about out of breath, I came up with it rolling across the white flat. Should I dive on it? Or should I try to stamp on it, or simply follow it until it stopped. It showed no signs of doing the latter so I tried to stamp on it. I hit it, and my foot slid across the white surface, which proved as slick as grease. It was not salt but bleached algae and just beneath the skid mark left by my foot it was bright orange. I landed with a grotesque “whump” on the surface, and all out of breath I saw my hat had stopped. Catching breath I reached out and grabbed it, and returned to meet Gene and John, who had been hunting on the opposite side of the lagoon.

Back at camp we toted up the total sightings and they showed 149 birds—a very heartening increase over the last count, a year ago, which showed about 50 birds. To be sure, we saw no young, and our count simply indicates that the previous count was in error.

A little camp story telling, a nightcap and to bed.

September 8, 1971

Laysan Island

Finch day. John Sincock is the Sport Fisheries and Wildlife man on Hawaiian endangered birds and so he laid out a set of transects, each 100 yards long and about 16 ft. wide, that are dotted over the entire island, covering all kinds of habitat. I drew transects 30-60, which were located to the south of camp on the west side of the lagoon. With a counter in hand I located the transect area, using an aerial photo supplied by John. On it were spotted the transects. Then one trudged through the sandy slopes and grass and birds till he found about where to begin. It took me 66 paces to cover the 100 yards and so I walked slowly along, clicking any finches I saw as I counted paces. Taking such a traverse makes you peculiarly susceptible to crashing into hidden burrows. When you are normally walking you exercise a remarkable amount of judgment about where to step and where not to. The transect regulates stride and to some extent course. Hence I found myself plunging into these burrows time after time. I laced my boots clear to the top which helped keep most of the sand out, but after the 50th crash nothing much would save my disposition. The finches love the *Portulaca*, and they cluster around the beaches and especially in the naupaka where the frigate bird nests are located. They are tame little guys that will hop right up to you if you sit still.

My course took me past the old railroad so I picked up a tie and a piece of track to make Eric an assemblage of Laysan.

At camp, a little lunch, a little water and a short snooze, and then out to the lagoon to photograph. The algae is very pretty as are the bubbles forming a white froth at the edge of the water. I was able to get photos of teal from quite close. They much prefer to walk but will fly in quite acceptable duck-like fashion if pressed. They love the *Pluchea* thickets on the far side of the lagoon, and there I was able to get quite close (25 ft. or so) and to get a good series of pictures.

The walk back took me by the little palm grove at the north end of the island. There are 9 big trees and as I recall, 4 small ones. They look in remarkably good shape though one can see the streaking of droppings on the fronds from the perching or flying birds. This sort of treatment has kept the ironwood from growing very well.

It's dusk as I write, sitting on an emergency radio kit, with my typewriter on a Kirin beer box, and the air has become literally swarming with returning shearwaters and

petrels. To the south, where we can see the farthest, the sky looks peppered with swirling birds—thousands upon thousands of terns. I asked Eric if it was like this when he was a boy “Oh yea, they always came at night.”

September 9, 1971

I took it on the slow bell today, as Eric says, not doing much of very violent exercise. I swatted the ubiquitous flies after breakfast (they get up exactly at dawn) and took a snooze. Our work is essentially done and we can do what we please. My pleasure was a snooze sans flies. Later we tried for recordings of the monk seals. I readied my gear and was floated out into the lagoon in the rubber boat. Gene and John walked along shore towing me and chasing seals into the water. I heard nothing but snapping shrimp until one yearling became curious about the boat and circled under it, actually going up to and inspecting the hydrophone. He was uttering a series of quiet little grunting sounds as he came. They were loud enough to hear over the snapping shrimp but the recording is not a very good one. After that was completed I took a swim with face plate and fins. The water is clear and over the white coral sand many of the fish are just ghosts of white as they streak along—especially the little goat fish.

I hiked to the north end and took some wide-angle shots showing the lagoon and the nine palms. I was challenged by a male frigate bird who was trying to steal a tern child (to gulp down unceremoniously if he could catch the parents away, which he did not). He even swooped on me, coming within inches of my unprotected pate. As he swooped by I could see his folding red throat pouch that told me he was a male.

Gene and Eric had gone down directly east of camp toward the lagoon to look for an old bottle pile (Gene is a bottle collector) and to dig for water. The first hole halfway between our ridge crest camp and the lagoon was 5 ft. deep before they quit. The next, perhaps 5-6 ft. elevation-wise above the salt flat and located just above the reach of the *Ipomea* thicket, struck water at about 4½ ft. Since it seeped in from uphill they assumed it was fresh. We will check tomorrow morning. I assume it is good water as all these islands have a freshwater lens made of rainwater that floats on the underlying salt water. It is usually a very adequate supply. Witness the fact that Midway uses this source for its waste water system for 2,000 people. Midway and Laysan are not much different in area.

I gathered up my tape recorder and the microphone to try for the airborne calls of the monk seal. I walked away from camp toward the graves to the north, and somewhat beyond them came upon an old adult seal sleeping in the grass clumps. I found the seal because it was sneezing periodically.

I crept up on my belly and stuck the mic through the grass at the seal's nose. It obligingly sneezed, and then woke up. He sat up with a wheezy roar, also recorded, and then began to emit the peculiar “glunk glunk” sounds. Later as I recorded a series of seals south of camp I was able to watch the mechanisms of sound production a little closer. They are best seen on the young and yearlings where the blubber coat does not obscure the internal movements quite so much as it does on adults. The sneezes are used in aggression, or defiance is perhaps a better word. The nostrils are suddenly blown open with a violent snort. The roars are made with mouth wide open and air being forced up past the tongue which is arched up against the posterior roof of the mouth—I don't think the vocal chords are involved—only the force of air past the palate and rear tongue. The animals often lunged at me during this exercise, especially the older adults, who

sometimes pursued me for a short distance. It was with minor joy that I noted their teeth to be ground flat. Likely they can gum one with a vengeance, however.

The glunk glunk sounds, which very likely are also produced underwater, are done without release of air and are produced concurrently with movements of the larynx—a drawing posteriorly of the apparatus and some lateral swelling, not marked, were noted. The nostrils are tightly shut, and the mouth may or may not be open during the production. I could not be sure whether or not the pharyngeal pouches of the larynx were or were not involved, but this may have been the swelling I noticed.

After dinner (spam, beans (from an old can left by the air force, but perfectly good after some years in the sand), vegetables, Bristol sherry, and cookies), we talked of this and that (retreating a couple of times for rainstorms that swept over us in minutes), watched the evening arrival of the sea birds, and then went to sleep, the trade wind working the tent. About 3 AM I awoke to a loud chorus of crooning wedge-tailed shearwaters just outside the tent. I readied the recorder and crept out, microphone in hand, to within a few feet of the calling birds. These birds are built for the air. In the bright moonlight I could see them creep along on their grotesquely short legs, their long bodies rocking like a pitching ship as they waddled along. They came at each other, head to head, began a crooning match and then began preening each other's heads. The call is difficult to describe in words—a rising clear whoooooo that sometimes warbled toward its upper notes—about as high as the middle register of a soprano—and then switched to a resonant inhaled groan. I was able to mimic it quite well and to interest nearby birds enough that they came waddling over toward me, coming within a foot or so before they became confused with my lack of preening activity, even though I had announced I was ready for it. My calls often induced the whole neighborhood. In fact, they did quite as well as my playback of their own calls.

A word about lizards and crabs. There is a little skink on the island, unlike any I have seen on the main Hawaiian Islands. It has a spectacle over its eyes like that of a snake, two paravertebral dark stripes and a general tan coloration. There is a greenish yellow metallic cast to the belly. They are little fellows—to about 4 inches long—and one often sees them skittering amongst the underbrush. We captured some by pulling up grass clumps down by the ironwood tree. I saw them sunning, lying out on open sand, but always near a retreat. I'm sure they must be succulent fare for the many birds always around them.

The crab is a little mottled white guy, like a ghost crab, and it makes vertical circular burrows over much of the island. We found them common amongst the grass roots. I wonder what they do about salt? How do they moisten their gills?

September 10, 1971

Laysan Island, Northwestern Hawaiian Islands

The boat might come in today, though we expect them tomorrow. After breakfast we hiked down to the well to test the water. It is sweet and pure as any from our jerry cans. Furthermore, when we scooped it out it ran back in so rapidly one could see little boils in the coral sand. It came from a stratum of hardened coral like rock at the bottom of the pit. It's my guess that if we dug down 3-4 ft. more we could have an abundant supply of excellent water. Eric makes the suggestion, and I think it is a good one, that once the well is deepened, a plastic pipe, perforated at the bottom, should be put in that

the hole filled with rocks and pebbles, and then a small hand pump installed above ground level. Likely a continuous source of excellent water could thus be had. In any event we have no problem with survival here. There's abundant water and the island can provide all the food one needs, from greens of a New Zealand spinach-like plant, to lobsters from the reef, to fish, to grapsid crabs, to seals, to mutton birds (the young shearwaters), and who knows, a broiled frigate bird might be tasty. For those addicted there is true tobacco on the island, brought in by the early settlers. And for booze Eric reports that one can ferment coconuts and that his father made beer (most ingredients no longer available).

Later in the afternoon Gene, Eric, and I went south and picked up some railroad ties and traced the little mule-drawn line back toward the harbor. We could follow it by the scales of corroded metal in the sand and once in a while a tie or a hunk of track would protrude. In 1969 there was a storm and one can see the old strand line, marked in flotsam, at about the level of the back wall of Eric's old cookshack. This would effectively have taken out that building and the guano house where the railroad ended, if it hadn't been washed out earlier. At any rate it is gone now.

The rain caught us and I had to shelter my camera under my shirt while Gene took shelter in back of a clump of bunchgrass. Either way we got pretty well soaked but the cameras didn't suffer. These storms blow across the island in the trades and one can see them coming—a gray veil sweeping across the far sand hills, the lagoon and up the slopes. Most are just clouds and they pass in a few minutes, but some dump quite a lot of water in the few minutes, but some dump quite a lot of water in the process—enough to soak clothes and anything else outside. Gene got a nice bath from the water of one that collected on top of the tent. Eric reports his father had them get on the roof with brooms when such squalls would come. First they would scrub the bird droppings off in the first moments of the rain and then they would switch the spouts into barrels to catch the good distilled water. He said they got a lot of their water that way, and the rest from the wells.

I was surprised to learn of the size of the guano operation—they had 15-20 Japanese working at a time. I asked Eric how he did school work and he said his sister taught him on a sort of intermittent basis. He later took a series of correspondence courses in electricity, wire slicing etc., and finally worked his way up in Hawaiian Electric, in spite of a lack of formal training. I'll bet he was good both as a worker and as a supervisor.

We had a swim at the cove, an almost sinfully sybaritic affair. The clear water laps on the clean coral strand and one can drift back and forth in water of exactly the right temperature—I'd guess it at about 71-73 deg. F—a little cooler than Honolulu. We dried in the sun and headed back up the hill. Some gear is getting packed now and we try to take some down to the beach with each trip.

Boned chicken and boneless ravioli were on the menu tonight. Followed by the last of the Bristol sherry or vodka and orange juice as the case may be. Eric and I washed dishes and watched an oil slick spread from the remains of the chicken. That little bit of chicken fat put a slick over about 2/3 of the bay and finally swept clear out the entrance. Amazing, and it makes you realize that such slicks probably exist over every bit of shore water in populated areas. A well-oiled (suntan) young lady slipping into this bay would have donated as many molecules of fat as our chicken.

After supper Eric and Gene engaged in a donnybrook of a cribbage game in which Gene wagered Johnston Island against anything Eric could name—Africa, South America, and emerged with them all. Poor Eric. He entertained us anyhow with ancient songs and ethnic jokes. Eric makes ethnic jokes out of any run-of-the-mill joke. They teem with rabbis, priests, and ministers, etc.

To the sack. Later I got up in the moonlight to look at the seals. They sleep all day. We find them in the morning up on the vegetation above the tide and by afternoon they have moved down near the water. By the time I got there they were back up in the vegetation. Sleeping. I have seen no social behavior and very little social interaction. The only thing in this realm is occasional disturbance of one animal by another. There seems no grooming, no signal systems, only three kinds of calls, and I suspect they feed in the early evening and that it is a pretty simple process as they are back asleep before many hours. A remarkably uninteresting mammal, behaviorwise.

September 11, 1971

At sea, enroute to French Frigate Shoals or French Frig as the seamen call it.

The *Buttonwood* was here at dawn, anchored out beyond the reef. The morning was spent breaking camp—cleaning up, smashing cans, toting gear, folding tents, etc. We left it nice and clean. The crew came ashore and raced across the island for glass balls. Some came back with enormous bags bulging with them. I wonder how long it will take to replenish the supply. Plastic ones make an increasing fraction of the total now, and may ultimately replace glass altogether—mores the pity, the glass is more attractive. By the way, my desultory attempts to find a ball with a natural magnifying glass on it failed, though I still think the idea has merit. A swim in the cove, loading on the ship, and a nice lunch (the biggest meal we have had since going ashore) and up anchor at 1630 for French Frigate Shoals, with a stop at Gardiner Pinnacle on the way.

Just at the edge of the bank on whose top Laysan lies we encountered 2-5 *Tursiops*. This point is 5 miles east of Laysan and the water is 100 fathoms, dropping steeply into the depths. The animals cut over close to us, but, I believe, never ran the bow. I raced for my camera and clambered up onto the bow. I had on the finder and everything set but the camera wouldn't fire—it was on "lock". By the time I fixed that they were gone. But I did get a sure sight identification.

More watching until dusk was fruitless. The number of birds dropped markedly as we left Laysan though we continued to see some Bonin petrels until dark. They must operate on a two days or more at sea schedule, with a visit to an island in between. I couldn't see how the flight track of the birds, at least these petrels, could be used to locate an island. Boobies might serve better since I believe they come in every day.

Ensign Al Sarra took notes and photographs of porpoises seen when the *Buttonwood* left us and headed for French Frigate. They had four sightings as follows [details of sightings].

Our trip to Gardiner continued uneventfully and we finally raised the tip of the largest pinnacle about 1240. By about 2:30 PM we were within a 1,000 yards or so and readying the rubber boat for the trip ashore. I asked Gene if I could go and he assented. The sea is quite calm with only a rolling 2-3 ft. swell and little wind. The task here is to look at the birds and to gather some hard rock samples for age analysis. I'm along to collect invertebrates and to see if perchance a lizard might have made it to this remote

spot. It is a saddle-shaped pinnacle of rock with a smaller pinnacle to the north. It is guano-covered and shines white from a long distance. I'd guess its length at about 300 yards and its width at 150. It stands nearly 190 ft. high. There is no real landing place. We went in with the rubber boat, nosing it against the sheer wall and waiting until a swell lifted the boat enough for a man to hop ashore. Gene was at the bow and lost his footing. He turned and did a neat little dive, swimming out to the boat where we hauled him unceremoniously aboard. He tried again and this time clambered up above the tide and the slippery rocks. I tossed him the bow painter and climbed out myself, sliding enough that I spreadeagled myself on the rocks and finally made it up. John landed with more aplomb. Gene, bless his soul, commemorated the landing by hauling a cool bottle of Lancer's Rose, with which we toasted our success. Thus fortified we clambered up the rocks toward the top. The Air Force had blasted the top flat for a helicopter pad and had put up a theodolite base. Com wire was strung over the rocks.

Birds were everywhere, including one new to me—the blue gray noddy tern, a pearl gray version of the fairy tern. Why it is called a noddy escapes me because it looks for all the world like a fairy tern and acts the same. I saw a brown booby on a nest that had pale yellow-green feet. Most have nondescript browning feet.

As for insects the rocks sitting in little pockets of soil revealed beneath them wolf-like spiders including some quite large ones, very large silverfish (to $\frac{3}{4}$ in. or so), earwigs, a millipede, and pill bugs. There were no flies that I noticed and the only plant was a very occasional patch of very beaten *Portulaca*. Most of the rocks, especially toward the top of the island, were smooth with guano. Some of the rocks had their upper surfaces almost glossy smooth with it, and if you could look under an overhang you could see that it flowed down over the rock-like pancake batter, and even hung down in little stalagmites. The bottom of the rock was uncovered.

I photographed the birds and my hiking associates and unfortunately missed Gene's fine dive and a subsequent one when he tried to enter the rubber boat.

As for rocks, the basic rock is a basalt, with olivine inclusions common toward the south end of the island. On north rock, two 2-ft.-wide dykes run nearly vertically, and on the upper part of the larger island what I take to be xenoliths are common—large boulders entirely surrounded by other rock. At the south tip there is a reddish rock of almost sandstone-like texture, which I expect is a weathered basalt. Some of the upper rock of the main peak looks almost like a rhyolite to me. I took samples and pickled a lot of insects and allies.

Gene landed briefly on the north rock and then we made it back to the ship for dinner and a shower. Several crew members had caught ulua—big guys in the 40-lb. class. One reported having a milling mass of perhaps 50 uluas around, and outside them a frenzy of sharks, one of whom clipped the man's line. Wow, it's never like this on the main islands.

After dinner Eric showed me his pictures and the log of the *Helena* and other interesting papers.

I've been having muscular aches of the chest and shoulders and can't seem to shake them. Sometimes this seems connected with histamine production—a sort of bursitis—and a cold tablet helps. I've taken some and we'll see. Oh yes—we saw three seals at Gardiner—two on the rock and one on the main pinnacle.

September 12, 1971

French Frigate Shoals

When we awoke this morning French Frigate Shoals was in sight. A row of white-walled tin-roofed buildings on a low, flat island. The edges of the island were sheet piling where dredging had extended the land area from a small sandy mote of land into an air field. The buildings are all tucked off to one side of the field and there is very little area other than the field. Fortunately the planes only come in once a week so the station crew can run on the field, can zoom their little two-wheeled cycles around, and can run the lonely weapons carrier around. The last one they drove over the edge of the piling into 30 ft. of water. One seaman, watching, saw it all, but failed to report it until the day after, saying "It didn't seem like any of my business." The CO, a young JG named Monsma seemed like a bright guy. He has about 6 months left on the island (they stay for a year). And he seemed to like it OK, though he had been told of the horrors of French Frigate. Some of the loran stations in Greenland, for instance, where they have to "cut their water with a saw" would be a lot harder to take.

Our ship's boat was having troubles. Its engine filled with smoke when we came over—the exhaust pipe had disconnected and later when they tried to take off to the ship it began to fill with water. We found them sinking just offshore and being saved by the truck and its winch. We borrowed the station outboard which was only a little better. Later we had trouble starting it—the starter cable wouldn't engage and other problems. But we finally got back. Gene, Eric, Erwin and I checked the islets around the lagoon. First we visited Eastern Island, where the old station had been. It was an unbelievable mess of old boards covered with guano, old machinery and so forth. The birds, of course, didn't mind; in fact they used whatever was available to them. There were a few seals, boobies, terns, and the like on a very low island mostly covered with much-battered *Tribulus*. The chief distinction of the island was its turtles. The land was pock-marked with the burrows of turtles, like shell holes from a war, over much of its area. Gene found one new one, where he thought the young may have emerged recently. I found a couple of dead young.

We left Eastern Island and cruised over the very extensive reef flat. It is rather shallow—in most places it's probably not much over 30 ft. deep, very clear water so that features of the bottom are clearly seen. The shallows are marked with brown or sienna, where heads come awash. Over coral sand the sea is light turquoise, in deeper water it shades to rich blue. The sandy islets and breakers mark the surface with brightest white.

On Whale and Skate Island we pulled into a shallow reach, secured the boat to a stump buried in the sand, and walked the beach. On the offshore side I watched a school of blue ulua cruise the beach, indian fashion. Each fish was of moderate size—probably 5-8 lbs. When they encountered a school of bait fish at the water's edge the fish left a hole of vacant water for the predators to occupy. This hole moved along with the fish.

We were to make a radio call at 12, and the difficulty of getting the motor started caused us to bypass Trig Island with only a cruise around its west end. On all the islands, seals occupied the shore. They are remarkable sleepers. I noticed one of Whale and Skate that was sound asleep with his head below the lapping surf. I guess he must have raised up periodically for a breath but I never saw him do it.

At the station we had sandwiches in the little restaurant (make 'em yourself) and a couple of beers. Then Eric and I went back to the *Buttonwood* where a beer bust was in

progress. The failure of both ships' boats required that it be on the ship. I had forgotten how the entire hierarchy of a crew is established by physical force, and maintained the same way. A couple of crew members became obstreperous and mostly were put in their place by the Boatswain's Mate, by simple threat of violence, in which he believes implicitly. It's not far to organized violence, or combat, for these people, and in fact it is familiar to them and completely sensible.

The ship lies at anchor just outside the channel and will take off tonight for Necker Island.

As we came in to anchor this morning we passed a school of spinner porpoises just outside the French Frigate Shoals reef. There were approximately 30 animals traveling slowly with some aerial behavior. A couple of young animals, in particular, were leaping and spinning. The time was 8:30 AM, and the animals were just off Shark Island. [Maps]

September 13, 1971

Necker Island, Northwestern Hawaiian Islands

During the night it got calmer and calmer until I scarcely knew the ship was moving. The Captain later told me that it had been so calm that he could see star reflections on the sea. The moon lit up the water later and cloud reflections could be seen. Nice for landing on Necker, but it made for a hot hike.

The ship was within sight of Necker when I first went on deck. She is a rugged hogback of an island, roughly in the shape of an L, with Shark Bay tucked inside the L. We landed on the backside of the L, and climbed a very steep defile up the face of the lava cliff, and then wound our way to the first crest (there were, I think, 5 in all, with varying depth saddles between). But to go back a bit.

The motor whaleboats turned out all to be on the fritz so we finally had to load everything in the rubber boat, which worked. The coxswain, 2nd Class Boatswain's mate Smotherman took us in. The swells rose against the steep rock wall of the island at the point we would land, and if one timed it right, you stepped out at the top of the rise onto a level lava shelf. Several things were between each of us and this ideal—slippery algae, uncertain movements of the rubber boat, unexpectedly high waves that flooded the shelf, etc. I followed Gene and John and grabbed handhold and squirmed my way up to dry terrain. Soon everyone had made it safely. We stashed such gear as we wouldn't take—extra water, food, some cans of juice, a radio. Then we gathered our own gear together—in my case chiefly my camera and lenses. Our purpose was to make counts on various of the nesting birds—the boobies, the frigates in particular. I took the blue-faced boobies, and using a little counter made a tally of all the adults and young I could see. There were 185 all told on the island, including about 40 young. The red-footed boobies were about three times as abundant. A count such as this imposes a discipline on your observation and soon I could easily see very striking habitat differences between the two. The red-footed boobies usually nested up on bushes, making little platform nests, while the blue-faced variety used the ground. Red-footed boobies selected a wide variety of terrain including some on rather steep slopes, while the blue-faced birds typically inhabited flats or gentle broad slopes.

The frigates nested in bunches and it was the running of a phalanx of squawking, pecking birds to go through one. They lunged out at one but other than turning on the

nest they did not change position. It became easy to make a judgment of the length a frigate could extend its neck and to get just beyond this. Vocalization seems tied to age. The youngest birds didn't squawk at all, or with less vigor than the slightly older birds.

Our first climb took us up the aforementioned slanting defile in the lava face and we emerged on the crest of one of the peaks, and there found our first marae. It was a roughly rectangular platform, about 30 ft. on a side, with a backwall of stones, with intermittent long ones propped up on end like tombstones. The story is that these are religious shrines of some sort but one wonders if the Hawaiians might not have come to do something mundane like gather eggs, and have camped at these places. Somehow the stones might have been part of a shelter or storage place for eggs. I suppose doubting the conclusions of Emory is some kind of heresy but I get a bit skeptical when anthropologists invoke religious ritual to explain so much. They might be right, however.

From this 200-ft.-high promontory we began to hike the length of the island and this quickly took us down a very steep slope to about 50 ft. above sea level and then up again to our old height. The dips from there on were about half this depth and easier to put up with.

Necker is nearly waterless, though we did see some seeps here and there along the cliff faces, especially down near the water. There is no real watershed so there can't be much.

Five types of plants grow on the island. *Portulaca*, and a legume with compound pinnate leaves that forms low bushes in many places and is widely used by the frigates, *Sesbania*. *Sesuvium portulacastrum* is a plant that looks much like a healthy pickleweed. It is moderately common. Another bush is *Chenopodium* and it is very common. The fifth plant is *Lepturus*, a grass.

The birds at this season are the boobies mentioned before, the gray-backed tern, of which many young were seen, the noddy and sooty terns, wedge-tailed shearwaters, Bulwer's petrels (most come later), and the fairy terns, and the beautiful Necker tern or gray noddy. These little birds have all the mannerisms of the fairy tern, except I did not see them hover in front of your face as the fairy does. They are about the same size and a glossy pearl gray with black eyes and feet. We watched and photographed them for quite a time—the little birds repeatedly landing a few feet from Gene, on a rocky ledge that they seemed to regard as their nest.

Then they fluttered quickly away to glide and swoop over the abyss below like so many toy gliders. What a feeling it must be to have no fear of heights, but to launch fearlessly over a precipice like this.

At the end of the island we came to a lava bubble perched on the very crest of the hill, one side broken out and the floor covered with pebbles. It was a shady spot and most welcome. Gene decided it needed a Guru selling Toyota Coronas. I was happy for it without a guru just for its shade. Gene and Al Sarra went downslope to look at some caves while the rest of us headed back for the landing. It was hot by this time and I was glad when I had inched my way down the steep defile and could engulf a can full of water. Erwin and I enjoyed sitting and watching the birds, the turtles that came up close and other sights while the others went exploring nearby. I lay back on the life jackets and even snoozed briefly. Later, as I learned, part of this was done on Gene's hat. It needs blocking.

On board we upped anchor at 1600 and when we were 10.2 miles ESE of the island, just over the 100 fathom curve, we encountered a school of about 30 spinners. They were shy of the boat, but several spun for us and a couple did head over tail leaps. With them was a monk seal.

The water was absolutely flat calm and I kept watch as long as there was light. We had a glorious sunset with the thunderheads all around lit up by the fading sun in various shades of apricot and rose. Their reflections streaked the sea on all sides of us. I remember such days when I was in the Navy and we travelled close to the equator, but never have I seen it so far north.

Notes, a movie, and to bed.

September 14, 1971

Nihoa Island, Northwestern Hawaiian Islands

Nihoa was in sight when I first reached deck this morning. The weather continues to be flat as a lake and the jutting mass of the island stood gray above the silver water. One of our engines is feeling a bit poorly and so we are now traveling on a single main engine which slows us to about 8 knots. Because of this it wasn't until about 10:30 that we came to anchor in Adams Bay on the south shore of the island. Before dropping the pick we circled the island. It has an almost sheer cliff (in places it actually overhangs) on the north and west, dropping about 900 ft. straight into the deep blue sea. Sea caves line the cliffs in many places. Two of them actually pierce the rock. One, on the east end, goes clear through and you can see daylight through it. The other, down the north shore a ways, is U-shaped. Late in the day, Gene and the skipper and Eric took a rubber raft through it. I'd hate to try it if any kind of sea was running.

As we came in, about a mile off the west end, a lone *Tursiops* made an appearance off our beam, dove and wasn't seen again.

My muscular aches and pains continue so I planned not to follow the others up 910 ft. Miller Peak, but to be a bit more moderate and hike to a grove of *Prichardia* palms. These are endemic fan palms, living only on this little island. The island is slightly less than a mile long, has two major saddles, clothed in green brush, and a series of promontories, of which Miller Peak is the highest. The others are close to it. The palms stand out as darker green groves in the ravines. They mark major areas of seepage. The one I visited choked a water course and must have received rainwater each time it fell, in addition to the ground water I found there.

Our landing, in spite of the calm sea, was a wet one. The rubber raft nosed against a cliff at the edge of a wave-cut terrace and the bowline was held a little tight by the man on shore, causing us to bend grotesquely as the wave dropped. Actually it dropped enough that the man on shore couldn't see what was happening to us. The water cascading off the shelf poured into our jack-knifed boat and I was most grateful I had finally decided to put my camera gear in the rubberized waterproof pack I have for the purpose. It came through nice and dry.

Everything and everybody was offloaded without mishap and we began to assemble for the activities each person wanted. I first spent some time in the fine tidal pools on the shelf.

The wave cut terrace, averaging about 40 ft. wide, was covered with tidal pools, most shallow, but there were some deeper potholes. The opii limpet was very common,

and very large, attesting to the fact that no one walks on these rocks from the main islands. They are such a prize now—something like 18 dollars a quart—that it will soon begin to pay poachers to visit the island to collect. A light-tan branching alga was very common, and the vegetarian high-tidal blenies were also very common. These are the very elongate fellows that one sometimes sees leaping from pool to pool in flight. The flat-spined purple urchin was very common as was a paler-spined species. I was interested in the colors and forms in the pools and spent quite a long time photographing there. The new camera is such a joy in spite of being heavy and in spite of the fact that I had trouble with its mirror later in the day (Nikon F with motor drive). The motor drive frees your hands to photograph—one can concentrate much more thoroughly on his subject that way.

I had to make a trip back to the boat to get a battery for the light meter and by that time the others had set out to climb Miller Peak, which I didn't want to do anyway.

So, I went the other way, toward the nearby canyon where the *Prichardia* palm grove was located. It was a steep rocky defile. One first has to scale a rather steep waterfall area where during rains a stream must cascade into the sea. Then, shortly one comes upon little fan palms, that look for all the world like junior-sized *Washingtonia* palms. Sea birds were everywhere—boobies, gray-backed terns and their chicks, noddy terns and chicks, man-o-war birds, and many Nihoa finches. These are bright lemon-yellow fellows that look very much like the Laysan finch. They are quite tame and flocked around me, landing on rocks a few feet away, fluttering in to seeps from the rocks for a drink, and especially, hopping from branch to banch in the palm groves. There were pools of greenish water in the rocky floor of the defile and from one of these I raised a female pintail duck. Later we found the body of a fairly long dead pintail drake in the same pool. There would seem to be very little for these birds to feed on here, but come they do in a long migration from the mainland.

Just above the main grove of palms, I came upon old stone walls—dikes of rock set adjacent to the stream course, and I imagine used as terraced fields by ancient aborigines. Up on the slopes above were a good many caves, some of whose mouths were partly blocked by carefully placed stones, and these I assume were dwelling places. At the back of some of the supposed fields were the upright stones that Emory says are indications of a shrine, which he calls marae. I don't know. One of the crew found what looked like a stone bowl which we left.

I tasted some of the water and concluded it could be drunk but that it would be better to control the bird population a bit more.

Especially I looked for the miller bird—the endemic little warbler-like, or wren-like bird that lies only here. John Sincock calculates that there are somewhat over 400 of them here.

At the upper grove I found them—sleek little grayish tan birds with a slender black bill. They love the dense bushes and seldom leave their habitat. They will come near to a waiting person but will usually do no more than stick out their heads to peer at you. To get the whole bird in a picture required a lot of patience. John says it can best be accomplished at the seeps where they will fly in and cling to the moss.

Gene, Dave Smith (the skipper), Al Sarra, and John Sincock came over the hill and together we clambered back to the beach and finally made it out to the *Buttonwood*. We were the last people on the island.

On board the Chief had caught an enormous ulua—about 70 lbs. It was heavy enough that it was difficult to lift for a picture.

At dusk the anchor was brought up and we are on our way home. It will take 36 hrs. from here, since the ship is using only one engine. Donuts after dinner and a good movie—*Zig Zag*—a thriller. Movies every night on this ship, and two if they get in the mood.

It's been an adventurous trip for me, seeing new places, and wild ones. It has been a pleasant surprise to find how well most of these important little islands have prospered under protection. The seal population is much increased over its low point some years ago, the birds seem stable, and the habitats, the most important of all, are being protected with considerable zeal by Gene and his men. In fact, I am mightily impressed with the job they do. They know their islands, the fauna, the flora, the history. They extend themselves considerably beyond the role of biologist in carrying out their job. Gene spends quite a lot of time seeing that good relations are maintained with the Navy and with people like our most affable hosts, the Coast Guard. All in all, very fine.

Not only these things but the islands themselves are national treasures and they must be given every attention. Their proposed status as wilderness areas is not only appropriate, but it would be a mockery of the wilderness system to exclude them. They are not clothed with pines and they don't have glaciers or mountain lakes, like most wilderness, but they are unique in the U.S., and they are wilder and more natural than many areas presently in the system.

September 15, 1971

Enroute to Honolulu

Imagine that—we saw our first ship since leaving Midway—a fishing vessel very far away under the Napali cliffs of Kauai.

The weather continues flat calm. Even the swell has dropped until it is essentially nil. In the lee of Kauai it was glassy enough to see the V-wake of a mahimahi's fin.

We traveled all night on one engine, and continue under this power today. We make nearly as much speed with the single engine as with two. The second engine is provided mainly for pulling power, I am told, since the *Buttonwood* is equipped to tow large vessels with a big chock aft.

I spent the day on watch, with a few moments spent packing up my scattered belongings. Amazingly, they seem to fit in the bags I brought.

In spite of the absolutely perfect viewing weather we didn't see a whole lot, and I mostly got windburned for my pains. In the afternoon we had two waterspouts drop down out of a large cloud. One could see the great disturbance on the sea surface and the swirling tube leading into the cloud. The expected remarks about clouds refilling, or draining or whatever were made and photographs were taken. Various folk revealed their not-too-exciting experiences with other water spouts.

Notes, a look at the engine room, and then to bed.

Oh yes—one of the mess cooks came in today with a lizard in his hand—a Laysan Island skink that he had found in his t-shirt. Gives you an idea of how these critters can get transported around the Pacific.

We docked at about 1 AM, a nice landing by the Exec. Steve Yoder, and prepared to debark in the morning. I paid my mess bill—an astonishingly low \$23.05 for the trip, said goodbyes, and so forth. It's been an exciting and wonderful trip in good company.

November 9, 1967

Balboa, Canal Zone

Fred White, Bob Sahara, Dick Rosenblatt, and I boarded a Pan Am plane at Los Angeles and flew to Panama City with one stop at Guatemala City. The flight was uneventful. Clouds obscured the countryside from Mexico to the south for the most part. We disembarked at Guatemala City for a while and found it delightfully cool. Great cloud-capped volcanoes rise up above the rolling rutted valley in which the city sits. As we rose from the humpy airport the aromatic scent of the rainforest was pumped in to us briefly and then was gone. It was night before the plane glided in from the sea at Panama. The city was lighted up like a small version of Los Angeles. We were met at the airport by the agent and the ship's skipper, Mr. R. B. Harnes. We were quickly escorted through and made our way to the *Alpha Helix* which lay alongside a dock adjacent to the canal. She is as white and pretty as ever. We were greeted aboard and assigned to bunks. I bunk with Dick Rosenblatt.

Everyone of the scientific crew is aboard but Eddie Shalenberger—Frank Carey and John Teal from Woods Hole, Malcolm Gordon, Chief Scientist, and Alexi Kuznetsov, a Russian ecologist.

After much palaver we went to bed and will leave tomorrow for a trip around Barro Colorado Island and the Smithsonian Institution's station there.

November 10, 1967

Balboa, Canal Zone

After breakfast most of us hiked down to the railroad station for the ride to Gotun Lake, about $\frac{3}{4}$ of the way across the little country of Panama. This trip is wholly through the Canal Zone, which looks like one big USA military installation in that everything is neat, all architecture is regular and sterile barracks style, trees and bushes are planted in military rows (straight lines or circles) and tend to be in even numbers.

We boarded the Canal Railroad from a neat little station set near a row of great leafy banyans whose aerial roots had been discouraged. We were greeted by a white American conductor who efficiently punched our tickets. We clattered along the canal watching the ships pass by and into locks. The surrounding hills are vegetated with rainforest—a bewildering array of tree types—palms and tall leafy species. Finally we reached the siding of Frijoles and were met at a nearby dock by a launch from the Barro Colorado station. In it we crossed the ship channel toward a large jungle-covered rather mountainous island. We had been warned that ticks and chiggers were surely going to attack us in droves and so slathered ourselves with anti-insect unguents—over shoes, cuffs, legs, and arms. The lake was swirling with black terns—a pretty little species in its winter plumage—black eye and beak, grayish elsewhere.

At the Barro Colorado dock we cast our eyes up an horrendous stairway of at least 300 steps alongside which ran a cable railway for old infirm visitors (we were all young and vigorous). Puffing in the heat and humidity we trudged to the top to be met by the [?] Dr. Robinson and his wife. He was a red-haired paunchy behaviorist from England. He led us into the main mess hall and office, a large rather mouldy building, gave us a beer (his wife did) while we laid out plans for the afternoon. First a tour of the lab, then a hike in the forest. The director graciously showed us everything—library, zoo where several monkey species were kept and a doe-eyed young tapir stood by silently. Later we

learned that she had been attacked by the wild territorial male of the area and had literally been lifted from the ground by him in his teeth and worried in mid air. She bore ugly wounds on her shoulder to prove it all.

The howler monkey at the end of the cage responded to Alexi's coaxing and began howling—a series of pumping howls as his throat grew large and filled with air and finally great resonant bellows. Never, we were told did he reach full volume though.

Around our feet ran, or slithered rather, a Central American otter—he followed our feet up the stairs and chittered at us. He took Malcolm's index finger in his mouth and while he did not bite down wouldn't let go and was gently eased off by the manager.

We moved on to the insect room. Orb weaver spiders were being studied and many had built webs in special cages equipped with wooden discs. All were fed on crickets encased in little silk shrouds. Each silver-backed spider was sucking his dinner from such a captive prey. Then we met the phasmids—stick insects. Some were 12 in. long creatures that looked like large dead twigs. Even in the hand the animal was scarcely visible beneath his camouflage of color, texture, and shape. They were utterly remarkable. One leaf mimic from the far east had hatched out. It was a magnificent example of concealing color and pattern.

Afterward we set off up the David Fairchild trail—up steep slopes slippery with red mud beneath the canopy of the forest. All about were dead leaves of all sizes and shapes, seed pods, some 3 ft. or more long—like great bean pods, lianas, air plants, tiny little lantern-like white mushrooms lined along the margins of rotting logs. Another fungus that we saw from time to time on rotting logs on the forest floor was a perfect cup, bright pink and fringed with white hairs. A good many birds flitted by us—a big trogon with a katydid in his bill, a derby flycatcher holding a moth too big for him to swallow. When he dropped it for an instant, in swooped a squirrel cuckoo and scooped it down. High in the limbs of a bromeliad-encrusted tree, a pair of mannikins sat calling—bright vermillion heads and jet black bodies.

Far off through the leafy jungle we heard the resonant bellow of the howler monkeys. The noise was, at times, on either side of us and sometimes so near we might have seen them but we never did.

John Teal led the way and finally up ahead we heard him call. I trotted up to see him pointing at a magnificent boa 9-10 ft. long, coiled and curved along the trail edge, partially under fallen leaves. He was nearly invisible and wholly immobile. The blue opalescence of his back scales shone in the mottled sunlight that struck down on him through the canopy above. He could not be disturbed but lay silent flicking his blue tongue in and out. After some prodding he “sidewound” (believe it or not) away through the undergrowth. We could see a depression where he had been lying, indicating that he had been there some time and probably had scooped out a place for himself.

Shortly afterward we turned back, stopped at the station for a beer (25 cents), hiked down the stairs, and boarded the boat.

Back on board Alexi the Russian gave us a Russian vodka party. He plunked two bottles of vodka down, opened up two cans of caviar, one black sturgeon, and the other red salmon. I liked the latter best, in fact it was delicious. The drinking consisted of pouring about 1 ½ in. of vodka in a glass, saying a long toast, and downing it in one gulp. It sure left a warm place in your stomach and after four toasts Malcolm was really getting gay. Alexi is a raw-boned, determined, crew cut fellow obviously full of party

spirit and definitely an organization man. He believes in team research and thinks little about the extreme intellectual independence our scientists show. There are routes for flexibility in his system but they are hard and the weaker spirits all conform.

Warm and cheerful we went to bed.

November 11, 1967

Balboa, Canal Zone

At 8:00 A.M. Dick and I left for the Smithsonian Marine lab for a fish collecting trip. We drove out on a cansway to an old World War II bunker that has been converted into a passable lab. Adjacent is an old cable storage shed in which the station is converting a series of large cement tanks for marine work. It will be a splendid facility when done.

We were met by Bob Tapp and wife who accompanied us. Bob is a grad student at Harvard working for his Ph.D. He likes fishing and his wife likes fishing and I think that is why they study fish. Ultimately I was not impressed that they are apt to learn a great deal.

The poisoning netted a variety of fishes not greatly different from the assemblage I remember from the Gulf of California.

While the poisoning was being laid out I swam around with face plate and looked at the underwater scene. At least three damselfish were in evidence—*Pomacentrus acapulcensis*, *P. flavilatus*, and *Microspathodon*. Several wrasses, including the pretty violet and yellow *Thalassonia lucasensis* (one of the sex-changing types). Two butterfly fish, a small grouper (*Epinephelus labifonius*), a sergeant major, smooth puffers, and others cruised by. On the rocks just below tide line the surface was covered with a big rounded barnacle and a very rough-ridged limpet—like a much oversized *Acmaea scabra*.

I hauled out on a lava shelf and rested in the sun, watching the passing scene. A big old *Tursiops* cruised by out over about 150 ft. of water, breathed a few times, threw his flukes and disappeared for a minute or two, presumably feeding on the bottom. Pelicans flapped and fluttered in the top of a nearby forest tree overhanging the sea from a steep rocky islet.

Shortly we turned back in and soon were back at the *Alpha Helix* where I spent the afternoon [?] my lab space. Dick Rosenblatt and I share the wet lab—a nice space adjacent to the afterdeck. Tomorrow we sail.

November 12, 1967

At sea, enroute between Panama and Galapagos Islands

The ship cast off moorings at dawn and soon we began crossing the Bay of Panama going nearly straight south in order to round Punta Mala, which bounds the west limb of the bay. Out in the bay we saw several groups of porpoises, mostly *Stenella graffmani*, I believe, except for one group of *Tursiops* that swam in toward our bow. Tony, a crewmember and a long-time tuna fisherman, said *S. graffmani* was the “spotter” of the tuna fisherman and that *T. truncatus* was the “black porpoise” that fish did not follow. A flock of brown boobies amused us by diving in front of the ship as we cruised along through the calm water. They dart into the water like arrows. When the angle of their flight became low enough we saw them bounce off the surface.

One young bird spotted a fish just ahead of the bow of the onrushing ship, flashed past our heads in a screaming dive inches ahead of the ship's stern, and plunged into the water just ahead of the tow wave. He was royally tumbled an instant later as the wave caught him—but never fear he tried again later on with similar results. The day was overcast and cool but only after we had cleared Pt. Mala did the calm disappear and a chop and swell build up.

Several birds more or less new to me were common—little flitting storm petrels, like daytime bats, cruised low over the waves, and were to be a constant accompaniment all the way to the Galapagos. Sabine gulls, likewise pelagic birds, were often encountered as were the larger blue-faced boobies.

Before the day was out the *Helix* was pitching mightily under scowling clouds and rain with winds of about 15-20 knots. Eddie and I stood porpoise watch and once the shore was left behind sightings became slim indeed; another feature that held true all the way to the Galapagos, in fact the open sea seemed wholly vacant of such species as *Tursiops* and one wonders how they have come to colonize most oceanic island shores. Certainly crossings of open sea must be rare for such species.

Islands probably collect pelagic animals, both because the sea floor rises and makes deep water food more available and because they simply lie athwart paths of movement. As witness to this, true oceanic species are much more common as strandings on oceanic islands such as Hawaii or the Galapagos than they are along continental shorelines like Southern California.

November 13, 1967

Enroute Galapagos Islands

More of the same—rougher even and nearly everyone seasick to some degree. I am affected much more by the ponderous predictable roll and pitch of the *Helix* than by any smaller boat. It took some fortitude to stand watch, particularly when there was so little to see—wind-whipped seas and swells, spume flashing over the bow and foredecks. We already await anxiously our arrival at the Galapagos.

Malcolm and I slept in the lounge where we could stretch out athwartship to avoid the jarring pitch as the *Helix* plunges into the sea.

November 14, 1967

Enroute Galapagos Islands

Things have calmed somewhat but most of us feel only half alive under the influence of Marizan [?]. Skies are dull gray or rainy. We saw one porpoise school in this endless sea—lonely indeed surrounded by untold miles without others. It makes schooling behavior, aggregation calls and even the possibility of mimicry in calls serving to identify a school more meaningful.

About five species of flying fish have rushed from our bow—a dull reddish-winged form, one with banded yellow and black wings, one at least with ventral and pectoral fins about the same size, a bumble bee-like fish, and one with black wings. I saw two fold their wings just before diving back into the sea.

This far out to sea—perhaps 400 miles or so, we see man o' war birds soaring overhead, and they can't settle on the water.

November 15, 1967

Galapagos Islands, Ecuador

Seas have calmed greatly and still we see no porpoises. By about 9:00 A.M. the sea was nearly flat and we found ourselves with San Cristobal Island (Chatham Island) on the radarscope. A heavy storm, however, obscured our view. Finally, the island emerged from the clouds—as austere and barren as the Kan desert of Hawaii—a volcanic landscape of cones, cinder fields, and one tall cone protruding into the cloud blanket. The sea fell flat calm sliced here and there by tide rips of agitated water. Sea lions began to appear, sometimes leaping porpoise-like one after the other. The Galapagos albatross, a relative of the great linpan albatross, was seen and many frigates and Galapagos gulls came to our masthead. Not a porpoise was seen. Finally we rounded an offshore rock and entered the unprepossessing harbor of Wreck Bay, which is lined by little Ecuadorian villages of Baquerizo Moreno, the site of the Ecuadorian port authorities and navy.

Malcolm went ashore with all our passports and a pair of Ecuadorian navy officers, one a very stern unsmiling Lt. Commander (at least he had gold oak leaves on his shoulders). When he returned some hours later he was accompanied by an armed guard, a pleasant young fellow named Olayo.

Fishing on the fan tail has stopped. Dinner is over and we make way for a new anchorage.

Actually the ship hauled anchor and we made our way toward Academy Bay some 45 miles away. We will cruise very slowly tonight and arrive tomorrow morning at dawn. After an unsuccessful stop to do some night lighting we hit the old pad.

November 16, 1967

Enroute, Lagus Cove

Up near dawn to find us about to drop anchor in Academy Bay. Lava floes had poured into the sea from the peak of Santa Cruz Island (Indefatigable) above, forming a rough cove bounded by 20-30 ft. lava bluffs. The entire shore is fringed with palo blanco trees and the arbousant platy opuntia—a cactus tree standing 20-25 ft. high. The village of 1,500 souls lined the bluff and back bay. We cruised in the skiff and landed alongside a series of cement steps on the lava.

Once up on this platform the village lay beyond—clusters of houses with rather ill-defined streets meandering between low lava rock walls. Most houses were on stilts with chickens, pigs, and goats beneath. Most had horses or burros in rock compounds. Some remarkable Galapagos dogs wandered the streets and much like Hawaiian poi dogs. Several stores advertising supplies, Ron superior, aguardiente, or various oil products lined the street. We walked along toward the Darwin Station which is reached along a 1/3 mile footpath through the dense shore-edge vegetation so tangled and thorny that one could not walk through it. Darwin's finches were everywhere and in bewildering array. Beak types and color patterns seemed to run the gamut, and to be all mixed up. The warbler finch and the cross-billed variety ate bananas alongside the cactus finch. Lava lizards (*Tropidurus*) were everywhere, very tame and in bewildering array of patterns and colors ranging from striped ones to more or less uncolored ones with reddish throats to grossly patterned individuals. One literally worried about stepping on them. I found that

I could bring my hand within about 6 in. of them before they scurried off. They were, however, wary of being touched.

Finally we reached the station which is a cluster of low white buildings set in the sand at the edge of the calm cove. There is a nice neat lab with collections, some library, a little set of display cases, and offices. The Director, Dr. Perry, is a paleontologist turned BBC commentator who does some work on the high-altitude composite tree *Scalesia*. He is an efficient administrator from all appearances who keeps a clean, well-running lab. I looked through his cetacean literature and found a bad paper listing some Galapagos cetaceans--*Extrait de Mammalia*, 55 Rue de Buffon, Paris University. Notes sur quatre cetaceas de l'Océan Pacifique. Tome 27 No. 4, Dec. 1963, and *Lista systematica de Maníferos del Ecuador* by Prof. Gustavo Orces, Escuela Politécnica Nacional, Quito. The latter looks like an honest attempt at listing the cetaceans. We then went on a tour of the lab and met a Scotch scientist working on human diurnal rhythms—she had been to the Arctic working with the Eskimos and now was here on the Equator. An old bandy-legged (?) blue-eyed Norwegian took us on a tour of the turtle species. They have built big lava rock-walled compounds in which four species of tortoises are kept. They are fed cactus and fruits, and seem to do very well. A heavy growth of tree cactus (*Opuntia echinos*) and a large tree cactus plus palo blanco trees and various shrubs grow in each pen and provide shade. The Hood Island species, which is nearly extinct is represented by a pair—they are rangy, fast-moving beasts with very long legs, necks, and a great arched shell. No egg laying had yet occurred but they were hopeful. One pen was full of young of Pinzon Island forms and another of Santa Cruz young. They were all doing well and would soon be invulnerable to pigs and rats, their worst enemies when young.

A grand old land iguana (*Corolophus*) crawled toward his crevice in the lava and eyed us with his skeptical red eye before retreating below. They are excessively rare now and most colonies number 10-20 animals only. We will visit one colony on Fernandina Island.

We wandered back to town looking at mockingbirds and finches and watching the latter hopping into houses and stores, seemingly oblivious to people. Finally, after a beer in a most idyllic "club" along the footpath (a lava house with coral paths, cactus, bouganvillea, and other flowering plants, swings, a cool shaded veranda, and a nice lady to serve us—50 cents for a huge Ecuadorian beer).

Finally our boat came in between two dugouts supported by balsa logs loading goats, and we returned to the *Alpha Helix*, which lay riding at anchor far out in the bay. On board we found that officialdom held us up pending authority to take marine iguanas. Finally it arrived and we hoisted anchor and set out into the calm sea toward Isla Isabela to the west.

To the south lay Santa Maria, a jumbled mass of volcanic peaks, to the northwest Pizzou and ahead Isla Tortuga, a nearly drowned volcano whose rim only lay above the surface as a steep, arcuate ridge. Behind the massive Isabela rose into the clouds. Across the glittering calm sea we cruised and for the first time saw porpoises and whales. A medium-sized whale (probably *Balaenoptera acutoarostrata*), perhaps 30 ft. long, cruised by us on one side and soon we crossed a school of perhaps 200 bottlenose porpoises. As many as 20 rode our bow at once including mothers and young. Later I listened to them squeak and click on the echo sounder as they played at the bow.

Darkness settled and a full moon rose as we secured our watch for the evening. Tomorrow, our destination.

November 17, 1967

Tagus Cove, Isabela Island, Galapagos Island

With the graying of dawn I poked my head out of the window (we have windows) and saw the great rounded bulk of Fernandina Island off three or four miles to starboard. The sun shone on it in patches, illuminating the fissured flows of its new lava slopes. Three cloudbanks circled it, one obscuring the peak which rises nearly 5,000 ft. above the sea. All except a thin fringe of green mangroves at its shore appears barren—cinder slopes, [?]. The slopes are clothed with a straggly growth of palo blanco trees and lower scrub—nothing like the density found at Academy Bay. Cool water (21 deg. C.) ameliorates the tropical clime and the air is cool, even chilly, certainly strikingly unlike tropical areas I have known elsewhere.

Eddie and I prepared our gear for the sound transmission test—a modified skiff—and all systems are operative.

Finally at 4:00 PM we set off to try for a porpoise. Tony took the wheel of the runabout (a 60 HP motor-fiberglass hull) and off we went—literally. He has no idea that there are intermediate speeds between stop and flat out—wow, my aching back!! We skipped from wavetop to wavetop at about 30 knots—one could hardly stand up and certainly couldn't sit down. With a rush of whitewater flipping lagging petrels who didn't rise fast enough we rounded the point and out into the channel. After some miles of this a school of about 100 porpoises was sighted leaping as they rushed along. We raced up upon them and as they lept I could see that they were the common dolphin (*Delphinus* sp.). They had the typical saddle, light belly, dark eye ring, and beak—only their beak appeared short to me, by California *Delphinus* standards. Several times we were able to race into the midst of the frightened school before they could turn away. Graceful leaping porpoises were on all sides of us. It was impossible however to shoot from the bucking boat when the only thought was of self preservation.

Later, as we turned back toward the ship, Punta Espinosa, where we will make shore camp, is a finger of jagged lava protruding out into the calm waters of the channel between Fernandina and Isabela.

The calm channel was dotted with swirling masses of petrels, man o' war birds circled and darted overhead, straggling strings of little white phalaropes flowed inches over the sea. The beautiful dusky gray-headed Galapagos gull fluttered down and stood on the rail—its somber colors set off by a red eye ring and bill.

Everywhere were sea lions, porpoises, rising up as they swam to eye us curiously and dive again.

The *Helix* rounded the edge of a layered cinder cone whose slopes dropped precipitously into calm black water and entered Tigres Cove, which occupies the flooded caldera. All along the bluffs are the names of vessels and the date they visited, painted in white paint on the ash beds. Some are said to date back to whaling days when this was a favorite anchorage for sperm whalers. Once at anchor, deep in the totally sheltered cove, there was time to look at the nearby island a bit more. The rocks are splotched with red crabs (*Grapsus grapsus*) and marine iguanas are common everywhere on the rocks above

tide line, spreadleg in the sun. Quite a few Galapagos penguins were noted standing just above water line on the sloping rocks.

Spouts were sighted again—broad, mushy, vertical ones. Often enough the spouting animal showed none of its body but finally I got a view and could see the little hooked dorsal far aft. Then we came in close once and when within about 30 yards watched a 30 ft. animal rise, swell its head, and blow from two nostrils that surmounted the swelling—a pygmy finback whale ([later note] probably Bryde's whale), without a doubt—a creature that I had been surprised to find as far south as Los Angeles in California—and here on the equator! One wonders if it represents the warm-water end of a breeding migration—perhaps from the south along the cool Peru Current. Obviously at least most of the spouts we have been seeing are of this animal

While far out in Banks Bay we saw Carl Angermeyer's sailboat working its way down. He has lived in the islands since 1937 and built this boat himself, much of it from native Galapagos materials—the ribs and frame, the nails from copper wire cut and pounded into nails, and so forth. Later, back at the ship, he pulled alongside and came aboard—a tall, reflective man with a curiously sweet if gnarled face, huge, tough hands, and a taciturnity made all the more intense by his sweet talkative wife. Forever pulling on a pipe he uttered little unless asked but then was revealed to be a good observer of his limited world as was his wife. Both are about 50 and very hale and hearty. Fred White will live on their vessel while he works at Punta Espinosa. Mention was made of my desire to obtain 2-3 *Tursiops* and Angermeyer clouded over and talk shortly revealed that he felt kinship as their schools swooped in toward his little craft and played in his wake or bow wave. I acutely began to feel an awful intruder, and the wall that rose between us. What need of men could make them want these animals enough to kill them he seemed to but did not say. To his wife it was enough that they would be “prepared” for a museum. To Angermeyer, not so. I feel my own presumption enough when alone in this task of killing porpoises but in Angermeyer's presence it might be more than I could bear—quite aside from his feelings in the matter. Such a curious tangle of emotions and motives. I hate what I am doing in part, yet press ahead with anticipation with another part. Why anticipation? I suppose it is because ahead lies some curiosity for how porpoises hear and phonate and a greater fragment of desire to document my bright novel idea for my fellows. These things override my long and sometimes personal association and attachment for individual porpoises and the tribe in general. They even sought to override the will and wishes of a sensitive reclusive man of whose world these animals are a real and important part, even to the extent that he might become an instrument of my wholly foreign wishes. What needs does he have, the sufficient man whose hands could fashion a perfect boat, that should compel him to take such a subservient and venal part of my own semi-mad motives? At any rate it seems improbably that I will do more than record from the good ship *Nixie*.

The Angermeyers told stories of a neighbor at Academy Bay building a house on the lava bluff above the tide line that was the home of a dozen marine iguanas. The iguanas moved in when the house was done, climbed the roof, and are still there. The owner, a Norwegian, lets them in the house but because they leave feces around periodically rebels and locks them out. Apparently they circle the house until let in.

Off to bed.

November 18, 1967

Drifting in Banks Bay, Galapagos Islands

Early this morning I heard a lot of bustling and stirring on deck. Emerging I found Fred White piling up his equipment preparatory to loading it on Angermeyer's little sloop. After some palaver Angermeyer decided not to load in Tagus but instead at Pt. Espinosa so off he went, sailing finely out into the Bolivar Channel. Finally, we followed along. My quandary about where to collect remained so after some hemming and hawing on my part I broached the subject of collection from the *Helix* with Captian Haines. The propellor cannot be stopped inside of 6-10 seconds—far too long to avoid a line pulled by a diving porpoise, but the Captain seemed not especially worried—there are ice deflectors—thin plates of metal ahead of the screw—that should sweep the rope by. So, the *Helix* it is and Eddie and I forthwith began to rig lines and buoys. After landing Fred and his gear (he will work ashore at Punta Espinosa) we began searching for porpoises—first across [?] Bay toward Cape Berkeley—heading our ship in toward an enormous semicollapsed volcanic cove broken into a sheer wall that plunges into the sea leaving behind a little cinder cone that was once deep in the crater. Finally two miles at sea from its towering slopes we came upon about 80-plus sleek porpoises—Tony calls them white bellies—I think they are *Delphinus* but they could be *Stenella*. It was obviously the school we harried yesterday. From the first they were wary and as we pursued them they grew more and more frightened and refused to come near us. Several times we cut the school in two and always they would veer away and race together again frantically, sometimes in so doing they passed us in a driving leaping rain of porpoises, rank on rank in the air in beautiful arced leaps, their glistening sides flashing in the sun. I saw amongst them babies swimming as fast as the rest and three individuals with a triangular white spot on their dorsal fin. Finally, after I had taken enough photographs to be sure of identification we left then and turned in toward Isabela Island. Shortly we encountered three large whales blowing tall columnar spouts. They seemed to be (still *B. edeni*) small finback whales—we paced off the length of one relative to our ship—35 ft. They were in 600 fathoms over a scattering area at 150 fathoms (on the fathometer). After quite a lot of observation and photographs we turned toward Bolivar Passage and Tapus Cove. No porpoises. Through the passage we went—through groups of seals and many birds but no porpoises. Just above Pt. Mangle we turned back to Pt. Espinosa, picked up Dick Rosenblatt and his fish, John Teal, and Frank Cary and cruised on out to the sea end of Fernandina Island.

Returning inshore I ceased my watch at sunset and Malcolm took over dipnetting in 900 fathoms while the boat drifted. Tomorrow we cruise Elisabeth Bay.

November 19, 1967

Adrift, Banks Bay, Galapagos Island

Up anchor early and after *Tursiops*. Down Bolivar Channel to Elisabeth Bay. The effect of cool water on climate here is amazing. I have to wear a jacket and often shiver at that because I failed to bring a warm enough one. It has been overcast however and when the sun comes out it beats down in good force. Twice today we pursued groups of about 10 bottlenose porpoises but never would they run our bow for more than a moment. Our traverse took us many miles, most over flat calm seas. Through Bolivar Channel, along under the bulk of a great truncated cone on Isabela Island, rising perhaps

4,000 ft. in one sweeping lava slope, thence to the Istmo Perry, a low causeway that crosses Isabela Island but is so densely vegetated it cannot be crossed on foot save with a machete and a week's work. Then we cruised along under the bluff of another and still another great dome as we worked along to Webb Cove at the extreme western point of Isabela, thence across wind chop to the south shores of Fernandina, the most majestic cone of all (and the newest), back up Bolivar and clear across and back across Bank's Bay by nightfall. Eddie and I kept watch all the way, watching every suspicious white cap with binoculars. It was tedious and we did not succeed, still we learned a lot.

In the deeper parts of both Elisabeth and Banks Bays the big whales were common. I suppose we saw about 10 in Elisabeth and 4 in Banks. The disparity only means that much more time was spent in Elisabeth than Banks. As I have never been able to see the asymmetrical color of the lips and because of the latitude I now think it likely that they are Bryde's or Sei whales, much more probably the former. Several times today we had them very near us and I believe I remember the typical ridged head of the Bryde's whale (*B. edeni*). We shall see. In Bank's Bay the big porpoise schools came in view again and my confusion grows. This time I could clearly see the black line running foreward on the belly from the vertical surface of the tail stock (see data sheets) and do not think it could be *Delphinus* but must instead be some species of *Stenella* that I cannot identify.

Twice today broadbill swordfish cruised up to us—shining bright blue in the water. You can always tell a broadbill from a marlin because both his dorsal and caudal fins stick out while only the caudal of a marlin shows, waving back and forth.

I must comment on the fishing of the Galapagos booby. These birds cruise high—sometimes 200 ft. or so and can be seen rocketing down in incredible dives from that height—like arrows they go—nearly vertically with wings nearly folded to plunge into the water for several feet. The green semiopacity of this water must make it difficult for them to see far down, but no matter. I saw one trimming himself during a near vertical dive, turning round and round like a rifle bullet. Getting the fish is the thing—angle of dive means little. Sometimes it is so low that they pierce waves and pop out the other side and I have seen them skip like rocks on the surface. Tomorrow Ed and I go ashore at Pt. Espinosa

November 20, 1967

At anchor, Punta Espinosa, Fernandina Island, Galapagos

While I was putting my dishes in the galley after breakfast I heard the call “porpoise”. We were just underway to drop a group of us off at Punta Espinosa and had no more than cleared Tagus Cove. I looked out the port hole and sure enough—a big splashing school of *Tursiops*. I raced on deck to find Eddie already rigging the harpoon. A few minutes later and he fired a perfect shot. The animal sank, apparently dead, but the line came away free. The harpoon becket had broken and the line came away. I scarcely thought they would run the bow again, but they did. Apparently the first animal had not alarmed the school. The second shot was not nearly as good and after a short fight with me and Tony in the skiff we brought the animal in—a 320 kg. male that looks for all the world like our California form. Ed and I set to work with the sound transmission experiment. We filled the boat, rigged electronic gear, made up blubber transmission equipment, and went to work on actual measurements. The animal was

photographed, measured, and dissected. Ears and eyes were removed, for electron microscope studies and pigment analysis by Ken Bloome and Bill McFarland.

The test dragged on and on fraught with experimental problems. I'm still not sure what was the problem though I know we need more room to work in, depth-wise. We did complete a fine series of tests on the refractive properties of blubber and blubber-muscle combinations. This took until about midnight, when we both decided we had had enough and called it a day. I stayed behind and washed down and hit the sack about 1:00 A.M. Tomorrow we go ashore to get Eddie set up, and for me to look at *Tropidurus*.

November 21, 1967

At anchor, Punta Espinosa, Fernandina Island, Galapagos

After a lot of preliminary fiddling around, like removing retinas for Bill McFarland, we loaded gear in the whaler and headed for the nearby shore. The way in is a bit tortuous—winding through lava outcrops lying just below the surface. Fortunately, the sea was calm and the traverse was made easily to a landing on some smooth lava just seaward of a dense mangrove forest. We were greeted ashore by a great blue heron who looked us over, stalking slowly back and forth in their peculiar slow, loping gait. I of course thought he would fly, but not a bit of it. True to advance publicity he looked us calmly in the eyes and walked away with considerable dignity. This and other advanced billing should have prepared us for the place but it did not. I came enthused to see the shore life and left feeling I had one of those rare experiences that a naturalist has a few times in a life of seeking them. The richness, tameness and curiosity of the animals had great impact.

Eddie, Olayo the Ecuadorian guard, and I staggered up around the main mangrove patch with our gear until we were above high tide. Eddie and I started off on a sightseeing trip, Olayo having seen it all his life. We were immediately faced with a group of sea lions (*Zalophus californianus wahlbeckii*) sleeping in the cool sand under a low growth of mangroves. They took little notice of us. Even when we stood on the banks of a big jade tidepool the seals continued to race back and forth and gambol at our feet. To be sure many of them would move away when we came within perhaps 15-20 ft., but how vastly different from the California form that begins to move anxiously for water 200 yards away. These sea lions are very small—perhaps ½ the size of comparable ages of the California form. The bulls bark, but it is a rusty, rather soft bark.

Ed and I worked our way out toward the main point. Every rocky promontory had its compliment of bright orange grapsid crabs (*Grapsus grapsus*). There is every gradation from a rather drab maroon small crab to the gaudy adults. The largest had a light-blue patch along the face of the shell below the chelipeds, and the chelipeds are brilliant scarlet. They too are tame, whatever that word may mean. They scuttled out of our way from wholly exposed positions into inadequate crevices when we trod a few feet away.

Their color against the somber gray of the lava is striking. Marine iguanas are everywhere, in the mangroves, and even up in them 15 ft. off the ground (so are the crabs), on the sand, and especially on the lava promontories where great herds bask, bicker, and thermoregulate. These herds are dense packs of animals, some sitting on one-another, with larger, gaudier, adult males interspersed, bobbing in a peculiar limber-necked bob that jiggles their ample jowels by the rebound.

In one such herd at the very tip of Pt. Espinosa, we estimated between 400 and 600 animals (each weighing a couple of pounds). Walking through such a herd was quite an experience—iguanas slithered away in front of one and then stopped a few feet away. Looking back one could see a wake where he had pushed aside the herd—about as wide as a driveway. This, Eddie tells me is about the treatment sea lions get when they enter a herd.

It's rather nice to get the same treatment a sea lion gets from the other wild life. Males bob at one another and seemingly in special areas and often come to physical combat, which consists of biting the neck, and butting. There is much thrashing about and then the quarrel seems settled. Females are nipped by males when they deign to wander through near an agitated male. Fred White feels that this is herding behavior by means of which the male keeps females near him. However, I'm not so sure. Quite enough big colorful males were present without females nearby. Besides the driving seemed as often as not to drive the female away altogether, but this remains to be tested more thoroughly.

Ed tossed a couple of baskers into the water, as Darwin had done more than 100 years before. The lizards still act the same. They race for shore in a panic and climb the nearest rock. It's as if you were dumped summarily into a pool full of cold water—all frantic thrashing.

We continued out the rocky peninsula, wandering among friendly sea lions. In one pool we found about 10 sea lions racing back and forth at full tilt in the shallow water. At first I thought we had frightened them and they were racing for sea, but once they reached the exit they turned and raced back into the deepest recess of the pool, only to start another race that humped up a long wake of water over their path. They were obviously enjoying themselves and we were no more than incidental visitors standing on the bank to cheer them on—perhaps not even paying cutomers. Then we chanced upon a green heron, a wary little bird in the United States. I crept toward him, photographing as I went. Then, when he did not fly as I wished, I sent Eddie on to shoo him into the air. All that emerged is a movie of a green heron mincing along with Eddie close behind. Until we nearly forced him into the water he refused to fly. Later I followed one that walked perhaps 30 ft. in front of me, for 75 yards. Finally I stopped and the bird quickly began fishing. He sequestered himself in a lava crevice at the edge of the pool and peered intently everytime the water rose and washed past his feet. His immobile stance and great patience finally overcame my inadequate attention span and I left.

Around the still racing sea lions we went to the outermost promontory of Punta Espinosa, a large hummock of lava some 40 ft. out of the boiling surf. The rock was literally plastered with wall-to-wall iguanas. I estimated 600 animals. They occupied the rock from waterline to the highest pinnacle of lava. In the overcast of the day they were oriented every which way, but when the sun comes out nearly all swing around within minutes and face the sun.

Here we encountered our first flightless cormorant. He is a perfectly normal-looking bird until he decided to spread his mighty wings for drying in the sun. One did this a few yards from us. The tiny wings are stocked with a scrubby array of flight feathers arranged so far apart it is difficult to see what function they might serve or why it is useful for these cormorants to dry them. The cormorants, too, are tame. While photographing one I managed to cause him to jump into a nearby pool full of seals. He

regretted his action soon enough as they raced around him nudging and nipping playfully at him. He emerged on the opposite bank, dignity reasonably intact, shaking his feathers.

All around the rocks, below tide line as well as above it were many of the little iguanid *Tropidurus*. Nearly all had evidence of salt excretion from the nostrils in the form of a white ring, or even little hillocks around each naris. I saw one lizard wipe the salt away by rubbing his nose on a rock.

We returned to camp and I left Eddie in the midst of preparing to test some of these escape distances in the various animals we had seen. I wandered on down the shore, through a series of sandy coves and rocky points. In some places the lava had fissured deeply as it poured into the sea and one could find seawater leads far back of the shore, sometimes deep down in crevices. It was startling to look into these deep recesses and see the red crabs clinging to the rocky walls, anemones open in the still water and a variety of marine fish lazily swimming back and forth. In one place a lava bubble had burst forming a sizeable pool, some 40 yards long by half that width. In the center of the jade green water was a dense ball of fish, tightly aggregated just below the surface—the Galapagos opaleye (*Girella fremenvillei*). They scattered as I approached—the fish to do not react like the land animals, nor do the penguins and cormorants act so fearless in the water.

From time to time mangrove patches confronted me, acting as rather effective barriers to progress. Their buttressed roots, and nubbly seas of pneumatophores coming up from the sand combine to make progress very difficult. It is usually much easier to walk around them in the shallow water. In one such grove I came upon two mother sea lions lying in the deep shade on the sandy berm beneath the trees. Each had a little baby sea lion nursing. Mother snoozed peacefully as the little one sucked from one of four nipples. The little ones have a peculiar strident cry or bark that only they make, very different from either the bull's call or the voice of the mother. Some of the babies were tiny indeed, weighing no more than 4-5 pounds. One mother woke with a start, scrouffed in anxiety, and crawled away deeper in the mangroves with her baby—perhaps 20 yards.

I was tired from the long experiment of the night before and lay down under some mangroves in the cool sand for a snooze. It proved a somewhat inauspicious bed as it was obviously a sea lion rookery by the smell which became more intense the closer I got. But tired as I was the smell didn't win out, but the flies eventually did, so I arose and walked on.

I came to another deep and beautiful cove. At the back John Teal and Fred Carey were busy trying to find out what happens to a marine iguana's respiration when it dives. They had a hapless beast strapped to a board with a lot of leads running out its mouth. I'm told the animal swam away unconcernedly after the test was over.

Out in the bay we noted the fin tips to a manta that had entered the shallow water. It swam to within perhaps 80 yards of us, with its wing tips sculling the air as it nosed into the corners and crannies of the bay. A pelican stirred on the bank and flapped into the air—they too are not tame by Galapagos standards.

I took the upland route back, behind the mangroves, and encountered many more leads into the lava-filled with seawater. Even a few marine iguanas could be found perched on the rocks, 100 yards from the shore.

Working my way back down to the beach I wandered out onto a rocky shelf where the surf was breaking. Iguanas dotted its surface. As a swell broke on the shore,

white water rushed over these animals. When it dropped they were still in place, as were the grapsid crabs. Later Eddie tried to pull a marine iguana from a rock on dry land and found that their grip is well nigh unto incredible once they have latched onto the surface with their long claws. He literally could not pull one loose, even though he thought he would break its tail loose (these beasts do not autotomise their tails).

Several iguanas were noted feeding, or even simply resting in the still water of tidal pools. The feeders crawled along the bottom, scraping algae from the rocks with their lateral teeth. They were able to crop it down very close to the rock surface. I saw two animals doing the same thing on intertidal rocks in air.

Hot and tired I emerged onto a big rocky swell at the water's edge adjacent to camp. There in the crevice at the crest I found a nursery for little marine iguanas. These animals are conspicuous by their general absence from the main rookery grounds. Here in this deep crevice they clung to the walls in numbers, often on top of one another. They are more fearful than adults too, and it is likely that they are subject to predation not experienced by the adults. This, I think, is also true of the chuckwallas of the Gulf of California islands. There the young are very wary while the adults are the pinnacle of stupidity and docility.

At last I noticed some penguins. Three rollicked in the water just at the base of the lava bluff. They weren't all friendship to each other though—nipping and quarreling. They bray like little donkeys and John Teal reports stepping on loose lava some distance from shore to be started by a groaning bray from underneath, which turned out to be a nesting penguin.

Ed and Olayo were already eating lunch when I dragged up the sandy beach. I was hot and tired and hungry. Our lunch of crackers, cheese, water, smoked oysters, and pieces of leftover steak was fit for kings. Rather shortly thereafter we returned to the boat sunburned and tired but filled with impressions of this somehow unreal world where humans are just another funny-looking upright seal to most animals.

November 22, 1967

This morning I am to go out on the *Nixie* in an attempt to record from the Bryde's whale, if indeed that is the species we have here. So, after breakfast I gathered up all the complicated wires and equipment that go with recording whale voices. It isn't easy for an electronic neophyte like myself. The *Nixie* is anchored far back in a lava inlet. The water is jade, the bottom white sand, and the shore an incredibly jagged mass of tortured lava, much too rough for a person to do more than crawl over with gloved hands.

The *Nixie* is a monument to this gentle man, Fritz Angemeyer, as I was to learn in more detail during the cruise. He designed it, scrounged pieces and parts from everywhere on the islands. The copper wire he used for nails came from the Navy base, now abandoned. The mast came from the sunken tuna clipper *Glory of the Sea*, that ran aground on the north end of Isabela Island, and various pieces of chain obviously came from other wrecks. Most are different styles, shapes, and degrees of corrosion. The keel Fritz cut out himself from a large matesarno tree far up on the slopes of Santa Cruz Island. This wood is fine-grained, and short of 100 years underwater, Fritz tells me, will not rot. In water its beautiful red grain comes up—in the sun and air it turns silvery. The tree seldom yields up pieces more than 20 ft. in length, but Fritz found a big one for his keel and shoe and stem post. Elsewhere he has used it to make bits and blocks and cleats.

Lovely stuff. He put three tons of cement, iron, and lead in the keel, built her beamy, installed a little 8-horse Saab diesel that pushes her at 6 kots. What a jewel, and what a lot of care went into her, not to mention sheer labor. The mast, for instance, he squared with a saw and adzed and sanded to its present dimensions from one twice the diameter. No two pieces of rope are the same—some blue and white polypropylene, manila, nylon, etc.

We put-putted out of the little nook in the lava and up along the shore of Fernandina. Rather shortly Carmine (his wife) spotted a whale. She, it turns out, is a thoroughly excellent observer and a well-read person of many capabilities. We came upon the animal shortly and by that time I had figured out which wire went where on my gear. We lowered the hydrophone in the water with the animal very close aboard. I at once heard some peculiar low-frequency plup-plup sounds repeated at reasonably regular intervals. These I successfully recorded. The big beast (about 40 ft. long) was cruising in more than 600 fathoms of water I guess from the chart, and it seems doubtful . . . [?]

On out across the bay we cut and rather shortly sighted a school of our little *Delphinus*-like porpoises, racing at full throttle across the bay, leaping in waves out of the water. No amount of pursuit brought us much nearer than 500 yards. After an hour or so we gave up the chase and proceeded across the bay. Lunch was brought out—very tasty potato salad, rye bread (baked by the Mrs.), and delicious Ecuadorian orange marmalade, plus lemonade. Two more whales were seen but they eluded us by diving for very long periods—I would guess at least 20 minutes or more. By the time we had fatigued and begun to move on, the whale would come up and we would return again. The animals were diving in one general area of very deep water, and may have been feeding.

We turned for home port at 2:30 PM and began the run home across the placid bay, wind in our mainsail and the put-putting engine throbbing through the wooden deck against our feet. We talked of this and that—how he had left Hamburg in the 30's when Hitler came to power ("Germany was no good to live in after that"), how his family had left in a 55-ft. vessel, but could not find work in England and had to sell it, worked their way to Ecuador and finally to the Galapagos where he has been since the late 30's. He talked of ship design, of hydrodynamics (he knows a lot), of disease being brought to the islands by imported cattle and people, of the two vessels that vie for trade amongst the 2-3,000 people who live in the islands—a gentle, bright, simple man who hates the advance of "progress" into his realm where he can make with his own hands most of what he needs. Dinner he can catch from the sea—he showed me a turtle hook he uses. The turtle is sleeping on the surface and he paddles up behind and hooks its front shoulder. The hook loosens from its long bamboo pole and the fight is on. Grand eating. On and on in the warm afternoon with the sea spray sweeping across from the bow occasionally as the little ship dug into waves. Boobies diving their incredible vertical kamikaze dives from 200 ft. up, an occasional broadbill with its two fins arcing above the water.

So the day went. Productive scientifically, but more so for the people and the scene.

November 23, 1967

At anchor, Pt. Espinosa, Fernandina Island, Galapagos

Today I had the unallowed joy of spending an entire day learning about one animal. My open-mouthed sightseeing trip to the shore was over and I could ignore sea

lions playing at my feet and green herons peering with curiosity at me while I worked. I could concentrate on a single little rather drab lizard and ask what his life might be like. The lizard is *Tropidurus* (to the Ecuadorians, "lagartija"). It is about 8 in. long (adult males) or about 6 in. (adult females). The females are the more brightly colored, having salmon orange on their chins and anterior bellies. The males have salmon only on the belly but do sport a fine dorsal crest of spiny scales that the females lack.

With rather little gear for a change Ed and Fred White and I cruised ashore and landed in the midst of the mangrove swamp. The tide was wrong for landing on the lava so we spidered our way through the trees. At camp I left Ed and Fred censusing their marked marine iguanas. They have a lot of gaudy marks and streamers on all the males in the neighborhood and are trying to make sense of their behavior. Just now the males are setting up territories and beginning to spread out over the rocks in geometrical precision that is constantly bolstered by border battles. In fact they attack anything that enters their ground, including females, and even look sullenly at us when we intrude, though they never actually run at us. A bull sea lion did today, however, as I passed between him and his harem up in a mangrove thicket. He came waddling over to me barking and looking intimidating. I was intimidated, folded my dewlap, tucked in my brightly colored shirt, and slunk away.

Anyway, Ed and Fred went about their business and I mine. Mine was to catch lizards and find what they had been eating, to take temperatures and look at the ecology of both beach populations and ones inland. I started on the beach. My little lizards were scattered around, even on intertidal boulder fields in some places. They enter rookeries of the iguana, and sometimes perch on these big docile beasts. I found *Tropidurus* several times on spray-wetted rocks amid populations of *Grapsus grapsus*, the big red crab. The chance observation of two days ago of a lizard attacking a crab nearly his size and nipping at its legs made me wonder if they ate crab meat. Indeed they do. The sum of today's efforts shows that their diet is probably 95% by weight of crab, mostly small ones that are eaten whole, but a good many legs as well, including the pinchers.

They do snap up the random fly, wasp, or bee that comes near and even find a spider or ant now and then, but it is mostly crabs. This diet is a terribly salty one for an animal that presumably must obtain its moisture through its food. Thus it is not surprising to note the hillocks of salt around each nostril on these animals as the nasal salt glands dump their concentrated load at the surface.

Tropidurus is not frightened in the normal way, though it is frightened. It resolutely refuses to seek shelter under rocks or deep in crevices, of which there are a vast number in its area. Instead it is often found spread-eagled flat on some lava surface many feet or yards from a crevice or other shelter. When pursued it allows approach within a few feet and then skitters rather slowly away, hopping over cracks and crevices. Finally it will often retreat to broad lava cracks many inches in width, and there it feels safe. On the surface I have never met a more noose-shy lizard. They simply do not want that string around their neck and turn away time and time again, but in the lava crack their wariness subsides and they usually can be noosed forthwith. They never seem to nip at the noose as so many iguanid insect feeders do, but simply turn away.

All this makes one wonder about what all this tameness of island animals means. They are afraid, but in the context of their milieu. The fish in ponds or the sea are as wary as any, the penguins in the water are wary, and I have never met warier porpoises.

On land it is graded wariness attuned to the local situation. Every animal still has its escape distance but it may be vastly different than those we are used to. The safety of the large lava crack may be quite enough to dissuade the only obvious predator the lizard may have—the Galapagos hawk, a bird with a 4-foot wingspan that would have no hope of extracting a lizard from a crack. How the lizard deals with the snake I am not sure.

The lizards were dark and cool in the morning. By lunchtime the sun had made fitfull attempts to break through and some lizards had achieved temperatures in the low 30's. They had begun to assume bright daytime coloration by that time, and by late afternoon all were lighter than in the morning.

After a snack in the little tent with Ed and Fred during which meal we were accompanied by the camp mockingbird begging for crumbs (which she received aplenty), I ventured inland to see what the lizards there were finding to eat. Much to my surprise I found that when the lava flow had poured into the sea it had cracked and heaved, leaving long fissures and even valleys that led inland almost ½ mile, dotted with ponds, and fissures with clear standing sea water in them deep below the hot surface. Everywhere were crabs, far from the sea. Crabs could be seen clinging to the walls of the narrow crevices, red shapes in the murk. As one would expect under such circumstances the lizards ate crabs. Some of the ponds were staganating though, and a variety of insect larvae grew in them, plus other minute animals that the lizards picked up, probably as they patrolled the shore. Never were lizards found far from such water. The rolling pahoe-hoe lava fields were barren of all life except grasshoppers, a few tufts of grass, and a species of cereus cactus with bright yellow-tipped branches.

In the deepest recess of this strange world of dry lava and salt water I came upon a big pond with a single sea lion in it, wallowing happily back and forth barking at the warm water and muddy bottom over which he slid in obvious delight. How he got in or how he would get out I did not solve.

Very nearby I topped a lava hummock like a loaf of good french bread, all cracked at the top and smooth on the sides, and came upon a lava bubble filled with absolutely clear water. A green alga had grown on the bottom and it looked for all the world like a hot spring pond out of Yellowstone Park, only it was cool. Some of these ponds are literally teeming with fish, including some of considerable size—like the 5-lb. snapper I saw in one.

Hot and tired I returned to camp where we were picked up and brought back to the *Helix*. Its water hours on board now so I had to do my laundry by hand. That and getting ready for tomorrow (I go after sounds from the Bryde's whale again) kept me busy till note and bed time.

November 24, 1967

At anchor, Punta Espinosa, Fernandina Island, Galapagos

This morning I wanted to check up on the funny popping sound I recorded from the little baleen whale. I have been suspicious that it might be false and due to some instrumental difficulty, and in addition have felt the necessity of recording it 3 or 4 times in the presence of the whale to be sure he made it. So, after breakfast I put my miscellaneous electronic gear in the whaler and went over to Fritz and Carmen's boat, *Nixie*. They were tucked back in a beautiful little corner of the anchorage—clear jade water set about by the jaggedest rocks imaginable. Soon we were underway and past the

Helix. Before we were a mile off the anchorage Carmen called to me that she thought the *Helix* was afire. Sure enough, smoke billowed from someplace on the midships deck. We watched for some time and it finally subsided so I felt it safe to go on. Later on it turned out that Joe the cook had been cooking fudge and it caught fire, and I gather smoke was pouring from the portholes but no damage was done.

Not a mile further on we came to a huge school of *Tursiops*. I estimate that there were 200 animals, but that is no better than a wild guess, they were spread over so much seascape. Once the hydrophone was in the water I could hear a bewildering array of clicks, squawks and whistles, a constant din. Several adults and young were in the school and when these passed by the squawk or bark signals were especially often heard. One baby was very nearly newborn. I could still see the light vertical creases of its fetal folding pattern. Much to my surprise this pair ran the bow for some time. One old dark adult came up under the bow with a sprig of sargassum in his jaws. He held it as long as we saw him, which was perhaps 15 minutes. These porpoises look and act like ours at home. The only difference I could see was that the pattern on the heads of these animals was not so well differentiated into lines and striping as ours. It is more a simple dorsal dark area sweeping forward onto the snout, with lighter skin below.

We left the school and proceeded out along the north shore of Fernandina (Narborough) and finally came upon a small baleen whale. Its tall slim blow looks for all the world like that of the fin whale. When the listening gear was put in the water there was the pup pup pup sound sure enough. I was naturally elated, though when it began to fade as we drifted to a halt I became suspicious and then when the whale surfaced very close aboard three times and I heard nothing I doubted even more. Finally, after listening to another whale with the same experiences I ran out into open untenanted water and then repeated the sequence. Pup pups at first, then none. When I suggested it had to do with slowing, Carmen suggested cutting the floats free, which Fritz did and the pup pups disappeared. The floats had been tapping lightly on the cable as both streamed aft near the surface. When we slowed, the cable sank and could no longer touch the floats. Well, the literature is spared another prime example of *Balaenoptera instrumentalis*. After a nice lunch aboard we went back and I boarded the *Helix* preparatory to going ashore to spend the night with Fred and Ed. I snatched Ed's rum bottle, a cot, a blanket, and some food, and other gear and headed for the beach.

After spending the afternoon watching *Tropidurus* feed (they do a lot of things from snapping at the outer segment of medium-sized crab's legs to picking parasites from marine iguanas, to catching flies, to stalking gnats in the intertidal zone), we came back to camp and settled down in the gathering dusk to make camp. In front of the little shelter Eddie had set up a hobo billy can and had a nice fire going. He and Fred had bashed a lot of crabs and we dumped them in three at a time, boiled them for about 10 minutes, and pulled them steaming from the water to eat. They are delicious and have quite a lot of meat especially at the bases of the legs. Lo and behold they have a black pigmented membrane under the carapace, especially dark over the gills. Eddie had to try iguana so we did one in and I surrendered up my monopod as a spit. It took forever for him to cook. When he was done he didn't taste bad but he was mighty tough. There must be better ways of cooking them. We broke out Eddie's rum bottle and mixed up some passable frou-frous.

Before long the world was looking bright and we decided it was time to investigate the nighttime activity of marine iguanas. The first batch we came to was huddled into a few widely spaced groups. These grounds were sometimes several iguanas deep. I crept up on them with a thermistor lead in one hand and was able to insert it under them. Only when the light shone on me did the iguanas stir at such familiarity. Otherwise they just lay there and let me push the temperature sensor under them. The piling behavior does keep them warmer—by as much as 5 degrees.

Some of the piles were spectacular—iguanas heading in to the center like spokes of a wheel. One group we looked at was back in the center of a mangrove thicket and I had some fun clawing my way through it to take the temperature—receiving as I did, appropriate comments from my colleagues. I won retribution though by coming upon a penguin and telling them I was going to get its temperature. It sidled down toward the sea and when just over the edge of the rock where they could see its head but not its feet, I pretended to push in the thermistor, which actually was in my mouth. My, my, such comments on my stalwart nature and the height of the reading—some 35.6 deg. C. as I recall.

Such creepery is an acquired taste. Iguanas are vegetarians and their houses are not neat. So, “dusting” myself off we returned to camp. I placed my cot out behind the little shelter tent while Fred and Ed snuck inside and rolled up in their blankets. I had no more than snoozed off to sleep when I heard a loud “That’s it, that’s enough!”, and out stormed Fred, grumbling. It seems that they thought there were grapsis crabs in the tent but when Eddie turned on the light there was a rat sitting on Fred’s chest. So they started up the little generator and hoped that the light would keep the rats at bay (it did), but it made something of a racket.

I lay there looking at the sky—the sun had disappeared in a blaze of glory lighting up the great volcanoes across the bay in colored “last light.” We had luxuriated watching the sea lions play below us, the boobies dive, and the frigate birds swoop and soar over our little domain. Now I could see that the ecliptic was almost straight ahead (actually we are in the southern hemisphere by a few kilometers). Finally I drifted off. Toward morning the wind blustered through camp flapping the tent and cooling my cot and my lower portions to such an extent that I had to take action. Finally I moved the cot over in the shelter of some mangroves and slept peacefully thereafter.

November 25, 1967

Punta Espinosa, Galapagos Islands, Ecuador

Dawn woke us as it is wont to do in outdoor camps. Fred presented me with a steaming cup of coffee, cooked on a funny little immersion heater he hooks to his generator. Without further ado I went off looking for *Tropidurus*. I found them marching by me toward the intertidal zone. They spend the night inland somewhere, probably in crevices or under rocks and after an initial warming period move toward the intertidal. One animal went right through camp and laterally along the intertidal for some 100 ft. to a marine iguana colony. I found the lizard picking parasites from the big lumbering iguanas who passively allowed this servicing to go on. Much of my day was spent trying to understand display in this animal. The females have aggressive patterns as do the adult males. Both lower dewlaps (neither very far) both compress laterally and both nip and intimidate. There seems to be grades of females, some more aggressive than others. The

brightest colored ones are the nastiest, and size means rather little. One nasty female not only took on her own kind but attacked males twice her size as well. When examined internally I could not be sure of her sex. Her pattern is female, she has no hemipenes and no epididymi, but has only one "ova" per side and that looks for all the world like a testis.

I tied this female to a string and lowered her into other lizard's territories to find these things. I also lowered her near a *Dromicus* (the island snake) and it struck at her but she was too quick and leapt across the crevice in a lightning movement.

Fritz brought us a bucket full of lunch—hot grouper fillets, sweet bread, crackers and some kind of juice. We enjoyed it under the welcome shade of a mangrove tree, since the day had grown hot.

The wind rose, and with it the swell. Great white rolling and curving breakers crashed on rocks off the point, their crests blown into skipping spume trails. Eddie and I went out to the outermost point. I photographed while he walked through iguana rookeries. The swath free of iguanas was left behind him temporarily and on one point he walked rather near the edge of the cliff. The iguanas on that side piled up in squirming piles. Twice these piles of perhaps 20 animals got out of equilibrium and literally dripped over the edge and fell into the water. Eddie has been flying models over the colonies and finds the young and females much more frightened than the adult males—at least they run for cover when his cardboard "hawk" goes over.

Back on board Eddie and I decided to go fishing at dusk and took the whaler out. We hadn't trolled more than a few moments when both of us hooked up—I caught a nice barracuda and Eddie a grouper. Closer to shore the fishing was even better. In rough water near the point where I had to watch constantly for both rocks and the huge breakers just beyond we caught a fish every two minutes. We came back with 24 fish, mostly small groupers, just as the last light disappeared. We are freezing them to take home in the freezer down below. We now have quite a collection of fish.

Tomorrow I try to solve the mystery of the sex of *Tropidurus*. Perhaps they have already solved it, I don't know.

November 26, 1967

At anchor, Punta Espinosa, Fernandina Island, Galapagos

As soon as possible after breakfast I loaded my gear into the whaler and left for shore. Unfortunately the Ecuadorian guard, Luis Olayo, chose this morning to go ashore so I will have to be circumspect about gathering data on the internal workings of lizards. Once there I set out alone with my gear and walked rapidly around the shore to a rocky promontory that juts out into Espinosa Bay. I began gathering data, watching carefully to see if I could learn to interpret color and pattern and sex in these animals. I could not. There are no distinct pattern phases, one that is associated with adult males in general—a barred and spotted phase with rose ventrally and a white chin and black throat. All well and good, but in the smaller lizards females and immature males are all mixed up. Females are brilliantly colored, especially gravid females. They have a shiny ventral surface of salmon red color, a red chin and throat, and gravid females have salmon cheeks and eyelids. Also all well and good. But, in some of the larger lizards carrying this color I found testes. These were still small by adult male standards (70 mm SVL vs. 100+ mm SVL) but larger than gravid females (55-65 mm SVL). I found two lizards that seemed to have both ova and very small testes. They were salmon colored. In two cases I

found lizards that were losing the salmon color—one had it just in patches on the snout and the other on the snout, throat, and anterior abdomen. Elsewhere rose color prevailed. I found one animal with perfect male color and pattern at 75 mm SVL, the smallest I found. Other smaller lizards were all females. All in all it looks as if there is a sex reversal here. There is also a geographic distribution of sexes. Adult males are only found where there is close access to water or shore regularly altered by the tide. Inland farther I found mostly females or young. Inland I also found most gravid animals. The young males in the process of changing were found either inland or in one or two cases, on the beach. At any rate, once maturity is reached for males they occupy favored habitats.

My walk took me over miles of rough lava and I was very tired by 1:30 when I arrived back in camp for lunch. I repaired to a sheltered spot under a mangrove and spread out my meal, watching the iguanas graze with their peculiar sideways swipes of the head. Their lateral teeth are slanted outward and are hoe shaped, allowing efficient scraping. They crop algae both in and out of water. On shore one can see how closely they can graze to the rock surface. It is within a few millimeters at most, including fairly rough lava surfaces. Efficient beasts.

The afternoon was spent in another hike, this one hotter than the other. I learned a few new things but in general confirmed the idea that these lizards have at least some animals develop into mature females who lay eggs and then transform into males. There is every stage of female development here, and not related to size either. There are females with tiny ova, females with large eggs in the shelled condition and everything in between. This is typical of the equator where the day length cue is absent and where water temperature is of no consequence, as it is for the amphibious marine iguana. The latter beast has a definite mating and egg laying season, which must be cued to the annual shift in water temperature. In a month or so they will be swimming in much warmer water and the rains will be with the Galapagos.

I came back into camp with a lot of pickled lizards in one jar and some live ones in another. It was some task keeping Olayo from seeing them, but I made it safely. I'm not sure he would object, but he legally could, has a great big gun in his stateroom, and could cause all sorts of trouble. So things are being kept under wraps for the nonce.

Back at the *Helix*, Eddie, Al the electrician, and I went out for grouper and came back with about 30 fish. It was much calmer than last night and I enjoyed a lovely sunset over Fernandina Island with boobie birds flying gracefully by like black cut-outs against the fading light.

The news onboard is that the record Malcolm is setting is still intact. He has still tested only fish that live in California. Two more days to go.

November 26 [?], 1967

Trawling in Bahia Banks, Galapagos Islands, Ecuador

A day spent breaking lava rock with my feet!! After breakfast the *Alpha Helix* got underway along the north shore of Fernandina. John Teal, Fred Carey, and I were dropped off to take a hike to an inland cinder cone where we hoped to find land iguanas. Tony took us inshore in the whaler looking for a spot to drop us. The shore is an abrupt jagged black lava bluff along this coast. Swells surged in welling over the top of offshore rocks and breaking on promontories in a boiling mass of white. Shortly we located a

little point of rock with a vertical lee wall. With the skiff alongside it was simple enough to hop onto the rock as the water rose. After a scramble up the 100-ft. cliff we draped our orange life jackets on a prominent pinnacle both so we could see where to come back to and so the *Helix* would know where we went ashore. They were scheduled to return at 4:00 PM. I emptied out some of the excess gear from my backpack—a spare canteen, some juice, a light, and some clothing. Then off we went toward the cone some two miles distant across the undulating lava field that sweeps up toward the crest of Fernandina about 15 miles away. In front of us lay a jumbled mass of rounded, smooth, pahoehoe lava, broken and tilted pieces everywhere, and just to the east of us an incredibly jagged recent lava flow—almost impassable. Lo and behold, within minutes we came upon a lava tube whose roof was periodically broken into little sinkholes, usually filled with vegetation and soil, and otherwise a very smooth, domed street, about as wide as a two-lane road. It led directly toward our cone, to be sure in a somewhat circuitous fashion, but we felt that it was following contours and not wasting our energy. The likeness to a street was greatly enhanced by the jagged tiled blocks and fragments that made up the terrain on either side of us. I made some such comment to Carey and Teal as, “Well, the least the Ecuadorian government could do would be to paint a center line in their streets” when one appeared. It was accurately central and it was lighter and about the width of a normal painted line. I looked closely at it and determined it had something to do with the layering of rocks around a lava tube that reached the surface along the top of the dome-shaped tube.

We ambled happily along, looking at the low vegetation about 3 ft. high that I think maybe a variety of *Scalesia*, the Galapagos endemic that flourishes in the high country of the islands. We had noted large tail tracks in the patches of soil along the trail, and we had seen some large burrows and scats that seemed to be from the land iguana, and then suddenly, right in the middle of one of the collapsed parts of the tube stood one. I wasn't prepared for him since the only other one I had seen was at Academy Bay. It was dark gray, and other than having a salmon-colored eye, was drab. This beast was about the size of a fox terrier—perhaps 5 lbs. in weight—and maroon over the abdomen and tail and his head was a bright yellow. He stood up in surprise at our intrusion of his home but did not flee until we approached within about 3 ft. Then he rumbled away with the widespread limbs of the reptilian gait, like some impossible creature out of a bad movie about the cave men. He stopped, bobbed in a grotesque limber-necked bob, jowels jiggling. Finally after some impositions upon his good nature he retreated under a tiled mass of lava sheets. Like a good Galapagos animal should, he left his tail out, so I extracted him, being very careful not to get within range of his very powerful jaws. His head is a mass of knobby excrescences, probably used during territorial battles. Finally, we released him, happy to have seen this creature that is reported to be so near to the verge of extinction. Reports are that only a few colonies exist and those of a few animals each.

On up the slope we went and finally our “roadway” gave out at the edge of an overlying lava field. We would have to cross it. It is difficult to describe adequately the impassable nature of these flows. One simply could not cross one of any great extent, without long and tedious, wearing effort. We had to traverse perhaps 500 yards of sharp cindery slag, loose pieces ranging from pea size to ones weighing 500 lbs., each tilted against the others at crazy angles and most in delicate states of equilibrium. Pinnacles of

jagged sharp knobs and spikes rose up everywhere. A footstep usually rearranged some pile of rock, some broken and other pieces tumbled into airspaces hidden from view. Shoes got wedged and had to be pulled free, sharp points sliced at soles and shoes, and sometimes higher. As often as not one had to brace for a step with a hand and there was no place one could put a hand that would bear weight without cutting or simply pain. We finally made it across, reaching an undulating mass of rounded lava bubbles and tubes. This was easier walking, especially since interspersed among the lava were stretches of soil and vegetation. The rock was dangerous walking too, as it was difficult to tell when underfoot lay a tube inches away. Several times my feet crunched through and it was all I could do to keep from falling.

The sun came out and we welcomed the nice sea breeze that swept the slope in periodic gusts. Even it was relatively warm this far inland and I began to sweat pretty heavily. I hate to think of what it would be like on a really hot day. I hauled out my canteen and was chagrined to find that it leaked. It was only about half full, but we enjoyed a good drink and pressed on toward the cinder cone ½ mile ahead. Palo santo trees made their appearance—strange leafless trees with a smooth white trunk, usually 10-15 ft. tall, plus a spreadig mass of obese-looking branches and twigs. Even bare they cast some shade and were welcome when we stopped. They also formed the resting places of the land iguanas (*Conolophus*), who at this time of day (12 noon) were seeking shade. We saw several, and the entire terrain, save the lava flow, was a mass of tracks and burrows and scats. I cannot believe that there is not a large population over quite a part of Fernandina.

The little lava lizard, *Tropidurus*, was present as far up the slope as we hiked. I noted two things of interest about it. First, in general, individuals were very much smaller than those living on the beach. Males with crests were no more than ½ size of those down at Punta Espinosa. Then, more interesting still, while those from Punta Espinosa were very brightly colored with salmon and pink, these animals were almost devoid of either—the merest hint of pink appeared on the abdomens and chins of adults. I think this is probably because these lizards cannot eat crabs and that the pigment comes from the food. The size problem is more perplexing but surely must be related somehow to available food. One normally thinks of animals as having an “adult size” but here it may be flexible to fit the conditions of the environment.

On we went. The trees became thicker and we could see that farther up the slope they formed a real if open forest over the old lava flow slopes. New lava is devoid of all life except lichens and an occasional spider spinning a web hopefully between barren craggy pinnacles.

Finally we reached the crater. It has a series of vents on the downward slope that must have poured rivers of lava at one time. Now they are empty chasms of red and violet lava, running underground into darkness in a couple of cases. One is a pit of undetermined depth. I could see down perhaps 50 ft. when darkness obscured the rest of the tunnel.

The crater itself is about 500 ft. across and on its rim we saw the first aborescent cereus cactus of the walk, a scraggly looking plant with jointed stems rising some 25 ft. from the very rim of the crater. Shortly after descending we ate our lunch in the company of a big land iguana, all of us basking in the sea breeze funnelled in between the crater and the adjacent slope. We decided to go a little farther into the palo santo forest before

turning back. I gathered the delightfully aromatic gum to take home. It must be much like copal gum used by the maya (or was it the mixtecs?) and the material thrown into Chitzen Itza with the maidens. It is probably also close to myrrh for which the ancients expended so much. At any rate a few trees were found from which the amber yellow sap had run and collected in big globs and hardened. I smell of the stuff now myself, enough to cause comment at dinner.

I sat on a smooth lava slope to watch the behavior of a big iguana while the others hiked on, looking at birds (many Darwin's finches and a few Galapagos mockingbirds and one Galapagos hawk). Iguana-watching must be closely akin to studying the habits of sleeping Mexicans. My animal did two things in half an hour. He moved his head from right to left and he flipped his tail out of the sun when the sunny spot next to him moved with the advancing day.

We started back shortly thereafter to meet the boat at 4:00 PM. Downhill is almost worse than uphill as cracking rocks happen more often as you step heavily upon them. I couldn't find the highway and instead walked to a big dune on the beach adjacent to our orange life-jackets. Enroute I encountered a few more iguanas—probably about 15 for the day, but signs literally everywhere, even the crater rim. I really do not think they are on the verge of extinction, though I must admit I saw nothing but adults. Not even a $\frac{3}{4}$ grown. Each was encountered alone, and usually some distance from the next animal.

Back at the bluff we all collapsed and drank some apple juice and nice cool drafts of water from the canteen. Then we slid down the sandy slope to the bluff edge and waited for the boat. It was a delightful spot, filled as I was, with pleasure at lying motionless on my jacket in the cool sea breeze. Below us was the green sea crashing on the rocky coast. A squadron of 6 penguins cavorted below us. They periodically ducked under and rocketed off like tiny torpedos. Their maneuverability and speed under water are well nigh astounding. We came to feel that they had two sectors to watch—above and below water and that periodically they felt it necessary to sashay around below the surface. They followed some bait that went by, with sooty terns above—a very dark gray form with the merest hint of white on its head—and penguins below. After a submersion the penguins pop up to the surface as if quite buoyant.

Marine iguanas were plastered over the rocks in front of us, the males huffing and puffing at each other. Several flights of boobies went by in formation. I hadn't really realized how graceful they are—but they are pursuit planes of the bird world, graceful, swift. I got a pretty good fix on one diving. He began his dive at bluff top, which we estimate to be about 100 ft. I know I have seen them start higher.

Finally the *Helix* steamed into view and we boarded without incident. It was delightful to get a shower and a drink of cold water. Fred and John produced three huge bottles of Panamanian beer which we cooled and swizzled down with great joy. Now we are trawling in Banks Bay and have just hauled up a scorpaenid fish that has been seen only once previously—that on the Albatross Expedition in the later 1800s.

I'll quit. Tomorrow I try to identify the baleen whale and collect a few samples ashore for chemical analysis.

November 27, 1967

At anchor, Tagus Cove, Isabela Island, Galapagos Islands

This morning I had intended to spend the day first in trying to identify the small whale and then in the afternoon finishing up on observations on *Tropidurus* and in collecting some of the grapsid crabs for analysis of the carotenoid pigments in them. This I hope, will allow me to say something about the source of color in the coastal lizard populations, and its absence in the ones from the uplands.

But, all was not to go that way. No sooner had we put the shore parties ashore (Malcolm and his crew are going ashore for their first time, having spent the entire remainder of the trip in analysis of fish muscle on board. How they could come to the Galapagos and do this is a mystery to me.) than we spotted a school of bottlenose porpoises. They soon ran the bow and Tony fired a harpoon into one. Soon we were off in the skiff with the animal towing us, about 300 ft. of 1/2-in. manila, a 50-gallon drum, and the whaler. This went on for three hours, and each time we thought the animal might be tiring it proved not true. We pulled ourselves laboriously up the line till we reached the thin, braided nylon line which was almost impossible to handle with bare hands and a plunging porpoise at the other end. The sun beat down, our arms and legs and backs grew weary, and still he plunged on. Finally I suggested trying to dispatch him with a .357 magnum pistol that we had for the purpose. I fired twice, feeling sure I had hit him once, but still he went on. Then we cut him loose on the buoy and speeded up close and tried again. I could see him flinch as I fired, but still he went on. We had to return to the ship for more shells and a new pair of gloves. On and on. We had passed Punta Espinosa three times at about 2 knots. Finally I got very close and shot. This time I was sure of a hit as the animal rolled over in a paroxysm and died. Whew. The harpoon had hit a rib and glanced out the superficial blubber. We had him by the skin and little more. The harpoon was nearly broken loose. I spent the rest of the day preparing him, measuring and flensing. Meanwhile we tried to find whales but did not succeed.

All is now preparation for leaving. Gear is being gathered together for storage, lashed down and rearranged. The Angemeyers came aboard and we watched a long film together, and then they left in their little cocklesheel boat into the darkness. We watched the dim lights turn on in the *Nixie* and then went below. Fine people. They will go to Quito for Christmas. I imagine that one or more of us will return one day to sail with them, who knows.

November 28, 1967

Before noon the *Alpha Helix* upped anchor and stood out into a windy Bolivar Channel. By the time we had rounded Webb Cove at the southwest corner of Isabela, a big sea swell topped by tumbling whitecaps hit us. Bob Sahara got sick first and the others of us more or less followed suite, at least to the level of feeling mean. Before very long the ship changed course and ran the southern shore of the island and finally, late at night, fell into more or less of a lee. We woke in the morning off Wreck Bay.

November 29, 1967

At sea, enroute Panama

Papers were surprisingly easily cleared up with the local officials. Olayo went ashore burdened down with gifts from us, alarm clocks he had bought, jugs of ice cream, and nameless blobs of meat that he had talked Joe out of. A nice, simple fellow, who will

be content with his family and a job in the cattle ranch on San Cristobal or work as a fisherman, after his three-year hitch in the Ecuadorian Navy is over. Once out in the channel I brought my lizards out and gave them air. The *Helix* rolls quite a lot but is much more comfortable with the sea on our quarter. A pool was set up for speed to Panama. I'm guessing 10.22 knots.

Ed and I set up the porpoise watch again—not a beast seen. Birds, even, are rather uncommon. We crossed the equator today and after leaving the northern parts of the Peru Current the sea began to warm. The sky is eternally overcast it seems, but it does abate the heat.

November 30, 1967 (or is it Dec. 1)

At sea, enroute Panama

Nothing today but moderate seas and trades. The weather is better and the swell less so we feel better. There are even very few birds. The sky has been overcast all day.

December 2, 1967

At sea, enroute Panama

Late this afternoon we saw a whale spout several times far out in this lonely ocean. Nothing else but scattered birds. What a long way between animals!!

December 3, 1967

At sea, enroute to Panama

Early this morning the land of Punta Mala was sighted and all day we have been passing debris in the water including whole trees. Birds are much more abundant including a couple of pomerain jaegers that have flown with us nearly all day for some unfathomable reason. About noon we began to sight sea snakes—one every few minutes floating on the sea surface. As we pulled adjacent to Punta Mala about 5 miles out a school of “spotter” porpoises came alongside and ran the bow—beautiful big stenellas—all flecked with white dorsally—some to the extent that the spots coalesce into broken chevrons and other pattern varieties. Among the school were some smaller animals with similar proportions and pattern except that they were brown without spots. These, I think, are immatures, since I saw one nearly as large as the spotted individuals with a few spots dorsally. At Punta Mala the pool was figured out—I had 10.22 knots and 10.25 won, believe it or not a guy had that number exactly Oh well, my record is still pure.

After settling the pool we slowed to about 5 knots so as to make our ETA at 3:00 A.M. Then Eddie and Terry were able to dipnet snakes—a thing dear to their hearts. Soon they had four bright-black and orange-yellow animals with oar-like spotted tails, black backs, and orange venters (*Pelamis platurus*). They were utterly incapable of crawling out of water, their deep ventrally keeled bodies not able or adjusted to making purchase on solid objects. They bit the snake bag each chance they got and hung on with bull dog tenacity. I'll not get too close though we did find that they can't rear up when picked up by the tail.

A few more porpoises, snakes, and then dusk over the shining gray sea under a blanket of clouds.

June-October 1968

South America Trip

June 24, 1968

Mexico City, Mexico

Norris packed up 16 assorted suitcases, plus a handbag each, filling Francis's car and Joan Wright's. We were 140 lbs. overweight but had chits for 240, so, with the plane flying at an angle to the horizontal, we cruised over the Gulf, looked down on Angel de la Guarda Island where Eddie and Rob Shallenberger were camped, over Mazatlan and thence over clouds to Mexico City. It was raining when we landed.

We successfully checked several bags, including the heavy book box (we are carrying everything as we can't trust Chilean customs). Shortly we were stuffed into an Avis car and left out to brave Mexican traffic—not as bad as Rome's—but bad enough, the old chicken game with no white lines or road signs. After about two hours we found our hotel on the Paseo de la Reforma—the Hotel Montego. Very nice—all hewn beams, tile, and carved wood furniture. Everyone was tired and perhaps a little shaken by the ride and glad to spread out bags and set a spell before dinner. Shortly we all rode up to the Cinto Piso for dinner. Except for Nancy, the kids ordered hamburgers and found the spiced and chopped meat not to their liking at all. The peaches for dessert were the same and by the time we ordered ice cream they were too tired to eat. Off to bed, for tomorrow we hike to Chapultepec Park and drive to the floating garden.

June 25, 1968

Mexico City, Mexico

After some dawdling around we trooped into breakfast which, because there were scrambled eggs, pancakes, french toast, and other E.W.A. goodies, was reckoned by the children as a grand restaurant. Afterward we walked through the rain to Chapultepec Park, a grand swath of trees and children's areas, etc. The Paseo de la Reforma is a lovely boulevard too—tree-lined, red tile walks being put in for the Olympiad, lots of traffic, smart shops, rococo sculpture of generals (none on horses so far as I could determine), amazons, and such.

In the park we visited the Museo Anthropologia, a magnificently architected building in the form of a closed square. The quadrangle actually is overhung by an enormous flaring roof supported by a single dark stone column. The roof is said to cover 2/3 a football field in area. The buildings take their motif from Aztec and Mayan temples being of tightly morticed stone.

Inside is a magnificent display of artifacts, from the very earliest times on. We walked and walked and everyone got very tired, so after a nice lunch in the bright, airy museum café we caught a cab (a new experience) for the hotel.

The kids rested while Phylly and I walked uptown. It is a teeming, cosmopolitan place with much European influence. I like it and would like to return for a longer stay. In the evening we walked to a very American restaurant (Shirley Courts) and had a very American and rather so-so meal, but the kids were reasonably pleased except Nancy who was served breast instead of legs of chicken. Back to the hotel. Tomorrow a drive to the pyramids.

The altitude and the traveling tire the kids so we are at about ½ speed.

June 26, 1968

Mexico City, Mexico

The great hamburger hunt is in full fig. Everywhere we go we look for hamburgers—plain, no mayonaisa, no tomates, no lechuga—only a bun and meat and french fries if possible. The Hotel Montejo is off limits because they put cereal and spices in their meat, the Restaurante Teotihuacan is off limits because they put sauce on their fish. Only the Shirley Court and the VIP restaurant qualify as edible. All the while Phylly and I year for food of the country. Oh well, another time, I'm too weak to fight.

Up this morning with Susie feeling a bit woozy and tired. I gave her a pill (for minor bellyaches) and after breakfast we hiked around the local shops. I turned briefly without peripheral vision and people divided into two pieces but this nearly passed by the time we returned [?]. We looked at all kinds of goodies, especially for a blue or a gold purse for Phyl which we did not find. We trooped down to our waiting car and it failed to start. It failed and failed and failed. All the wisdom in the parking lot failed to start it. (This wisdom almost failed to get the air cleaner back on as well). Finally I found a knob sticking out and pushed it in. The car purred to life miraculously—it was the choke disguised as an air vent knob. I quietly accepted the miracle, tipped the magician, called the family from the lobby (and nearby johns), and drove out into the hurly burly of Distrito Federal traffic. We made our way circuitously out Hwy 85 to the north of town. Shortly we rode into farmlands, cornfields, maguey patches, little shanties that the children could hardly believe housed whole families, even though they stood in the muddy doorsills and their laundry was strung outside.

The road lifted up to a new toll road and shortly we came to Teotihuacan—a ramshackle farm town of Aztec people I am told still speaking Naujuatl, the Aztec language. Just beyond were the grand remnants of a 2,500 year old civilization—two huge tiered pyramids (of moon and sun) and many outlying buildings and canals.

The kids left the car, stooping over. Norrises all seem to have their eyes on the ground—this time looking for obsidian flakes and potshards (both abundant). The obsidian blades flaked from a cylindrical core are everywhere—all broken.

After stoking up on pounds of these goodies (will we ever make it to Chile?), all fled to the nearby rows of shops and emerged little scathed, visited the small museum and walked out into the Cierdadella—a group of low pyramids and patios alongside the Canal de los Muertos which runs down the center of this ruin for more than a mile. Its name comes from the many skeletons found during its excavation.

All picked up potshards—black ones, red and orange ones, ones with some kind of glaze, and ones with incised patterns. Before we reached the pyramid of the sun the showers swept over the broad valley and us. We hot-footed it back to the museum and had lunch at the nice restaurant above. Dicky didn't like the sauce on his fish and therefore had to share other people's roast beef (from which the gravy was carefully scraped).

After this we drove around to the pyramid of the sun, a great tiered mound, faced with stone. Up the steps we went to the top (except Phylly who puffed to the first tier). The top proved higher than the bottom and to have a slightly better view. It rained again and I got wet as my coat was pressed into the service of Susie (who has a beastly cold).

The temple of the moon was next—at least the priestly outbuildings that are being restored. Frescoes of red paint were everywhere as were carved columns, symbols of planets, and wind.

On back to town more directly and a brief but highly accepted meal at the VIP.

June 27, 1968
Guatemala City

Up this morning with visions of a leisurely look at downtown Mexico City and a drive to the airport! After breakfast (and a copy of the *L.A. Times*—the world seems to be holding together fitfully), we caught a cab for the Alameda district. Downtown is a bit busier, smokier, older, and more tawdry than the district of the Montego Hotel—even though our guidebook says it is the “pink light” district. Barbara bought a glass cat and a glass chipmunk so small I could scarcely focus on them—1.50 pesos each.

We poked around various stores for a while, looking at brass bedsteads, stuffed boa constrictors, and such. We jumped in a very scruffy cab with a very scruffy driver and soon were back at the hotel where I called the airport and found to my horror that the plane left an hour early. We rushed—paid the bill, packed the bags, fidgeted while the car didn’t come, sat Barbie and Dick on a suitcase, the back being full, and braved the way out into about the worst traffic we had encountered yet. It seemed forever before we got around the block to the Montego again. Out in the Paseo de la Reforma we crept and crept. I became a bit acclimated to traffic and even buffaloed a few Mexicans in my desperation. One never knows what street is next as there is never a sign. The local folk all agree when you say, “Is this Avenida Consulado?” and it turns out to be Avenida Juarez. Finally, by luck and seat-of-the-pants navigation we found the airport, missed a miniscule turn, and got trapped on a throughway that took us nearly back to the Montego before we could get off! We had half an hour to plane time and no lunch.

Finally we screeched up in front of the terminal. I sent Phylly off to cope with Pan Am (a rough job at best) while I turned the car in. Somehow we retrieved our checked luggage, had passports cleared, and made it out to the plane. Praises be—even though it was only an hour and a half flight we were to be fed. We all sank into our seats, only to find that I had been assigned a space with no seat over the emergency slide. The plane, after all, was Pan Am. As we took off we skimmed over the valley of Mexico covered with broken clouds. Popocatepetl reared its majestic fluted head, covered with streamers of snow, part way out of a cloud.

The meal was good and the flight calm. Below us we saw the low isthmus of Tehauntepec and Yucatan stretching away to the east, obscured largely by clouds. The broken hilly country of Guatemala came quickly and soon we landed in a light rain at Guatemala airport. After the outdoor exercise of dealing with our mountain of luggage through customs we caught a cab with a nice driver who told us about the aqueduct built by Alosnaz in the mid 1500’s—arches like those in Rome, the mini Eiffel tower dedicated to the Revolution back in the 1800’s when one president replaced another, etc.

Our driver stopped for pedestrians and other drivers—unheard of behavior in a driver in Mexico—we began to like Guatemala. The town has between ½ and 1 million people and is of varicolored stuccoed flat-roofed buildings, grated, narrow sidewalks, all kinds of people filing by, indians, suave businessmen in dark glasses, kids, beggars,

vendors of cactus candy, and many nameless lumps of food, nuns, little cars, wagons, trucks piled high . . .

A walk in the plaza, a shoeshine from a smiling little boy named Fernando, band-aids on Phylly's blistered feet, a look at the old tiered Spanish fountain, the Palacio Gobierno, the big church with bells clanging tinnily—pigeons on the sculptured door and back to our hotel. We had a fine meal of which everyone approved even though there was nary a hamburger. Great Scott. I had carne asada, Maya style with salsa picante, frijoles refritos (it looked awful—a blackish purple blob that looked like an error or someone sick in the kitchen—but good once I screwed up my courage to try it). Phylly and I had some kind of roots cooked like potatoes with a sauce—very good.

Off to bed. Tomorrow we drive to Chichicastenango and Lake Atitlan.

June 28, 1968

Up about 8, ate breakfast and signed up for a car. A Plymouth station wagon showed up, piloted by a trim Avis lady. Soon we were off toward what we hoped was Santo Tomas de Chichicastenango. Before we ever left Guatemala City we became enmeshed in a maze of roads without signs. After much palaver and retracing of steps we found we had been on the right road all along. However, not for long. Going blithely out of town, we passed an innocent, buff-colored sign about 2 ft. square and a dirt alleyway. They turned out to be the Pan American Hwy., while our broad paved road proved to go to San Raimundo, back in the hills, wherever that is. It was a lovely if circuitous drive through farm land and mixed conifer, cypress, and oak forest. We stopped twice above rushing muddy creeks cut far down in steep canyons. Diverse broad-leafed vegetation clothed the walls, ferns, labiates, melastomes, what look like nettles amongst many others. Up in the oaks were sometimes dense florals of bromeliads, intermixed with ferns and tree cactus. A racer with two dark stripes flowed off into the brush.

Periodically, we came to little towns, usually on hilltops. In each we were supposed to take a one-way street to the right—it took two towns before I caught on. The indian influence is strong here. Most of the campesinos were in indian garb, which is markedly regional. In most towns the plaza was occupied by squatter indians under cloth shelters, baskets of nameless roots, orange cooked objects like shrimps, wood, cloth, ollas, etc., spread out for barter. Streaming into town were men and women carrying items. The women walking in pairs, a twisted roll of bright purple or henna cloth on their heads surmounted by a burden—an olla at a crazy angle if empty, upright if full, laundry neatly wrapped in a bright cloth, and men and even small boys 8 years old or so, bearing great burdens of firewood, racks of ollas, sawn boards, etc., by a [?] line and leather forehead band, walking in little choppy steps. Many men dawdled along the road, machete always in hand, bearing huge skinny hoes for terracing and weeding. We saw them working plots that must have been nearly as steep as 45 degrees.

Finally we ended at a little sleepy pueblo and I stopped to ask a cobbler where the road led. He peered at me through his Benjamin Franklin glasses and explained I was already there—namely San Raimundo. We backtracked and finally cut off on a good graded road from San Juan near a shrine where the kids had found a lot of pottery and I had located a now apocryphal survey marker stating “Don't deface—International Hwy”.

Up over rolling hills we went—the air delightfully cool and breezy—thunderheads all around. At one point the kids found obviously old pottery and obsidian

in a road cut. Finally we dropped down a long forested slope and came into a little town from the back side—San Lucas. Soon we hit the “Carretera Nacional” as they call the Interamerican Hwy in these parts. It is a splendid 2-lane road with good markers and a center line of all progressive things.

Before long everyone was starving and no lunch in sight—so I drove into a village along the road, located the panaderia and bought an armload of pan dulce for 75 cents. We munched more or less happily but dryly until after cutting off at Panchull we stopped for gas and naranjas all around (gasevsas). The tasted like papaya juice and were warm but slaked various thirsts.

Our road took us up over mesas of carefully tended fields, through long alleys of cedars, through hamlets and villages and down long circuitous grades and up again. These were usually heavily forested with pines and oaks. Often in them we saw terraced gardens clinging to slopes, the terraces formed of walls of adobe bricks set on end in long rows. We passed several beautiful ranches or granjas set in forested glades with beautiful brick, plaster, and tiled houses.

In one village the women were carrying ollas on their heads as usual but 3 or 4 had garish ones of polyethylene plastic. I suppose the end of the olla is in sight. All the women gathered around the central Spanish fountain and held hollow bamboo poles up to the overflowing lip of the topmost tier on the fountain and let the water run into their ollas. Thus did they obtain a day’s supply of water for the house.

Finally after two hours or so the road led us up on the steep slope of a volcano and Lake Atitlan broke into view. The travel folders cannot exaggerate it hardly. It is set in a precipitous walled valley, cliffs in many places, and bounded on the NW by three nearly perfect volcanic cones of large size. Many of the slopes are tiered gardens—others mixed conifer forest. A few little villages sprinkled on verdant lava fans on the lake’s edge. The lake itself is clear blue and nearly 1,500 ft. deep in places. All around are clouds in white and gray billows—wisps of fog cling for moments to the cone tops, move away, and reappear.

We wound our way slowly down to a little village of Panajache above the lake and thence to the Tzan Tuyu Hotel, where we had sandwiches to sustain us on the way home. The girls were decked out in their new colorful Guatemalan shawls which we bought in the village. We watched the lightning flash in a storm caught between two volcanic cones and then were on our way again—up the winding road to the “Carretera Nacional”. Everywhere were indians walking on the road, hiking long distances up and down this precipitous land to their thatched huts. Many were drunk from some source, either staggering along across the road, shaking fists at the sky and muttering or being helped by others. One pitiful little boy sat beside an adult out cold on the ground near the road’s edge. No women were drunk—it apparently being a man’s privilege. I suspect pulque as the source, but it could have been a narcotic (it was corn beer).

One man flagged us down on a curve and when I saw he was drunk I drove on while he yelled imprecations at us and shook his fist.

The men were very uniformly dressed in purple-striped floppy pants which I coveted though it is unlikely that I could get into a pair, since the indians are nearly all small and wiry—5 ft. to 5 ft. 5 in. in height. Most had a rough brown and tan jacket around their waists, no shoes, a camisa like the pants, and a hat. Some had a long cotton

ribbon of red, purple, and yellow with patterns of birds and other objects wound around the head like a turban.

Finally we joined the highway and pressed for home. At times rain fell in sheets. I turned every knob on the dashboard looking for the windshield wiper—lights went on and off, wind came in and stopped, the car choked and purred, the back window went up and down, and finally I found the wipers and water squirter on the windshield. The warm concrete sent wispy clouds rising from the road so thick that they nearly obscured the road from view at times.

In San Lucas we flashed by an object lying at the edge of the road. I saw it was a man and swerved enough to stay clear by 3 ft. or so. I could see his head was actually on the road and his body off to the side—obviously drunk. Clearly no place to run over anyone.

Finally, after a long ride we arrived back at the hotel and quickly retired for the night.

June 29, 1968

Guatemala City, Guatemala

What adventures today? Who knows as we start but the day evolves and an almost endless kaleidoscope of impressions seems to result. The kids insisted on a ½ day moratorium on sightseeing in favor of swimming in the hotel pool. Phyl, Susie, and I watched while Barb, Dick, and Nancy cavorted in the pool. Back in the room the kids decided to take a rest so Phyl, Dick, and I took a walk to the big mercado, a few blocks away. We pushed our way down the crowded sidewalk under hundreds of varicolored signs vying for our attention.

Soon we came to the mercado and were surrounded by salesmen trying to sell wares. Phyl turned bargainer (thank goodness one of us can do it) and I joined in. What a deadpan uninterested team! We beat the tradefolk down to less than ½ for a shawl and some bedspreads! Imagine that! Whole undreamt of vistas open! We wandered into the main mercado—one of the most interesting I have ever seen. Hundreds of tiny shops under canvas with stalls filled with everything imaginable. Inside the great barn of the main mercado were similar stalls full of produce—meats—(cows parced into 800 fragments), fish from the lakes and rivers and even the sea (I saw sierra and mero, or seabass), robalo, periwinkles, cichlids of several kinds, catfish, turtles, etc. We asked all kinds of questions—learned about split acote wood for lighting the house, incense, yucca root, etc.

After lunch, amid general griping about relentless parental sightseeing, we piled into the car to go to Antigua, the ancient capital not only of Guatemala but much of Central America, and a center of Spanish culture.

Once in the car we rapidly left town—this time knowing the way and knowing how to deal with pedestrians and other local eccentricities of the highway. It was a lovely drive to Antigua, many of the roadcuts showed contacts between a 20-30 overburden of volcanic tuff (ash) and an underlying conglomerate. We could even see, in one place, where an ancient river cornice had been obliterated by this volcanic “snowfall”. Antigua soon appeared, nestled deep in a verdant valley between two huge volcanoes. This old town had been established with the first coming of the Spaniards in the earliest 1520’s. In 1541 a great eruption of Volcan Agua covered the old town with a

flood of mud and water, burying it. It was rebuilt on its present site only to be destroyed again in 1773 by a fiery eruption of Volcan Diablo to the east. This time many stone buildings stood, partly in ruins, and remain today. Some of old town has been excavated.

As we drove into town we were met by a young fellow on a bicycle who offered himself up as a tour guide. He seemed knowledgeable and pleasant so I piled his bicicleta in the station wagon for a tour. His name was Juan Jose Hernandez.

First we inspected an old convent, including a catacomb that had survived from the eruption of the water volcano. We crawled down into a domed crypt and could see the old altar and painted cross from more than 400 years ago, and the place where the dead man was calcined before being placed in one of the row of crypts.

Dick liked this place as he found a little clay effigy in the muddy floor.

On down the cobblestone streets toward the old city—partly excavated but mostly yet below ground. Jose had to show us a new hotel not yet open, in the old Spanish style. It was lovely—formal garden and fountain, rooms of original or carefully copied furniture, beautiful tiled floors, hand-hewn beams, arcaded passageways, and an old formal dining room, armor on the wall, and great high-backed red brocade chairs. Rising almost from the garden walls edge is the verdant green peaceful slope to the huge water volcano. Its easy to see how its coming to life would cover this peaceful place and the entire adjacent town.

The author Bernal Diaz lives at this place, we were told. On we went, to an ancient spring from the slopes of the water volcano, contained in a dark old cement channel and pouring into a deep vat where the clear water spread to a rectangular pool perhaps 80 ft. long and 30 ft. wide, each side lined with a row of little sub pools used by the washerwomen of the town. Today it was pool cleaning day so baffle boards had been removed and a moderately industrious scrubbing was going on.

Next we pulled up in front of the homey old church to find a black suited marimba band playing as 3 giants swayed and danced to its strains. These giants were cloth over a wooden framework and two had store dummy heads. The festival of the giants comes once a year and celebrates the feast day of San Cristobal. Later we met them again, swaying and swinging along a cobbled street with a flock of half-frightened small children running well ahead of them, looking over their shoulders as they ran. Behind followed a crowd of gabbing adults. Others came to doors or peeked out of windows.

Jose led us through dirt streets out into the coffee plantations nearby—all shaded by huge silk oaks. Reed screens lined the road to keep pigs and other sundry animals out of the little patches of corn. On we went, up over a ridge and down into a deep verdant valley which I thought was the caldera of a old volcano. In its bottom was scattered the indian village of San Antonio de Aguas calientes, home of the Aguascalientes indians, noted weavers. In the center of town stood the stolid old catholic church, very ancient, clanging its bells.

As we started down the steep, rutted road a flash of color caught my eye. Up on the slope above the road stood a thatched ramada and house. Under the shelter brightly clad women were working at waist looms, weaving exquisite shawls and clothes of one kind or another. I stopped the car, asked Jose if they would let me photograph them weaving. "Sure, for a price."

As we hiked up the trail to the ramada I saw two pleasant-looking, broadfaced indian women and several children, two of whom were weaving intricate patterns. All were decked out in wrap-around skirts of heavily decorated, multi-colored material, slip-over blouses likewise decorated with elegant shawls bearing a variety of motifs. Their black, shiny hair was braided and caught in bright cloth. No shoes. They sat on mats with the loom attached to one of the poles of the ramada, their bodies leaning back just enough to keep tension on the loom. Smooth, shiny, wooden beater sticks and two sticks to separate the warp were inserted.

I watched one child of 8-10 putting in a Quetzal pattern. She reached to her hair and pulled a wooden needle free, bearing white thread. With this she picked at the warp inserting the white thread at the right place and a quetzal row emerged.

The indian lady wanted Phyl to try on a blouse. Phyl demurred, but with my urging agreed. In moments they had her dressed from head to foot, even including a head circlet and basket perched on top. All had a giggling good time.

I ascertained that the elder lady (perhaps 40-45 years, 4 ft. 5 in.-5 ft. 1 in. tall) was named Florentina Hernandez Lopez. She was an Aguascalientes indian, was married (she wore an orange skirt, unmarried women wear green), had never heard of a whale or porpoise, knew about scientists and typified them as archaeologists, was delighted that we were interested in her work and appreciated its beauty. She was jolly, I thought, and her children fat and happy from all appearances.

We had to commemorate the occasion by buying one of her finely woven wares which she insisted took 3 months to weave (I expect it is more like 3 weeks). We picked out a shawl with things of importance to the local people. These include motifs of margarita flowers, arrowheads (puntas de la flecha), pepitas (seeds of a gourd), the crown of the queen of the pueblo, little chickens (pollitos), and quetzals, done in several colors.

On the way out I gave some of the little children dimes which they clutched eagerly. On our way back the lady waved but the kids rushed out for more dimes—which I didn't have.

A brief tour around the village and we turned back to Antigua where we visited the Pension Ruiz, a lovely place of 10-12 people, run by the Ellis family, Sylvia and Mr., the place to stay, I think, if one goes to Antigua.

After saying goodbye to Jose we had an uneventful trip to the hotel.

June 30, 1968

Somewhere over Colombia

After leaving the somewhat tattered and garish "Las Vegas Modern" confines of the Maya Excelsior we checked in at the airport and completed a lot of complicated negotiation over baggage and tickets, mostly to convince the agent that we had more baggage allowance than we needed.

We killed a little time at the zoo and in a drive out of town a way and then checked our car in. Phyl picked up a couple of wedding necklaces of interlocked silver bands made in the upland village of Coban some 100 miles inland from Guatemala City. During the marriage ceremony the partners place the necklaces over both their heads and then the girl continues to wear the "unbreakable band" as a wedding ring.

We boarded in the rain and flew uneventfully to Panama where our time was spent in immigration matters getting Dick a wallet and in teaching Braniff about baggage allowance certificates.

We boarded again at 11:30, an hour later, and were awarded some tokens worth a buck each for our inconvenience.

The plane landed at Guayaquil, Ecuador, where we trod on Ecuadorian soil and took off shortly for Lima.

July 1, 1968

Lima, Peru

We landed through the overcast at a little past 1:00 AM, with everyone dazed with sleepiness and walked into the brilliant glassy terminal. I changed a few bucks into an incredible wad of soles (431). We shoved the entire load of baggage through customs with rather little trouble and hired two taxis to take us and it to the Hotel Continental. My driver told me a whole lot of things in Spanish and when I explained that one of his words was unknown to me he said it louder—still I didn't understand. He came around from behind and said it again—no sabe, señor? No. He came in the other direction but I never did learn what was up. Before he could try inversions or reversals we arrived at the inauspicious-looking entrance of the Hotel Continental—a sort of businessman's hotel deep in the city. No one had any change, and our driver was angry at having to handle all the luggage and so finally I let them have a 500-sole note between them—about 11 dollars, and off we went to bed. The rooms were barren though clean.

We soon found that there were no more than 10 springs per box spring and at least 3 boards of stout dimensions. One caught me halfway from knee to hip. The pillows were very elongate sacks filled with lumpy masses and balls of kapok. They gave not at all. Sleep was impossible for me, compounded by the roar of cars honking their horns on two sides (our rooms were on the corners of two floors).

I was angry at the taxi drivers, at the hotel, and at our tour guide for all this and couldn't go to sleep. I finally hauled the mattress off onto the floor (much better), wadded up my overcoat for a pillow, and stifled my anger and drifted off.

In morning things looked slightly brighter. A continental breakfast and a walk around town helped. Later we visited the Natural History Museum, ate camarones for lunch, had a couple of harrowing taxi drives, checked plane reservations and Bolivian visas and reservations to Cuzco, shopped in busy Lima, ate a nice leisurely dinner atop the hotel and had our rooms changed to some up on the 9th floor above the noise and with good beds. All is peaceful again and Lima seems O.K. and even interesting.

July 2, 1968

Lima, Peru

We arose a bit late today because so much time was spent last night reading to each other (*Voyage of the Beagle*) that we didn't get to bed until late.

A little morning walk took us to the Plaza San Martin so we stopped for breakfast at the spiffy Hotel Bolivar. The kids even liked it because we located pancakes on the menu. Afterward tickets were straightened out at LAN for the Cuzco flight and we went to the Bolivian Embassy for a circuitous 20-sole taxi ride that brought us within a block or so of where we left. As the desk clerk in our hotel says "Peruvians are muy vivo."

We did need visas in spite of everything and emerged with them and a sheaf of lurid travel folders. We all poked in the shops for a while. The kids fell in love with the alpaca fur rugs as I knew they would. Everyone was tired so we retreated to the hotel for a slim lurch of soup. Phylly, Barb, and I left the rest in the hotel and went off to the archaeological museum. We found it a very interesting collection, especially of pottery, cloth, and burial sites. Afterward we shopped a bit and came back to find Dick clean from a nice bath and everyone relaxed and happy.

For dinner we located a place with real barbecued chicken and chocolate cake! Wow, a social success.

A word about Lima. It is frenetically busy. People pour up and down the sidewalks. Most are neatly dressed, but as in all these South American towns there is a compliment of beggars—the poverty is not so evident as one might expect until one enters the barrios of the outskirts—great sprawling shanty towns.

Traffic rushes and cars miss people by inches at terrifying velocities, both driver and pedestrian judging perfectly. Taxis are everywhere and cheap (20 soles for an 8-mile trip—40 cents). Many are incredible rattletraps with flapping fenders and hoods, cracked windshields, and smoky motors that bid fair to quit any crucial time. Everybody honks, jabbers, etc. There are endless jewelry stores and unseemly numbers of clocks for sale. Che Guevara is feted in books everywhere, as in a series of books on the power of American dollars, taxi drivers want to know what we think about the assassination of Robert Kennedy—we see writings from before his death extolling him as the hope of South America. No one knows the others, except Johnson. They doubt that he has been good.

The scene is the same in Mexico City, which could be a carbon copy of Lima—both old, both full of history and conquest, full of new, glassy skyscrapers and both full of ferment, of poverty, of crowding people, of cosmopolitan attitudes, of cruelty I suspect, and both beautiful in their way.

Tomorrow to Callao to the Instituta de Marina.

July 3, 1968

Up early and propping up sleepy children. After a continental breakfast in the lobby we caught a cab for the Instituto de Marina in Callao, where I met the director, Dr. Jorge Sanchez, a specialist in population dynamics and a very gracious man. His English was worse than my Spanish, believe it or not, so we conversed in Spanish. Soon he referred me to his cetacean specialist, Dr. Jorge Mejia, a biologist who has worked at whale tagging, especially the Chicalote, with Robert Clarke of the National Institute of Oceanography in England. He told me that next to nothing is known of the porpoises of Chile, Peru, or Ecuador. What is known comes from old literature based on very few specimens or dubious modern identifications. Clarke had really done nothing on the small cetaceans. His identifications are not based on analysis. Mejia told me about sighting of various cetacean species, and most interesting, that perhaps 1,000 *Phocoena spinipinnis* (harbor porpoise) are caught every year in Peru for food nearshore in Paita, Chianlote, and Callao. They are netted but he did not know how. *Tursiops* is likewise caught for food. The Paita station is the only functioning whaling station in Peru and it is rented to a Japanese firm who freeze the meat of the fin whale for food and render blubber for oil.

They work from November to about May and catch largely blue, humpback, and fin whales though he mentioned the sei whale too.

Fin whale—ballena de aleta

Humpback—ballena jorobada

Sei—ballena boba

I question this identification of the sei whale here and wonder if it could be Bryde's whale (*B. edonii*). Also, Clarke talks about *Lagenorhynchus ornages* here which I suspect.

I arranged to have some workers to collect for me at 4 places along the coast and for us to return in September to pick up specimens.

I also talked to the very nice lady ichthyologist, Norma Chirichigno, who seems very competent. She showed me some very strange angler fish from the stomachs of sperm whales.

Meanwhile the family walked with Phylly and a secretary around the beach of cobbles at La Punta where the Instituto is located.

The harbor at Callao has a staggering number of purse seiners. I never saw so many—hundreds. They fish a 52-day season for anchovies and still are fishing the species out of existence. Callao itself is nondescript. I am told the stretch of open country between it and Lima has all but filled in the last ten years. Growth is explosive. Enroute we passed some great sprawling barrios—compounds of adobe huts with tile roofs, dirt floors, and no facilities—containing perhaps 500-700 people or more. These people are pretty hopeless and on the verge of starvation. Little economic changes could eliminate them.

After a rest which turned into a boxing match between me and Ricardo (I relatively unwilling), we went shopping. The girls took me out to get some alpaca bedroom slippers. Finally I found a pair large enough for me, much to everyone's joy. Then we ate a nice steak dinner and came back to the hotel to sleep. We get up at 5:00 AM to go to Cuzco.

July 4, 1968

Cuzco, Peru

All Norrises arose at the horrendous hour of 5:00 AM, trundled sleepily down the elevator with all our damn baggage, hustled ourselves into two cabs and headed for the airport in the dull dawn. I was staggered by some of the huge *barriadas* we passed—great adobe-walled compounds stretching for a mile or more in some dimensions and teeming with people.

Getting on the plane was a pretty typical hassle. Our LANSA flight was moved from 8:00 AM to 11 AM and we were moved to Faucett Airlines leaving at 7:50. No one would take my overweight baggage *chit* so I had to pay about \$20.00 to get our junk to Cuzco. What a milestone. For all this my breakfast was interrupted twice. Unluckily we did not get window seats. As the plane rose it pierced the perennial Lima haze and out into the bright sunshine. The flight cut diagonally across Peru to the SE. It is extremely rugged terrain, very barren, cut by deep canyons that sweep more or less directly to the sea. Downcutting is rapid as streams swing back and forth across broad alluvial beds. Trees are very sparse—even brush is scarce. Even so, I could see marks of tilled walled fields on incredibly steep hillsides, some obviously just old traces. As we neared Cuzco,

the mountains became higher, occasional chaparral-like patches occupied canyons and north slopes, the multitude of spiderweb trails of grazing animals laced over the mountains. Small clusters of tan adobes could be seen in the verdure along streamcourses and on adjacent hillslopes intricate terraced gardens, all without roads and certainly only in communication with the outside world by horseback or foot. Here the language is ancient Inca or Quechua, not spanish.

I turned across to Phylly and found her marvelling at a very different landscape on her side of the plane—immaculate white peaks, incredibly rugged, with thin clouds blowing in streamers past their peaks. Some were even higher than the plane, especially as we began our descent into Cuzco. Soon we cruised over the tiled rooftops of the town. It is set amid barren, rather rounded hills with patches of grain growing on the most unlikely slopes. One could see the domes and crosses of several churches and the winding narrow cobble streets. The airport is new and bright and one could feel a friendliness from the people so rare in Lima. People are much more without reserve. Pleasant, as I'm no city slicker. A brisk young fellow took us in tow, arranged to get our baggage in order, got two cabs (one his), and off we went to Cuzco. His name is Ferdinand Pinares Cuadros and his card declares him to be a "student". He is in law school and learning english. The latter is good. I hired him to take us on a tour tomorrow after we have had time to adjust to the altitude.

The hotel is in a great old stuccoed building in the heart of Cuzco—all adzed beams and overhanging tile roofs. Indians in their truly unusual clothes walked the stone sidewalks on all sides and traffic, I am glad to say, is light and most of that people, carts, little austin-sized men carrying huge loads on their backs, school kids, politicos, policemen, beggars, and little bitty kids.

We stashed the family in our two adjoining rooms and Phylly and I went out for a walk. The City of the Sun, the ancient Inca capital, is quaint and filled with interesting sights. Many Inca walls are part of buildings, some like the baroque church on one of the main squares. It is amazingly precise—blocks without mortar fitting together with great precision. The streets, too, are formed of smooth stone blocks built with great care. Phylly and I poked into all kinds of stores, asked questions about potatoes, cheese, cloth, television stations, and endless other things. I have learned to explain that I am just a curious tourist in a new and strange world and this usually brings a smile and a cordial response.

Back at the hotel we found the kids pretty well flattened by the altitude and fortunately we had left a day for high-altitude acclimation. Dick, however, was bouncy so he and I went out for a walk. We soon found ourselves in a huge indian market winding down street after street with stalls, a covered mercado, and hundreds of indians with their wares spread on clothes on the street. Everything imaginable seemed there—whole streets for fruits, an alleyway for making shoes out of truck tires, dye merchants, indian shish kabob merchants or at least their indian equivalent, cooking spitted meat and vegetables over little hand made grills fired by pieces of charcoal—also deep fried little doughy sweet meats in little carts.

We watched women spinning wool thread with little weighted spindles which they spun and dropped, pulling the wool with one hand to assume evenness. Later when the thread piled up it was held by bare toes and wound off. I asked one gold toothed indian lady squatting in the center of the street if I could take some pictures. Immediately

she wanted money. I offered 5 soles and she held out for 10. Finally I gave in, much to the delight of the surrounding gaggle of ladies—most a bit envious at their friend's windfall. I took quite a few pictures amid general palaver when my spinner's meter ran out and she demanded 20 soles for any more photos. Dick and I left amid general laughter. How would anyone pay 10 soles (20 cents) to take pictures of anyone spinning for heaven's sake?

One indian momma whisked her child away when she thought I was going to get a free photo (got many by adjusting distance and exposure first against a wall or somesuch and then snapping surreptitiously as I walked. Most women carry either a child on their back in a wool poncho or shawl tied around their neck or goods of one sort or another. They wear brightly colored shirts and sometimes sandals. Most have braided black hair. Some nurse babies as they barter. Mothers in their early teens, I would guess, are not uncommon.

We walked back slowly, allowing for the altitude (about 11,100 ft.). Later I took Phyl on the same route and we picked up a poncho for Leslie Hinton, woven of wool by hand. Aside from their obvious universal tendency to exploit the tourist these people are relatively close to their old ways though goods from the urban world finds its way into many crannies of their lives.

Phyl and I watched a magician pulling 5 sole notes from a bag surrounded by 50 indians. The keen interest and finally true amazement on their faces was a hint to their strong "country folk" attitudes. They all laughed uproariously when the little boy pulled nothing but shredded paper where the sole note was supposed to be.

A lovely dinner of Lake Titicaca rainbow trout with local champagne (we freeloaded on someone, we think) followed. Even the kids except Barbara who slept, found something good to eat. Tomorrow a taxi tour of archaeological items in the morning and getting tickets for the Machupichu train and to Puno. All's well and we hope the kids will acclimate by tomorrow. Happy Independence Day!

July 5, 1968
Cuzco, Peru

Ferdinand was waiting for us, in a light drizzle, at 9:00 AM to go out among the ruins. Some rounding up of children was necessary, but we made it about 9:30 and set out southeast of town on a good graded road that is apparently typical of the main mountain roads in Peru. Our road wound up above Cuzco to over 12,000 ft. and we ended at the old spring of Tambomachay. It flows through a pre-Inca rest house, out 2 stone spouts and into a little rill. Pre-Inca is differentiated from Inca because the stone blocks are polygonal rather than square. The sides do indeed fit with no mortar so closely that no knife can be slipped in anywhere. The walls slope from the vertical in such a way that they are very stable. Periodic reentrant openings were apparently placed to compensate for the motion of earthquakes. It was cold and the kids shivered as we walked around. Ferdinand is a very well-educated mestizo (spanish and Inca indian), studying to be a lawyer so he can work for land reform among the indians.

He knew a great deal of Peruvian history and the modern indian. He was practicing law by representing his fellow taxi drivers. He showed us how the watching posts were set, line-of-sight, on hilltops so messages could flash by eye. Down the hill we visited a fort called Pircara and then stopped at Kenco, a very strange amphitheatre-

like structure. A half circular wall about 5½ ft. high circles around a square altar of cubical stones. In the center of the altar is a large rock, supposed to be a god. Around behind we came to a honeymoon house for the ruling class people (workers had trial marriages). (This is contradicted by Bushnell.) In it was an uncomfortable looking stone bed, an altar for animal sacrifices and a shaft that admitted sun two hours per day. The couple stayed for a 6-day week.

On down the hill we visited the great fortress of Sacsayhuaman. Its zig-zag walls contain boulders weighing many tons and perfectly fitted. Behind are two more walls that encircle a knoll. Ferdinand described a modern fiesta to the Inca gods that on June 28 brought 150,000 people to this spot—so many he said rocks could not be seen. This fiesta was one where indians could mix with whites since the whites were, in effect, paying homage to an Inca god.

Ferdinand classed himself as white—though a dark-skinned mestizo. He said when he suggested he wanted to help indians obtain land, they turned him away saying, “Why do you, a white man, want to help us? Go help the white man.” Ferdinand said he had 40-odd indian children in a very poor village near Písnj, plus 4 of his own. This, he said, had held him back somewhat in schooling, but that he would graduate in a year. The idea that land was held by big owners with indians as share croppers he recognized as wrong, but the notion that subdivision into plots too tiny to work efficiently is bad, had never entered his head. I asked if he knew about cooperativas in which many people pool their resources, as is often done in Mexico. He did not but listened. He seemed surprised that I felt negro ferment in America was pointed in a good direction and that I didn’t think democracy was much good for his indians. The socialist Inca state seemed to appeal to Ferdinand. I suspect he dreams of bringing them to some sort of dignity and perhaps glory again. On the seat lay a copy of *The House of Seven Gables*, which he was reading for english class.

At one point he showed me a hammer and sickle chalked on an Inca wall. As if to still my fears, he explained that South American communism was not other communism—after all, how could that be with 60% of the communists catholics? He viewed the catholic church as a great enemy of his indians—taking their last sole when they have so very little. He explained that Indian catholicism was a bit strange too, since they maintained 4 or more gods in addition to the catholic one. With each meal they spilled a little on the soil as an offering to the water and soil gods from whence their food sprang.

I asked about health, birth, and hospitalization amongst the indians. Hospitals, he explained, were for mestizos and whites. Indians bore at home, helped perhaps by a midwife. The baby was then summarily dunked in a stream. If it moved it would be tough, but many, perhaps most, died. A witch ministered to sickness and many herbs and potions were used, but never the hospitals. Their food was relatively varied—wheat, maize, potatoes, some meat, fruit, etc. Peppers were important since prehistory.

We arranged tickets to Puno and Machu Picchu, a very complicated affair involving telegrams to Puno to get another compartment attached to the train.

Later Phylly and Dick and I walked around town looking at the ancient churches, walls, shops, people, and so on. At one point Phylly thought we had located the sacred inca temple of the sun, which is now the foundation of a Dominican church (there are 23 catholic churches in Cuzco). A fine-looking old spanish man walked up and asked if I

spoke Castellano. I said, “a little.” He went on to show us at the base of the great curved wall, which was indeed the temple of the sun, some little knobs and pits in the otherwise perfect blocks.

These “pechos” he explained were to accommodate the end of a crowbar when the stones were prized into place. He explained more about how the contours and thicknesses of stones were maintained. The wall was indeed fit for a temple of the sun (that of the headman, or Inca)—perfectly fitting, perfectly rounded and smooth and blocks of amazingly uniform size—all utterly without mortar.

Back through the slight rain we went arriving very cold at the hotel. Dinner and to bed. Up at 5:30 tomorrow for the train trip to Machu Picchu.

July 6, 1968

Machu Picchu, Peru

First thing this morning I looked outside and it was snowing. Later in the morning it was splashed over the newspaper. “Cuzco Nevada!” It was unheard of at this season. Some said it was the first snow in a century. Anyway, we trooped in to breakfast while Nancy took it easy upstairs with our first sickness—a tummy ache which we treated. By the time we went upstairs for our bags she was better and ready to go. Everyone tumbled into a cab even though it was just about 5 blocks. The station was a bustling mass of indians and tourists and railroad functionaries. The second class train typically left on time, crowded to the guards, while first class remained behind in some sort of administrative tangle. We finally embarked on a single view dome diesel car, all frosted with cold and the dome gray with snow. Up through the adobe and tile or tin-roofed hut section of town we went, everything turned white and fading into indistinct forms in the swirling snow. The ubiquitous eucalyptus, Cuzco’s most abundant trees, were bent down like birches, phone wires arced low, made 20 times larger by a sausage of snow. We backed and went forward, backed and went forward, over the crest of a 12,000+ ft. grade and down into the drainage of the Urubamba River, which in turn drains into the Ucayali and thence into the Amazon.

The snow was deep enough that cars and trucks were being stuck on the road paralleling the track and was still falling fast. We crept along and various adventures combined to make our trip 6 hrs. long instead of the predicted 3 hrs. First just snow, then assorted small rock slides, then a grand $\frac{3}{4}$ hr. stay while the road crew cut away about 100 yards worth of eucalyptus saplings that had bent across the tracks. A stocky little porter hauled out a wooden case and plunked it down in the aisle. It proved full of goodies such as chocolate bars, cookies, cheese, and the like, all available at astronomical prices. I tapped for two bars of milk chocolate, which by this time were greedily consumed by all hands.

At each little village the train stopped while various inexplicable things were done. Indian kids in bare feet paddled around unconcernedly in the snow. Shoes (sandals really) obviously made their feet cold as some held them while walking barefoot in the snow. We were objects of great curiosity with some little children just staring deadpan and half frightened at us, without a smile. Nancy, who was feeling good, was able to elicit a few smiles though.

The countryside is barren—rocky snow-clad hills ridged with animal trails, austere little adobes, wobegone stock standing silently with snow on their backs, thin

rows of eucalyptus and a few cedars and little patchwork fields of maize and potatoes on the slopes.

After a while the snow began to thin as the tracks led us into the river valley. The canyon walls soon became precipitous, even overhanging in a few places—heavily vegetated with aloes and brush. Finally the snow was left behind. The canyon now rose some thousands of feet above us to snow-clad crests. The river rushed and roared over granite boulders. Our train clicked along not far above, periodically ducking through little tunnels. Many times I wondered if the snow above might not loosen really substantial slides down the almost vertical walls. Far above snow storms whipped around rugged white peaks, many of whose slopes were terraced with Inca terrace gardens.

Streamside vegetation became dense—beautiful red-flowered trees like coral trees were everywhere, as were wild begonias, tiers of ferns including some of small tree size, bromeliads in many trees, even orchids. A peculiar crawling bamboo draped itself like green feather boas from trees along the riverside. In one bend of the canyon we looked above us and saw a great Andean condor circling. Later I saw five more very high in the air, circling.

Finally the train arrived at the little station and suspension bridge that leads to the Inca ruin. A group of small buses were busy ferrying people up and down a switchback road that rose right up a very steep slope to the hotel and the ancient city. The hotel itself is built on the midden of the old city and is perched on a cliff 1,400 ft. above the Urutamba River, rushing below. The scene is almost indescribably rugged. Upstream sheer granite cliffs plunge very near the vertical into the canyon from points above the river. Across the stream sheer peaks rise far above the level of the ruin. Downstream a [?] of jagged scenery ends with a backdrop of pure white Andean crests. If one tries to see from whence he came it looks utterly impossible for a train to have traversed the mountain.

The Urubamba upstream seems to follow clefts in impossibly rugged mountains essentially impassable to man let alone a train. Above it all rises the white crest of Veronica, a mighty Andean peak some dozens of miles away and 17,000+ ft. Alpacas walked leisurely down the road in front of us as we unloaded at the hotel and checked in.

Soon we began the hike to the nearby ruin. It too, defies description, set as it is, on a ridge that drops vertically on either side 1,000 ft. or more into the Urutamba. At the end of the spur on which the town is built there rises a subsidiary peak to a precipitous dome. It is sobering to see terraced gardens near its crest where a misstep could send one flying a 1,000 ft. into space. I suspect that Machu Picchu was a comfortable town, probably with more conveniences than the present Hotel, in its way. The present hotel is an outpost, the ancient town was a magnificently executed and complete city. Great stepped garden terraces rise a thousand ft. on one slope, houses are tightly made of stones with sharply peaked roofs, magnificent temples, what may be a stadium, an ingenious water system in which water was led in precise grooves cut in granite from pool to pool, often through rocks or under them. The precision of the stone work, here with granite, is perfectly precise in the temples—ranges of cut stones form perfect lines many yards long.

In houses long stones with an eye hole cut through one end were embedded in the walls to serve as tie points for the roofing. Cylindrical rocks projected at regular intervals to take rafters, and in some temples large clefts, precisely made, could take huge roof beams.

We hiked until tired, returned to the hotel, ate dinner, and admired the alpacas, including a couple of grand ½ grown babies—all camped on the front steps of the hotel.

July 7, 1968

Cuzco, Peru

Before the rest woke up I walked out of our little hotel (it takes 35 people) and walked out on the terrace overlooking the Urubamba. The sun sent shafts slanting into the deep greenish blue of the canyons and lighted the peaks whose summits glistened with snow. Deep in the canyons all was dark and must remain so most of the day.

After breakfast we explored this amazing ruin again, this time hiking up to a burial area at the very top of the ruin. We were amazed all over again at the consummate craftsmanship of the place. Irrigation water was led through grooved granite blocks to all the fields. At the top was another freeform altar supposed by some to be involved in burial. Several large terraces occupied the upper ridge, being held in place by terrace walls set on precipitous slopes so steep it gives me vertigo thinking about them. Just below these retaining walls was a free drop of 1,000 ft. or more.

Along the wall of one of these terraces entered the Inca road that connected this town to others in the Inca empire. It led up through a notch on the ridge above Machu Picchu. We could see stone steps and some sort of monument in the far away notch. The road was part of a 2,000 mile system on which teams of runners bore messages and even fresh fish for as much as 150 miles a day.

The order of the day was the collection of pieces of serpentine which Nancy insisted on calling travertine no matter how many times we told her. When I got back to the hotel I cut a design like an idol on one piece and sat in the sun on the porch scratching away at it. Before long one of the waiters came up and looked over my shoulder. He developed a worried look and wanted to know where I had gotten the rock. In the ruins, I told him, continuing to chip away. He was horrified to think that I was defacing an artifact. I explained that I had made it. Somewhat mollified he wanted to know where my model had come from, as the design was clearly Chimu, the oldest culture in Peru. No, I said, it was “Los Angeles Culture, early Mack Sennett stage, showing an early movie director with hole trephined in his head, because of the empty material he worked with.” Needless to say, all this impressed him but went over his head a few meters.

Anyway we decided it would be easy to get 500 soles for the masterpiece. All this activity so stirred the kids that we went off on a combination alpaca and travertine (oops serpentine) hunt. The alpacas grazed up and down the precipitous switchback road to the hotel. When we saw the alpacas about halfway down the 6th switchback we turned back.

Shortly the autobus loaded up and we raced at near breakneck speed down the road. Soon we were on the way back with a noisy load of school kids from the east coast—Boston, New York, etc. Nancy ended up pretty car sick so we were all happy to get back in the cold dusk at Cuzco. The short walk to the hotel helped there, however, we were greeted with no room. A Sierra Club group had come in after being stranded in the rain and snow for 2 days and had commandeered all available rooms. I explained that we had reservations, etc. Finally the management came through with the presidential suite for the Sierra Club leaders, moved some reluctant lady hikers out of our room and in we went. Nancy quickly went to sleep while the rest of us went down to dinner. Oh joy!

I found that we could order plain rice with butter. Children of most dimensions rejoiced at this familiar fare, and had one of their best meals in days and days.

A word about Peruvian pillows. They are awful creations—like long, flat sausages packed with some uncompressible material. One's head gets propped up at untenable angles. At Machu Picchu, praises be, all had fluffy America pillows and slept like logs. I hope a decent version is available in Chile.

Once the kids were tucked in, Phyl and I droppd by the bar for a couple Pisco Sours and thence off to bed for early rising tomorrow on our way to Puno.

July 8, 1968

Puno, Peru

Another predawn awakening, and breakfast with half-anesthitized kids. We had a lunch packed in case there was no food on the train. The taxi driver who was to take me to the train didn't show in enough time so I hailed a couple and had our luggage loaded in. It was mildly complicated at the station as my book box was too heavy to load into the buffet car and had to get it aboard the baggage car. One tends to accumulate as many porters as you will allow I have found—we ended up with 3 who heaved all our goodies into the car and left with the majority of my small bills (each worth 10 cents or so).

Our car had our family and a very pleasant 4H club group who were on a sort of "experiment in international living", and would end up on farms all over Peru. They were a lively and extremely friendly, personable group.

The train was equipped with a couple of stewards who plied us with soft drinks and later food. Phyl and I liked it but the kids, as usual, found rather little to please them.

From Cuzco we ascended the Milcanota River valley toward a summit at about 14,500 ft. The valley was dotted with little adobe towns, all tile roofed, serving the surrounding farmlands. Farm plots extended nearly to the crests of some hills. We saw mostly corn and wheat or barley. The eucalyptus was the most common tree though stunted pepper trees were common and occasional slopes were covered with brush. The cedar is also cultivated though most wood is eucalyptus. At the higher locations even this was gone and ties for instance were steel and cement.

The snow line dropped as we ascended the valley. In schoolyards melting snowmen more and more often stood. Interesting that this was supposed to be the first snowfall in 100 years and yet the snowmen sprung up as if ordained.

Cattle and sheep predominated and scarcely a llama or alpaca was seen at the low altitudtes, but as we approached the pass the cameloids appeared in huge flocks grazing on the bunchgrass-covered alteplano.

Once we reached the altiplano the canyon walls dropped away and mountains were usually rather low and often distant. The usual scene was of yellow grassy llanos, cut here and there by meandering streams, revealing red soil in the cliff banks, while a mile to ten miles away, low mountains, crested with snow, rose in barren peaks. The flocks were tended by groups of two or three indians, dressed in shawls, bowler hats, full dresses, sandals, or more often none, and often dropping a spindle as they walked along spinning llama or alpaca wool thread. They were often miles from the nearest adobe. Instead of garden plots there were stone corrals for the flocks.

Passing villages gave us glimpses of life in this treeless land—a soccer game well attended, uniformed children goose stepping on parade, tiny men with huge burdens (no

tump lines or head bands here, only a rope slung around the load and then over the shoulders to a simple knot held tightly with both hands). At some stations we had time to get off and bargain with the local folk who had their oddments spread on the station platform. At one of these the 4H clubbers ran into some pottery of men and women in graphic attitudes which the indian lady calld a “matrimonio” and they came back tittering. Later one girl was bargaining for a shawl with an indian and offered more than the lady asked. This caused general hilarity by all

Our most exciting moment, however, came at Juliaca, some 48 kilometers out of Puno. We had a ½ hour and as I wandered back to the platform after about 15 minutes the train gave a chuff and started off down the tracks. Dick, Barb, Susie, and I ran for the platform of our car (Nancy was inside already). Susie got aboard and so did I. I had to pull Barbie up and Dick clambered onto the steps of an adjacent car. Phylly stood back amid a group of indians and others from the train impassively watching all this. The trains, as can be imagined, was doing some complicated switching and came back again.

Soon we began to see marshland and in the early evening light the silhouettes of reed boats at anchor on the shining water. I didn't have time to watch however, but had to assemble all our baggage preparatory to getting it off the train at Puno. What a pile of stuff. The biggest box, including all my papers was, of course, back in the baggage car.

We pulled into Puno—all low adobe buildings, indians, dirt and swarming porters. Phylly and the kids went ahead with their hand luggage while I wrassled with the bigger pieces. I commandeered two porters and soon we had most of our gear piled on the dock with Phylly tryig to count it, amidst 150 people in the dark, while keeping track of kids. She finally realized that we were missing one piece so I went back and found it. Porters were screaming and grabbing at our luggage when I returned. Our two headed for a taxi while I stood guard on the remainder of the suitcases. They began to quarrel about who should help and I actually had to beat them off. Two tugged in opposite directions on our big suitcase. Finally our men returned and we took the rest to one big cab and piled it on the roof in the back, etc. Meanwhile the train had gone off somewhere with the big trunk. I gathered it would be back so raced back to the cab, paid off various people, including one to run along behind to watch the open turtle-back stuffed with luggage.

The hotel proved to be about 2 blocks away (25 soles or 75 cents for the ride). I stashed all the luggage and family, checked in, and headed back for the train station with my two porters to find the book trunk. Once on the platform there was not a train in sight but very quickly it backed in. I looked for Buffet Car 29 as the porter had my receipt for the trunk. Praises be, he had loaded it on the buffet car and we quickly hauled it off. The darned thing weighs about 150 lbs. but one man hoisted it on his back and started off for the hotel. I had expected to hire a taxi but instead had hired a pair of men. I walked along behind feeling embarrassed.

They were glad to plunk it down at the hotel, and so was I, giving them 25 more soles for their aching backs. Phew! All our luggage and all people in order and nothing lost or stolen.

The Hotel is a rather sparse affair but the bastion of culture here in Puno. No purified water, all boiled in pitchers in the rooms and only a little electric heater per room. It's very cold here and we were delighted indeed when our houseboy showed up with steaming hot water bottles all around. All of us still joggling from the train ride, we

had dinner, went directly to bed, tired and happy to be intact and in good beds (alas with Peruvian pillows).

July 9, 1968

Puno, Peru

We all slept in till 8:30, ate breakfast and took a walk around town, rapidly finding ourselves in a big mercado. Nancy and Susie hadn't yet seen one so it was interesting to them, especially to see all the heaps of foods and goods, the barter, the nursing mothers, the spinners, and all the rest. We bought some tangerines at Nancy's insistence which I rationed in halves to keep people from getting belly aches.

Later we visited the Cuerpo de Paz to find out if there is a Lake Titicaca biology station. There is, and it is concerned with the trout hatchery. A young fellow named Jim told of his work on a experimental farm on the forest slope of Peru and at Puno. He took us shopping for alpaca sweaters and socks. Most everyone is equipped for the cold of Tierra del Fuego and, for that matter, Vina del Mar!

Later, Phylly and I left the kids and went for a walk after we earlier had visited the dock where the steamer ties up. It takes a overnight trip to the port in Bolivia where transportation into La Paz is easy. It's a pretty good-sized ship (125 ft.) for this lake and was, we are told, fabricated in Puno.

Dinner and to bed. Tomorrow we visit the hatchery or go out to the peninsula for an outing.

July 11, 1968

Puno, Peru

This morning at breakfast we were met by a young fellow named Jerry who is a Peace Corpsman from North Dakota here working in the trout hatchery near Puno. He told us about the problems of his operation—basically poaching. Not only are fish caught out of season but his planted fish are taken out of the streams with throw nets. He also mentioned the problems of working with Peruvians of different political extractions. In the lake he told us is a species swarm of cyprinodonts of the genus *Orestias*, an introduced atherimid that looks a great deal like a top smelt, the Peze Rey (from Argentina), the rainbow trout, and a pyginiid catfish. All are used for food. He knew about the frog *Telmatobus*, but had seen only one caught in a gill net. He thought it was typical of deep water. Since there were no frogs to be seen at the hatchery I decided we would go out to the Uno India village instead of to the hatchery.

Accordingly we rented a launch and an operator named Adolpho. We were joined by a pleasant young german named George Zimmer from Stuttgart. He spoke good english and was an instructor of deaf and dumb children.

We pushed off past the moored steamer that goes across the lake, and headed toward the balsa, or marshland. Many birds could be seen amongst the reeds, including many coots, grebes, and seagulls. Some of the coots were seen displaying. They puffed their feathers and raised their wings and tail. A bright white patch shone above the tail of the displaying pair. Soon the reeds closed in on us and we found ourselves in a channel. The water was shallow and clear as glass. Most of the bottom was covered by 2 or 3 species of water plants. Very few fish were seen. Apparently only the cyprinodont is common here. The day was calm and sunny but chilly in any shadow. We wound

around in the channel, with only Adolpho knowing where we were going. A couple of balsas were passed. They poked in the reeds here and there. I asked Adolpho what they were doing and he replied that they were searching for pato eggs (duck or mudhen) and working bird traps.

We came across some men cutting and bunching reeds for new balsas or reed boats. These are nicely built craft composed of two main bundles of reeds forming the hull and two smaller bundles of the sideboards. All are laced together. Most were poled along, with indian ladies in derby hats and full dresses either sitting in the back or poling their own balsa.

Before long a silver roof could be seen over the reeds. This turned out to be a floating schoolhouse donated by the Seventh Day Adventists. It consisted of a shed on about 20 oil barrels moored at the edge of a dense mound of reeds. On this same mound of reeds were the matting houses of the Uros and most of the population of about 50 souls. They live entirely in these reeds with no solid ground at all. One must be very careful not to fall through soft areas into the 51 degree water below. So far as I could see they looked like the other indians though they speak an ancient language not allied to Quechua and some members are said never to have been to Puno.

As we came up a hot soccer game was going on on a broad patch of reeds and the major goal seemed to be to keep the ball dry.

The moment we landed we were swarmed around by a dozen broadfaced, black-eyed little children. Some held out model balsas (for 5 soles). One held out his little hand for us to put money in.

Another led a little squealing piglet around on a leash. Pots were steaming on little charcoal fires up on mounds of reeds. I suppose the reeds didn't burn as they were too moist.

I had a grand time with the kids and got most of them to tell me their names or tell other's names to me—which was a big joke. We laughed and laughed at Tlak Tlak Tlak. I asked Adolpho what they ate and he told me food from the shore—bird's eggs, trapped birds, fish, and such. I thought they looked well and much healthier than most indians on shore. There seem no insects about, or at least we noticed none. All in all they were a happier lot than most we have met.

On the way back the kids caught reeds and trailed them in the water. I looked for frogs but saw none. We arrived back at 1:00 PM, sunburnt and tired. Later Susie and Dick and I walked through Puno to mail some letters. We came upon the museum and marvelled at the mummy with at least 6 trephined holes in its skull. Then we dropped in a weaving factory where indian girls and boys sat weaving alpaca yarn rugs. Great old wooden ceiling-to-floor looms had two or three people working apiece, seated on benches. The warp was lifted up with a wooden stick and yarn sipped through. An instant [?] knot was tied and the yarn clipped—all so fast we could not make out how it was done. A three-meter long rug with a design of Tiahuanaco style sold for about 4,000 soles (\$100) and took a month to make.

Back at the hotel we made arrangements for an early morning departure for La Paz. It looks like more baggage problems as the tour has grown to 25 persons they think and there may be too little space. We may have to rent a car for about 700 soles to haul the stuff to Copacabana. It will be worth its weight in gold by the time we arrive at Renaca.

A word about the indians here. They are Inca descendants of not such long lineage. In the 1500s they had an intricate society—a theocracy, magnificent artisanship, a technology really, unparalleled in this hemisphere and in many ways the superior of Europe's at that time. Now they are degraded to low-level serfs on large ranches, or marginal farmers on poor sloping land. They are the beggars, the tattered (incredibly so, often) porter of incredible burdens, the dirty and suspicious. It is worth pondering that social circumstances can so change the lives of a people, and can so change the ways they make their livings or compete. They are on the downswing of the pendulum and we on the up—but it could be the opposite easily enough.

July 11, 1968

La Paz, Bolivia

Well, we didn't have to rent a car as only 21 takers showed up and we had luggage space to spare, even with our enormous pile.

We were hustled into 5 cars with drivers and started off by land to circumnavigate the Peruvian border of Lake Titicaca. From what I could gather the border between Peru and Bolivia across the lake caused some problems as well as rough water. At any rate more than ½ the trip was by land. We had never been on an organized tour before and didn't quite know how to act when all 21 of us were led down up [?] some balsa boatmakers by the shore. The tour guide, an efficient, aquiline-featured Bolivian girl named Maria Elena got them to pose at work and everybody clicked away. The indians had obviously been prepaid by the Crillon tours. Back in the cars we continued through the austere landscape of the altiplano—every inch, clear to the top of most mountains, is terraced with stone walls. All fields were barren and brown, or simply stones and dirt. The large flocks of stock graze it to a nubbin. Erosion is a prominent feature. Dotted everywhere are tiny plastered or painted adobes, and indian ladies in derbies, spinning as they walk. Many spin the spindle and let it spin its tip in the ground like a top.

Three or four times we had to stop for various officials to check our papers. Our worst one was at the cavalry headquarters where a very fancy looking guard demanded our passports before lifting the iron gate across the road. Since our tour guide up ahead had our papers it seemed like an impasse but some rapid spanish by our driver solved the problem somehow. Up the hill was a little village spread on the slopes around a huge red sandstone church. This, we were informed, was the most beautiful colonial church on the altiplano and had once been central in the spanish administration of the area. The stone came from local beds, tilted into great fins and minarets nearby.

A wake was in progress—or at least nearly over as the women were sitting in a huddle at one side of the churchyard, in their black derbies and shawls and skirts, while the men were gathered standing, also in black, at the other side of the yard. The women, we were informed, were chewing coca leaves (from which cocaine is derived) while the men drank straight alcohol out of tiny little, long-necked greenish bottles.

We trooped inside the great church, passing by the stone belfry with its ancient stones sprouting little bushes of plants and its huge bronze bells hung on hoary old logs. The façade on the door is carved of sandstone into baroque complexity. One can see indian faces in the carving here and there. Inside the great vaulted roof of square stones ran to the transept and apse with its fantastic gold encrusted altar running from floor to ceiling. A yellowish light shone through alabaster windows in the dome, said to have

been brought from Spain. Everywhere were wooden painted santos and old paintings of saints or the crucifixion. An ark of glass and gold contained the bones of some important soul. A few votary candles flickered.

All in all a monument to the power of this church, with its mystery and various ways of subjecting its subjects as wholly subservient to it. How else could an indian feel facing that altar?

On we went, through the dusty rocky streets of the town, between adobe walls, past goats, indians, pigs, wagons, bicycles with glass boxes full of bread on the front and out again into the barren altiplano. Soon the lake came into view again as we approached its southwestern corner and the Bolivian border.

There is uncertainty in somebody's mind about that border as there were 7 (count 'em) stops involved and I never did find out which one was supposed to be the real McCoy. Heaven help the tourist driving this road. He'd be stuck for hours or even days trying to figure it out. We had our papers cleared at the plaza of a little town a couple of kilometers back of the most important looking border. While all this was going on I poked in various shops looking for some line to tie my camera box on the cab's top rack. The cab driver insisted it was safe but with \$1,500 worth of important camera gear in it and these bumpy roads I refused to take his word. In every store was a bale of coca leaves. I found that each indian lady has a special little cloth in which she wraps her daily ration of leaves for chewing. Thus nearly all indians are to some extent, addicts.

Soon we came down from some rocky hills to the quaint little town of Copacabana. It sits up in a cove of Lake Titicaca and is dominated by a huge church which is also a shrine. The building has an almost moorish look with blue and rust-colored tiles on roof and domes. Near the door sat indians selling candles and another group singing peculiar plaintive reedy songs led by a blind indian playing an ancient violin.

Inside we viewed another baroque altar and the shrine in a little chapel above. This one was all silver and mirrors. I felt out of place and was glad when we left as I felt no reverence, I'm afraid, only curiosity that people should come from miles to pray at it.

We had a nice lunch (trout soup, amongst other goodies) and thence down to the hydrofoil moored in the cove. It is a trim craft called the *Inca Arrow*, made in Philadelphia, and powered by a Cummins Diesel. It was all but full. Shortly it got up on its wings, cutting through the water at 25 knots or so. Every once in a while we would hit a wave and the bow would dig in briefly, but for the most part it was smooth and swift.

We moored at the Island of the Sun and went ashore for about 20 minutes to look at the Inca terraces. This island has near its crest ruins and artifacts of people supposed to be ancestral to both Incas and Tiahuanacos and during Inca times 10,000 people were supposed to have lived here. Now there are about 80 families on the whole island. Certainly the number of potshards on the terraces indicates heavy past use. From the dock up a ravine ran a long series of steps, rising perhaps 200 ft. in all, with a rushing rill of clear water tumbling down alongside in a stone channel. The entire canyon was filled with large trees—shaggy old eucalyptus and what look like beech trees—dramatic contrast to the bare hills all around. The kids and I foraged for pottery. In spite of the 12,300 ft. altitude we ended up, puffing to be sure, at the highest terrace and hiked down to get back on board. Across the lake, beyond La Paz, Bolivia, we could see the 18,000 ft.

snowy summit of Illimome and off to one side _____, one of the highest peaks in the Andes.

Our guide picked up some trout from the local people on the island and we were off. She said no one drinks the lake water as it is mineralized, but instead seek spring water.

On we went, past the Island of the Moon, where the Incas kept their “Chosen Women”, selected girls used either for wives of the nobles or sacrifice. We saw the compound where they lived. On the other side of the island is a present day Peruvian prison.

Our course then took us through the $\frac{3}{4}$ -mile wide straits of Liquina where we met several Felucca-like craft with big lateen sails and peculiar arched hulls with high bows and sterns. Also, here we passed the ferry which consists of several very broad beamed sailboats that can take two trucks each.

All the kids were sleepy by this time so Barb and I, then Susie, then Dick and Nancy, and finally Phyl came up on deck as we flew along and stood in the brisk cold breeze. Before very long the boat nosed up to a anchorage at the Crillon dock, while hired picturesque natives plied reed boats around us. Soon after we landed these same guys were cementing a wall in everyday working clothes.

On shore we had tea and sweet rolls and soon were off to La Paz in six cars. The road is graded and very dusty. Our driver pushed his car along so we constantly came upon cooperativa trucks which were utterly invisible in huge clouds of dust. It was some entertainment to lunge into these clouds hoping they contained nothing but dust, in order to pass and breathe again. Twice, by the dimmest of signs our driver held back and a truck going the other way materialized, thundering along.

At one point we rounded a turn and the whole spine of the Andes or 75 miles was before us—a jagged snow-covered sawtooth. I could see some valley glaciers and below snowline, moraines and glacier cut valleys sweeping down toward us.

During a couple of stops for flat tires (neither car had a viable spare but had to borrow one) we stepped outside into the bitter cold air and were glad enough to get back inside again.

Dick, by this time, was snoozing peacefully. Suddenly La Paz was before us as we came to the edge of a deep glacial canyon some 2,000 ft. deep. There it lay, lights spattered across the canyon bottom and up its sides. We wound around through heavy truck traffic to enter the city. None of the cars use their headlights except to signal, but turn them off when confronting one another, a ghostly mass of rumbling cars and dust only dimly seen.

Down through the center of La Paz we went—through the mercado and finally to our shining new hotel in Embassy row. The Crillon is very cosmopolitan, has superb food and immaculate rooms through which maids pour in phalanxes to turn down beds and polish already polished floors. We still have Peruvian pillows and impure water in the taps though, but all in all it is a haven after the austerity of Puno. We found we could even get plain spaghetti with butter. WOW!

I had trout and it was superb. Phylly’s meal of pork with sauce was likewise excellent.

Gratefully, we went off to bed, with Dick especially tired, perhaps from a combination of the long trip and the 12,000 ft. altitude.

July 12, 1968
La Paz, Bolivia

Dick was indeed very tired and had a slight fever and so stayed in bed all day. We tried to get some food into him and finally succeeded with some ice cream and a banana. Best of all, however, were some chalk-like tablets called Coramina glucosa C113A, which are specifically for altitude. They perked Dick up dramatically but before he could eat lunch he had subsided and went back to bed. That evening, however, we planned better and got a huge plate of spaghetti and meatballs into him. I walked up to the University of the Andes and felt some bit uncomfortable as I read the bitter anti-Yanqui tirades on the bulletin boards, all directed at Viet Nam. The propaganda was a peculiar mixture of talk about 24,000 folk music groups in Viet Nam and denunciation of our use of modern weapons and of the cost to us.

Later Phyl and I and Barb and Susie went uptown and visited the mercado, the ancient Iglesia de San Francisco (ca. 1540) and snooped in stores. La Paz is hilly, full of little parks and stairs, traffic, cobblestone streets, new shining buildings, and tattered, odorous, mud-bespattered, indian sectors. We walked all the way home and arrived very tired back in our nice warm hotel rooms.

This night Susie developed a king-sized bellyache at about 12 midnight and after a siege and administration of the “remedy” she drifted off to sleep peacefully enough. The remedy is a tiny white Lomatil pill—almost instantly calms the stomach down and makes one comfortable and stops diarrhea like magic—it contains an opiate—plus Kaomycin, which slays all Salmonella bugs like a magic fly swatter for microbes. I can remember when one was in for a week of debilitating sickness with this bug. Now, if you catch it quickly the real disturbance lasts only an hour or so.

July 13, 1968
La Paz, Bolivia

Susie is well and perky enough to have breakfast with us. Dick is bouncy and the rest are perking along well. After breakfast Dick and I went out for a refill on our medicines—just in case, \$13.00 worth. Thence we caught a cab (1 peso or 8 cents ea. to downtown per person). We poked around some of the stores back of the Iglesia de San Francisco and I bought a native poncho of very fine weaving and natural vegetable dyes, plus a little mandolin-like instrument called a charango. The sound box is made of the shell of an armadillo and it has 5 pairs of steel strings. It comes from Oruco, about 250 km. S. of La Paz and is used in most of the native music of that area.

In getting out of our taxi Dick and I landed in a maelstrom of cars, trucks, and marchers in a parade. Today all the native cooperativas come in from the districts around La Paz and have a day in their honor. It was such a colorful assemblage that we quickly went back and got Phylly and Barb. Susie and Nancy were happy just to stay in the nice warm room.

After becoming dismally ensnared in a traffic jam we jumped out by the parade and walked along as they made their way toward the Plaza Murillo. Each cooperativa carried banners telling their area and how good cooperativas were for Bolivia. Almost all wore the clothing typical of their area—ponchos or hats differed, one group wore hats trimmed with flamingo feathers projecting radially from their hat brims. Another group

had a grand flute band. They puffed on double bank bamboo flutes to a peculiar rhythm of 4 or 5 drums, old weatherbeaten indians dancing along the streets and every now and then taking a nip from a communal bottle, while out ahead danced and gyrated 4 men in costumes and masks, obviously playing out some part. In a truck supplied by the *Allianza para Progreso*, a sort of float went by headed up by a man dressed up in a condor skin. His arms extended out under the wings which he manipulated by means of two wooden grips at the base of the primaries. He shimmered them at passersby and was occasionally challenged. Another group featured big bassoon like flutes played vertically, plus wood and skin drums. These flutes had a nose piece but were played with the lips. [drawings]

Still another group played a horizontally held flute that had what I take to be a sort of chanter lashed on top of it. There were different sizes and I was told the chanter tubes each played different notes arranged in a sort of orchestra.

The parade circled around Plaza Murillo and the red-suited presidential honor guard marched up and down smartly clutching their mangers and soon out on the balcony of the *Palacio de Gobierno* appeared a gaggle of suave-looking politicians. They included the president and vice president. Several speeches were given including one fiery one in what we took to be Quechua. The president is an impressive large neat man and his vice president a balding bespectacled smaller man who spoke forcefully. What I could understand told how important the cooperativas were to Bolivia.

Feelings run strong here. Even the old “War of the Pacific” still rankles. One taxi had a slogan plastered across the front window—“Autofagasta es y sera Boliviano” (Autofagasta is and will be Bolivian) referring to Bolivia’s loss of seacoast in this war back in the late 1800s (I believe). The driver didn’t like us much either and I suspect classed every norteamericano as the same.

Now we pack (trying to figure out what to do with the charango) and head for the airport modestly early tomorrow morning for a 3-hr. flight to Santiago.

July 14, 1968

Santiago, Chile

We made it! All our baggage cleared including several obviously illegal goodies like violins. But all that comes later.

Another one of those horrid early morning arisings—somnambulistic children bumping into pillars and sneering sleepily at everything but chocolate on the menu. Then, the luggage, with us steering our 17- jewel millstone topped by the black monster (my 150 lb. book box) into a couple of cabs, shoveling troops aboard and setting off for the airport. To be sure our plane was quite a bit more than a hour late. This, however, gave us time to get overweight baggage allowances in order, seats selected, and immigration taken care of.

The airport advertises itself as the world’s highest (it is near 14,000 ft.). It is located on the plane above the valley where the town is located. Air is clear and cold. Nancy and Susie got shoeshines (1 peso each) while Dick watched the shoeshine boy’s technique with such care that we wonder if he is going into business.

It was pleasant to get back in a new shiny jet—the stewardess was giving herself oxygen, having just come in from New York, while we acclimated types just breathed normally without all that lowlander’s folderol.

Finally, up we went and over southern Lake Titicaca and quickly out over the altiplano, dotted here and there with volcanos frosted with snow. Occasional salinas filled valleys with gleaming salt or reddish pink ponds of saline water and halophytic algae blooms in them.

The land grew increasingly rugged and arid and less and less evidence of human use could be seen. Finally as we entered the Atacama Desert of Northern Chile some extensive areas of sand were seen, broken in two or three places by oases thick with greenery but surrounded on all sides by sand. Finally even this was gone and clouds obscured the view nearly until we touched down at Santiago. Once we dropped down toward the end of our 2½ hr. flight, high hills covered with low brush or what look like dotted oak groves came into view. In the intervening valleys large farms, most with silver-roofed farm buildings covered the landscape. Vineyards and groves of fruit trees stretched away into the haze. For some reason, Santiago was having smoke—long brownish strands highly reminiscent of a smoggy day in Los Angeles streaked bands across the hills. All in all it was pure southern California.

Soon we touched down on the single concrete runway and taxied up to the terminal, wondering if our violins (illegal it develops) or other contraband would make it. Would we be met? We were, it turned out, by a suave-looking fellow named Francisco Silva. He hustled us through customs like magic. While our fellow passengers were having every bag checked, not a one of ours was opened and even our obvious violin cases went by unquestioned. Even the bag Phylly carried, with the neck and pegs of the Bolivian mandolin sticking out went through. There's skullduggery here and I love it and am amazed that our University has the foresight to promote it for our welfare.

We were met by Mr. And Mrs. Hector Hermosillo and their son, the people who are renting us their house. Charming people who promptly invited us to their house for dinner tomorrow night.

Susie had a rough ride because of the altitudinal change and a head cold. She was awfully glad to be on the ground and promptly went to bed at our second Crillon Hotel of the day. This one is downtown a couple of blocks from the central park and is a great gracious comfortable affair with high ceilings, rococo plaster, woodcuts all about, carpets and real drinking water in the faucets. All of Santiago has a purified water supply. Haroo!

Also haroo! We now bill everything to the Convenio, including tips.

Phylly and I took a walk around this European city. Traffic is light because of the high import duty on goods produced outside Chile.

Dinner at 8:00 PM and to bed. Tomorrow we start the dreary process of obtaining our [?]-identification cards allowing us to drive and travel throughout Chile. It may take a week.

July 15, 1968

Santiago, Chile

Early this morning I checked in at the Convenio offices and began our paperwork. Great joy, we were able to contact Leanne Hinton in a nearby hotel and all of us got things going on our carmets[?] (identification cards).

In the evening we had a very gracious dinner in the lovely house of our house owner in Renaca (Hector Hermosillo and family). They could not have been nicer to

meet or be friends [?]. Hector is secretary of the private pilots of Chile and somehow earns a comfortable living. His family has 3 cars, each costing 3X the USA price etc. I'm tired so no more today.

July 16, 1968
Santiago, Chile

We visited the Museum in the Quinta Normal and made contact with the Sub-director, Nibaldo Bahamonde, a crab specialist and a very accomodating and pleasant man. He helped us a great deal, lining up a man to help us study specimens from museum cases, and with library matters.

The museum is old and musty and obviously poorly supported by public funds. There are about 15 staff members. Nibaldo is a crab specialist.

There are some interesting specimens in the collection, mostly misidentified—not surprising since no one has done much since the turn of the century.

A stint of photo taking for the carnett, various details in the offices and some shopping, an once or light tea at 7:00 PM and to bed, nursing a cold. Tomorrow we work at the museum.

July 17, 1968
Santiago, Chile

Leanna and I left Phylly tending kids and caught a cab for the Museum. The cab ride was the highlight of the day. The driver had Von Supe's light cavalry overture on the radio and as it speeded so did his driving until we were weaving through traffic at a true Laurel and Hardy pace. The overture ended about 100 yards from the museum gate with us exhausted with emotion. After that we spent the morning out in the frigid concourse of the museum measuring whales. There are a couple of Philippi's old types out there (*Cephalorhynchus*) stuffed, wizened, and black, with drooping dorsals and rotting pectorals. He apparently didn't know you can't tan porpoise skin (except for the beluga) but did it anyway. After nearly 100 years one could still smell the isovaleric acid odor. Leanna was a celebrity of some sort as the school kids kept asking for her autograph (once mine), but we both lost our charm once we stepped over the railing into the public passageway. At noon we dropped by the local wurlitzer parlor for a bite to eat (freezing too) and thence back into the museum where we waited for a cat named Sr. Tamayo, who is the resident mammalogist here. He finally materialized at about 3:30 and quickly let us work with the skulls we saw on display. He is a tiny frightened man but very accomodating. He spent the remainder of the afternoon peering over our shoulders as we took measurements. Frozen, stuffed up with my cold and weary we quit at 4:30 and headed for the hotel. Tomorrow comes the task of moving to Renaca. I am getting a full-fledged tic over the baggage and likely will not sleep very well tonight just trying to imagine how we are going to get it all to Renaca, and how I am going to handle all those porters.

July 18, 1968
Renaca, Chile

After a fitful night I stirred around at 7:45 and roused the troops. Phylly had packed most everything the night before so it was a rather minor job getting the rest

stuffed in and calling a couple of stout porters. We paid our rather horrendous bill and ate breakfast. Francisco showed and we went off to get a car. We were assigned a nice Ford station wagon and after checking every defect on a sheet (soldered spots on a bumper, scratches on the door, etc.) it was signed over to me and I began the well-nigh impossible task of following Francisco back to the hotel. Chileans drive a game of chicken. It's whose nose is out front and none of this American garden sass about white lines and such bushwah. I was forced to fake out some hardened Chileans but somehow managed to keep Francisco in sight. Soon we were loaded, Leanna was picked up and we exited from smoky Santiago into the campo. The countryside looks just like southern California. May plants are counterparts in the ecological sense. Growth forms are similar—there is an *Adenostoma*-like plant, and other chaparral species, and actually some genera are the same—for example *Baccharis* is here, as is the bay tree. Some birds seem ecological counterparts too—like there are brush birds that have long tails and tend to dive into the brush rather than make long flights. I saw a jay-like bird that was very reminiscent of our scrub jay. The hills are similar too—sparse rocky soil, gullied under the brush. The land has been more heavily used than ours though overgrazing is the rule and the farms seem poorer on the average than ours. Now, however, they are undergoing a very severe drought—the worst in 100 years they say, and this may account for some of the appearances though not all.

As we neared the coast the Monterey pine appeared in full force. Most of the hills back of Valparaiso are tree farms now of this fast-growing straight pine. They cut them when the stumps are perhaps 20-24 inches through and perhaps 85 ft. high. It looks like a good and valuable crop for them.

Finally we crested a hill and dopped down into Vina del Mar. It is a lovely clean town of spotless streets, lined with trees, very nice houses, many shining modern buildings, a pretty well-tended plaza with flower beds, bay, palm, sycamore, pine, and araucaria trees, plus a fine fountain.

We continued on north of town along the coast and within a few minutes came to Renaca, which is a little village clinging to the hills above the sea. Before we knew it we were at our house. It is a fine artistic affair set on big poles and made of cast cement slab walls and wood. The house is separated by sliding glass panels or sliding doors in several places. The wood is a soft beautiful kind that Hector couldn't name for me. We have a bedroom that overlooks the sea (we can pull the drapes open from the bed and peer at the winking lights of Valparaiso across the bay). The surf booming on the nice beach just below us keeps us company during the night. Our living room looks out across a broad front porch to the sea as well. The kids have bedrooms in the back and an extra bath. Leanne is occupying one of these rooms too. There is a fireplace too, but I think we may have trouble getting much wood for it, though likely I will try.

Our kitchen is tile floored, with a little stove with an uncontrolled oven, a propane heater that turns on when one demands hot water (I had a terrible time with the pilot on the one in our bath but finally mastered it). Garbage is dumped through a chute in the wall and thence into a garbage can. The "basura" is picked up 4 times a week. Talking to the tradesmen, in this case the garbage man, is the toughest experience we have met with so far. They absolutely do not understand that they must slow down to be understood and they clip all the remaining syllables off their words. I have enough trouble

without this. For insistance, sabado (Saturday) becomes “sa”. For heaven’s sake, that won’t do.

We love this house and it is comfortable for all of us. The kerosene heaters are left on low all the time and keep us comfortably warm, a major blessing we can see, as it gets chilly at night or when the fog closes round.

Phylly whipped out a bunch of spaghetti mix, and after a foray into the local stores (the local supermarket sells only canned and packaged goods) we visited a *carniceria* (meat store) where we picked up some ground meat (*carne molina*) and a couple of chickens and some great big eggs, and home. The spaghetti was built and everybody sighed in relief that the food was once again just like that at home. Dinner was held on our long pine table, darkly stained.

The *Hermosillas* had put flowers around and the place was immaculate. What grand gracious people. Both the Mr. and the Mrs. She is very thoughtful and told Phylly many valuable tips. Their children too are fine folks.

July 19, 1968

Renaca, Chile

Breakfast watching the great breakers curl over and crash on our beach. Birds are everywhere especially pelicans, cormorants, and Peruvian boobies. The pelicans amuse us all as they swoop along the crests of the waves almost touching their curling faces before they break, rising over the crest just in time as the crest curls out of equilibrium.

This morning I dressed in suit and tie and walked to the nearby marine station. It sits on a rocky point of land jutting out into the sea about ½ mile from our house, an easy and pleasant walk down the shore. Good thing I went, as even though it was Saturday I found the Director waiting for me . . . a rather ponderous pleasant gentleman, bowed down with paperwork, bearing a jutting set of chin whiskers. I felt a bit chagrined that I had not come in the day before, but I guess it didn’t matter too much. *Senor Anelo Aguayo*, the Director, was leaving on Tuesday for London and a conference on Antarctic matters and was anxious to get me settled before he left, so we discussed where I might work (he offered me both his office and his lab—I took the latter) and then we toured the lab. Marine labs are such grand places—all full of smells of the sea, salt water, urchins, nets, boats, rubber boots) and full of little nooks where people work amidst their piled-up papers, microscopes poking out here and there from the pile, with little aquaria behind full of scuttling little animals, and usually partly filmed over with algae. Nearly everyone can look out at the sea or the algae-covered rocks if he turns up from his books.

Sr. Aguayo works on cetaceans and sea lions. He offered to turn over to me the data he had gathered from a pilot whale and a couple of beaked whales. I think I may offer him a coauthorship with me on my marine mammals of Chile. NSR had not yet written to him about inviting him on our trip, so I avoided discussing that issue.

The lab is really an excellent one, I think, and has the usual mixed staff of Argentines chased from their country by Onganía, and Chileans, working so it seems, happily side by side. There is a very nice auditorium, and they have several small boats here and a larger vessel in Valparaíso.

Back at the house we left the children happily playing in the neighboring vacant lot and set out for *Vina del Mar* to attempt to mail letters. The place closed up in our faces so we poked up and down the main commercial street, buying bananas, bread

(sawed on order from great, heavy loaves), tried unsuccessfully to find some spices, but came away with pepper and hot sauce, smoked sierra, cheese, avocados, salami, some towels, and a whip (we have no egg beater or spatula).

I found an absolutely glorious lamp composed of a great stuffed 6-foot snake curling up from a base with a socket in his mouth, standing a full 5 ft. high or more. If I can figure out how to pack him I will dicker with the owner. It is a herpetologist's dream.

Phyl and Leanne and I then drove down to Valparaiso, a fading city of tiers of houses, rising on the steep hills, of extensive wharfs, of old Victorian mansions with cupolas, widow's walks, scaly shingles, belgian glass windows, and ornate iron work. Otherwise a jumble of little houses cling to the hills. We stopped to talk to some fishermen who had come in on a shingle beach in their long double ender clinkerbuilt canoas—perhaps 20 ft. long, and each venerable with use. The catch was mostly merluce (a cod) and we found one boat full of sierra, bought one for 5 escudos from the boat (it was delicious baked). Leanne bought some locos—a big limpet that tastes like an abalone and has to be treated in much the same way. Then we stopped at the main fishing dock. Several merluce boats were tied up and unloading. All fished with big trawls apparently at considerable depth, and all were filled with fish being boxed and filleted in many cases. To the sea side waited an incredible fleet of birds and sealions (*Otaria*). The harbor was perhaps ¼ mile wide and nearly covered with birds, mostly cormorants and pelicans. Little boys on the boats tossed an occasional merluce to the flapping hoard. Sea lions rose amid them and aggressively advanced with mouth's open, the birds retreating a few yards. Finally, as if on a signal of some sort (I'm sure there was some mode of information transfer involved), the birds flew in a few moments away from the boats and settled near some navy ships nearby. We did not think there was any food at the other place and were at a loss to explain why they left or what the signals were. One thing, the boys continued to toss fish and we could see schizophrenic pelicans, drawn toward their fleeing friends, but hopeful of some food. Finally all left anyway. In this lies the explanation of how birds can quickly congregate over food at sea from long distances, with probably only slight visual cues involved. Or is there sound involved that we cannot hear?

We retreated to home ourselves, first mailing our letters and determining that we could use the Marine Station Mail Box (Casilla 13D).

A nice dinner of fish, boiled locos in sauce (Leanne first prepared a sauce that tasted like crankcase drainings but did it over with better success), and thence to bed, and since I had mastered the pilot light in our bathroom heater, a nice warm bath (the bathtub sits in a glassed enclosure overlooking the bay).

Tomorrow is Sunday and we will do little until after lunch and then take a ride to the north of Renaca.

July 20, 1968

Renaca, Chile

The morning was spent puttering around the house getting various things in order. Dick and Susie are constructing a grand fort down in front of the house in a huge castor bean tree. Forts seem to be essential wherever one goes. Nancy and Barbie have found some skate eggs and upon opening one found it to be alive with a big orange yok sac.

They put the hapless beast in a salt water bucket and the unopened eggs as well. The beast wriggled on for 1½ days (this is being written late).

In the afternoon we piled into the car and drove northward toward Con Con on the Aconcagua River and Quintero, somewhat farther to the north.

The road runs along the shore which is a series of rocky bluffs and coves, very reminiscent of the Monterey coast. Many picturesque houses, some built in the rocks, are to be seen. Clean, prosperous looking villages dot the coast, each with seaweed salesmen (they bake the stuff) and marisco stands (shellfish). We watched birds—kelp gulls, Inca terns, grey gulls, cormorants, pelicans, etc. The road went behind extensive gray beach dunes at the river and led us through fields with eucalyptus and Monterey cypress windbreaks. At Quintero we visited the shore and on our way back stopped at a cooperativa meeting where the girasos and their senioritas were dancing the Cueca—an attractive dance of separate partners twirling a handkerchief or a small poncho in one hand accompanied by tapping feet and jingling spurs. The guasos came in on horseback, very erect and splendid in their horsemanship, perched on peculiar soft saddles held with a broad leather strap over the saddle. The guasos, with their bright striped poncho run through an epaulet of one shoulder and flat broad brimmed hat, were very “macho” and grand—all tanned with mustaches.

Back at Renaca we are settling in, learning how to do the ordinary things of life which is really great fun and the fabric of what makes our experience so interesting.

July 22, 1968

Renaca, Chile

Today was banking day. We set out to arrange to draw our salary. At Vina the bank director referred us to Valparaiso and a American, Mr. Rogers, there. That brought on a rather harrowing ride through that sinuous town of ups and downs finally ending at a busy square which we circled and circled and finally parked in. Banking is complicated but Phylly's courtesy card did the trick and we can draw either dollars (for the black market—they draw 9.5 escudos per 1\$) or escudos at 7.9 escudos per. Mr. Rogers, when he saw us drawing escudos, confided in us about the market.

We then returned to Vina and opened a checking account. Women have troubles and Phylly would have to be notarized to go on this one so only I am on it. It's obvious that the woman's place is several steps below that at home.

We shopped and I worked in my cubby hole of an office at home. Kenny Bloome and Berit came in this afternoon from Santiago and will now have to get settled. They had a very interesting trip down.

July 23, 1968

Renaca, Chile

Today was spent getting our lab space straightened out at the Estacion and in getting Leanne and the Bloome's houses nearby. All came over for dinner which was a towering social success with 2 bottles of wine (80 cents each) (delicious) and \$1.10 worth of lamb chops (also delicious).

Crisis of the day solved. There is a toilet paper strike that was just settled but we managed to get 4 rolls even though the supply has not yet begun to flow back to the stores.

July 24, 1968

Renaca, Chile

I picked up the Bloomes at their hotel and on the way back we noted a biggish blob on the Renaca beach, rolled up during the night of high waves. Soon I could see it was a beached whale. The kids came screaming up telling me it was a beached whale. Closer inspection showed it to be a badly decomposed specimen of a Cuvier's beaked whale, probably 3 weeks since death. Leanne and I measured what we could and then I set about getting the skull out with a kitchen knife. It was a miserable stinking job. I was accompanied by a continually chaging flux of visitors. It finally came out that we even had been on the local radio. Shortly buses came up and I was forced into delivering a rotating lecture in halting spanish to kids, school girls, old folks, etc. One gent was highly exercised when he learned I was an American and not Dr. Aguayo who knew everything about whales. I finally mollified him by explaining I was working with Dr. Aguayo. It was interesting to see his anger subside. These visceral things are so chemical and cannot be shut off with the speed of thought, but instead must subside while the chemical balance is reestablished.

Even through the stench I was interested to see the very peculiar anatomy of the beaked whale head—it needs careful study as it is only reminiscent of the delphinid structure. There are, for example, quite different sac arrangements, and the melon does not appear near so completely fatty. I, however, was some busy holding my nose so my dissection suffered.

Phylly and I hauled the skull dwn to the Estacion where it was put on the roof in a big plastic bag. By the time this was all over I retreated for home and attempted, but failed, to get the odor off. It lingered all night and gave me nightmares of eating rotten pot roasts.

July 25, 1968

Renaca, Chile

All night long we could hear the boom of the surf, and yesterday the paper had advertised "Olas Altas en Valparaiso". Boy, they sure were. First thing this morning we looked out and great combers probably 30 ft. high rolled in from the southwest, row upon row, curling and splashing into sprays of foam and acres and acres of creamy aprons of water before the crashing breakers. Streaks of brown foam striped the waves as they curled and broke, from the eroding banks on shore. The sky was clear and calm, making a very peculiar storm indeed—but a storm it was as the waters rushed over the beach, over sea walls, into homes, across the main highway in sweeping masses of roiling water, crashing against anything in their path. Garage doors left closed were dashed to kindling wood, boats left on the beach were heaved on the crest of retreating water into the maw of the great crashing masses of water. Towering spurts of water rushed into the sky when the water hit embankments, tearing out planting, upturning park benches and rolling up masses of succulent ground cover.

Before long we made our way down to the shore with our first business of the day—the preservation of Nancy and Barbara's skate eggs. I had promised them to take them out to the marine station on this inauspicious day to put them in a sea water tank. As we rounded the corner from our house we were met with a road strewn with debris,

half flooded with water, and running as wave after wave spilled onto it. Here and there aimless homeowners wandered, wondering what to do. In places the sidewalk had been undermined and stood in separate pieces, separated by chasms flooded below with surging water. We tried but failed to get to the station. Instead we were stopped at a promontory where one of the estacion scientists was pushing his car for protection. Beyond us lay a bend in the road and then the station. It was a stretch of chaos not to be passed in safety by anyone, let alone a family group with a bucket of skate eggs. The water slurped onto the road by the thousands of gallons, enough to wash a person out into the maelstrom. The 50-ft. high rock in front of the station breasted the swells and caused them to break in shooting sprays of foam and white water that shot into the sky twice the height of the 60-ft. station roof. Behind the station another mass of rock broke the full force of the pounding water and added a white backdrop to the wild scene. A spray haze was everywhere in the air.

Dr. Buckle, whose car was pushed out of danger, looked back with haste in his face but paused long enough to tell us that the station boats were gone, the water had rushed through the windows into the lower floor of the labs and into the basement causing much damage. We asked if we could help, which message seemed to have translated "Can we work today?" No, the station is closed, he replied, turning and trotting off close to the cliff side of the road, back to the station. We watched him go, threading his way between the breaking waves.

We turned back toward the house and had no trouble reaching the safety of the dry road and finally our house up safely on the side of the hill where we could watch the scene below us. Where I had flensed out the whale yesterday was in the midst of the breakers, with water surging over the crest of the beach, under the bridge and up our little lazy river channel. The abutments of the bridge were being cut away and I wondered if the surging mass of water would not simply lift the bridge from its foundation and drop it into the water. It did not, and before afternoon, the worst was over.

The afternoon was spent getting our children ready for their schools. Dick was taken to "El Tigre" in Valparaiso, where he was outfitted like a little dandy with a navy blue jacket, gray pants, a neck tie, a kind of overall used for activity involving dirt (which I am sure Dick will indulge in). He also has a lovely insignia with a lot of latin letters in it.

Later we took Barb and Nancy in to be outfitted for St. Margaret's school. They are now decked out in red jackets, gray jumpers, gloves, gray knee socks, ballet tights (red), special gym shoes. Tired, empty of loose change, we made our way past army road blocks set up to tell people the road is closed beyond Renaca, to home. A nice dinner of lamb chops, boiled potatoes, carrots, and cookies.

July 26, 1968

Renaca, Chile

The storm has subsided a lot, though there are still groups of high waves that come in once in a while. The shore road is a mess but passable between the station and Vina del Mar, but beyond this is blocked and the troopers still stand guard shunting people up our street, and over a detour to Con Con. The papers blame it on a subterranean disturbance somewhere between Easter Island and Australia. It could not, in my opinion, be properly called a tsunami, however, as the typical pattern of a series of

swift low waves that draw water away from the coast was missing. It was simply a rash of high waves, much more reminiscent of a storm than a shock below the surface. Further, the high waves lasted for nearly 48 hours and were very regular during that time. One could predict that groups of very high waves would pound the shore every 15 minutes or so, and the intervening waves could hardly be called small, since they too washed up onto the streets and shore.

Leanne and I went down to the marine station to see if we could help. It was a most frustrating experience. Everyone was just standing around. We finally realized that their reactions and methods for dealing with such a situation are very different from ours. We wanted most desperately to get a shovel in our hands, to pick up debris, to be assigned a room to clean, to pick up wood off the beach, to dry books, to gather Dr. Fisher's sample bottles. But no, they would inventory first, then begin to clean machinery soaked with the water, and likely the professional staff would merely direct activities. I was given a job—that of photographing the damage. It was extensive. Water had rushed through windows on the lower floor, breaking doors free on the opposite side, homogenizing the contents of samples, furniture, equipment. Down in the basement was chaos. Incubation cabinets had been flung 30 ft., nets, tools, supplies, excelsior, etc. were all mixed up with seaweed, shattered fragments of boats, pebbles, shells, and sand, and even a live fish or two (one *Sysiastes*, the huge local clingfish). I photographed everything and even caught one new series of waves crashing over the rock out front.

We listened to a little pep talk by the station founder and now head of science at Valparaíso, Dr. Yanez, and then went home. It was pretty obvious that we would be more in the way than anything else.

I spent the afternoon writing on my book, which is coming along pretty well for a change, though I'm not sure I like the tone or the style I'm using.

July 27, 1968

Renaca, Chile

Dick's birthday today. Yesterday we had done a little shopping in the afternoon and had taken the kids out to do some shopping for him. They wrapped his presents out in the form of bugs (Nancy), dogs (Susie), whales (Leanne), or just presents (me and Phylly). We entreated him to open the bug in the morning and it proved to contain a perfectly lovely three-tiered bird cage for his little finch Cabeceo (means nod)—a Chilean mourning sierra finch (*Phrygillus fruticeti*). This bird is called a mourning finch because the male is mostly black. Ours is a pretty female with a nice buff mask and otherwise sparrowlike body. The street salesman said it "canta bien" but thus far she just cheeps.

Leanne had to get her driver's license so we dumped her off at a government building in Vina and went on to Valparaíso, around the shore, to pick up jackets. No jackets so we had to return and killed a little time getting photographs taken in case we needed licenses (we don't as our trip to Peru will renew the three months time on our international licenses).

We picked up Leanne and went back to Valpo where after getting the clothes, we spotted what looked like a market out in the center of the mall. It proved to be one of the most complete and biggest we have seen. It was composed of two four to five-block long

lines of stalls. There were mountains of lovely produce of every conceivable kind, and men and old ladies shouting out in rapid spanish. Boys held a handful of lemons and chanted a cry over and over, or walked along garlanded in strings of garlic, chanting its virtues. There were neatly wrapped bundles of kelp (cooked with meat), stalls full of rabbits (conejos—little guys, and great big liebres), killed and cleaned right in the stall, chickens, ducks, pheasants, all kinds of shellfish (how did they get them with the storm?), congrio (a delicious big brotulid), hake in great quantity (the area's most abundant fish), and believe it or not, what look like sticklebacks about 2 inches long. There were stalls with nothing but clock parts, ones with old pipe fittings, ones with records blaring out. Best of all there was a pile of bird cages with a lot of local birds, behind which was a wizened white stubbled old man building cages and peering at us out of dirty Benjamin Franklin glasses. He also had two parrots, one little one and a bigger one. Phylly automatically gravitated there. I asked the price of the bird. Cincuenta y cinco escudos (about 6 dollars). After much hemming and hawing about quaranteens and additional travel millstones he was bought and proved to be an Austral parakeet or "catita chica" (*Microsittace ferruginea*).

He proved a great hit with the kids as we walked through the market, and an even greater hit at home. He is duly named "Chispa", which means sparky.

It wasn't long before he was riding on everyone's shoulder (he likes the girl's long hair and cares very little for a ride supplied by me).

Hector Hermosillo Jr. dropped in during dinner as we were having our cake and joined us in singing to Dick and in watching him open presents—a new Chilean knife, a Chilean top or trompo, a lot of chocolate (the Bloomes showed up with some of this and the top). All in all a grand party, complete with a Duncan Hind's cake improvised by Phyl, from a box sequestered in the suitcase.

July 27, 1968

Renaca, Chile

I wrote today on the book. In the afternoon the kids and I went down to the beach to gather bright-colored pieces of wood for a collage of the storm I am planning. We found all kinds of limpet shells and lo and behold, the ribs of a very very old wreck cast up by the storm. They were teredo riddled but the massive red wood and old iron tie rods held in place with lead still there. We hauled them back to the yard, after a fearful struggle. It will make a magnificent base for a table in our new house, but doubtless will cost a penny or two to ship. It must weigh 250 lbs. Delicious roasted conejo, notes, and to bed.

July 27, 1968

Renaca, Chile

The kids start school tomorrow, except Susie, and both the Bloomes and Leanne have found houses nearby. We hate to see Leanne leave us, but she will be having many meals with us, and working a good deal here.

July 28, 1968

Renaca, Chile

Today is woe day. Oh, woe, woe, tomorrow, we hope, will be better. Sleepily we gathered ourselves together—breakfast before dawn with the fog casting haloes around all the street lights down on the street below. At the first light came over the gray water we piled into the car and took everyone to school. I ushered Dick into McKay—very British—like Groton, all the kids in their gray blazers, scarves, etc. Most looked bigger than Dick. He was led off by a swarthy young fellow who gave him directions in spanish, which Dick rightly enough ignored. He tried to follow me but we successfully turned him around as I left. Later we found he had been in 3rd, 4th, and 5th form, but finally reached his own level. He has classes for 7 hours and then has games or study until 4:30 PM. He came home happy with 3 small friends.

Then we took the girls to St. Margaret's. It is a lovely posh girls school for 550 girls. It occupies a whole block of shaded streets, pretty buildings . . . Susie, who had not wanted to go, was spirited off with a couple of English-speaking girls. Nancy and Barb, in uniform, went off into the depths. Both Susie and Nancy were in classes taught only in spanish. When they came home at 1:30 they were both grumbling and moaning about the classes and the turkeys who gobble (people who speak spanish). Oh woe. Susie downright refused to go back tomorrow. She was traumatized by the social situation. The woe persisted until Susie went to sleep. After much consideration we decided to declare a moratorium and have her and Phyl seek alternatives before making a decision. The stress of being forced to limp along on a few words of spanish was just too much. She was just too obvious and different—things Susie cannot take at this point. Nancy will cope with the situation and Barbie already has “millions of friends.”

Leanne and I went out to the station and worked on the *Globicephala* and *Ziphius* skulls there. Comparing the pilot whale with the old figures in True. The example we had before us was obviously closer to *G. milaena* than any other form, though there are obvious affinities with *G. scammoni*. How does an animal on the west coast of S. America have such affinities, from the historical standpoint? It indicates interfertility, at least in the past, plus climatic changes sufficient to bring stocks across the equator that now only come as far south as New Jersey. Did the crossing come in the Atlantic and go around the Horn? Which is oldest? Could the Humboldt Current play a part? What happened to *G. macrorhyncha* during all this? Any chance the stocks could have made an interglacial crossing of the Arctic Ocean? With the presence of a probably *G. melaena* type in Japan and the southward sweep of the California Current matched by a similar northward sweep of the Humboldt Current, isn't the Arctic route the more likely?

July 29, 1968

Renaca, Chile

Leanne kept making mistakes—she spelled the latin names wrong, and when I corrected her, did them right and then put the wrong name on the animal anyway. It seemed that every incorrect permutation was attempted and we never did get things very close to right. We tried to work with the *Ziphius* on the roof and had to quit before getting things very well in hand. Shopping intervened. There are so many things the kids need. It is unbelievable the amount of clothing the kids have to have to attend St. Margaret's. We have to equip them for the “sporting club” where they do the long jump, play hockey, etc.

Moosemeat and Frau have a nice house just down the road from us and will move in probably tomorrow. They will be very glad indeed to get out of a sterile hotel into a house where they can cook all their goodies.

July 30, 1968

Renaca, Chile

The cursed alarm rang so far before sun-up that it was pitch black. Leanne and I had to go with the Bloomes to Santiago to tend to a lot of business there. I had museum work to do, and the Bloomes had to pick up a car and settle other domestic issues. We drove to the train station and left Phylly with the car (her first solo flight in Vina) as we boarded the spanking clean train. It is connected to a club car where one can have martinis at 7:40 AM if he so desired, or better, a cup of coffee. I slept mostly as we lurched along. The roadbed is very rough—the railroad equivalent of a washboard road. We fairly loped along in places. At the great, vaulted steel station, all fixed with metal curlicues, we disembarked about 2:20 minutes from Vina. It was a modest walk to the Convenio offices. There we tried to settle our travel advance for Iquique-Antofagasta at the end of the week, and a variety of domestic issues like torn sheets, and how do we get a heater for our house.

Leanne and I left for the cheerless Museo Ciencias Naturales, where we set up our work in the library, photographing and reexamining the 100-year-old type specimens of Professor Philippi. Mostly, we think he is wrong, but there are some interesting things to be seen, including several skulls that are difficult to assign to a species. We decided to eat after we finished and Leanne almost didn't make it, being famished from nearly no breakfast, and being saved only by a thoughtful librarian who gave her half an orange to tide her through about 3:30 PM. I was so happy to be working on specimens that I couldn't have cared less. We finished at about 4:00 PM and took a cab for the Convenio, stopping on the way for an empanada (a pastry with meat filling) and some other food, which revived us (I having faded perceptibly, once we left the museum). We found Moosemeat and frau at the Convenio, marched off with about 2,000 dollars in checks for our work in Iquique (the Convenio operates on a cash budget of \$10,000 at any one time and there are 25 participants in Chile, so we did make a bit of a dent). Moosemeat had a car, and after arranging flights, etc., we drove back, arriving at about 10:00 PM, very tired, and happy to go to bed.

I am using the lovable technique on the Convenio office. The head man, Gene Menzies, we have named Smiling Jack. He always looks like he was on the south end of a semiripe quince. I have made him smile though, painful as it was. But we are getting cooperation.

July 31, 1968

Renaca, Chile

Today was another day spent trying to straighten out our world here so I can go to work. First we had to buy Chilean traveller's checks with the money from the Convenio and that involved a lot of going from bank to bank and finally to Valparaiso, where calls were made to Santiago, and finally the checks issued. The amount—about \$1,500—is so big here that special precautions are taken. It's better, however, than carrying escudos around in that amount. The biggest bill is a 50 escudo note, or about 7 bucks (7.8/1

dollar). Then we went shopping briefly. It takes all one's time just to shop. We bought a cogrio, a big, tasty brotulid, at a shoreside fish market, a leg of lamb cut in a curious way (people make several meals from one such leg and require them to be cut into parts representing meals), some more clothes for the sporting events of the girls and Dick, and things like eggs (wrapped three at a time), bread from another store (sliced on a machine—very dense and very good), wine from another store (cheap and the best dry wines are delicious—they don't do well on sweet wines), vegetables from another, and finally a sort of dry stores store where one gets powdered milk, jello, marmelada, spices (what few they have here), paper products, etc. There are lots of sort of delicatessen-type stores in which all kinds of peculiar goodies can be had. Most of these the kids will not touch. They are on a boiled potato kick now.

Carne means beef and we get it Friday and Saturday. On other days everything else is available—chickens (with the heads nicely left on, and obscure innards retained), lamb in all classifications and cheap, pork, likewise. One can buy heads of all these with the eyes balefully peering at you, or hooves on all, with the hard outer coating removed. There are several delectable ways of presenting the intestine. The most charming comes in a braid.

In trying to outfit the kids we ran into a lot of oddments. They have to have copy books specially printed for geometry (lined on one half a page and plain on the outer half), but there are none anywhere. A couple of texts are likewise unavailable.

So it goes. Chileans are trying to develop their economy and hence have high tariffs on most foreign goods. They now make a surprising array of goods. This includes things clear up to autos (they make a funny little pint-sized pickup with two front seats called a camioneta, which is very popular, the price being much lower than imports). An imported knife may cost 15 dollars vs. about 2.50 for a Chilean version. We tried for days for an egg beater and finally found an astronomical imported version (which we bought).

I unpacked a lot of my gear at the station. We are now complete there. The station is settling back to work though many windows are boarded up and some walls are smashed and much gear is ruined.

Everyone is very tired so off to bed.

August 1, 1968

Renaca, Chile

More time getting everyone settled and minor details out of the way. Leanne is moving into her nice little house up the hill. It has a grand view of Valparaíso across the bay, a fireplace, and a splendid backyard which stretches out into the campo with no break for 10 miles. She had to buy a little portable heater though, to warm the house, even with the fireplace.

We bought some coal and firewood, for so many cents a stick (10 chunks of eucalyptus cost about 30 cents). It turns out that the fireplace plus our two kerosene heaters are too much and we have had to open the sliding glass doors in front for a little air.

I ordered a couple of handles for my harpoons and it was like entering a new world—a whole new set of terms to be negotiated. I ended up with some octagonal

handles about 4 meters long made of aurucaria wood. This, it turns out, is the best for work in salt water.

Nancy went to the sporting club today for her gym class and we threaded our way through back Vina to pick her up. It turns out to be an incredibly posh huge place with a great old Victorian grandstand and an immaculate track and acres of green grass, horses standing around nibbling contentedly and various teams hockeying it up. All around are huge old trees, well tended, lining broad paths with appropriate instructions about how far cars can go.

We found Nancy amidst a gaggle of her schoolmates and some boys from another school all getting ready to leave.

At the station we unpacked the remainder of our gear and made ready for the trip to Iquique-Antofagasta coming up next Monday. The station is functioning pretty well now though they find that there is absolutely no money for repairs in the University-wide budget.

I finished Chapter 3 of the book this morning—things go pretty well on that front now. I start describing the bubbles capture next.

August 2, 1968

Renaca, Chile

Today was hike day. Some time ago I had decreed that we would begin walking beaches in search of stranded marine mammals, and the inactivity was beginning to tell on us so today we took a hike.

In the morning Leanne, Phylly, and I drove to Valparaiso where I shopped around in the naval stores places for manila line, buoys, tools, and the like. It was fun poking in these musty old places, and amazing how little they have to offer. One was apt to find all kinds of things mixed in with the ship materials—old clocks (horribly expensive), L.C. Smith typewriters of ancient vintage, old oil cans, statuary, guitars, shoe repair machinery, etc. Being essentially a junk collector it was pure ambrosia to come trundling in, burdened down with a coil of rope, nosing around these nooks. We bought a couple of pack sacks and a fresh sierra mackerel plus some merluce roe (a hake very heavily fished here—females yield up nice-looking roe—called “regalos” or “gifts”). Leanne picked up a heater (butane, portable) and we headed for home. Oh yes, we also bought some wood and coal for the fire.

In the afternoon Phylly drove Leanne, Susie, and I up to the Aconcagua River above Con Con. Our plan was to hike on the dune-lined beach toward Quintero, 22 km. distant. If we got tired we would turn back, presuming we knew which direction was better to go at the time. If we made it to Quintero we would catch a bus back.

So, with new pack sacks on our backs, loaded with apples and oranges, TP, cameras, and other sundries, we left Phyl on a dirt road about ¼ mile from the beach. Our first encounter was with a farm house equipped with easily 15 dogs, all docile fortunately, all skinny. The farmer was out in his field sowing grain by hand as we went by down his dusty rutted road. Before long we reached the flat marshland back of the beach where we saw some interesting shore birds, a beautiful black-and-white stilt, some caracara-like raptorial birds. Thence, over the gray dunes to a very broad beach dotted with the shells of the macha—a kind of clam with a calene triangular shell, about 4 inches long. The surf boomed in, the gray gulls rose ahead of us as we walked, and

occasionally small flocks of a little, puff-sized plover scurried over the sand in front of us. This species had a black eye bar, a black bar beneath, and a sandy white back.

I walked the dunes behind the beach where the storm had swashed over, spilling now and then across the railroad tracks behind. Great piles of trash had to be scanned for bones, smelled for hidden carrion and inspected for attractive junk for my collage.

We passed railroad men repairing the roadbed where the waves had cut in, we passed a lagoon where I found a dead goat and Leanne spotted a perfectly good (but dead) Humboldt penguin lying on the sand. We inspected his scaly, flipper-like wings, the tightly imbricate body feathers with their dense underlying down and then went on. Ahead of us were two Chilean men with huge bags on their backs trudging along as were we. They may have been blindlestiffs—folks that have all but disappeared from the American scene, or they may have been farmers or fishermen walking home. We never learned as their purposeful hiking took them farther and farther ahead of us.

Everything on the beach was worthy of our curiosity—kelp bones (the dried stalks of the local giant kelp, which with their holdfasts look like grotesque bones), vast numbers of wine bottle corks, corks everywhere. Soccer balls made of plastic and broken were also everywhere, as were the handles of little hand scrubbing brushes. A couple of kinds of plastic objects—one a funny little sphere with holes in it, another a lattice work of various colors, never were identified.

Leanne developed blisters so both girls took off their shoes. On and on we hiked, the sun dipping lower into a clouded horizon. No chance to turn back now as there was too much distance behind us and those lines on the cliffs ahead were seeming to materialize into houses of some sort.

I picked up an immaculate little bird—a whale bird (slender billed, blue-footed whale bird, rare in these parts). He was still alive, though very weak. Black-capped head, blue legs, white breast, and long, graceful, pointed wings made him a lovely bit of life. We hoped we could save him. Susie tucked him in her coat and held him in both hands as she walked along. Patiently thus she carried him until we reached home some hours later.

The houses materialized into some nice-looking A frames with grassy plots around them. Horses appeared dancing in the sand. Up and over the dunes we went into the little hamlet of _____. Stopping by a battered fence we asked a man drawing water from a well by hand, where we were. “Como tres kilometros a Quintero.” Three kilometers we could negotiate but it was clear, not before dark [?]. As we sat upon a big eucalypt log eating oranges and apples a spring wagon, gaily painted with red wheels and bearing two bouncing children and an older boy jogged by, bouncing over the ruts while its shaggy horse paced along.

We trudged up the dirt road, and soon met curb to curb cattle, driven by a man and a boy, followed by two big dogs. The cows gave way to us as we passed. The hills around us look like Southern California—rolling, grassy, lined here and there with windbreaks of Monterey cypress trees—old, gnarled, dark trees with spreading, pointy limbs shaped by the wind. Monterey pines grow here too—in big groves.

As darkness became complete we topped a hill and could see the lights of Quintero ahead of us—soon we came upon a little magazine store all alone in the darkness, giving a warm glow of light from its opposite side. I walked around, sending kids scurrying in every direction. Inside was a lady ironing, waiting for some business in

this lonely field. Her iron was a tall, heavy, metal affair filled with red-hot coals, which glowed through ports in its sides. She told us we could wait at the corner for the bus, which we gladly did. Weary, we sagged down on the welcome wall of a cement viaduct and waited for our bus, hoping we could recognize it when it came. One thing in our favor, there's no place for a bus to go but to Vina from here. All kinds of rickety cars went past, we listened to the frogs calling over yonder, watched a plane land on the very short runway. Finally Leanne said, "I'm going to hitchhike." Up she got and flagged the next truck rattling down the road. Miraculously as she did so, lights came on its front and it transformed into the Vina bus. Happily we climbed aboard, paid our 4 escudos 20 centisimos (about 50 cents for all three of us). After a while people enough got off so we could sit down, Susie with her bird, then Leanne, then me.

The bus let us off right at the base of our hill and it was almost more than we could manage to scale it. Then, everyone at home was so full of his own doings we had great trouble getting them to listen to our heroic adventures. "Why didn't we bring the penguin?" Oh well, another generation will realize how great was our effort.

August 4, 1968

Renaca, Chile

Saturday and we slept late. With Dick having to reach McKay's at 8 and Barb and Nancy, St. Margaret's at a quarter to 9 we have to get up before it is light weekdays, especially Phylly, as sometimes I goof off and snuggle down under the covers looking small after she has left. Anyway, blissful sleep after it was even light.

I wrote on various things this morning, mostly regarding plans for the coming trip. Later we dropped by the marine station and picked up some of our gear. Phyl and I did some more shopping for the kids. Amazing but Dick needs some more clothes—tennis shoes for the "sporting club". They'll think of something else, I'm sure, before we get out of their clutches, and by then we will have three children with complete wardrobes including everything a young girl (or boy) can be expected to wear when presented to the queen. What queen? This is a republic. Ah, but the English here, even though Chileans for generations, are as pure Devon or Cornwall or whatever as they can be—ginger moustaches, accents, tweeds, and all. The headmahster out at McKays is one of these.

Dick has been pining away to go fishing and I have vague, amorphous plans for a bit of trout in the south, so we bought an inexpensive outfit (by their standards here). Dick and I went down to our beach before sunset to try for corvina in the surf. They use a silver fish, cast out into the waves, and retrieve it. Dick says they were catching them right and left the other day, but true to surf casting fashion, no one was catching anything this day. Dick did get to practice casting though.

August 5, 1968

Santiago, Chile

Today was spent in preparation for the Iquique trip, in writing, and in a little hiking with Dick on the beach, along with some practice casting. (He is getting better, I worse.)

After dinner (roast pork—good), two cars of us left for Santiago. Elda Foggetti from the station and Leanne came along to take the car back. The other car was a Fiat

driven by a Chilean-Italiana dubbed Straight Arrow. She fired through traffic like a guided missile. She carries a Berretta pistol which she shoots periodically at birds and things. Straight Arrow led us to the Hotel Foresta—nice, clean, full of nice art, with signs saying “Keep your baggage off the plush.” So to bed.

August 6, 1968

Iquique, Chile

Before breakfast into all the chaos of the Chilean local airport where LAN and one other line go to various places in Chile. After quite a lot of confusion and \$25 for overweight baggage. Thence into a nice Boeing 727 and off to Autofagasta and Iquique. The flight led first out up the central valley alongside the towering Andes, which we could see were only flecked with snow, the glaciers standing out in unaccustomed relief against the black rocks, all due to the extended drought. Farther north there was more snow.

Soon the landscape became arid. Salinas appeared flat white in the valleys and absolutely barren hills appeared below us. By the time we landed at Autofagasta all was barren, sand accumulations flanked the steep fault scarp coast. Only in occasional washes could bushes be seen. Some slopes were dotted with cactus, very far apart.

Autofagasta rests on the coast south of a protective peninsula, cliffs and hills blocking it from behind. The sea was blue and only traces of swells marked it. On land not a vagrant blade of grass could be seen, only bare soil, pebbles, and sand. Water comes in to this considerable city by pipe from the Andes many miles distant. It is bustling and from what we could see modern. It is a major port for copper from the mines at Chuciquemata (the largest copper mine in the world).

Shortly we changed planes to a turboprop and were off again. Strand lines from many regular recessions of the sea mark the Mejillones Peninsula, just north of the airport. I suppose that along this fault coast these mark movements are occasioned by earthquakes. The extremely rapid elevation of the coast is very evident. The scarp is rough and jagged, without well-defined water courses in many stretches while above is an old erosional surface, nearly level and marked with well-defined stream courses that end abruptly at the scarp—cut off by its movement which has been too new for them to cut courses into it.

We stopped at Tocopilla, a nitrate port now suffering from the reduced value of nitrates (synthetics from the air have lowered the price). The terrain around is absolutely barren, while far in the distance one can see the white crests of Andean volcanoes.

It was only a short hop to Iquique.

This town of 80,000, once the major port of this area, and once part of Bolivia, is now a fading town full of Victorian mementos supported mostly by the fishing industry which depends solely upon the anchovy. It lies at the base of a steep scarp, perhaps 2,000 ft. high, above which is the pampa, or trackless desert. On the mile-wide bench at the base of the scarp is situated Iquique—which laps up the hill in a ragtag *barriada* [?] of shacks, most unpainted wood. Five big wooden tanks still farther up store water for the town which comes in by pipe from the Andes, just like Autofagasta.

It was a short hop to our hotel—the Arturo Prat—named after a famous naval hero. Prat died defending Chile in the War of the Pacific. When attacked by a Peruvian battleship Prat attacked a smaller ship and was killed attempting to board the Peruvian.

Snide word here has it that he may have been pushed off the bow by his own men, but it's best not to disturb such heroes in their fame.

Our taxi, full of luggage, took us into town along Baquedemo St., the main drag. The houses have old fronts, grilled windows, and many have widow's walks up top, some have towers. One hotel is the place in town right on the square adjacent to the clock tower. The tropical influence is evident—bougainvillea everywhere, palms, *Solanum* trees, and such. The hotel is old and gracious, in need of paint, clean and pleasant.

I called Louie Marcovich, my friend who set up most of the fishing along this coast. He came right up in his 12 hp 2-cylinder Camionetta and gave us a tour. Louie will return to the states in a couple of weeks to stay. Both he and his wife hate Iquique, even though she is a native. I can understand that in the long run, but for our stay it is interesting.

He showed us the 6 operating fish meal plants for anchovies—great stacks of bags out front of each, standing in witness to the huge catches. Peru last year took 10 million tons in the 52-day season.

He showed us “chippies”, the appropriate name for the local Madam's stash. He showed us the railroad switchbacking up the scarp back of town, and other sights.

We went to the Cooperativa where the gerente, another Slav, arranged for a 30-ft. boat for us—2 bunks and \$70 a day, including fuel and food. It will make 10 knots. We were amused that they almost caught us 2 Delphines (I think *Delphinus delphis*). The calderon (*Globicephala*) is abundant about 15 miles out, the marsopa lives close to shore. He gave a fine description of them blowing and am sure he was speaking of *Phocoena*. The killer is here occasionally, and *Tursiops* is found off shore. He was a little taken aback that I should want a calderon but agreeable that I should try.

After tea at the Marcovich's old, vault-ceilinged, two-story house, we headed back for the hotel and caught a guitar concert at the local auditorium. It too was full of fading elegance, the tattered curtain hanging over the performer, he in immaculate full dress and very good indeed.

Preparations for tomorrow when the boat comes in and to bed.

August 6, 1968

Iquique, Chile

The caballero at the hotel kindly forgot to wake us so we arrived at the dock a little late, hauling all of our heavy gear.

The mighty *San Mateo* (30 ft.) was there waiting for us. It is a narrow (7 ft. 6 in.) oversized double ender with a little low deck house, two bunks, a 25 horse Volvo diesel, and a tiller aft. The sternsman stands clutching two ropes, one going to each end of a crosstree on top of the tiller steering, another line leads down below to the throttle. Our crew consists of three men, Capitan Enrique Pierron, marineros rank y Mario. Good men all. Mario cooks glorious things on his midships primus stove. She's clean and the engine sounds good. There's no skiff though, so she's all we've got.

Quickly we loaded our gear after Enrique bought a little food uptown, and were off into the nearly flat sea. It's nearly always calm here we were told.

Enrique assured me that we would meet with the chancillo, which I now think is the bottlenose porpoise. We were also likely to see a “blackie” or pilot whale. It was

“café oscura” above and white between the flippers they said with a white mark between the eye and the dorsal fin (on only one or all, I wasn’t sure).

Past the big stone breakwater, with stacks of the anchovy reduction plants sending billowing plumes of white into the air.

We travelled all day, arriving home at dusk and saw one cetacean but were not able to get near it. It was medium-sized, perhaps 12 ft., with a small, sharp fin far aft, dark brown.

Many birds were seen. Big, white-bodied albatrosses reluctantly stirred themselves and ran flapping across the water until their wings locked in glorious soaring flight. Shearwaters flew by in great flocks, little phalaropes dabbled and twirled on the water surface, picking delicately at surface plankton. The kelp gull is here as are the tiny black petrels they called either “golondrina” or “bailerina” (ballerina). These little birds fluttered and circled like butterflies over the surface.

We heard a good many fisherman’s tales—about encounters locally with 30-ft. white sharks, in whose stomach was a tonina snapped in two (*Phocoena spinipinnis*). Killers were scarce here they said. Our skipper, who went to “Fishing School” in Valdivia came out with *Orca gladiator* so I guess we were thinking about the same animal.

On shore Vicente, the head of the cooperativa, had two toninas for me, caught by gill net fishermen at 5 AM this day. Bizarre animals in some ways. These harbor porpoises are dark above with a broad band leading from the lower jaw to the pectoral of the same color. The belly is white with longitudinal striping around the vent. These things were hard to see on our animals as they had turned dark during the day.

The peculiar dorsal is very far aft. It slopes up from the back in a straight line on which are lines of little knuckles or spines, rough to the touch. The posterior fin border is convex and just above the anus. Flippers and flukes are large.

We could not photograph so froze one animal and flensed out the other, then trudged over to the hotel, had some dinner, and went to bed. Tomorrow we get up at 5 for a long day at sea.

August 7, 1968
Iquique, Chile

For a change our hotel desk clerk woke us at 5 AM. Soon we were underweigh to the dock in the darkness, heavy suitcases and packs on our backs. Our crew was already there and ready to go so we descended the anchovy-anointed steps of the dock and jumped aboard the comfortless craft. Through the silent harbor, out past the jetty, and into the smooth sea we putted. The boat is supposed to make 10 knots but settles for about 7. I looked back at Iquique. If one could paint stars with a brush, a single stroke, a dozen stars wide, along the water line would suffice for her. [?] Behind, the looming cliff and the faintest hint of dawn.

Enrique, our skipper, said we had to get out beyond the “agua verde” and had to go to the south, since the animals had gone that way. Agua verde is close to shore and from 10 to 30 or more miles wide. It is cold (12 degrees C.) and apparently rather lifeless as far as surface fish go. Beyond it the water clears into oceanic blue—they call it “agua blanca” or “agua limpia” and it is warmer (15 to 16 degrees C.). Tongues of green reach

out into the blue and when one travels the interface as we did one crosses patches of green from time to time. The animals like the border area.

We travelled and travelled. Nothing but birds and an occasional “azuledo” or blue shark. Mario the cook and harpooner says they cook the blue shark by soaking the meat in salt water since it is “muy acido”.

There is a magnificent petrel or shearwater here “el pintada”—with black wings and head and upper body and head, pure white below, marked with three white spots on the wings—a speckling on the back and tail.

Enrique tells me the red-tailed tropic bird and one of the petrels, in addition to the gray gull, nest on the pampa or desert near Iquique. The literature lists only the gray gull. He tells of collecting their eggs. I wonder if this desert isn't so austere that birds are relatively safe there, much like they are on an offshore rock.

On and on we went, out to sea and south. Mario cooked a Chilean cassela for us. It is a sort of soupy stew of hunked corn-on-the-cob, beef bones, potatoes, squash, cilantro, garlic, and peppers. Good though.

Then the engine started acting up a little. Enrique went back and fiddled with it and it quit altogether. Thirty miles at sea, out of sight of land, three gringos and three Chileans in a small craft with food for the day and no skiff. Such thoughts crossed our mind. What a setting for a Steinbeck novel. The starter groaned and didn't catch. Enrique fiddled further. Groaned again as if it was just too much work to turn the reluctant engine. Next time it caught, belched carbon out of the exhaust pipe just aft of the cocina. Mario crossed himself in a flash and we gringos thought our thoughts of relief. Steinbeck retired.

At about 3 PM Raul, whom Enrique said had the best eyes on the boat, called out “blackfish”. He pointed in agitation to an absolutely unmarked sea. It was a long time before we saw them—spouts and tacks showing. They proved to be *Tursiops*, the bottlenose porpoise, a school of ancient old fellows, some probably 11 ft. long and weighing 900-1,000 lbs. I hit one just below the dorsal fin and the fight was on. Mario and Raul fought him by hand. We tried the buoy but gave that up since we could not maneuver near him with our boat. The braided nylon from the gun is terribly thin to pull by hand, and didn't allow us to pull him near enough for a blow with the hand harpoon.

I missed with a second line, which shot just over the beast's back, ricocheted over the water, bending the harpoon badly. After an hour's battle I tried again, this time without a line. I hit near the other and my shot went right through, bouncing over the water beyond. Still he fought on unabated.

I attached my last line and tried again as Mario and Enrique brought him close, straining on the nylon with their bare, tough hands. This time I hit him amidships and actually cut his heart as it later turned out. He died quickly and we then struggled to bring the 450-lb. beast aboard by hand. It wasn't easy but soon he was on deck. We turned for home, leaving a school of blackfish behind. It would be 2 AM before we reached Iquique. It had taken more than 5 hrs.

I saw the pilot whales (blackfish) stand up in the water as ours do in California, and saw them slap their flukes as they passed. I wanted desperately to see them but said nothing.

The long, long trip back was spent measuring and flensing the animal. A bloody hard job in the light of a coal oil lantern. I had blood and gobbets of meat everywhere.

Enrique was happy though, as the blood had poured out his shark lines and the smell brought fish. Furthermore he had a mountainous pile of bait in all my leavings.

About 12:30 I climbed on top of the deck house, zipped up my coat, pulled down my knitted cap, lay my head on a pile of bloody manila line, and went to sleep. Tomorrow, work ashore and some beach walking.

August 8, 1968

Iquique, Chile

Today we spent ashore getting things straightened out—lines coiled, harpoons straightened, batteries charged (on tape recorder), assorted parts pickled, animals photographed and flensed, clothes cleaned, and bills paid.

Once these things were done we made for the old whaling station south of town via taxi. It has been closed for 3 years but seems in good shape still. The afternoon was beautiful—sunny and calm but cool and pleasant. As a matter of fact, the cold Humboldt Current makes the climate here exceptionally mild and pleasant all year. No rain though. We deplaned at the station and wandered down to the beach. It was covered with a wrack of seaweed, old baleen plates, and whale boes. There were many sperm whale teeth amongst the pile so I had a field day recovering ivory and my pack was burdened down before I had ventured 50 yards. Further down the beach we came upon many intervertebral discs that would make good hot pads or saucers. More load.

The mountains behind drop in a single sandy scarp into the sea. A big tan dune mass stands nearby where the cliff recedes from the shore. We walked on through sandy coves and rocky headlands, looking for porpoise bones. I found two vertebrae of a *Phocoena* and that's all. We marched on into the gathering dusk—reddening sky and calm sea.

Before long our packs were getting a bit heavy and Beiret and Ken flagged down a local fish spotting pilot who gave us all a lift into town in his car. Nice, clean-cut fellow who spoke good English with a German accent learned in Chilean schools.

I went down to the dark docks amongst the old rotting nitrate sheds, and found Vicente, the head of the cooperativa, who opened the fish market where I flensed out the last animal. Back at the hotel I cleaned up and found Kenny in the midst of the last harpoon line moaning at the rat's nest of loops and tangles.

Off to bed. Tomorrow out for blackfish.

August 9, 1968

Iquique, Chile

On board the San Mateo at 6 AM and off a bit to the north following a tip from Vicente that blackfish were seen 1½ hrs. out. We didn't see them though. In fact no porpoise or whale broke water near us at all. And none were onshore waiting for us.

Enrique said the water was never right even though we went 35 miles offshore. Enrique is a bright, entertaining guy who has spent some time in school (Concepcion)—fisherman's school and one year in the University in Marine Biology. Every once in a while he breaks in with a latin name. Especially, however, he entertained us with the fisherman's secret language used to hide intentions during bargaining with outsiders. He learned it as a child. It's like a Castillian pig latin. Syllables are dropped or transposed

and it is utterly unintelligible to me. It is called Caraganza, and he says every fisherman in Chile knows it but he doesn't know if it goes into Peru or not.

A word about our crew—Mario is the older, perhaps 40, tough as rawhide, with a thin, muscular face, Errol Flynn moustache, bright, small dark eyes and swarthy skin. He can haul on a line for hours, it seems, without tiring. He is a helluva cook on his single burner stove. Casuelas come pouring out of his shoulder-deep galley pit, along with steaming mugs of heavily sugared coffee or tea and other good foods. The chicken of today, however, had led a rough life and was in the chicken olympics running the mile. Flavorful but nearly impregnable. I was literally unable to dismember it by hand.

At dusk we came in. I had heard of a restaurant called La Canada that serves Peze Sapo or clingfish as a specialty. This is the world's largest clingfish (*Sisyogaster*) and is found locally clinging to rocks above high tide. It can live out of water for about 3 days. It is considered a delicacy here and brings a very great price (escudos for one fish—about 50 cents). The fish may weigh $\frac{1}{2}$ to $\frac{3}{4}$ lb.

We hopped in a cab which took us through town and out on a peninsula south of town to a frame building, vaguely green where the paint hadn't peeled off, light pouring out the door onto the crushed shell street. Inside was a high, vaulted room with a couple of unshaded clear bulbs hanging down, several very indian people standing around drinking beer. Behind one glassed counter an indian woman sat knitting amidst a gaggle of dirty children. Tattered tables and chairs were scattered around under menu signs written in chalk. Peze Sapo wasn't even listed—I found because the price was so high—10 escudos for a meal, or \$1.20.

In the back were several private booths that looked more like a house of ill fame than a restaurant. Each had a table and chairs, a curtain door, and crushed shell and dirt floor.

As we sat down somewhat uncertainly I thought how Boyd Walker would have enjoyed this to the last crumb. We ordered Peze Sapo and beer (later a bottle of good white wine—bien fria). The cook emerged from the cocina and fished three squirming fish out of the glassed cabinet, and went off into the kitchen. We made a pilgrimage to the cabinet and found it filled with live fish clinging to each other or to trays—wholly out of water, but could see by their clear bright eyes and occasional movements that they were alive. This beast is certainly one of the ugliest creatures living—a giant tadpole with a lumpy skin, big fleshy lips, spiny opercles and funny short-rayed, inefficient-looking fins. We understood they looked up at you out of the casuela and sure enough, when they came in porcelain trays (like bedpans) a little while later, there was the fish, all purple now, peering up glassily out of a rich orange brown broth, a crown of onions, peppers, and sea urchin gonads, lavishly slathered over him. It was absolutely delicious. The sea urchins made a sauce par excellence and the fish was meaty, tender and delicious. We all stuffed ourselves, caught a microbus a few yards down the street for 1.40 escudos for all three of us and got off at the hotel content to go to sleep and digest. What a meal from what a seedy restaurant!

August 10, 1968
Iquique, Chile

Louie Marcovich came in early this morning and helped us round up a taxi driver for the day, since the San Mateo is preparing for the trip to Autofagasta we will make

tomorrow. Ken and Beiret and I decided to spend the time looking over the pampa, or Atacama Desert, above the cliff back of Iquique. Our driver, Victor Corrales, had a bright shiny Impala and a modestly outlandish price for the day's drive to Pica and back (\$35.00).

So, off we went, up the road that switchbacks up the cliff, and over into the incredibly barren pampa.

I was at once struck with the effect of a total lack of rainfall upon the terrain. The hills are rounded and relatively featureless. It looks to me as if old water-eroded terrain has been filled in and smoothed by wind-blown sand and soil for one can see the dim outlines of streamcourses down slopes and in valleys but filled and smooth.

Not a plant was to be seen. Not a blade of grass, a cactus, a belly plant, or even any living thing. The ever-present cloudcover of Iquique had gone and the sky was utterly blue. I suspect one can read into these hills the story of past climatic change, probably of Pleistocene age, when water did play a part. Now, even the long-lived seeds of desert plants are dead. It's clear why birds can find safe nesting grounds here. No animal, not airborne, can afford to search away from the areas of skimpy vegetation that do exist in places, especially around salt flats when saline water does occur.

Our good paved road led us past a couple of well-guarded checkpoints (Arica to the north is a free port and much smuggling results). We stopped at Humberstone, an abandoned salitre [?] city, complete with streets, houses, churches, schools, there at processing plant, and acres and acres of junk. It has been dead for nearly 50 years.

A few families live there, helping to reclaim pipe scrap iron, building materials, etc. As we walked through the abandoned streets, a few dogs followed us yapping. I looked for native life and found some birds—a flycatcher, pale as desert birds generally are, and the ubiquitous English sparrow. We chased a lizard in the dead and dying trees of the tattered plaza and then stopped to talk to a fat jolly matron leaning on the picket fence in front of her house. We could look in her door and see its sparse furnishings as she talked.

One decoration especially, struck us. She had a large nude photograph on the wall, in color, the model holding roses over the appropriate places. But the head had been replaced by the head of the Virgin. With what reverence do they treat their religion! While we contemplated this unusual icon she told us that there were foxes and rats and some big lizards in the region. At the moment this seemed hard for us to believe.

Every time our driver stopped he broke out his dust cloth and cleaned his car. It was absolutely shiny and spotless. I felt like some kind of criminal bringing my dusty feet inside.

We joined the Interamerican Highway—a fine, paved road—and shortly entered a “tamarugal”, or experimental forest using a relative of the mesquite tree. In 15 years after planting these trees were 30 ft. tall and shedding seeds everywhere, as well as shade. Sheep grazed under the trees. The trees are planted around salt areas where there is salt brine and salt rising from the ground. Also common in these places is *Distichlis*, or saltgrass, sometimes growing up in mounds 8-10 ft. high. I noticed the burrows and scats of some modest-sized rodent—much like those of the kangaroo rat. A large lizard with neck collar of brown and a tan body not unlike a low-slung *Dipsosaurus* was seen several times amongst the tamarugas or sunning itself on the caliche. Probably this tamarugal

will prove valuable enough to be a commercial way of raising sheep here, as well as wood.

A word about the nitrate deposits or salitre. It occurs as caliche, or layers in the ground and is very hard. The stuff is simply ripped from the ground with bulldozers or shovels and loaded into trucks for processing. The Guggenheim process is used, whatever that might be.

Rather shortly we turned off across the broad, long valley through utterly barren country toward a straggling patch of green set on an absolutely barren scarp. I think I could see the marks of a long fault and suspect the springs at Pica are along this fissure. This seems likely as the flow is pretty large and never varies.

We skirted through town—all bouganvillea, morning glories, and some kind of yellow flowering tree. Orange and mango groves are everywhere and scent the air. We ended up at the little hotel, stopped for a bite to eat on the porch under a bamboo ramada.

A group of German people, including Papa who looked straight out of Bavaria, talked a bewildering mixture of German and Spanish.

We wandered down to a nearby pool where a group of young girls were swimming. I chased the local lizards but found them extremely noose-shy. Later I learned this was because the local kids collect them by throwing stones at them. I gave up and inspected the pond. A nice-looking, aquiline-featured chap came up and I asked about frogs and toads in the pond. (Frogs common, good to eat, toads either absent or rare). He turned out to be a French-Canadian priest headquartered at Victoria. The girls were his charges and all were out for the day. There were two priests in his parish covering most of northern Chile, an area the size of Belgium, he said.

The ride back was more or less uneventful except for a lizard chase in the tamarugal. Our driver was anxious to get going, I think because he didn't want to get his car dusty in the dust devils. We stopped him anyway at a tamarugal and went lizard hunting. Under each tamaruga there were lizards. They were skittish, but not so much so as they had been at Pica. They retreated under caliche shelves into large, interconnecting caverns. Moosemeat and wife cornered one and I noosed one. They have a collar and a modest dorsal crest and no femoral ones that I could see on brief inspection. They are dun colored with the male being darker and about 10 in. long.

Back in Iquique we paid our driver his 300 escudos, at which he looked very glumly, why I can't say because it is excellent pay around here and taxistas usually don't expect to be tipped.

Tomorrow out to sea.

August 11, 1968

Drifting at sea off Caleta San Marcos

My birthday and what a way to spend it! I did get a present though—Enrique gave me a splendid set of foul-weather gear. Things started out inauspiciously enough, with all sorts of trouble getting the skeletons out of the freeze box. Then, just as we were about to shove off in our mighty felucca a rope got caught in the screw and we spent a jolly time trying to cut it loose. Enrique insisted on some spare oil, which I liked, but finally about 10 AM we made it out of the harbor.

I spent lots of time talking to Enrique who speaks very clear Castellana for us Yanquis. He can, however, launch off into the well-nigh unintelligible patois of the fishermen when he wants to.

We have some jugs of water, a little food, no lifejackets or skiff, an engine that seems reliable but has to be stopped every six hours for additional oil (the gauge doesn't work), two bunks for 4 people, and all my dead porpoises.

We skirted the coastline staying within the *agua sucia*, a markedly greenish water with poor visibility. It has much planktonic life as we could see from the phosphorescence at night and there are many bottomfish and fish in bays, but larger forms like albacora (swordfish) and porpoises and whales occur outside in the *agua blanca*, which comes in variable distances from shore and is markedly warmer. It is clear and nearly oceanic in appearance. Why should it support the top of the food web when the seemingly richer water does not? Enrique reports that almost never is *Tursiops* or *Globicephala* found in *agua sucia*. Enrique reports that the merluce (hake) does not occur either at Iquique or Autofagasta but does at Coquimbo, along with langostinos and camarones. Thus the waters of Autofagasta and Iquique probably support the same marine mammal fauna in general.

As we cruised along he told me of this shipwreck off Talcahuano when the ship capsized and he came ashore 7 hours later sans clothes and with no idea of how he had done it. He told me of spearing an *Orca* near Isla Santa Maria near Talcahuano and feeding its flesh to the dogs of the island, who promptly all died.

On down the steep coast we went, cutting close to points and slicing far out across the bays. Every six hours Enrique stops the engine to put oil in it and then it goes "runnk", "runnk" very slowly before it starts and I wish Mario would stop crossing himself when it starts.

The flight of seabirds fascinated me as it has many another naturalist. Why do so many such birds glide with their wingtips within inches of the waves and how do they manage to stay above the surface without touching it? It looks to me as if they do not touch the water, or else they would leave wakes where they touch and they do not as I could see when they flew close.

The view from the San Mateo is especially good because one is only a couple of feet above the surface and birds swing within a few feet at times. The wingtips are closest to the water—within an inch or so and highly sensitive to its position. The body is higher [drawing].

I suspect the wingtips "feel" the proximity of the water because of the moving air a few centimeters above the surface and that having the body a few inches higher allows the animal to move its head about while judging its distance from the water.

Enrique decided to make an anchorage in a little caleta (bay) called San Marcos. It was pitch black as we slid around a point he said was called "El Sombrero" toward the anchorage. We felt our way along, groups of sardinas shooting away from the bow like underwater fireworks.

Dimly I could make out white marks through the fog, glowing very dimly in the dark. On and on we went. I saw white patches growing near which Enrique thought were schools of fish but turned out to be foam flecks.

Raul and Mario were talking faster and faster in the stern and finally without Enrique asking them to they turned the boat rapidly around and headed out to sea. The

spanish rose in pitch and volume as we continued southwest. This I didn't like. The captain didn't control his ship but only argued with the crew. I didn't want to even be a witness so I went below while the argument continued. Finally Enrique came and tentatively stated they had decided it was safer to drift at sea. I readily agreed. So 5-6 miles out, with no lights, with a sea anchor astern, we are drifting along at the conclusion of my cumpleaños (birthday).

Raul and Mario hauled out two mattresses which they said were full of plumas de canarios (canary feathers)—but were actually full of straw. With ponchos and sparse blankets they bedded down on deck while Enrique and I did likewise in the tiny cabin. As a last parting thought for the day Enrique had tried to light a light with the spare battery and it glowed most dimly. The reserve I thought we had was a weak reed indeed.

August 12, 1968

Tocopilla Harbor, Chile

With the first streaks of dawn, the rocking ship awoke, the sea anchor came in. All night I had rolled and pitched in my bunk, bracing with elbows and knees in the swell. The *San Mateo* is really little more than a big canoe and it rolls a bit. The motor caught quickly, Mario heated coffee and we were off, dimly in sight of land through the haze. On down this incredibly barren coast we went, past guano-covered headlands, some with a scattering of big black *Otaria* clinging to steep rocks above the heaving sea. I counted over 100 for the day. Guano is scraped and blasted from the rocks, heaped, and either carted off down perilous trails, or loaded into skiffs.

Between points we cut out to sea. At one point, several miles from land, we came upon groups of feeding giant squid or jivias, which Enrique said were very dangerous to a man overboard. They flapped wings above the surface, and occasionally jumped. I judge them to be 4 ft. long or so, including tentacles.

As we neared Tocopilla the shore became a single near-cliff rising perhaps 1,000 ft. One could see the marks of shifts in the fault by shear lines and truncated slopes. Cactus began to appear—a large, arborescent type standing in very sparse groves on the steep slopes. Enrique said there was a kind of mesquite there too that had seeds used for rattles for the “wawas” (babies).

I learned a good deal about Enrique's life, his plans, what it was like to work in Iquique, etc. He was having trouble with pulpos, (meaning octopus), who are the fish dealers and who were keeping him from getting an engine for his new boat.

At dusk we came to Tocopilla after a rough, windy traverse. The town is a nitrate port (salitre) and handles some copper ore, too. It is tucked in a cove of the cliffs. Its waterfront is bright and new. Three big freighters were at anchorage.

Houses sweep up the hill in orderly rows, steam belches from the fish reduction plants.

We decided to anchor there and start at 2 AM when the seas were calmer.

August 13, 1968

Mejillones, Chile

I lay in the sack as the *San Mateo* started out in the dark. It was a rough, cold passage with poor Raul taking the brunt of it while Mario lay curled up under his Japanese nylon tarp and Enrique snoozed in the bunk next to mine. I, personally, scratched my

jerjeles bits, picked up on our beach walk. Kenny Bloome is an even bigger mass of welts. These jerjeles are a “no see um” that lives in the kelp wrack on beaches and undoubtedly we had picked them up on our beach walk. They leave a nasty welt that won’t go away for 5 days or so and they hide in clothing. In summer they get so bad people are hospitalized with them and there is a special ward in the Iquique hospital for sufferers.

Around dawn I hauled myself out for a cup of coffee in the stiff cold breeze.

More coast of an austere sort, a single sighting of a *Phocoena* slicing away from the bow and disappearing, and before long the seas began to calm as we reached the arc of Mejillones Bay. Shortly it was flat calm and we could see 5 anchovy seiners in a set, their nets up like tents in the power blocks (called powerbloc in spanish). One was a South African whom everyone hated because he would set inside another person’s set, stealing all the fish. This time he had all the fish, too, though perhaps gained in a more gentlemanly manner. We watched as the anchovies were pumped aboard in a glittering stream into the hold, gulls squawking in wheeling hoards.

As we came deeper into the calm bay we began to see harbor porpoises in twos and threes, dark backs with peculiar fins silhouetting against the light. We saw ten all told, all fairly close to shore.

I was fascinated by the little petrels they call bailerinas. Here you can see why they get their names. They run and pirouette on the water, using their wings in graceful fluttering to keep themselves aloft—all the while dabbling at the surface with their beaks.

On the dock was a *Lagenorhynchus obscurus* (southern striped porpoise) from a school of 200 or so. It had been caught in a net and partially dismembered for food. I got photographs of the remaining body and skeleton.

Once ashore I looked for my compadres whom I expected to be present—but no one was about. I made reservations for everyone at the best—there are two—hosteria in this graceless fishing village. The hosteria sits right on the beach and seems reasonably clean though nearly none of the plumbing really works.

Raul, Enrique, and I set out on foot to try to obtain a shipping box for all the porpoise parts. Enrique thought we could get two tea crates and stick them together, but there was none such in old Mejillones. We walked the sandy streets between ramshack storefronts, many made of eroding corrugated iron salvaged from the salitre ruins. Finally, far out in one end of town, we found what we wanted in a fish meal plant. These deserve descriptions. The anchovy boat stands offshore and is connected to the plant by a big suction hose. The fish are sluiced into cylindrical mills and oil is pressed off. Finally the smelly meal is sacked and the oil put in big grubby drums. The residue of blood runs onto the beach at the edge of the sea amid thousands of screaming gulls and pelicans turning the water red for dozens of yards. The stench of all this is pervasive. In a shed dozens of girls were filling big barrels destined for Spain. Layer upon layer of fillets were laid out radially, a layer of salt put on and so on till the 5-ft. barrel was filled a few inches above the brim. Then it was pressed down with boards weighted with heavy stones and capped.

We found our box amid a pile of new machinery, received permission from the plant superintendant and walked off with it in a wheelbarrow. There, coming down the street with hands waving, were Leanne, Kenny and Beiret. They had put up in a fisherman’s shack as all rooms were full, they were told, at the hosteria. Of course that

was because I had them reserved. Soon everyone was settled, Leanne instructed on the recording techniques (she will try for records of the *Phocoena*), dinner of porotos (beans) and assorted vegetables and nameless hunks of meat plus some grand fried fish (cojenol—a shad). To bed.

August 14, 1968
Santiago, Chile

A day of travel tangles—the plane had a bad pancreas at Autofagasta and I had to wait 5 hours and thus did not get to the Corroenio office. I had the eeplus from too much wine (drowning my sorrows) in Autofagasta so spent the night in my room reading *Time Magazine*.

August 15, 1968
Renaca, Chile

Up this morning feling a bit droopy and uncertain about my interior. I think, however, that it will recover in good style. All offices were closed for a “fiesta of the dead”—everybody visits the cemeteries. I asked the man in the hotel what the best way to go to Valparaiso was and he suggested a micro which was coming to the hotel in half an hour. It was “muy barato” he said. It was a shiny new Mercedes bus and I thought it odd that there was a microphone up front. A few blocks out the man demanded 65 escudos—it costs about 8 by train. I was on a tour that would return to Santiago later in the day. Too late now, so I got a nice guided tour, peered at Aconcagua (nice), went through Quillota where cherimoyas and avocados grow in everyone’s yard. It was all new country and interesting but hardly what I expected. While the tourists were having lunch the bus driver took me home. Glad to get there and find everyone well and happy. Unpacked and rested the rest of the day.

August 16, 1968
Renaca, Chile

All day spent writing letters, reading manuscripts, and untangling expenses.

August 17, 1968
Renaca, Chile

A quiet day with the family. The rest of the crew came in from Autofagasta. They had obtained two more Burmeister’s porpoises and had spent a day at sea during which they encountered sperm whales and *Lagenorhynchus obscurus*. The sperm whale had come over to investigate them, rising part way out of the water within 6 ft. of the rail. Leanne recorded about ½ hr. of superb recording showing different kinds of sounds simultaneously from one animal. The crew were frightened for the boat, which was about the same length as the animal (30 ft.). The porpoises are coming down by refrigerated truck. Everyone stayed for a good steak dinner.

August 18, 1968
Renaca, Chile

Sunday—all the kids are home. After a morning of desultory writing on my book we went for a ride north of Quintero to a little village called Ventana (there is a natural

bridge there). All manner of goodies were gleaned from the beach including a nice live dead penguin, which we left on the sand. We hiked out to a rocky promontory and watched the waves rush into spume and boil into kelp-filled inlets.

I cooked some merluce and lenguado—both are good fish. The merluce is very cheap here but of low esteem because of worms. Cooked, who cares? Answer, most people, I guess. That's why the price is so low.

Now follows a series of days at home. Most was rather uneventful—the usual round of dealing with the tradesfolk, little discoveries like a new mercado in Vina where one can buy lovely produce and fish, work on the book, work on house plans for Hawaii, a little fishing with Dick etc. etc.

A few things stand out. We went to the Stanislavsky ballet in from Russia, right in the middle of the Russian invasion of Czechoslovakia and wondered if the audience would boo or demonstrate as feeling runs high against this act here in Chile. Especially I wondered if Leanne would but she behaved herself. She is a romantic person in many ways and highly incensed over the Russian act, but perhaps our stolidity suppressed her. The ballet was full of technical excellence in the classic tradition and full of schmaltz in their attempts to be contemporary or funny. Fun though.

Then, Leanne invited us all to the “circo celin”, a one-ring, one [?] circus, set up down in the river bed. Phylly was feeling a bit low so she stayed home while the kids and Leanne and I went off to the Circo.

It was well worth the price of admission (5 escudos, however much that is). When we arrived about 2 people were gathered around the ticket booth, of which 18 later proved to be circus employees. After some time a bubble gum chewing fat little girl of about 13-14 waddled into the booth and sold us tickets. Since no one was going in we too waited outside while 5 majestic musicians whipped up a little music to draw the customers in. They had a drum which sounded like a wet laundry bag when hit, 2 flugelhorn, a trombone (played by a guy with gloves on), and two trumpets. They were unbelievable—strictly unbelievable. But they did make noise, which was the object.

Finally we went in. Our seats were right by the ring. No one else was there except some little kids and a majestic goat. We went over and met the goat, whose name was Pepe. Pepe chewed straw with a rhythmic relentless rotary motion while he solicited scratches from us. He smelled but we liked him. That obligation out of the way I talked to the little boys and inspected the knots used to hold the tent up. The bleachers were held up with two rows of wooden poles, two to a pair, wired together with the main riser resting on the wires. I'd hate to be there in bleacher seats at a full show.

For 45 minutes we waited (it was scheduled to begin at 9:45 PM) while the orchestra tried to drum up trade to no avail. Finally with about 20 people in the stands they began. A modestly good trapeze artist was introduced by the gum-chewing little girl, now dressed in spangled tights and bearing a big baton.

Then came the goat, Pepe. We clapped furiously and he nodded at us. Then the clowns. Dick was convulsed every time one did a pratfall or slugged another clown. They jabbered on in Spanish and did more pratfalls.

Toward intermission I had noted on a pencil-written program tacked to one of the tent poles, we were to have some bulls. When it came, the bulls were of cloth with two people under them and 4 clowns were butted and finally when the bull was to be killed he

gingerly stepped out of the ring and sat down in two seats near Dick. Dick watched with unadulterated joy as the bull crossed both pairs of legs and refused to go back in the ring.

When we left at midnight a thing called “Ritmo y sensualidad”, featuring the little fat, gum-chewing girl, was coming on. We had had a family of acrobats including the little kid I had played with earlier. He was joyously bad and did only a back bend.

It was, we decided, a smashing success and the only circus in which each one of us could be a useful part without training. I should mention their other animal, besides Pepe—a grand dog who jumped through hoops and jumped rope.

Our other main adventure was going to jail. Susie, Leanne, and I were trying to buy a guitar as we just have to have some music around the house. We finally asked a man in a hardware store and he told us to check with the jail up on top of the hill, which we did. It was an austere-looking pile of stone. I went up to a guard and he said, yes, they did have guitars, and that I should give him my carnet and go inside to see them. Leanne and Susie and I all trooped into the jail through a dirt courtyard to the visiting room—all bars and gray chipping paint. There a gestapo-looking guard bawled into a microphone for Sebastian Guzman to come out of stir. Shortly he appeared, a tiny, ferrety little man with snapping black eyes and a sad expression. Later, for romantic reasons, we decided he was a mass murderer. He explained he had guitars but they weren’t complete. We asked to see them and he went back in the inner prison and brought out two—both inlaid, made of Oregon pine and ___wood—a very pretty Chilean wood. We snapped one up for 220 escudos—about ½ price, and besides, it isn’t every one gets a guitar made by a mass murderer.

Later, when I went to pick up the guitar, the guard took me inside the inner prison. The cons were playing futbol in the narrow cement central aisle. Up on either side went three tiers of cells to a vaulted glassed roof. Three hundred men were locked up in these austere lifeless cubicles—wow, it made my flesh crawl just to think about spending time in this place. I wished Sebastian luck and left rapidly with the guitar.

August 28, 1968

Caleta Agua Verde, Chile

This morning, Phylly took Leanne and I down to the *Explorador*, the research vessel of the University of Chile. We were scheduled to try for some marine mammals out of Valparaiso. Before dawn we loaded our gear into a slim, double-ended skiff, and clambered aboard while Phylly went home to tend the kids. Even in the harbor the 60-ft. *Explorador* rolled. Out in the first graying light we inched through skiffs and [?] and finally out into the big confused swell outside. It is cold, forbidding, and overcast, and rather rough. One has to brace constantly to keep from going over the side. All day we looked and saw not an animal. This, we are told, is the usual case here in winter. Very little in the way of marine mammals, save the resident herd of *Otaria* in Valparaiso Harbor, is to be seen. However, in spring and summer—January, February and the first half of March, the water has warmed from its present 12-14 degrees C. to 17-18 degrees C., and then the calderon (*Globicephala*) and the tonina (probably *Tursiops*) make their appearance in some numbers.

Eduardo and I went over his log for records. He told me of encountering *Orcinus orca* near Tacna, Peru. Everyone says there are many animals at Juan Fernandez Islands.

The sea was full of birds as we started out, with fewer and fewer as we went farther offshore. Just out of Valparaiso Harbor we passed a raft of Pajaro ninos—Humboldt penguins and shortly began to see probably three species of albatross, one a huge, old bird with a white body and wings dark above that is either a white-capped albatross (*Diomedea canta*) or a wandering albatross (*Diomedea exulans*)—we couldn't be sure which. At any rate its wings are so long they droop in flight—flexing as the animal beats its wings. I note that there is less camber than in smaller petrels and hence the body is closer to the water during wing beats. The wings are around 10 ft. in spread—a huge creature as it flies toward one—like Howard Hughes's giant, droopy-rotored helicopter that never flew. We also saw, I am fairly sure, the gray-headed albatross (*Diomedea chrysostoma*). The cape pigeon, or as they call it here, tablero, was very common—the beautiful black and white painted petrel with the black head we saw up north. They wheeled and circled around us all day. I watched again, and even in rough water their wingtips do not touch the water, but jitter up and down just above it, a centimeter or so away. I cannot think this is accomplished by sight—but instead by touch, only touch in air.

I wonder if we have two major formal areas in Chilean marine waters inshore—one a northern area going up into Peru and Ecuador, in which we find *Globicephala*, *Tursiops*, *Lagenorhynchus*, and another group to the south in which southern species such as *Cephalorhynchus*, *Lissodelphi*, etc., are found

In winter the northern group retreats northward while the compensatory movement from the south isn't as great, leaving a very sparsely populated, or even vacant sea in the center, as we now see off Valparaiso. Then, as water warms animals move south again in 16-18 degrees C. water. Farther offshore, say 200 miles, very likely the oceanic fauna is encountered and this is what is aggregated around Juan Fernandez Islands. Likely this is oversimplified.

We noted a 1.5 degrees C. increase as we moved offshore 40 miles today. Likely, this would continue and it may be that an offshore-onshore movement occurs too, perhaps to the exclusion of the north-south movement. Only tagging will tell for sure. Water mass data could give good hints.

August 29, 1968

Renaca, Chile

Before dawn the ship began its daily life after a night comfortably attached, sleeping, to its anchor chain. Anchor winches roared and clanked, auxiliaries began humming, and soon the rhythmic thrumming of the main engine. I lay in my bunk, waiting for the swell to begin rolling the ship—but it did not do so very much—the night had calmed the water and when I sleepily ascended the ladder to the bridge I could see it was gray and overcast but calm, only an undulating swell.

Captain Reyes takes me back to my navy days. He is two men. One gay, urbane—ashore, the other a no-nonsense captain, totally assured of his competence, expecting each toot on his boat's wains pipe to raise a marinero or two instantly. At dinner one brings him his bottle of wine which he drinks impassively at the same table with them, who are permitted none. I squirm a bit but understand that is a system of harsh, clear rules, designed to contain all types of men, transients, responsible ones, and irresponsible ones. The selections from the dockside are not always reliable.

When the Captain announced we had to be in by 5 PM and I wanted more time his eyes grew as hard as agates, his slim features set. Nothing I could do would change the situation. So it goes. I am a guest and must not push, even though, as happened this day, I am working with an animal unknown in Chile and don't want to leave.

As we cruised out over the continental slope I saw spouts far off on our port bow. As we drew near I could see that some were diagonal—slanting forward from the animal's head—sperm whales. Later I saw the unmistakable square snout and peculiar dorsal ridge that passes for a fin. The animals moved resolutely southward along the slope contour. They were divided into small groups of 2 or 3, spread over a mile or more of sea. Never would they let us approach very closely. Having determined that there were about 12-14 animals and that no other smaller species swam with them, we turned out to sea again.

Reyes says they often catch jivias (giant squid) on the continental slope too. Perhaps the whales know this too and congregate to feed.

Not long afterward, as we were keeping our watch on the cold wings of the bridge, dancing up and down to keep warm, Leanne shouted that animals were ahead. Sure enough, within minutes we were in the midst of a big school of *Grampus griseus*, the grampus. These big fellows look for all the world like an obese, high-dorsal-finned bottlenose dolphin, all covered with scars. The heads of many were nearly pure white and gleamed emerald green as they flashed by us underwater.

Like the bottlenose porpoise they often broke water as they swam along—often breaching $\frac{3}{4}$ length and falling back on their sides with a great splash. One animal would make repeated leaps, leaving a trail of splash marks on the water surface. Somewhat less commonly animals leapt clear of the water in arcing leaps, revealing their entire chunky forms and pattern. All were white below, grading in variable fashion into plumbeous gray laterally and dorsally. Usually the younger animals were the darkest. Some of the older animals were totally white on head and anterior flanks up to the anterior insertion of the dorsal fin and farther back laterally.

I got the impression that both pattern and scarring are involved. Anyone who eats squids, as these folk do, is bound to be scarred by the tentacles.

There were subdivisions in the school—we saw two pairs—a large and small animal together near a similar pair. We saw aggregations of older animals as told by their whiteness and some tight groups of 10-15 animals.

As far as I know this is the first record of the genus in western South America.

I tried to shoot one but failed. On the first shot the entire cannister flew out over the water as the line jammed. The harpoon fell short. The next shot I left to Mena, a crewmember. His too didn't run free and the animal escaped. I missed the last shot, firing low. They were difficult shots with the animal a long way ahead of the bow.

By this time the captain was getting itchy to head for port so I made the most of our opportunity by putting Leanne in the skiff to record. She and Ruiz cast off and were soon tiny bobbing forms on the sea surface, a long way off. When we retrieved them Leanne had recorded a variety of sounds, squawks, and barks and clicks, and one sound that may have been a whistle.

Ruiz entertained with some good Chilean guitar music on the way in. We arrived at 4:30, called Phylly, and headed for home.

August 30, 1968

Renaca, Chile

A day spent trying to get ready for Peru. The Convenio, it turns out, will not support us on this extra-Chilean jaunt, so we pay for it ourselves.

We took a nice hike up in the chaparral back of the house to stretch our legs. I was fascinated not only by the genera in common with California chaparral (*Rhus*, *Clarkia*, *Lupinus*, *Sphaeralcea*?), but also the ecological equivalents. There is a tree that looks for all the world like a scrub oak, but is not. It has highly aromatic leaves, unlike our form. A poorwill-like bird, a robin that's not a robin, a trilling bird that's not a wren-tit but has a long flicky tail and is brown, and an equivalent of our yucca, only it's a bromeliad—the life form is the same, the climate the same, and many species are different. We saw a white-tailed kite soaring like his namesake, bounced on Susie's lovely long pine log that springs one up and down like a diving board. Back home with a *Puya* spike over our shoulders, much like *Yucca* but with green, spiky flowers.

August 31, 1968

Renaca, Chile

The time on these days was mostly spent getting ready for our trip to Peru. Phylly and I will spend two weeks there collecting, with Leanne staying with the children. All the children and Leanne are scheduled for German measles except Dick. He and Berit are the only ones remaining who have had them, and Dick just an incubation's span before. We had to fill the coffers with money and advice on the care and tending of families of four, which took time. The Convenio has seen fit not to pay for our specimens or trip to Peru, so we will go, squeezing our money with unaccustomed firmness.

September 2, 1968

Lima, Peru

Off to Santiago by Automotor, the nice rapid train—and with darned little luggage, too. What a switch that is, and what a relief. It's like taking your pack off after a long hike—one raises up with the ease of movement. No kids and no luggage to speak of.

We settled various issues with the Convenio, picked up (and paid for) tickets and all the plethora of papers one needs to go out of and return to Chile.

We paid a visit to Fuad Yaru, a big industrialist here in Chile—he runs the country's largest woollen mill and the Robinson Crusoe Fisheries, which works local merluce, langostina (shrimp) and the lobsters of Juan Fernandez Islands. I wanted to see if somehow I could reach these islands and obtain collections. He was gracious, indeed, and said that the best way to go was to fly—a local airline makes the trip once a week or so. He said he could provide an introduction to his representative there who would help us obtain a boat and specimens. He thought I had best plan to fly my collections back as the boats have no refrigeration facilities. He hoped to learn more about the commercial fishing possibilities around Juan Fernandez and had brought a boat from France to explore these islands and St. Ambrosio y San Felix. I hope to obtain some information for him from my various ichthyologist friends.

On out to the airport we went where we waited for what seemed an interminable length of time before our jet took off in the dark for Lima. Three and ½ hours later we

were through customs and nicely ensconced in the Hotel Maury, a block away from the Plaza de Armas where Pizarro's body lies shrivelled up in a glass coffin. Our hotel is very nice and has grand food.

September 3, 1968

Lima, Peru

Today we began the motions of collecting data and animals and of getting our return trip arranged. Our first venture was to the Chilean Embassy where we arranged for visas which cost us \$20.00, not soles, but bucks. We will have to wait till tomorrow to get our passports back, appropriately stumped. How I hate to let anyone, however official, go out of my sight with my passport.

Then Phylly and I hoofed it 10 blocks down to the Natural History Museum where we measured and studied a small dolphin skeleton. I think it is a young *Stenella* since I was not convinced that the palatal grooves were those of the common dolphin. Instead, the pterygoid hamulae dropped in a smooth curve to the margin of the jaw, with no indentation. Tooth counts, too, were low.

We hauled our specimen out in the sun and photographed him. The folks at the museum were very obliging and took the skeleton off its mount so I could photograph the palate. Everyone has been that way here.

Then, we made our way out to Callao to the shiny new marine lab where we met Jorge Mejia, with whom we made various arrangements to gather animals. He will meet us tomorrow for a tour through the "Terminal Pesquero" in Lima, where they often sell porpoises. These come in by refrigerated truck from all over Peru.

Phylly and I marched around Lima, free as birds with no children to tag along bitching because we were shopping too much. We found a grand brass "tocador" or door knocker for our new house in Hawaii. It is an antique that the saleslady tried hard to pass off as new, and dawn her eyes, she had the boy in the back room polish it up like new—unbeknownst to me.

On our way back we visited a marvelous old antiques store with a marvelous old antique gentleman [?]. His store was full of Chimu goodies, including whistling pots and lots of Chimu weaving—all expensive as might be expected of relics 1,000 years old. We bought Nan Hackett a sample of this ancient cloth since she is interested in it.

After a grand dinner (pompano in black butter with capers and a lovely bottle of vino blanco) we went blissfully to bed.

September 4, 1968

Lima, Peru

After a sparse continental breakfast, Jorge drove up with his friend Sr. Guterrez, a very bright, pleasant biologist who is Jorge's assistant. We then picked our way down to the terminal through the back streets of Lima. As we neared the market the muddy streets became a mass of stalls crammed with every conceivable kin of merchandise—blocks and blocks of it—amidst teeming masses of people. In the vegetable sections garbage was ankle deep in places from previous mercados. We threaded our way among trucks, people, incredible jalopies, and vendors, and finally reached the fish section.

Every fish and shellfish they catch in Peru was spread out in stall after stall. Sharks of several species. Guitarfish dried and fresh, gervids, dried parrotfish, skipjack,

and bonito, cojenoe cureles, espejo (lookdowns), mullet, rockfish, several species of croakers including one big one like our white sea bass, and on and on. Finally we found the porpoise stall and sure enough, there was a *Lagenorhynchus observus* laid out, end to end. His head (the part I wanted) was in back as it was pretty undesirable. I got it for 10 soles or 25 cents. Pretty good for a new northern record 1,000 miles north of the last record I set at Iquique last month.

We hauled our prize off to the Instituto where Phyl and I photographed it, flensed it out, and then packed it in salt. I made arrangements with Jorge to buy more while we are up north. He will collaborate with me on a review of the delfinids of Peru eventually and thus is personally interested in our success. He is a nice guy, and I think, a good biologist. His work seems thorough and careful and I am impressed with his Institute, which seems well supported and at least as efficient as places like Scripps.

He will buy 5 of each species (3 in all, we believe), including 4 heads and one whole skeleton each, a packing drum, and salt and will hold them for my return.

I learned that the tonina or marsopa (*Phocoena spinipinnis*) is caught generally close to shore in corbina nets (about 2,000/year) that reach from surface to bottom and that the *Lagenorhynchus* may be taken offshore in drift gillnets set for sierra. The dolphins are not sought but simply caught and sold opportunistically. At Hauco, north of Callao many were taken, including what they called chanco—gray above with a modest snout and white below—which I take to be a *Tursiops* and that everyday at Chimbote one could find *Phocoena* coming in by 4's and 5's. Jorge said it was absolutely sure I would see them there. So, that's where we go. Jorge has provided me with a letter to his man there, giving me all facilities. We'll try to get to sea there, too, to see our animals in the flesh.

Jorge told of the calderon or pilot whale, which is sometimes taken at the Paita whaling station. It is dark gray overall except for a bright white triangular blaze mark between the flippers or a bit forward and it does have a grayish saddle back of the dorsal fin. Sounds like a cross between *G. melaena* of the eastern USA and *G. scammoni* of the west. The skulls look that way a little, too.

Phylly and I hooked a ride with Jorge and he let us out at the Plaza San Martin where we straightened out tickets, paid another horrendous airport tax, and hoofed it for our hotel. Having had no lunch we were most grateful for a seafood chowder and some coffee.

September 5, 1968

Chimbote, Peru

Up early and off to the airport. We arrived with much time to spare but finally about 8:15 boarded Fancetts prop plane for Trujillo. The flight was uneventful and even unscenic as the everpresent blanket of clouds covered everything but the distant mountains. We dropped through the haze to the short little field at Trujillo where a taxi driver took us in hand and delivered us to the Colectivo center.

There are signs on us as a member of a party of 5, plus driver, going to Chimbote. For 40 soles each (90 cents), Phylly and I got the two hour drive across the stark desert and the river valleys to Chimbote. There is much windblown sand on this mountainous stretch of coast including lots of well-formed barchan dunes. Just north of the Viru Valley we came across a remarkable dune resting on the shingle-covered flatlands. It was a compound barchan of large size—perhaps 2,000 ft. across the cusps, with a single

crescentic slip face, just like the small dunes have. Spawned from each of its lateral cusps were whole strings of small barchans stretching out ¼ mile or so from the parent dune. It's rear slope was a crenulated mass of interconnecting dunes [drawing].

How I wanted to stop to photograph, but the colectivo raced on. Soon we were in the Viru River Valley, site of ancient Chimú ruins. Now it is green and looks prosperous with corn, sugarcane, bananas, and vegetables. Up on the opposite bank the desert began again. It's not so stark as that of northern Chile. One can see drainage courses everywhere, and water erosional features, to be sure usually liberally dusted with sand. In many places the dunes were covered with the dark spring leaves of a bromeliad, a low wind-formed *Prosopis*, or mesquite relative, and in places clumps of a crawling *Cereus* cactus were all the vegetation we could see. Then, for long stretches little or no plant life could be seen.

Finally we sped into the grubby outskirts of Chimbote, barrios of unrelieved squalor. It got little better as we entered Chimbote. It has very few trees and is mostly of unpainted adobe or brick though some new modern buildings are evident. The street markets are dirty and the produce we saw rather poor looking. Over it all hangs the swirling clouds of steam from the stacks of the 32 anchovy meal plants. The aroma of fish meal pervades everything.

More than 2 million tons of anchovies were processed here last year. We holed up in the Hotel San Felipe, which is nice, new, and clean, and I might add, costs about 1/3 the price of our hotel in Lima (220 soles a day--\$5.50). It's been open 3 months, has about 25 rooms (numbered in the hundreds—ours is 202). We walked down to the waterfront and there we met face to face at first view with a school of bottlenose porpoises gamboling in the little surf. Phyl and I walked a circuitous path through fishermen's gill nets, along the noisesome strand until we found the Instituta Marina annex. Our contact was on vacation but three fine fellows took us in hand, especially Francisco Vasquez Pata, a biologist working on anchoveta.

Right across the street is the porpoise landing where we found a nice dead Burmeister's porpoise, waiting to be cut up and shipped to Lima. Phylly and I decked ourselves out with aprons and measuring gear and got a set of photographs and measurements while hoards of curious Peruvians ogled at us funny folk.

Francisco priced the animal for us and it came to 300 soles, which he thought was too much. I kept quiet for a change and think we will get heads free, plus other samples. It'll cost me 5 bucks or so, though, if I want a whole animal. We'll play the waiting game for a while. They say 4 or 5 come in a morning so we should have a lot to keep us busy.

Afterward we obtained a fine drum and 60 kilos of salt to put our materials in. Francisco thinks I'm a little nuts, but then, so what? I'll get my animals. So far it's been a porpoise a day.

Tonight I take Phylly to a real circus with sea lions in it. Then dinner and then bed for we are on the dock at dawn tomorrow.

I should mention a thing or two about Chimbote harbor—it is magnificent—the best in Peru. It is nearly ringed by rather high rocky hills and sea swell is blocked at the entrance by a group of guano-covered islands. I would guess that the nearly circular bay is 10 miles across, sand bottom throughout and shallow enough for anchorage over a very wide area. Flat sandy bottom goes for 40 miles or more offshore here, accounting in no

small part for the huge fishery. We'll try to get a boat here but there apparently are no swordfish boats to be had.

We didn't make it to the circus.

September 6, 1968

Chimbote, Peru

Our funny little Peruvian alarm clock stirred us out at 6:15 and before 7:00 we were at the dock waiting to see if some materials of either *Phocoena* (tonina here), or what we think is *Lagenorhynchus obscurus* (called chanco marino or chanco tonto). Neither were there, but the little *Phocoena* was still on the dock. We waited under the ramada where the porpoises come in until a fellow started to cut the beast up and retrieved the head, viscera, and such. I cleaned it carefully, labelled it, and put it in the big drum, all full of salt.

The ramada did a busy trade in a variety of fish species, chiefly a deep-bodied sardine-like fish called a machete. These are gill-netted in the bay and transhipped into smaller skiffs in large round baskets. Two men haul the baskets up the beach on poles over their shoulders. In the ramada there seems always clustered knots of people yammering in rapid spanish. Ragged urchins scurry about retrieving fish that fall from the baskets. Old tottering men shuffle around—also retrieving what they can. I think many of the children are orphans who live in the streets and sleep in corners on the ground. One thing, here winters are mild and it almost never rains.

The waterfront streets and beach are incredibly filthy—trash, human excreta, dead fish, and in the water a gray, swashing mass of scales, blood, and slurry from the fish meal plants. It's a raw, rough, wholly utilitarian town where life is rough, everyone urinates when and where he likes, and I suspect violence is common. Down in the high rent district, which is unaccountably downwind from the 32 fish meal plants, the streets and sidewalks have windows of fish meal covering them.

Pancho (as Francisco is called) took us through a fish meal plant that can turn out 2,000 tons of meal a day. It's an impressive stash of big cookers, dryers, steam plants, fractional centrifuges to take off oil and so on. It must have cost a very great amount. Out back the meal is stacked in rows of sacks 10 ft. high that run for hundreds of yards. The bulk of fish here is incredible when one tries to transform it to living, swimming fish.

Phylly and I decided on a hike down the long swam-backed strand at the south end of the bay. I hoped for some skulls on this uninhabited shore, especially of *Tursiops* (they are called bufeo here) since the net fishermen do not catch them. I suspect this is because of their refined echolocation capabilities.

Our walk was a very pleasant and leisurely hike down 3 miles or so of strand, a light breeze keeping things cool, sea birds, including two species of egrets, phalaropes, sandpipers, and plovers rising ahead of us. Offshore the boobies and terns dove in schools of fish. We found a battered harbor porpoise skull, some remains of the southern sea lion, and lots of interesting flotsam and shells. On our way back we talked to a weatherbeaten stubble-bearded old fisherman taking his catch of small sharks to market on his shaggy burro.

After a snack we did take in the Circo Ferias. It was very good in spots—a fine pair of gymnasts, a wonderful old French contortionist, some remarkable child aerialists, and an exceptional slack-wire artist.

Off to bed, pretty well pooped.

September 7, 1968

Trujillo, Peru

Before even reaching the ramada we found Pancho down on the beach dickering with a fisherman over the body of a striped porpoise (*Lagenorhynchus*). It had drowned in his gill net about 15 miles outside the entrance of the harbor and he had cut its tail off and brought it in.

We measured and photographed as best we could and then took him (for it were a he) out into the ramada to skeletonize it where the blood wouldn't get all over the lab. Soon we were surrounded with a pressing mob of babbling Peruvians, all watching and commenting on our every move. I won them over to some extent by explaining that later I would transplant a heart into the animal and put him back together again.

Finally we were done. I gave the heart to a raggedy old man who asked me for it. Then, there was some kind of signal from someone that we didn't want the meat and everybody dove—pulling and snatching at bits and pieces. In seconds it was all gone and miraculously the parts we wanted were left. At first, they reminded me of seagulls fighting ravenously over a bit of offal, but no, they had waited, every muscle tense, until some sign came that we didn't want the meat. More like disciplined dogs quivering until the master says it's all right to eat. I guess the law's effect is strong even though these folk might seem rude and lawless.

We salted our bones down, cleaned off the blood and made arrangements to send our drum to Lima.

Phylly and I then said our heartfelt thanks and goodbyes to Pancho. He had been gracious indeed and of great help.

Phylly and I then retreated to the hotel, packed, caught a colectivo for Trujillo. A colectivo is a car going to and from two set points—in this case Chimbote to Trujillo—and they leave whenever 5 people sign up which takes a short time. Our trip through the desert took 1½ hrs. and soon we reached the very gracious Turistas Hotel—all arches, red drapes and chairs, tile, and dark wood.

Then we arranged flights and walked the town. It is one of the most interesting old towns in Peru—ancient old churches, some dating back to 1513, with bronze bells slung on ancient logs, rude wooden barrel windows—everywhere are grills and great old doors with littler ones cut through them, so one isn't forced to swing open the big one. The post office has a bronze lion's head through which one drops mail. A quaint, rather quiet, and lovely town.

This is the area of the ancient Chimu and Mochica civilizations—with the huge old town of Chan Chan nearby. We found an antiquities shop and I bought a Mochica pot of a "Lechusa" or quail. It was dug from a ruin called Huaca del Sol nearby and dates back to the 8th Century AD.

A nice dinner and to bed. Tomorrow, Chan Chan and off to Puira.

September 8, 1968

Puira, Peru

As our plane didn't leave until about 3 PM, Phylly and I, after breakfast, hired a cab to drive us out to the ruins of Chan Chan, the ancient Chimu City set on the north

bank of the Moche River. It dates back to the 8th Century, and as such, is one of the oldest cultures in Peru. The ruins cover 11 square miles—more than modern Trujillo. They rest on the river bank and extend from the sea to the rather distant hills. All are adobe of some special sort, so hard it is glossy in some excavations. It is thought to have been mixed with cactus mucilage to achieve this hardness. We visited two temples, each surrounded by 14-15 ft. high walls 6-8 ft. thick and with an intricate maze of interior walls, chambers, and courtyards. Nearly every room had a different motif to the friezes—rows of sleeping pelicans, rows of flying pelicans, ground squirrels, stylized pelicans which looked like they had run into a wall at full tilt.

One temple was surrounded with 14 deep crypts thought to have been granaries and its motifs were two-headed dragons, every head eating something. One form chomped on the heads of mace-bearing soldiers. At one end of one temple a deep oblong pit was dug and its reeds and pools attested to a fresh water supply. Actually, the pit fed on the fresh water lens that so often floats on sea water where the two meet behind sea beaches. In this case inland fresh water comes down the Moche River valley.

Behind the village of partly fallen walls an aqueduct of grand dimensions brought water from many miles into the mountains to this city. In places we could see the ancient motifs had been colored buff, yellow, red. One temple was a ramped pyramid, perhaps a precursor to the grander ones at Teotihuacan in Mexico. The similarities in incised motifs certainly suggest such a lineage to me.

It's sobering to reflect that here was a society of great size and obvious refinement about which we know next to nothing.

Our pot, a refined bit of stylized art, comes from such a temple—which we could see across the valley to the south.

Back in Trujillo, Phyl and I wandered the streets in the warm sun looking in leafy garden courtyards, at the ancient studded double doors and wooden gratings on windows—altogether the most Spanish scene of any town we have visited.

Our airflight was a most interesting one. It took us up the coastal plain to Chinclayo and Piera. Much was desert, mostly sandy and barren but becoming increasingly studded with clumps of brush as Piera was approached. South of Chinclayo crescentic barchans were very prominent. Wherever a rocky hill jutted up it trailed a long streamer of sand NNEastward in the form of a single longitudinal ridge. At length this then began to break up into hummocks like dashes, which then became a string of barchans. Finally, farther away, if more than one such streamer was near, they coalesced into a sea of interconnecting barchans. In totality it looked for all the world as if the eddies and vortices of smoke streams had been frozen in sand. In many barchans one could see that they were markedly lighter than the substrate on which they moved—buff against a light peach color. In many barchans one could note a dark top—or turnip-shaped mark within the cusps and beyond—darker than either sand or desert. Scoured in some way by the wind I suspect, so the desert pavement shows.

The desert was a mass of ancient lines, straight as dies, intersecting at acute angles, each running for miles, often as far as one could see. On closer inspection many were double—like ditches, which they well have been. No modern agency made them, is my guess, and why ancient folk should have done so is an unsolved mystery. I had not heard of them being reported except in southern Peru, where they are much talked and speculated about. Often we could see marks of ancient walls and enclosures, nearly

buried in the sand. One gets an impression of large populations very long ago when the climate could not have been so austere as now.

Piera is in a river valley far out on a very flat plain, a short distance from the sea. The Humboldt Current weakens here as it passes out to sea and the climate is warm and subtropical. The town is heavily shaded with Indian beeches and algaroba trees. It's a rather sleepy farm town, close to the Ecuadorian border, so we "extranjeros" have to register with two groups of police to show we are not bent on some evil intent. Our hotel (the gracious government Turista Hotel) is right on the shaded Plaza de Armas and we were graced with a fine military band concert, with kids roaming in and out happily among the musicians.

Tomorrow—off to Paita, which is reportedly too small to have a hotel. It does, however, have a whaling station and a Starkist fish meal plant, plus a substation of the Instituto de Marina to which we have an introduction.

September 9, 1968

Paita, Peru

We were quickly cleared by the police as pure. They explained that they had orders to keep hands off the tourists. So we quickly assumed the guise of tourists. I found that we could obtain a colectivo to Paita and that there was a first-rate hotel—the Miramar—there. So, we quickly packed and left across the arid undulating plain to Paita. It's as arid as some of the more arid areas in our deserts—studded with Algaroba trees and bushy clumps of vegetation, some of which one of the people in the car thought were sapotes, but I doubt it. There is much drifting sand and pinkish desert pavement. After an hour we arrived at Paita, which looks for all the world like Santa Rosalia, Baja California, being set in an arid canyon with mud-walled shacks and unpainted wooden buildings. Unlike that hellhole, however, the weather is about as nice as it could be—warm and breezy. The port is ancient and picturesque. We located our hotel on the waterfront in an ancient dilapidated Victorian building—all gingerbread and diamond glass, three stories high with great hardwood balustrades, a special staircase, and huge vault ceilinged rooms. The two beds are lost in ours. One could skate up to the john. I'm sure it's cheap—I haven't found out. Next door is the best restaurant in town under a pleasant ramada.

We stashed our things and took off to find our substation of the Instituto del Mar. After much running up and down rickety stairs we located it right on the Plaza de Armas where it was supposed to be. We were greeted by a slight, affable biologist, Sr. Enrique Vasquez Sanchez. He quickly took us in tow and we went off to rent a boat. There are swordfish boats here and we are dickering for a likely looking one. Then, we walked down the beach and found a *Phocoena spinipinnis* skull stuck in the sand, and later what I think is *Tursiops*—a somewhat battered skull minus rostrum. Enrique said that *Lagenorhynchus* was here, as well as probably *Delphinus*. These he said, occasionally came in with fishermen. He seemed unsure that the pilot whale was here.

They have a nice little lab here in a new cinderblock building set on the bluff south of town where we went next to flense out the mildly noxious *Tursiops* head. The bay of Paito lay below a shingle beach berm and a nearly flat sandy strand that I feel drops slowly offshore, producing extensive shallow flats. It was calm, as we are told it nearly always is, though in the afternoon a strong offshore wind swept off the miles of

cooling desert flats above town, ruffling the water with williwas. The eternal cloud blanket of Iquique, Callao, and Chimbote is gone so the sun shines down through the clear water and at night, the stars shone and twinkled brightly for us.

Fishing here is done in a variety of ways. The bigger boats use a variety of nets—otter trawls, here called arastres, balloon nets, and seines. Quite a lot of gill net fishing goes on in smaller vessels. Sharks are taken by hook and line. Two major packing plants freeze fish—the merluce is important plus a variety of warmer water species. One fishmeal plant operates but not on anchovies since their range stops somewhat to the south—instead a variety of bottom fish are used. This large fishmeal industry is all exported—mostly to West Germany and the USA for animal food supplements, a typical and sad case in which a protein resource designed to alleviate poverty has been subverted to use by the “have” countries, the money flowing into the hands of entrepreneurs, many foreign.

The poverty here is extreme, as it often is in desert towns. Big barrios sweep up the canyons back of town—houses of plaited rushes or simply ramadas of sticks and mud. In them human smells assail one as a wave of odorous revulsion results. We saw that in similar places in Lima. Water costs these poor people as much as 33x the cost to central city residents—arriving in ancient tank trucks or in tins at so many soles a tin. Disgraceful, and clearly the place where selection now acts with great force. It acts elsewhere too, but in more subtle ways.

It’s hard to see how there could be 12,000 people in this port until you remember the barrios.

Disfigured and maimed people are common and the thought came to me today that being so maimed could be a fair trade-off for the poorer folk as it becomes a possible occupation to beg. The more bizarre the injury the better the stock-in-trade—certainly every effort is made by such folk to maximize the impact of their injuries. One man with no legs, trundling himself on a little square castor cart quickly assumed a prayerful pose when a likely prospect drew near. I gave him a sole and when we passed him again he whipped into his pose, like those pictures of Jesus on the cross, only to see in apparent embarrassment that it was just me again, whereupon the half-open mouth closed, the palms separated, and his eyes became those of an everyday man instead of a beleaguered soul.

Well, it’s very late as I sit here in this vaulted room, diamond shadows on the wall from the moon outside, sounds of surf on the shore, chickens crowing plus a few desultory dog barks. Tomorrow perhaps we will go out to sea to look for porpoises.

September 10, 1968

Paita, Peru

After some hemming and hawing about, with both Enrique and Fredy Franco dickering for me we settled on a price of 1,800 soles for two day’s work (or about 40 bucks). In a very short while we (Fredy and I) were on board the trim, clean little raft. Jose Pita and his brother own two boats of similar size, both immaculately kept. They have GMC diesels in them, are about 30 ft. long and very beamy. The Pita brothers fish in a variety of ways, mostly with gill nets though.

These are fine twine nylon but with perforated pieces of beach shingle for leads. I guess lead is expensive here, like it is at home.

Phylly wanted to stay ashore so off we two went around the arc of the big bay at Paita, close to shore looking for bufeo, or *Tursiops*, which the brothers said comes into feed on lisa (mullet). It and the little harbor porpoise are the two species that come into the agua sucia near shore. Others stay out 20 miles or more in clear water. The dirt comes from a river north of here.

We passed a neat little beach resort called Esmeraldas where the gentry of Piura come to swim in summertime. Shortly we came upon two Burmeister's porpoises swimming slowly along. Tiny animals that never let one get very near. These flicked their tails and disappeared, changing course underwater each time we pursued them. 50 yards was about as close as we got.

We cut back across the bay, hoping for *Tursiops* in the eel grass on the opposite side near the whaling station but no luck. Since we couldn't go far enough offshore in the time we had, Fredy and I decided to go ashore and work at the whaling station.

Fredy commandeered a ride for Phyl and I and himself in the Toyota jeep of the Japanese superintendant, a taciturn fellow who hardly gave one the time of day.

At the station, which sits on the arid shore a couple of miles south of town, we began work in the museum.

The road is a long, circuitous affair leading over the nearly completely desolate plain above town. One can see the cut layers of soil in the cliff face and the extreme flatness of the surface made me feel secure that it was rather recently seabottom and that a great, shallow bay extended nearly to Piera, probably in Pleistocene times.

Jorge Mejia had built up an interesting whaling museum which included a lot of whaling gear and pickled whale parts, stomach contents, and some jaws and skulls. We worked over the skull of a male killer which was said to have come from an animal found on the beach south of Paita. A male and female were found together, the male with a probably mortal wound at the base of its dorsal fin, as if bitten by another whale or a large shark. Later, up in their little lab above the flensing deck, Phyl and I worked over two more skulls, one the female of the pair and the other a huge, old male.

By the time we were done and had conversed with the superintendent, Georg Schmidt, it was nearly dark. Schmidt had put up my friend John Cushing when he was here studying whale blood.

Phylly and I had a nice dinner of halibut, a walk around the Plaza and the clubs from which Wurlitzerized music poured, and to bed.

September 10, 1968 [?]

Paita, Peru

In the dark I assembled all my things and pushed out into the dark quiet streets. Down at the pier a man was unloading sea bass and merluce into gunny sacks and over at the other little pier several lanchas were unloading fish into a variety of waiting trucks. For me, however, no boat was to be found. I asked where the *Estrella Luminosa* might be and most everyone looked blankly as they passed fish into the trucks. One man allowed as how it docked at the fish plant ½ a mile down the coast, which surprised me some as he was standing on the dock where it tied up yesterday. But, not knowing what else to do, I trudged off to the plant where a group of men were unloading a truckful of guitarfish destined for the fishmeal plant. No such craft there they said, most likely back at "Puerto Nuevo" from which I had come. So, off in the dark again down the dusty

road. Finally, after two or three more transits between docks, I finally learned that he hadn't come in yet and was probably offshore, fishing. It was pushing six by this time and light was beginning to show over the sea bluffs. The scene would have been picturesque if I hadn't been too angry to notice much—the old church bell tinnily clanging out the time I was wasting in frustration on the dock, boys with bicycle carts toting fresh bread from the bakery whose smells wafted over the quiet streets amidst more redolent smells, old women in black mourning clothes scuttling along with dripping bags of fish, and on the water, rafts of pelicans flapping and wheeling toward a boat where a young boy was cleaning the hold, every now and then flipping an ancient fish into the water into the flapping, squawking mass of birds.

I finally gave up and went back to the hotel for breakfast, took a brief nap on the front porch sofa, and walked wearily back—still no boat. I located his wife who informed me she knew I was to go out at 4, but he wasn't in yet, being out somewhere offshore fishing. She didn't know when he would arrive but thought soon. I hoped.

Enrique found me waiting and was incensed about the whole affair. He took my contract and carted it off to the port captain, who would issue some sort of reprimand. Finally the boat came in but no one came ashore, but instead sat picking and patching their gill nets on board. I left, said to hell with it, and had some lunch with Phylly. In the afternoon, Enrique, partly because I think he felt a bit of responsibility for us, arranged a trip to Playa Grande, a big beach to the south where we might find bones. Fredy and the engineer of the local fresh fish plant, Americo Rodriguez, Phylly, and I hopped in Americo's Dodge sedan and took off across the tablaza, the flat land between here and Puira.

This plain is gently undulating, but with no major washes or arroyos as far as we could see. It is reportedly covered with shells, even far inland. Here, there is little sand—one can drive almost anywhere across it—like driving on the bottom of a dry lake. Scattered about are low bushes here and there. We drove south about 15 km. And then dropped down a graded road to a little village of summer cottages set on a lovely crescent cove, rocky and rugged on both limbs but a smooth unblemished playa between. Fishermen worked on nets and one could see that their activities mostly concerned the mackerel shark, *Isurus*, as the nasty heads and jaws of this species were scattered everywhere. I wanted to retrieve teeth for Jerry Goldsmith but could not pry any loose.

We walked northward toward Paíta along a beautiful flat strand backed most of the way by an abrupt cliff some 200 ft. high. The same layers as seen north of Puira cap the cliffs here, and I supposed cover the entire tablaza. Below was mudstone dotted here and there with rounded boulders of fossiliferous sedimentary material. At the shoreline the sand often lay in a thin sheet over an extensive bench out in this same material. We watched the flocks of capuchin gulls (red beak and legs, gray capped heads and mantel) and the scurrying groups of red beach crabs. These crabs could detect us an amazing distance away—100 yards or so and would stop their business of rolling little sand balls in search of food and sidle away toward their vertical tubular burrows, down which they popped before we were very close.

I checked the wrack at the strand line for bones. About halfway in our two-mile stroll I spotted a *Tursiops* skull resting at high tide line. It proved to be a nearly perfect specimen—quite clean and odorless. The rest of the hike netted nothing more than exercise in the warm, sunny afternoon.

On our way back Fredy pointed out a coastal condor resting on a hilltop—a beautiful big bird with black wings and a white mantel—not so big as the Andean species, but noticeably bigger than the black vultures nearby. Fredy said they could carry off a young goat.

Back at Paita I stopped by the Instituto office to see Enrique and instead found Jose Panta, the fisherman, circulating around looking worried. He explained that the Capitaneria (Port Captain) had his contract with me and wanted to know why he had not fulfilled it. Jose said his crew had decided their lines weren't strong enough to hold a porpoise at sea. I agreed that they might not be. Why, however, hadn't he come to discuss the matter with me? No answer. The port captain wanted to know, he said, if Jose owed me money. No, I said, I had paid him 500 soles for about ½ day's work and that was enough. So we marched over to the port captain's office and got Jose off the financial hook. That was that. He had been reprimanded and that was enough, for me anyway.

Dinner, notes, and to bed.

September 11, 1968

Lima, Peru

Packing, a lunch for the boys, goodbyes, a lift to Puira by the hotel owner and wife, a wait at the airport, and off to Lima on LANSA.

Below us the gathering dusk cast its reddish haze over the dunes and marked them with dark shadows. Before we reached Chindayo the clouds had banked up and all was darkness. Much wiser than before, I refused the vulture-like throng of taxistas until, after the third question, I was given a price—about 1/3 what I had paid before for the trip to our hotel. They like to get both you and your luggage in before giving a price as they rattle along with their captives. Collectivas are the thing though. At set points cars wait and when 5 people arrive for a trip, off they go to another set point, usually for a very low price. For instance the colectivo from Lima to Callao cost 4 soles (10 cents) per person and a taxi 50-60.

September 12, 1968

Lima, Peru

At the Instituto I found 6 animals waiting—3 *Lagenorhynchus* and 3 *Phocoena*, all obtained from the Terminal in Lima.

Phylly and I spent the day preparing them and filling our drum which had arrived from Chimbote. We will leave Peru with between 18-20 specimens having been obtained—a superb record for 2 week's work, and especially from an area where essentially no material now exists.

We washed up and headed for Lima via the cheap colectivo, had a grand steak dinner, walked around town buying presents for various relatives, and went to bed. Tomorrow, Saturday, we will work again at the Instituto if material arrives from Huasco, between Callao and Chimbote, and if more comes in from the Terminal. My harpoon, too, is coming down via express, from Paita and may be here. If none of these things materialize we may head for home early.

September 14, 1968

Lima, Peru

Jorge called and two more porpoises had come in so we packed appropriate gear and headed for Callao, Jorge driving. We found two more *Lagenorhynchus* waiting for us. I prepared them and Phyl and I tagged and prepared the skeletons that Jorge had obtained while we were up north. I put everything in the drum, salted it down, and had the satisfaction of leaving the drum clear full of specimens and salt, ready for shipment to the Smithsonian.

It's a nice batch, and certainly the best dolphin collection to come out of Peru. Jorge will collect up to 10 of each species and ship them on. I will return whatever Dr. Ferrya at the Museo Ciencias Naturales wants. The rest will be distributed, mostly to the Smithsonian.

Phyl and I were getting pretty itchy to get home by this time and time began to weigh heavily. We walked the town, poking in shops, buying peanut butter (unavailable in Chile--\$1.20 a bottle here), a few gifts, especially carved gourds from Cajamarca and Huancayo, a knife for Nancy (Swiss Army with a magnifying glass, pens for Sus and Barb, and models for Dick). We ogled at pots and the silver-based scepters that local alcaldes used to use in Peru (4,000 soles).

I called Hersch Peak, my old Navy roommate, who is now Political Attache in the American Embassy in Lima. Unfortunately he returns on Monday from vacation and we will be home in Renaca then. Woe, woe, as I wanted to see them both.

A nice meal, a bottle of wine and off to bed.

September 15, 1968

Renaca, Chile

Our flight was delayed two hours while I fidgeted in the airport (Phylly tends to take these things calmly). Finally, after what seemed an utterly interminable wait, we boarded our plan (in from Hamburg) and headed south. It was so good to be underway. There's nothing like going home to make me anxious and with the delay it was even worse. Three-and-a-half hrs. later we touched down at Pudahuel Airport, hopped on a bus for Santiago, by hook and crook reached the colectivo stand where a pirate colectivo took us in tow—and then we waited, and waited while the driver tried to round up his fifth passenger. Finally each of us chipped in an extra 5 escudos and we were off. We reached home after midnight, roused poor Leanne (we had tried to call Leanne collect but somehow couldn't rouse the system into any kind of useful action). Three of the kids had had measles but the house was full of artwork, flowers, and junk, and all had obviously had a grand time. Grand to be back.

September 16-20

Renaca, Chile

At home during this time. The little store down the hill had been holding stacks of mail since they didn't know who K. S. Norris was and they were too lazy to investigate the address. We can throw a rock and hit them (and may) from our house! Great Scott—20 letters—some important, just lying there. So I answered mail and tried to straighten out accounts. I wrote some on the book and boiled up the *Ziphius* skull, a very smelly job, but good to get it done.

This was accomplished by setting up an oil drum in the sand at the station and building a fire under it, putting the stinking beast in, and then tending the fire until it was done.

We took a nice hike up back of Leanne's cottage—Dick, Susie, Phyl, Leanne, and I. We saw the beautiful Chilean lapwing, a big plover with a black belly, reddish epaulets, a gray back, and red legs and bill. It's a big bird, standing perhaps 1½ ft. tall. There was a pair and they may be nesting. We find that these birds are sometimes kept for pets and watchdogs. They apparently take no guff from man, cat, nor beast, and raise a ruckus if anyone approaches.

We also stirred up a pair of burrowing owls. When standing quietly they are barred all over, but after being frightened when they land, they do something to the angle of their feathers and become strikingly white as they bob up and down doing deep knee bends.

All the kids are pressing flowers now so we collected many, including a lovely yellow lady slipper and a nettle bush with pendant yellow flowers, red-tipped in their centers. I was stung for my pains, right through the callus on one of my guitar fingers. Hurts!—and won't go away.

Our hike took us through young stands of Monterey pine and across lovely grassy meadows.

September 20, 1968

Caleta Laguna Verde, Chile

Down to the *Explorador* at 6:30 AM where Leanne and I boarded on a jaunt to look for porpoises out in the Humboldt Current.

It turned pretty windy around noon and all afternoon the ship rolled in a choppy sea. The white caps all around made it very difficult to spot animals and though we kept a close watch all day, saw no animals, except birds.

In watching gulls and cape pigeons I marvelled at how perfectly their feet are folded up in flight and become part of the body.

Gulls fold their feet and tuck them up under the tail so that they are nearly perfectly flat into body outline. Cape pigeons are even better. I thought for a while that they raised their feet inside a feather flap, because no legs were evident as they flew—only the unbroken white body contour ending at the little short tail of dark feathers.

Actually, however, by watching them land on the water I could see the legs drop down from a position lateral to the belly, with the feet being held under the lateral margins of the tail and of the same color. At any rate the contour is remarkably well maintained.

As dusk came we headed back and the huge bulk of Aconcagua loomed pink over the coastal mountains. An otter trawler stacked her net, rocking in the swell, and darkness came, the Captain navigating in with his fathometer.

September 21, 1968

Renaca, Chile

A long day of watching in windy seas, my parka cinched up tight and thankful for my thermal underwear. We saw nary a mammal as the ship went 40 miles offshore of Valparaiso and returned in the evening.

All we had to enliven the activities were the birds, one shark, and a school of fish. But we did improve on our observations—the leg position of sea birds. A kelp gull flew by with two lumps showing where its legs ought to be and no feet. Aha, I said to Leanne, a gull who lost his legs and look he's perfectly healthy. We watched him for a long time and could tell him by a displaced primary feather. Later Leanne called me to the bridge and told me to look again. This time the gull had legs and no lumps. He had straightened out his legs so that his feet came out from under the feathers. Then we saw another gull with one leg protected and the other exposed. It's what you do if you're a gull and your feet get cold, I guess.

We arrived home, sunburnt and weatherbeaten and tired. It's hard work to look all day at a white-cap-covered sea trying to discriminate a porpoise splash or a whale spout from them.

September 22, 1968

Renaca, Chile

Writing at home and in the afternoon a drive to Bahia Agua Verde for a walk on the beach, and home up through the beautiful fertile valley above—all cows and green fields, with forests of Monterey pine on the hills above. The kids collected flowers which they are pressing. Barbie collected maidenhair fern stems for her basket. Back through the hillside barrios of Valparaiso, wondering how the people get water up there to their shack houses and what it must be like to live in them.

September 23-October 1, 1968

Renaca, Chile

These as mostly taken up with routine affairs, trips to Santiago to tend to expense accounts, routine at home writing and preparing specimens and getting affairs ready for the Valdivia trip and the expedition to the fjord country. We met with about 15 Peace Corps people here on various fisheries missions in hopes that they may be able to help us gather material of porpoises that happen their way. I think it will work.

I cancelled a possible trip to Juan Fernandez Islands because of lack of time.

On October 1 I delivered a lecture to the University of Chile, Valparaiso, in execrable Spanish. It went over well though, especially the question period where I answered in my pidgin Spanish-English mixture.

October 2, 1968

Valdivia, Chile

Having come up in the night on a colectivo and stayed at the Crillou, I set out this morning for Valdivia. We flew in a prop plane at about 5,000 ft. down over the patchwork of prosperous farms that occupy the entire central valley of Chile, while to the left was the magnificent snowcapped scarps of the Andes. On the west intermittently rose the lower coastal range—all rocky and chaparral covered like the hills back home. The further south we went the more tree farms were evident, on hillslopes and along the many rivers that braided their way across the flatlands.

As we neared Valdivia the plain stopped and moderately rugged hills rose beneath us, all clothed in trees and a spiny yellow-flowering bush (a Caesalpinaceous plant) that

splashed the slopes with color. Water became abundant, shining in lakes and rivers of silver.

The plane set down on a little country strip, and as always in these cases, one became immersed immediately in the local scene. What was above an abstraction of the environment became real and one could empathize with the parts related to one's experience.

In this case there was much to empathize with at eye level (ignoring the encompassing sky above)—it was the northwest USA in all its pastoral beauty. Green hills, farms and pastures, belled cows grazing, frame houses with steep roofs and diamond windows and Victorian gingerbread. Water was everywhere evident. Lakes and shallows with reedy borders or stands of white barkless dead trees [?]. Water-washed roadcuts, gullied and red, dark glowering stands of pine, arranged in blocks but nonetheless soft and cool and beautiful.

Leanne had arrived in the jeep and we rattled back to Valdivia in it. She had had the battery quit on the way down but everything was now going smoothly.

Valdivia is a quiet old town where one can walk across the street with a reasonable chance of making it before a car heaves in sight. The air is clear, the people have time to say hello and be friendly, and the area around is lush and beautiful. The Rio Valdivia, which is the confluence of two other streams, is light green, deep and swift, flowing disciplined between its two banks with nary a ruffle except on the rudders of the ships moored to the cement pier in town. Bluffs mark its course downstream.

We put up in the Hotel Schuster, a place of faded and fading elegance—scaly outside walls in the Victorian manner, columns and capitals in wood, and high rooms with creaky wooden floors and magnificent jumbles of plumbing overhead in the john, pull toilet and not enough light.

We drove out to the new University Austral campus where 1,500 students learn in a 1-story set of buildings on an island between two branches of the Rio Valdivia. Quiet, beautiful, and friendly.

Hugo Campos (a student of fish ecology, studying *Galaxius maculosus*) greeted us and helped us with innumerable things—a very pleasant and knowledgeable young scientist educated in Germany (many here are). He helped us rent a local drag net boat (45 ft.) for 750 escudos a day including 6 men (including cook and captain). This boat belongs to the local cooperativa which is managed by a Belgian fellow who arrived here as part of a Catholic mission and stayed on to build the cooperativa. It has an excellent galvanized building, a dock, and two refrigerator trucks. Our boat is a bit scruffy but with a good hull and engine and a very accommodating crew.

We took Hugo and his girlfriend to dinner at the Spanish restaurant where we got to vote for a local beauty queen who might ultimately get sent to Spain for the finals—if she can get by Miss Copaiapo, Miss Vina del Mar, etc. I voted hardest for the wrong girl, only because the girl (the wrong girl) was a friend of Hugo's girlfriend.

We ate, among other undistinguished things, *Galaxius maculosus* post-larvae. These 1¼ in. long critters are like sardine larvae—transparent with black eyes. They are steamed in a sauce and are very rich and delicious.

Off to bed after walking back across sleeping Valdivia.

October 4, 1968

Corral, Chile

Up before dawn in a cold, quiet morning. Leanne and I located the cooperativa and found a door open and were able to get all our gear down to the dock by the last light of the setting moon. Soon lights came on in the *Alejandro D* and the crew piled out, all 6 of them. Very shortly we cast off in the river and made our way in the growing light toward Corral Bay at the mouth of the Rio Valdivia. Our craft is a typical dragger, covered with wires and chains and pretty dirty. I set the crew an example to cleaning things up a bit and got my gear ready. Leanne fiddled with her recording gear.

The river runs between tall bluffs and is deep, light green, and with a current of a knot or two. The bay is a beautiful snug one, bounded by 1,000 ft. wooded hills and with some islands. Much is shallow but there are channels sufficient for pretty large ships to reach Valdivia, 13 miles upstream.

We turned northward and encountered a school of *Cephalorhynchus* under the bluff on the north border of the bay. These little dolphins were full of fear and refused to let us get very close. I could see the peculiar rounded dorsal, like that of the adipose fin of a trout, and the dark gray backs.

The school was small, about 6-8 animals, and swam right up against the rocks. Farther up the bay we chased another school with similar results. I was struck with the behavioral similarity of this species to *Sotalia* of the Rio Amazonas, in which these small animals take fright, crowd together, and rush off, breaking spray as they dash the water, plunging along tightly schooled.

The *Alejandro D* cruised around the south limb of Corral Bay and out into the open Pacific. Our path took us close to a shore, which is made up of steep bluffs largely clothed with a gray-green trees heavily pendant with gray moss. Many hillsides are cleared and green with grass and everywhere are nooks and canyons or on knoll tops are little isolated farmhouses or barns, none seemingly connected by roads to Corral over the hill.

The day grew rough with strong SW winds so we went back into Corral Bay and finally before dusk headed for Corral, a village of about 2,000 people, where we would spend the night. Corral is built on a rather steep hillside and consists of tiers of brightly painted frame houses rising up to meadows and groves of Monterey pines (pino insigne) above. The seafront is dominated by the parapet of an old spanish fort built in 1645 as part of the general fortifications of the bay, a pier featuring nice benches of fancy ironwork, and the remains of an iron smelter. Today the town subsists on fishing (all the crew of the *Alejandro D* live there), tourism during the summer when boatloads of tourists come in from Valdivia, and a sawmill. The fort was taken in the early 1800s by Lord Cochran and the steel mill was supplanted by a new mill in Tolcahuano in the late 1950s. It had functioned with charcoal made from local trees but now the Zalcahuano plant uses coal.

We disembarked through a crowd of onlookers on the pier, including Jorge Guzman's (skipper's) family—mother, red-haired frecklefaced wife, round dark-eyed daughter. Jorge is a fine man, humorous, bright, cautious with his boat, and skillfull. He is small but wears his size with extraordinary grace. Leanne and I walked around the hill under an overhanging matting of trailing bamboo that completely covered the broad sidewalk, 10 ft. above the pavement.

The Hosteria gave us a couple of nice rooms overlooking respectively, the lily garden and chicken pen. We walked around the friendly town watching boys play soccer with a tennis ball while a chorus of little girls sat huddled on the bluff above shouting out in high falsetto voices, modern Chilean songs, in a spirit of pure joy for the nice afternoon. We queried the guard at the iron plant and learned of a redwood-like tree that lives in the mountains nearby and must be of very great size. The wood is remarkably like our own redwood.

The fort consisted of a neatly dressed stone wall with inletted cannon slots, some covering the base of the wall. Behind was a deep pit with a tunnel leading to the outside. At one time, the pit was probably a marshalling point for men and arms, then it became a yard for machines for the iron smelter, and now it is abandoned and full of relics of its past—locomotives and old iron scraps.

We walked on, warming up for dinner, and came upon a huge grotto with a vaulted roof, perhaps 80 ft. high and 80 ft. deep in which there was a shrine with candles flickering over the entrance. From the cliff above depended a sheet of vines with light filtering through their lacework. They stopped at about the height of a man's head, and over the roof was a coating of mosses and ferns. It was obviously an old sea cave that had been lifted up, probably during an earthquake.

The earthquakes here (terranotos for land, maremos for sea) in 1960, killed over 100 people in Corral as a wave washed away all of the lower town. A big ship was sunk offshore as the waves stranded it and then returned to break it up.

Dinner and to bed.

October 5, 1968

Up in the dark, and so was the dueno who sleepily suggested a cup of coffee to which we readily assented. Lael, one of the seamen, was there waiting for us, drinking a glass of beer. We walked to the boat, boarded and cast off, leaving the little sleeping town, and cutting out into the dark calm bay.

The Captain took us north along the rugged coast, many times just outside the reach of the breakers. All along the coast were groups of toninas—2's, 3's, or groups of up to 10. Only at a broad open roadstead called Chan Chan did they show signs of running our bow, but even then only fleetingly—enough to get me up in the bow, gun in hand, and safety off.

Just beyond Chan Chan a rocky headland of jagged platy rocks breaks the sea into foaming welling mounds of water that spurt and spray up over the flanks of the stacks. Beyond, out of the reach of the southwest swell was the little village of Mehuin, where the University Marine Station is located. Mehuin is a cluster of houses, mostly up on the slopes, a low river mouth and strand, dominated by a big tourist hotel.

On northward is another cove and another hillside village, Nigue. Here we turned for Corral Bay and had an uneventful trip back. I'm surprised at how close to shore oceanic birds come. The black-browed albatross comes into the mouth of Corral Bay. Most common of the soaring birds is the silver-gray fulmar, an immaculate bird that sometimes skimmed within inches of our prow. Another common bird here is the red-footed cormorant, a beautiful bird, which seems a strange thing to say about a cormorant. Its legs and feet are bright chinese red, its beak yellow, and at the base red. White feathers mark a spot on its neck. Body is speckled gray and white. When these birds take

off from the water they don't run like a shearwater or albatross but flap both feet in unison.

At dusk we entered the bay. Before long Perez on the bridge shouted, "Tonina a la proa!" I rushed up and, by George, there they were, riding the prow. I grabbed the harpoon gun and in the fading light fired at one animal as it rose. This time, for a change, I hit it, and the line raced off the deck. Perez and Erprel, a long, lanky, likeable deckhand, jumped into the skiff, taking the line with them, and while we watched, fought the animal, bringing it close while Erprel wielded a wicked-looking hand lance. Soon the animal was aboard and I could see it was boldly marked with dark gray and white. We towed the skiff into Bahia Amarga where I finally got a look at *Cephalorhynchus* at long last. The animal lay gasping on the deck, so the unpleasant task of dispatching it with the lance lay to me. Hastily out of mercy for the suffering beast I plunged the lance into its heart and lungs and it soon lay dead, thank goodness. What a beautiful creature. It is a very short-tailed species, gray above with the large peculiar, rounded, dorsal, paddle-shaped flippers, no beak but instead a sloping forehead, a white spot behind each pectoral, and a white belly and throat with a broad, dark-gray chevron between the pectoral flippers.

We turned and went up the river and Leanne and I measured it (an old male) between rain squalls, finishing the job on the dock and in the cooperativa warehouse. I took many pictures by the light of the suspended lightbulb held by a little girl who was watching us, along with a couple of dozen other folk. We left the animal in hopes that tomorrow we could get pictures in the daylight and returned to the Hotel where we found Moosemeat all pooped and in need of sleep. Tired, we went to bed. Tomorrow, out to sea again in hope of obtaining materials for Moose.

October 6, 1968

Valdivia, Chile

The lights of Valdivia appeared around the river bend and we docked at the cooperativa. As Leanne jumped off, her camera fell into the water and sank out of sight between the ship and the dock. The Captain rigged lines and hooks and had his crew fling them in, pulling them across the bottom in an attempt to snag the camera case. A wild array of things came up—old rotting hawsers, dead fish, loco guts, wire, old fishing gear—but no camera. I advised Leanne to call a halt, which she did, but still they fished on and finally Lael came up with it on his last toss—dripping and full of water but likely repairable as the water is river water here and not corrosive.

Leanne invited all hands to have a Pisco so off we went. I tried to give the Captain a gift for his help on the boat but he refused it, saying it was an honor to have us on board. He did, however, let me reward his crew.

After the Pisco, off to bed.

October 6, 1968

Valdivia, Chile

With Moosemeat on board and up bandying words with the skipper, Leanne and I tried to measure and photograph the tonina. It is, I suspect, what has been generally called *Cephalorhynchus entropia*, though that name probably lumps animals together.

Rain squalls periodically forced us off the stern, but we finally finished. One of Hugo's students was along, a bright lad who asked quite a few questions to which he already knew the answers. We followed much the same course as yesterday but the wind had changed to the SW and we could expect to head into it on the way back. The surf, too, was much higher and it was difficult for us to go very close to the beach.

At one point, just outside Bahia Corral, we saw a group of llampas near the surf. They fled from us and when under water changed course and came to the surface going in a different direction and very far away from the last point we saw them. They fled until they actually rode in breakers. We could see them riding down the crashing breakers and into white water. Jorge says rough weather drives them off shore where they can be chased more successfully. The animal is reportedly as much as 2x as big as the tonina and has no black band between the pectorals and the gray of the flanks grades gradually into white of the belly. Its behavior makes me suspicious that it is another *Cephalorhynchus* (wariness, tendency to swim in or close to surf all the time)—perhaps it is the large *Cephalorhynchus* in the Museum at Santiago.

The cook, called "El Maestro" by the captain, had a field day since we obviously enjoyed his efforts. First he whipped out locos and mayonnaise with a slice of aji (delicious and tenderized by swinging them against the deck in a sackful of sawdust), next out came a great chupa full of all kinds of champignons, followed by rice and a sauce.

Just when I was holding my tummy in completed satisfaction, out came a steaming potfull of spaghetti and that followed by pina nevada (or pineapple with a sweet white egg sauce). Wow! We staggered from the galley looking for refuge from the next course. Sure enough, he pursued us to our various lairs and offered us coffee or tea or aguitas (hot water and lemon, and often tea).

El Maestro once cooked for 250 people in a copper mine (Condor) high in the Andes and he obviously yearns for a captive audience such as us.

Just a word more about the skipper. He emerges as one of the most human, sharp-witted, honest, and nice people I have met. He is accomodating beyond any need on his part, as well as being very bright. He runs his crew well and with a touch of humor that makes the *Alejandro D* an unusually happy ship.

We turned just beyond Mehuin and began the trip back into a gathering sea. I stood watch in my foul-weather gear as long as it seemed possibly profitable, but before long waves crashed over the bow and it was obvious we could not work further.

We all returned to the afterdeck, galley, or bridge, as the ship plunged along in the cold sea, spray flying against the bridge windows while the captain ran his "automatic windshield wiper" by hand.

Moosemeat was very tired and spent much time below in the bunk and finally emerged, much refreshed. I was glad he could have this break as he has been working very hard at Valparaiso.

No porpoise came to our bow in Corral Bay so we ascended the river in the gathering dusk, bluffs and tree fringes black against the sky and reflected out over the water.

October 7, 1968

Sunday and off for an asado at the University Marine Station at Mehuin. We met Hugo and his nice ayudanta, Lucy, at the University and a long, red-headed fellow named Patricio Steffan, or Patcho, who is a fishing advisor on gear and who provides government loans. All of us loaded gear into his truck and our jeep—wine jugs, bags of vegetables, a whole side of lamb, and were off to Mehuin where Hugo has built a station. Our road took us up through the rolling farmlands that surround Valdivia, through the tree-covered hills, over the extensive shallow lakes caused by the 1960 earthquakes and on to San Jose, where the road cuts to the coast at Mehuin.

This earthquake must have been a terrifying thing—it split roads in a hundred places, lowered thousands of acres of land and tumbled houses and buildings, not to mention the tidal waves in the bay and the catastrophe in Corral.

The fields are green with new grass or wheat or rape. Cows graze and trees and streams are everywhere. Some of the trees are remarkably reminiscent of deciduous oaks, like our valley oak and others are duplicates, in life form, of other California plants. In fact the mimicry of the lush plants of California or southern Oregon is extreme.

We left the paved road at San Jose, proceeding down the lovely river valley to the coast. An uneventful drive through rural Chile—guasos erect on horseback, complete with panchos and spurs, black broad-brimmed hats, ox teams with yokes lashed to their horns, plodding patiently along while their driver directed them with a long withe of willow, which he tapped against this flank or that. These same teams seemed to do most of the plowing too, with tractors very little in evidence.

From the sea Mehuin had a terrible isolated look as if the few families living there had no opportunity for contact with the outside world. Actually the area is well populated with a good road. The village at Mehuin stretches behind the sand bar, with a fisherman's village—"Mississippi" on the south bank of the river and all the boats upstream at the "Caleta Pescadores". Then, there are the summer folk, who come later and double the population.

Hugo has put his station up out of the reach of the waves, which destroyed the last one and his visitor's house is a hard hike up on the knoll above. The lab is nice, clean, with running sea water (through a [?] pipe strung on poles to a beach sump). We trudged up wearily the 80 steps and the trail above to reach the bunkhouse—a nice neat affair with john and kitchen and livingroom and room for about 10 people. It sits on a knoll overlooking a grand sweep of sea coast. Behind is the caretaker's house. He and his family are bright and pleasant. Soon he was preparing the asado. He skewered the side of lamb on a long sword-like piece of iron which he then rested over a special iron wicket. Every few minutes he turned the meat over the bed of coals below. The twist in the iron sword kept the meat from turning on its own. [Drawing]

Before long Lucy came out with jugs of wine, salad, bread and all the sauces. It was a delicious repast with all of us sitting on the lawn looking out over the sea.

After the asado we retired to the bunkhouse and discussed all kinds of problems until everyone got sleepy and went to bed. Especially interesting was the newness of American contact—since J. F. Kenedy. They feel it is important for more of us to come so everyone can see we are not ogres and to increase further contact.

Off to bed.

October 8, 1968

Valdivia, Chile

I rose in the cold morning, dressed, went out for a walk before breakfast. Up in back of the caretaker's house is a trail leading to the canal for water to Mehuin. It goes over a heavily wooded hill and dips down to the aqueduct which runs in a ditch running around the perimeter of the hill. It originates way back up in a heavily wooded cayyon full of gnarled old olivilla trees with an impenetrable underbrush of ferns, fuschias, and recumbent bamboo. One could not hope to walk through it. Birds called everywhere, but I could not see them. Back to the bunkhouse.

Patcho and I took a walk before breakfast and he told me stories about the local plants—he pointed out the “dientes de leon” or dandelion, so our name is probably derived from the spanish one which describes the heavily dentate leaves. He pointed out the foxglove plant, which he said is the best for “papel higienica”.

After breakfast we packed up and said goodbye, which consumes quite a lot of time and energy in Chile, and the three of us set out for Queule, where we hoped to view the *Otaria* colony (southern sea lion) on the rocky point.

The road proved a real 4-wheeler, climbing up sea bluffs and butting through the brush. In the shade it was full of mud holes many of which had been filled with brush. There were grades up which no one could go when it rained. We clanked off into one mud hole in a sickening fashion but were able to emerge unscathed. We finally picked our way down the steep slope to Queule, a town clustered on the slopes above the mouth of the Rio _____. We had picked up a hitchhiker and he led us to a fellow with a boat to rent. The river edge was lined with little piers and boats tied up. Our future skipper was located—a Peter Lorre type with little puffy cheeks, beady eyes, unshaved lips, wearing a silk shirt and suit pants. After a quick financial session, 20 escudos for a trip to the sea lion rookery was agreed on. I inquired, as usual, about the porpoise situation locally. They used them for congrio bait and knew of the three species—tonina, antonina, and llampa. They said one had been taken 4 days before in corbina nets and that it was “over there” by a distant dock. I went over and sure enough, picked up an almost complete skeleton of a *Cephalorhynchus*.

Soon we cruised out over the river bar and along the north shore of the steep mountainous peninsula. Here and there in river valleys were clustered little farms whose fields climbed the verdant slopes. Pines and olivillas topped some hills.

Skittering from the sea surface were dozens of red-footed cormorants and as we neared the tip we began to pass them rising from the water with sea grass in their bills, we supposed to build nests. Hundreds dotted the steep sea cliffs near the peninsula's end.

At the point the large waves produced a mountainous and confused sea of peaking waves. They surged up cliffs as mountainous welling spume-capped swells, peaking and rushing down again. On the southwest corner of the point, on a great fissured stack, rested about 50 southern sea lions, and ten more cavorted in the spume-covered sea. The males are huge old guys with larger heads than is the case with our northern animals.

As we rounded the point Peter Lorre looked at his gas and announced it was “muy baja.” Comforting thought as we tossed in the swells not far from a jagged rocky coast.

Then we spotted a school of toninas (*Cephalorhynchus*) which ran the bow beautifully. Peter Lorre grabbed his harpoon and, silk shirt and all, mounted the prow. He couldn't hit his hat as he missed 3 times, and didn't try on a dozen easy shots. Finally the toninas said “to hell with it” and swam away. We went back, paid off, and began . . .

After lunch in Mehuin (incredibly cheap) off to Valdivia.

October 9, 1968

Valdivia, Chile

Hugo insisted that we see the lake country and arranged along trip for us. Lucy was assigned to us and I felt she might rather have stayed home—not that she complained at all.

After a fair amount of fumbling around, we headed for Villarica with a lake of the same name, one of Chile's famous fishing and vacation resorts about 100 miles to the north. The drive north is through low hills and rich grassy ranch land, dotted with groves of trees and scattered farmhouses and barns. Nearly all plowing is done with ox teams patiently plodding across the fields.

About 2 hour's drive north of Valdivia we turned eastward on a rough washboard road leading to Villarica. Ahead we could see the nearly symmetrical and pure white cove of Villarica poking up.

Here the Andes are low with only occasional volcanic cones such as this one reaching high altitude.

Finally as we ascended low, rolling foothill country, all tended farms and planted forests, before us appeared Lago Villarica. It is large, blue and rimmed with wooded hills and farms—lovely. I was surprised at the low altitude however—it can't be over 2,000 ft. high.

We poked around the chilly [or hilly?] little town of Villarica, threw rocks in the lake, and then drove to the tourist town of Pucon at the east end of the lake. It is lovely—fruit trees in bloom—the great white mountain behind and hills covered with the Chilean robble and a live oak mimic. The parallelism in physiognomy with our own valley oak, live oak woodland is very striking.

We hiked out on a peninsula into the lake—all “oak” woodland and grass, everything green and lush with spring.

Near the end we encountered a rare thing in my experience, a flock of hawks—the tinque or Chimango carrion hawk. There were about 30 birds in one field and occasional aggressive encounters also took place, with an aggressor bird chasing and tumbling after another which did its best to escape.

We also spent some time noosing lizards—the *Liotaenus* here is much like our *Uta stansburiana*—males have brilliant shining blue tails and flanks while the head and back is flecked with a rich yellow. Females are darker and have paravertebral light lines. I caught several. They were exceedingly common on the big robles—as many as 15 being seen on a single tree, though these groups were mostly young females with no more than two males being observed on a single tree.

I snoozed on the drive back, curled up in the rear of the jeep all covered with road dust.

At night I gave a seminar on porpoise acoustics in spanish (with a translation) and it went well.

To bed.

October 9 [?], 1968

Up early and after many goodbyes to our wonderful hosts we rattled off down the road north. The trip was uneventful and pretty much a repetition of our Villarica trip until we decided to cut off at Traiguen and reach Araco, our destination, from the south rather than going north to Concepcion and backtracking to the south. The tradeoff is that the track we took is on graded or dirt roads and the other is paved.

We passed westward through rolling farmland, all verdant, set off by dark lines of windbreak trees. The road dropped down into a moderately deep valley into the tile-roofed community of _____. It is seldom touched by tourists, I think. The signs are absent—hotels, tourist shops, taxis. Instead bullock carts, and the utilitarian things of life.

Passing on, the road rose into hills and then mountains verdant with ferns and trees, streams rushing below. Once we stopped and Moosemeat, for comic relief, I'm sure, fell in the creek. It was ice cold.

On over a steep crest and then we could see Lake ___, tucked between the hills with nary a pier or a boat [?] long shoreline. We understand there's good fishing, but alas, the season doesn't open for 5 days.

Just beyond the lake we hit the coastal plain—all tree farms for the Monterey pine and eucalyptus and farm lands.

At one point we stopped to see an old abandoned mill, complete with water wheel. In the mill pond I watched the big trout rise. There are so many streams and lakes that nothing is fished out, I'm told.

Finally we cut off to Aranco at the southern limb of the Gulf of Aranco, south of Concepcion, and found a nice homey new hotel, the Hotel Huimpalay. Rooms, a tasty dinner, and to bed.

October 10, 1968

Aranco, Chile

Up reasonably early, rousting out the reluctant ones and off to Llico, or so we thought. Llico, it turns out, was destroyed in the 1960 tidal wave and is unreachable anyway, except by boat, so we settled for Tubul. Tubul also is unreachable by car. It is a town of 200-300 people built on a sandspit at a river mouth about 10 km west of Aranco. We jeeped to the opposite bank and caught the government-subsidized ferry over the river (a row boat powered by a brawny smiling fisherman). On the way across we inquired about boats, as we could see the fleet of launches leaving the river mouth. Tito ____ was our man, we learned, and his launch was the only one not occupied in Cholgá fishing. This is the big cold weather industry. These mussels live in the sandy bottom of the Golfo and are collected by divers using either hooka gear or scuba equipment. What a life! The water is near 11-12 deg. C. and they dive all day. There are better ways to earn a living.

Tito lived near the skiff landing and proved to be a barefooted man in middle age, curly gray hair, snaggle-toothed, and speaking perhaps the most impenetrable fisherman's patois we have met yet. We haggled a bit over price, all the while having the irrelevancies of an old gent in a beret thrown in. This fellow simply seemed not to understand about money. At one point he suggested "mil pesos" per day or 12 cents. Then he contradicted Tito who was holding out for 40 escudos a day, by saying it was for two days. We settled on 250 escudos per day, which is a good wage, far over what he

would earn a day fishing. Tito stopped making copper nails from wire and we were off to the mighty lancha *Lupita*, which was anchored in the river behind the village.

It is a double ender about 25 ft. long and powered with a Pontiac auto engine, with the foot peddles still on. Tito had improvised a thrust bearing and a through hull fitting that leaked water at a horrendous rate, requiring bilge pumping about every ten minutes. The carburetor too, was in ill health and so the motor constantly changed speed and sometimes quit altogether.

Soon we were out over the bar and cruising westward toward the defunct town of Illico. Before I could get ready a group of toninas was sighted. No question about it—*Cephalorhynchus entropia*. They sliced quickly past the bow and were gone. We sighted another group and Tito took off in a torrent of rapid-fire incomprehensible fisherman's spanish. No matter how hard we tried we could not slow him down. Speed is part of his language as it is with most fishermen and they simply can't seem to say words individually.

On we went in the calm water of the Gulf of Aranco toward Illico, along the chalk-bluffed coast. The weather was cool, pleasant, and clear.

At the sandy cove of Playa los Frailes we encountered another school of toninas, this time of large size, composed of scattered groups of 4-6 animals. I fired at one that ran ahead of the bow and hit it. For a brief time the others circled some distance away but then left for nearly the entire battle. Leanne could hear no sounds other than snapping shrimp

As Tito tried to gaff the animal it broke away, the harpoon having hit a bone and bounced out, producing only a superficial wound. It disappeared in the murky water.

Try as we did, we could not relocate the school, and as it was nearing lunchtime we returned to Tubul to buy some bread and something to drink. Tito invited us to lunch at his house, which we accepted. It is a low, wooden affair composed of a kitchen, a living room, and probably two bedrooms all going at odd angles to one another as if the house had relaxed over the dune sand beneath. It was immaculately clear. Two of Tito's four daughters (one son) emerged and helped with the meal. They were shy at first but soon proved vivacious and full of laughter. The eldest, Raquel, a slim pretty girl, showed us her needlework and some of the things she had made with shells. The other, Mary Illysia, was shy but emerged after time. She, too, is a pretty girl, and of about 20 years.

Mama, a pleasant graying woman, was the soul of politeness, offering us bread and bringing out a plate of cholgás (mussels) for each of us. In the kitchen pots of unidentified food cooked on the big iron stove, warming the whole house.

I had a cup full of harina, or toasted wheat flour, in cold water. It tasted more like essence of puffed wheat than anything else. After some urging we got Raquel to eat with us but Momma would not, saying bluntly that she could not sit as she had to tend to the food.

In the afternoon the girls accompanied us on a fruitless cruise up the coast. Tito was having troubles with his carburetor and with the stuffing [?] where he had removed the universal joint and installed the main propeller shaft. The fit was poor and much water came in, which Tito or the girls periodically pumped out into the scuppers.

The toninas had scattered, and we saw many individuals and very small groups, most father offshore than before. The wind came up and it was blustery when we went over the bar with inches to spare.

We all landed and made our way across the strand to Tito's house, the dog was still asleep in his basket and Momma still cooking. She said it was a hard life and I believe her. All around are Monterey pine groves but no wood is to be had. It must be bought at 70 centesimos per caja—about 2 ft. square—water comes from the town pump, transportation is bad, and one always wonders if the next earthquake will wipe you out.

Tito talks of the "ricos" when speaking of the Rotary Club which has a ratty looking clubhouse across the stream from Tubul. By our standards the Rotarians here are poverty cases. What must it be like to live in Tito's family. Happiness yes, but niceties of life, no.

We trudged over the mudflat to the waiting skiff, made our way across the river to the jeep. At the same time men were swimming their horses across upstream, leaving them, whereupon the horse turned and swam back, and stood glistening on the sand.

In Arauco there was scarcely time to shop but we wanted to buy some gifts for the girls and Momma and so settled for some quick purchases—scarves for the young ones and a pretty little aji dish for Mother's table. They have so few pretty things that each is a treasure, even including a simple little ash tray that Raquel had fashioned for sea shells.

October 11, 1968

Arauco, Chile

At 8:00 we waited on the bank for Tito to come. When he didn't I dispatched Kenny to the opposite bank and soon the old doddering *Lupita* upped her anchor (or arana, as they call the grappling hook he uses—the anchor line is a long slice cut from a rubber fabric conveyor belt). Tito then explained that the water was't yet low enough to get across the bar—we wondering why he had asked us to appear so early.

Not far out in the calm bay, along the white strand of Playa los Frailes, we encountered what must have been most or all of the toninas along this shore, apparently harrying a school of fish from very near the surf line to ½ a mile offshore.

There were scattered groups of 4's and 5's or maybe a few more—it's always hard to guess how many animals are below the water. Occasional ones sliced into our bow and finally one came alongside right below me. I fired down on it through perhaps 2 ½ ft. of water. The animal instantly stretched in rigor and rolled dead at the surface. It later turned out that I had pierced its heart and perhaps the spinal chord. What a relief!! While I can kill these animals, it is with anguish, especially when they fight and struggle, and to have an instant kill was very relieving to us all. I doubt that the animal could have uttered more than a few seconds worth of sound, if that, and yet two others circled near until the rigid animal was brought aboard. She proved to be a female, as it is so often the case when other animals stand by.

Kenny quickly went to work, obtaining his samples for selectron microscopy of the ear—a process which must be completed in minutes after death if the samples are to be good.

The school evaporated into limbo while we worked on the porpoise—photographing and measuring. It was never found even though we looked diligently. Our track took us west toward the point that marks the western limb of the bay, and there in the shelter of a steep bluffed cove offshore from Illico, we hauled out our food—loaves of french bread, sardines, empanadas, soft drinks, and chocolate, and enjoyed a quiet meal as the vessel rocked quietly at anchor. Illico, as a town, is gone—washed away by a

tidal wave, but in its place is a lush series of field, nice neat barns, a University of Concepcion oceanographic station—all on the flats where the next wave will repeat the damage.

We saw a few porpoises in this area but none would allow us close so we turned and headed back toward Tubul. From time to time Tito rejuvenated his engine. He was so adept at this that we began to be lulled by his efficiency.

All trip sooty shearwaters had streamed by us, coming from deep in the bay and flying toward the point and the sea beyond, on their 6,000-mile circuit of the Pacific. Some red-footed shearwaters (or is it pink-footed) were amongst them. Down in front of Arauco the engine quit more completely than usual, and while Tito fiddled with things too fierce to mention, deep in the guts of the *Lupita*, we watched the shearwaters feed. They had located a school of some sort of surface fish. The forefront of the shearwater flock, thousands of birds strong, glided in on the fish and disappeared as a front of diving birds. 100 yards behind, those who had dove before emerged and took off, running over the water to get weight on, and then themselves became the diving forefront once again. I estimated 10,000 birds were in this milling mob. The fish school moved fast so the site of the diving changed rapidly. It swept toward us and almost before we knew it we were in the midst of the melee. As the fish school moved by the stream of birds rushed past us, all in the swift graceful flight of these glider-like birds, before they dove in a little cloud of spray. As quickly as it came the flock was gone, the noise of wings, of splashing as the birds dove, of swift running webbed feet that took the birds aloft again—all these receded and were gone.

Tito even fixed the engine, but with a nod of agreement between us, tempered by somewhat guarded relief on Tito's, we turned for the river mouth. The tide was pretty low and the old *Lupita* kicked up a cloud of brown bottom mud as she slid over the bar, but in minutes she was at anchor again, in her quiet river retreat. Tito told me it looked calm now, but that when the south wind came howling over the point it funneled down the valley and had capsized a few boats like the *Lupita*.

We went ashore to deliver our gifts. Momma and a neighbor lady were out in the back yard getting ready to bake bread. They had built a fire in the big round mud oven. It had consumed itself and lay as embers across the bricked floor of the oven. The oven was at belt height on a sturdy wooden platform. Momma scraped the coals aside, out the two entrances, and then dusted the floor carefully with a broom made of leafy branches tied together and moistened. When the floor was clean the ladies uncovered two big wooden troughs full of round lumps of dough, each 6-7 inches across and each topped with a dollop of fat to glaze the loaf. Momma put them in carefully, balancing each on an oar and sliding it onto the hot bricks. Then she carefully banked a little hillock of coals near each door, spread a handful of flour over each, which instantly rose in a cloud of smoke. This, she explained, would make the loaves brown. Then doors were propped over each entrance and a wet sack laid over to seal it. As the door closed I could see the loaves rising. We had tasted this bread earlier and it was dense and delicious.

I was anxious to get back to Arauco and so hauled my companions away, while Momma surreptitiously opened Raquel's package in the oven room, looking with obvious pleasure at the pretty scarf. Our goodbyes said, we returned to town.

On trips like these one works closely with companions and little things can magnify. Leanne had gotten thoroughly on my nerves, mostly I think for petulantly

invading the man's domain of decision in which I ran into direct conflict with her. My trip, my decisions—I thought.

So it goes on long field trips. One must work with saints or these things inevitably arise, particularly where challenges to leadership or status are involved. There is almost no situation where the hierarchical feelings of man are more clearly shown. Anyway, I was glad she was leaving tomorrow as I could probably not have held my temper much longer.

October 12, 1968

Arauco, Chile

Phylly and I hope, Susie, are due tomorrow at Concepcion airport to drive back with me. I took Moose and Leanne to the airport and dumped them off, returning down the long trip to Arauco. The afternoon was spent walking the beach between Tubul and Arauco, looking for skulls. I found none. It was pleasant though, the sand covered with machas shells, the gulls, paired Lapwings screeching aloft as I drew near, and the pastoral scene inland of fields, grazing cattle and occasional farm houses.

The long trudge back to the jeep parked on the bluff before Tubul, sack on my back, just about used up what energy I had left—I guess my hike covered about 12 miles, half on the soft sand of the beach. Going back I ruminated that this was daily fare for most people down here—cars belong only to the ricos, what with the 200% impost and low wages. It was easy to dislike them as they swept by, raising a cloud of dust that settled on one and from which there was no escape. No one so much as indicated they might give me a lift. My steady pace took me through the going-home foot traffic of the Tubul soccer game, and then I felt rico again, what with my nylon coat and good hiking shoes.

October 13, 1968

Arauco, Chile

Another day of beach walking. This time going the other direction from Arauco. I made my way through crowds of holidayers—this weekend was Columbus Day and everyone was out for various entertainments. The bombones (firemen) were out again in their shiny regalia, and at one point I had to pick my way through the horse races. About 15 guasos (the local gaucho) came thundering down the road and up the street on which I was driving. “Damned gringos, don’t they have sense enough to get out of the way?”

On the beach I found three skulls of *Phocoena spinipinnis*, a species I had not seen while on board the *Lupita*. Tito had led me to believe that they were here though, and called “pope”. All these porpoises—the tonina, the pope and the llampa, were fished, we learned by a company, headed by a lady, who came down in summer and circled them with a big net. They were used for oil, and Tito said the black pope wasn’t nearly as rich in oil as the tonina. I wonder now, if there isn’t a seasonal migration of the pope into this area in summer, coming in with the thinner blubber coat of a more northerly animal, while the cold-water-loving *Cephalorhynchus* is here the year around, and sports a much thicker layer of blubber.

Toward noon I returned with my prizes and left for the east limb of the bay. There I walked another long beach, this time in the sun. I found nothing but a few beach lizards (*Leiolaemus*), had lunch at a ratty little cafe, and made my way to the airport.

There I waited for 1½ hrs. or so, feeling dirty and out of place with all the spiffy folk who use that facility (built with Alianza para Progreso and USA funding). It was so good to have Phyl and Susie step off the plane. Especially I worried about Susie—she had had trouble with her ears on the flight from LaPaz and was frightened to come with Phyl, but somehow she had come along, and looked triumphant.

We piled into the jeep and went south. I don't like Concepcion much—it's rather soulless, even though set in the midst of forested hills on the banks of the Bio Bio, a river which at this point is nearly half a mile wide and swift.

We returned to our hotel in Arauco, where the Italian dueno cooks delicious meals, and where everything is neat and clean, even if the beds are swaybacked and the plumbing uncertain. I still recommend it—the Hotel Huimpalay.

A nice drive, a nice meal, and to bed.

October 14, 1968

Traiguén, Chile

All of us wanted to visit the Arucanian Indian country to the south of us. These people had actually stood off both Spaniards and Chileans, using the Bio Bio as a barrier, and only in the past 80 years had let them enter. They represent just about the only source of indigenous art and craft, though much diluted for the tourist now, as is the case most everywhere.

We planned to drive southward along the coast, to the Rio Imperial and then drive inland along its banks to Temuco, the Indian capital. Easier said than done, so it proved.

I made a seat for Susie in between the two of us and piled all the luggage in. We have a drum full of porpoise parts and salt, and other collections and field gear plus Phyl's and Susie's luggage. I tied the harpoon gun on the front bumper and we were off. All enjoyed the long drives through tree farms of Monterey pine that dominate this part of the coast. At Canete we shopped for some food and materials for Susie's plant collection, and left munching fresh French bread and slurping pop. To the south our road became gravel and then the resonant characteristics of jeeps sprang into full expression. After a few hours of such jouncing one sometimes gets sensitized and wishes for quiet.

We stopped at the old mill and poked around, finding the arastra and ancient bagging machinery with wooden toothed gears.

It was all farms now, with native brush on the hill tops and ox carts came to dominate as the mode of transportation. Horses were used only for riding and the slow ox cart, with driver maneuvering by means of a long wand, took over. When the driver wants to get out of the way he leaps out and lays his stick lightly against one or the other animal causing him to turn. Then he props the stick against the yoke and both animals stop. I had to be careful as many of the animals seemed unused to car traffic—certainly we saw little but occasional trucks. Our road wound through the hills, past Lake Lheu Lheu, past Indian ranches with a mixture of types—pure Indians, some dressed in garb with the peculiar pendant necklaces and headbands made of pounded coins, full skirts, sashes and scarves, aquiline-featured Chilean men, hard and tough looking, by a life in the saddle, and occasionally pure caucasian types.

We finally reached Dibuco, a small fishing village set on a black sand beach. We asked about the road ahead to Tirua and Rio Imperial. There were two roads it emerged—one to Relun that ran up the hill behind town and another to Tirua that

followed the coast, going across the rickety bridge south of town. We followed that one, having to drive on the strand just about high tide, at one point. It was steep and looked unused by folk like us, though we did encounter a truck or two. Before Tirua we had to ford a stream that ran over the foot of a sand dune. I had visions of quicksand but could see reassuring wagon tracks. In Tirua, another little shoreside village where the inevitable futbol game was going, we asked again and were told the road was bueno to the river. Muy bueno indeed. Right across the river that edges the town we came to a mass of rutted dried mud that looked like the Devil's golf course. We clawed our way over that, and up the ravined hill behind (in the road that is). Shortly we came to a sea of mud with a pig happily playing in it. Inquiring at the farm house alongside, the lady confided in me that ox carts were common enough but she couldn't remember when a car had tried to make it. I think she was probably born in the house too. Prudently, we turned back, to the road at Dibuco that led inland to Relu.

It was touted as the best road and I hate to think what the road beyond the pig must have been like. As we climbed the hills, the open farms gave way to a gloomy and dense forest, probably all but impenetrable to a man on foot. The dried mud patches became wet ones and little cricks came to run down the rutted road. Once in a while we passed a guaso on horseback—his poncho pulled up around his ears, only the eyes showing.

Soldiers too passed on horseback, rifles slung across their saddles. These always polite folk gave us directions and distances, all of which seemed to indicate a long trip ahead. There has been guerrilla activity in the Concepcion area and one can understand why cavalry are needed, and why there are so many soldiers about. It would be tough indeed to track down a redoubt in that jungle.

At one point a fullblown stream gurgled down the road and by dint of picking the hard spots and the high ones, and by use of 4-wheel drive we made it OK. I began to look at both the time—late afternoon, and the gas gauge (less than $\frac{1}{4}$ tank) with some apprehension. If the map was right we should make the next town—Capitain Pastenes—easily enough, and I had a 5-liter can in reserve behind us, but as the miles of winding road stretched on interminably I couldn't help wondering though Phyl and Sus said nothing and neither did I.

Finally we reached Relu, descending down a long, twisting road through pretty leafy forest to this cluster of farm houses. The best we could say was that the road got better. Finally close to dusk we reached Capitain Pastenes, where the map indicated gas. The first person I asked said there was no gas in the whole town. We drove around reluctantly using up a little more of our precious supply and sure enough when we found the pumps—the old type with the glass tops and diagonal meshwork of wire wrapped around, they were dry and locked. We simply couldn't reach the next town 40 km away and this one looked inauspicious for a night's stay—dirt streets, ramshackle housing, street-side sewers in places. It started to rain as I began to query people if there wasn't someone with gas (benzena, they say) in a drum. A couple of people who ran businesses and colectivos were suggested. The first was peopled solely by little people, the father being up the hill someplace. They wouldn't do anything unless their father said yes. The next, the man with the bus, lived in the grandest old house in town—nice garden, diamond-paned glass windows, two stories, came out and said he would check. We walked to his shop and there, blessings be, was a drum with some gas in it. I talked him

out of 15 liters, paid an astronomical price and were off. The problem had been that the gas distributor was trying to force his subdistributor out of business and as a result had cut off the supply for the 100's of square miles surrounding the town.

In the rain, and long after dusk, we reached Traiguén, a town of 8,000 or so. There we located the mighty Hotel Traiguén. It is about 80 years old and we were the only guests. The huge portly bartender signed me up for two rooms. We ascended the shiny, waxy wooden staircase to our funny old high-ceilinged rooms. There was the washstand, the chamberpot, and no heat. The beds were nice and clean and topped by piles of comforters. Down the hall was the bathroom, equipped with a huge old tub with eagle claw feet, and toilets up on daises that made one feel like "The Thinker".

A nice gracious dinner in awful lonely splendor in the nice old panelled dining room and off to bed, where joy of joys, they had placed steaming hot water bottles for us.

October 14, 1968

Chillán, Chile

During breakfast I hauled everyone in to see the kitchen and to converse with the cook, a nice old lady who had lived all her life in Traiguén. The hotel was older than she, she said, and then we admired her stove—a great, green enamel and brass woodburner. She showed us how it heated the water for the entire hotel and how she cooked various things on it.

The trip to Temuco was down paved roads and an uneventful and beautiful drive through bright green farmlands, mostly of the great fundo owners. Temuco proved to have darned few Indians—only a few hawking rugs in front of the main hotels. We bought a reed basket and a rug for Kenny Bloome. The baskets are made like those of the Papago Indians—coiled work wrapped with a pliable strand. The coil is of "junco", probably *Juncus*, and is pale green, the spiral wrapping is like the striped outer cover of bamboo and of a reed called Niocha.

On up the central highway to Chillán. Also a pleasant and essentially uneventful drive, looking at farms, watching the bullock carts change to a four-wheel horse cart, collecting flowers for Susie's pressed collection, and just generally watching the scene pass. Late in the afternoon we reached Chillán, a rather typical farm center town—a pretty Plaza de Armas, all trees and statuary of proud-looking military men all painted silver (why they do this, I don't know, but town after town paints their statuary either silver or worse still, a shiny enamel green). We put up at the nice Hotel Gran, lovely rooms and flowers everywhere, and then visited the earby open-air market, said to be one of the most "pintoresque" in all Chile. It was like an overblown Olivera Street in Los Angeles. Mostly junk but with some nice things hidden in the interstices. We bought little and dickered more.

Dinner and to bed.

October 15, 1968

Renaca, Chile

Up the main highway, collecting flowers and watching the four-wheel carts turn into two-wheel pneumatic jobs, usually made of the front wheels of an old car. At Talca I began to hear a clank everytime the clutch was thrown in. Suspecting we needed grease and oil, I stopped at a service station, and climbing down in the grease pit with the

service man I soon found that the rear universal joint was on the verge of going out. It was slipping from side to side in a ominous manner. As best I could, not knowing any of the terms for car parts, I inquired about what could be done. I suggested that either we could put in a new part, if they were available in Talca, or simply remove the section and drive in front-wheel drive the rest of the way. When we returned from lunch the latter had been done and we scooted off, minus clank, and minus rear drive. It went fine.

Near Rosario we turned off to come into Valparaiso by the coast route through San Antonio. That proved an error, but a scenic one. We went through tree-shaded hamlets and lovely green farms and as we moved northward, through increasingly arid land, mostly covered with the espinosa tree, now all in bright yellow-orange bloom.

Some parts of the road were horribly washboardy and the light front end of the car caused it to dance around a bit, making driving a greater chore than usual. In this drying land we came upon the great white dish of the COMSAT relay station where satellite telecommunications come to Chile, and there we had a flat tire. I changed it in the dusty road, thanking my stars I had had experience with lug bolts with opposite threads and remembering Carl Hubbs who had stayed for two days in the desert not knowing this, or so the story goes.

While I was under the car Phylly noted water leaking out the front, and I asked her to check. “The battery” she announced. I wriggled out and sure enough the battery had broken loose and the case was cracked. I quickly started the engine for fear it wouldn’t work much longer, lashed the battery down with nylon line and we were off, feeling our redundancy disappearing, and wondering if the final end point where the whole mechanism failed like the one hoss say, would come before we reached home, or in the driveway.

At dusk, in the little farm town of Melipilla, I decided to renew a bit of redundancy by buying a new battery. One last stretch of dirt road remained, that to Casablanca. It seemed interminably long and rutty. We jounced and bounced for what seemed hours, while we worried for fear the kids at home would become anxious over us.

At long last pavement. And the car couldn’t take it—it shimmied relentlessly every time I reached 20 mph, and finally, by dint of putting one wheel on the dirt shoulder, being careful of culverts, and the other on the rough pavement we reached the main highway, where, blessing be, it saw fit to run without shimmying. It made peculiar sounds that got louder and louder but we reached home, tired, and glad to see everyone (Dick was already asleep).

Now, how do I get this wreck back to Santiago?

November-December 1968

South America Trip

November 2, 1968

San Juan Bautista, Cumberland Bay, Masa Tierra Island, Juan Fernandez, Chile

At 8:30 AM we were waiting at Rodalillo Airport, between Vina and Valparaiso. Right on time our plane appeared and landed, rolling to a stop amongst a gaggle of horses who wandered on the runway. We then waited for 30 minutes or more for the gas man to show up so we could top off our tanks. He arrived, without keys, lifted off the lid, lock and all, and filled us up. We left Phylly waving us off. We were crowded to the guards. Bill McFarland, Elda Fagetti, Leanne Hinton, and I plus two Peace Corps workers, Glen and Eleanor Meagher, plus the dashing young pilot of our Aero Commander, plus our gear. A nice 2 hour, 45 minute flight—first over the Humboldt Current and over the boundary where cumulus clouds started. We flew low the last 50 miles—looking for whales. Finally the island appeared—a short jagged outline of 20 km length, with plunging cliffs. We cruised the coast—deep valleys, transparent blue coves, plunging cliffs of many colors—grassy slopes, calderas, high fluted valleys clothed with trees of many kinds.

At one point, just by some great vaulted cliffs all laced with lava dikes, we flew over about 10 pilot whales. Their heads looked white though I'm sure this is an illusion of looking from above. They were no more than 150 yards from shore, moving lazily along, very near a fishing boat.

Our plane cut out on the long thin end of the island which winds around as a hogback notched on either side with coves.

The plane sat down on a tiny runway set in a caldera. The end of the runway swooped up to its rim and so did we as the plane halted near the precipitous edge. Taxpa was busy building a road to the town in Cumberland Bay but we had to portage our gear down a long tortuous trail to the beach—the last section being a series of switchbacks down a cliff. Once there we loaded our gear in a 25-ft. double ender that had been pulled through a patch in the cobbly beach with a winch set on shore (hand). We went the opposite way by hauling on the anchor line. Once in deep enough water a Swiss outboard was lowered into a well aft and off we went, cruising along the shore. The cliffs remind one of Hawaii, all fluted and steep and green. They are brilliant in places with reds, ochres, and even blue.

In one cove, we came upon 6-7 fur seals (*Arctocephalus philippi*), sitting on the rocks. We were able to approach within 20 ft. or so before they slipped into the water. A musky odor was very strong. They have a rather pointed snout, a silver mane, and black lower parts. All had been cut with bites around the neck and flippers. One old male slipped into the water and then promptly inverted himself, flippers waving. He maintained this posture—on and off—for 15 minutes until we left. On down the cliff we saw a baby—all black—resting on a rock, but I noted no females. These animals were resting on slabs of rock near lava tubes and caves at the base of an abrupt cliff. On we went, after provoking one to snarl at us by yelling and waving our arms. Bill gleefully photographed the proceedings.

Before long we passed Bahia Ingles where Alejandro Seltete (Robinson Crusoe) had lived. We could see his cave back of the beach—a low-roofed lava tube. Behind was a vaulted valley clothed with trees while lower down green grass painted the steep valley walls. On the ruin we could see chonta trees, a protected species of palm with a beautiful black and white wood, luma trees (*Eugenia*) and others. The luma is native and quite common, a rounded almost reddish tree with a white trunk.

The boat rounded the next point and slid into the little harbor of Cumberland Bay. The little town of San Juan Bautista is where the island's 400 people live. It consists of a jumble of frame houses climbing the slopes, mostly hidden amongst the trees. A small pier extends into the calm clear blue waters.

We were met at the pier by Rinaldo Green who is the big man here—owner of boats, fishing company representative, owner of the hosteria, and a fine, plain, simple, insular person, balding, bright clear eyes, constant sweet expression. His family includes 8 handsome children of which Robinson is one.

Upon the hill is a Spanish fort and all around the plaza are old caverns[?] plus a cross to the German sailors lost in the sinking here of the *Dresden* in the First World War. It lies in 60 ft. of water at the entrance of the bay.

Our hosteria features one communal bath insecurely closed by bolts that enter the plaster. Our rooms are fine, with sway-backed beds. The food is delicious, featuring, of course, the lobster.

Bill and I took a hike to the neighboring caleta where a new hosteria is being built. We walked a precipitous goat trail along the cliffs, through steep, grassy fields, dotted with a yellow-flowered caparidaceous plant. We descended to a little tumbling stream running under fig trees and thence to the cove where we watched the peze sapos clinging to the rocks. This fish, weighting up to $\frac{3}{4}$ lb., is the world's largest clingfish, having a suckerdisc on its throat. They are very alert and flipped off into water when we got too near. We could see them grazing on algae.

Dinner, a bit of pisco, and to bed.

November 3, 1968

Juan Fernandez Island, Chile

We slept well, arose, and made our way to the little pier where Orlando and Juan were readying the lancha. I found that a whaler of the old sailing days had stopped by some 8 or more years ago and in a storm left 2 whaleboats behind. Since then island craftsmen have been building them on the exact plan, of cypress and linque cut in the hills above and sawed with pit saws which we saw in several places near the town. These boats are raked sharply up, bow and stern, nearly double-ended, have a stepping post for a mast and sail. All are copper nailed, many have a cleat for a steering oar, and all ours had the Swiss long-shaft motor going through a well astern.

We cruised out from Cumberland and soon were in blustery water and ever-increasing swells. A big broadbill surfaced near us. I volunteered to try to harpoon him for the islanders but each time we got close he flipped his tail in foam and disappeared. Later, a school of peze luna swam by—*Ranzania*—the oceanic sufish. It was obvious that we could not work farther offshore so I asked Jose to cut around in a circle, ending in an hour or so at Hornitos for lunch. Nothing was seen except the swooping albatrosses (black-browed), cape pigeons, and giant fulmars. We finally entered the lee and slid up

among the cliffs and caves. Mac, Jose, and I went ashore to look in a sea cave for bones, but found instead it was full of fur seals—a dozen young females. They tumbled out, barking and flinging themselves along over the rocks. No bones. Some of the animals crouched in the farthest recess of the cave. We clambered back, boarding the long boat over the algae-slick rocks. Leanne had recorded the melee and had a long tape of underwater barks. On down the coast to a better anchorage we went where Orlando broke out the little wood stove, which he banked with wood while Jose prepared the mess.

We had obtained 2 meros (sea bass—*Epinephelus*) from a couple of fishermen bobbing off the point. Our men replied when given the fish on a gaff, “Que dios te lo pague”—“May God pay you”—a nice touch. It is typical of these people, even the dogs. Everyone has enough to eat, no one frets about money—in fact they seem rather little motivated by it. Witness the presence and even abundance of the broadbill, which draws premium prices on the mainland, and no one has a harpoon or a pulpit. As I said, it extends to dogs who are all kind, well fed, and friendly.

The mess was cooked in the smoke, turned once, and came out brown and absolutely delicious. Some bread and the fish made our lunch. Elda caught cureles (a yellow-tailed jack) with a hand line while we ate.

Another walk on the beach produced some big limpets, and no bones. Tired and windblown we arrived back in Cumberland. Dinner and to bed.

November 4, 1968

Juan Fernandez Island, Chile

The wind was still blowing so I decided we should stay ashore and perhaps take a hike to one of the beaches on the opposite side of the island where we might locate a bone or 2. Actually I was pretty sure we wouldn't make it across the ridges but we all wanted to see the forest in the middle of the islands. Reinaldo suggested we take a guide and obtained a 12 year old boy, Carlos de Rodt, whom he said was a walking map. He was, indeed, as well as being largely mountain goat. Mrs. Green gave us some lunch and we left, back of town. The trail led us up into a steep valley rimmed with nearly vertical lava walls. Except for the vertical cliffs vegetation clothes everything, a fringe of trees showing up along the ridges. After leaving the sloping fields and livestock we entered a low growth of ferns and luma trees and cycads, plus a *Eugenia*. The cycads, called palmitas, form large banks up the steep slopes. (I believe they are a species of fern that looks remarkably cycad like.)

On the horizon we could see the chontas—a slender palm producing a black-and-white-striped wood so beautiful the tree has nearly been extincted but is now protected.

After a steep hike up a switchback trail, through places where the trail was deeply cut into the hill (it is a wood slide of cut trees) we reached the mirador de Alejandro Selkirk, a deep notch in the knife-edge ridge.

We puffed, out of breath, and sat down to enjoy the view. To the east, far below us, lay the little village and Cumberland Bay and to the west lay the long hogback of the island, 3 precipitous fins called Leones, and a long sloping grassy land ending in the cliffs and coves.

We ate lunch, sitting on the rocks in front of an old iron plaque dedicated to Selkirk. It told of his 4 years 4 months on the island from 1704 and of his death at the

age of 47 as a Lieutenant in the Royal Navy. The plaque itself was 100 years old and cast in Valparaiso.

We looked at the steep trail down and I, at least, wondered about the stiff hike we would have to make back up. We started down into a wetter luma forest, passing canelo trees (the bark does not smell like cinnamon). The lumas are gnarled and twisted and their upper branches are wind pruned so that whole slopes are smooth and one can almost see where the wind has pressed hardest by sweeping indentations in the smooth slope. Farther down the wind is less and the trees taller and straighter.

We were accompanied by a pair of dogs—grand, friendly fellows named Blackie and Toby, who enjoyed the hike immensely. They located a strayed cow and succeeded in chasing her ½ mile farther from home. The trail led us down through a deeply cleft trail, sometimes so deep that light dimmed and some ferns seemed almost translucent with lack of chlorophyll, and green moss clothed the moist banks. This trail must be nearly impassable in the rain—a torrent of stones and mud.

We reached a little stream, nearly on the flat. I poked around, rolling stones as is my wont, and discovered both an isopod and an amphipod, both in the moist earth. The amphipods hopped around just like sand fleas when one turns over a pile of kelp. I wonder if they do not represent an invasion from the sea of a form somehow able to convert from salt to fresh water osmoregulation.

We turned and made the hike back up—arriving an hour later at the Mirador, tired, and welcoming the chance to relax for a few moments—especially the dogs who lay down beside us panting furiously. The hike down was hard, especially the lower half, where the slick dirt and small pebbles made slippery going. Every step had to be considered. We collected Elda some ferns and cycads, arriving laden down, full of aches and pains and happy to stop. It had been a steep, rewarding hike, and we were distressed to learn that the new road from the airport will cut right through the mirador, ruining that hard-won spot where we had taken our rest.

Someone had promised Sergio who ran a small fishery that we would visit him, so tired as we were, we all trekked across the weedy city square to his house near the pier. Sergio is a lonely man, deep in the grip of alcoholism. He led us through his house full of toys, mementos of his fled children, 7 of them all gone. We sat at the pine table while Sergio bustled around, coming out with cheese and candies and then setting a wine glass in front of each of us. This he filled with an orange fluid, mucilaginous like the white of an egg. It proved to be made of lobster eggs and livers, lemon juice, and gin. Elda almost couldn't hold herself in check as she sipped. It was the unidentifiable stringy yellow things in it that turned me. Somehow we managed to drink it but Bill, Leanne, and I were only a sip or so ahead of Elda. It was like the pledges at a fraternity initiation drinking horrible concoctions for the old frat.

With Elda carrying the brunt of the conversation we heard of Sergio's desolate life—a wife and children on the mainland, 35 years on the island, illness, loneliness, and especially, little to do. His company was all but moribund now that the fishermen had organized themselves into a cooperative. He was set with some kind of paralysis and hadn't money to go to Santiago and he wouldn't ask his family for any. He deals in lobsters but now has only 2 boats, hardly enough to support him. His lot is idleness, up to 10 liters of wine a day we learned later, uselessness, and a feeling of having wasted his life.

It is hard here in some ways, and remarkably benign in others. Illness is difficult to treat though they have a fine old lady who serves as practicante, and keeps her little dispensary neat and clean. The life is so tranquil that events like our arrival cause great stir and everyone knows what we are doing—yet nearly everyone is simple, direct, a little suspicious of outsiders (though we fitted in quickly enough at our level of acceptance) and everyone is well fed, if not well clothed. The climate is delightful; it's no job to pick big limpets from the rocks, or to catch a meal of peje sapo with our hands, or to trap oysters or catch the mero, or to raise a few vegetables in the fertile soil. There is plenty of good water. "Progress" is coming though, and seems alien, like a cancer. People want it with the lonely half of their hearts, and despise it with the tranquil part of their hearts. We, who know it better, despised it more. The road to the airport—the new hostel will change this place. The timelessness will disappear and those who are taken advantage of will lose their insularity bit by bit and become withdrawn into themselves. In 10 years we could probably not enter life here so easily.

It's tough in paradise though. A man can be somebody, and everyone will know him. If he is strong or wise or clever they will know. If he is weak, mean, or lazy they will know too, and these like Sergio, know too, and sink, destroyed by the idyllic life.

November 5, 1968

Juan Fernandez Island, Chile

At 9:00 AM, after a refreshing sleep, we ate breakfast and headed for the dock, beneath which the school of yellow-tailed jack swam (jureles). Robinson, the young son of Reinaldo, was there waiting for us. He is betwixt and between. Raised on the island and bearing his famous name, yet educated in mainland Chile, holding his bag of swim fins and plate and wetsuit, and not one of the fishermen. He is tolerated by them, not as good or wise about the sea as they, and not one of us either. His compadre was Ernesto, a gnarled fisherman whose whole life has been spent in these seas. We packed the whaleboat and left the harbor under leaded skies, but with very little wind. We headed out to sea off the east end of the island. The motor must have quit 20 times—bad gas, a carburetor that leaked, a spark plug whose wire was held in with a nail, etc. Far off Caleta Francesa we sighted whales—2 or 3 vertical spouts. We closed on them, making our majestic 6 knots, but were able only to see a dorsal fin of a large whale and they were gone, far outstripping us when we came to the same course. No sounds were heard. We came back in with our uncertain motor and landed on the cobble beach at Francesa. Our long walk was marked by learning how to capture peje sapos by hand—they aren't very quick—and by Bill slipping and hitting his head on a rock. He yelled, dazed and bloody, but proved to be OK except for a headache and cut forehead.

We quickly made for the boat and called it a day at the harbor, with Bill resting and visiting the practicante to see if stitches were required—none were.

November 6, 1968

Juan Fernandez Island, Chile

This day Mac and I decided to try to obtain a sea lion. It was blustery as we headed for the dock and we knew we could only work the lee. This meant going around the east end and up the cliffed shore opposite Cumberland Bay. By the time we reached the Caleta Francesa area my stomach told me it was not going to be an easy day.

Between rain squalls and williwaws I hung over the side but was soon thoroughly sick and at the long beach of Caleta Caravahil I had them dump me ashore while Mac went on with the hunt. I scraped a flat place among the beach cobbles and lay down, full of misery. Just to keep me from generating too much joy it rained occasionally. I could look out through some driftwood and see Mac stalking his seal. Soon I heard a shot and then saw the boat playing a carnival[?] on the harpoon line. It came close to the beach, all thrashing and upside down. It was a big male. The shouts suddenly stopped and soon Mac trooped up through the cobbles, looking dejected. The fishermen had tightened their rein over the big bull too much. It had circled a rock, cut the line, and escaped. By this time I was wobbly but better and so got up and attempted to put another iron into the poor animal. We found him out off the point, rolling slowly, harpoon still protruding from his side. We could not approach however as he sounded.

Time was growing short as it takes 3 hours to get back to Cumberland in these outboard driven whaleboats. I asked for one more chance, having them put me ashore on a big rock near the entrance of the fissure cave frequented by the seals. Here the animals swam very close by—within a few yards. Finally when the lines were rigged to my satisfaction I fired again, into another male as he swam no more than 20 ft. away. He raced into the cave, trailing line but in moments the harpoon came out clean. It had hit his back, [?] out, catching only a fold of skin, we believe. At any rate—no sea lion.

There was nothing to do but turn for home with only a few beach bones to show for our effort. It was a miserable trip—all spray and rain. I curled up in the bow watching with a jaded gaze as the rest ate a little food.

This was black Wednesday for sure—back in Cumberland Bay we found that Elda had not been able to get her lobster eggs, and neither had the girls been able to get permission to buy lobsters for our planned party for arriving HERO expedition members, the rain came through on Leanne's bed, and one of Reinaldo's sons fell from a horse and broke his leg in 2 places. Bill's peje sapos died in their bag under the pier, apparently drowned by lack of opportunity to crawl into the air as they do normally on the rocks, there was no way to get warm after our trip (no fireplace in the Green home), and finally, we learned that Nixon had defeated Humphrey for the presidency. Woe, woe. The crowning blow came when we learned that we had been bumped from the plane tomorrow by a load of lobsters. This angered me some in my weakness as I had chartered the whole plane for the trip. It will give us another opportunity to try for the sea lion, and to walk some more beaches.

November 7, 1968

Juan Fernandez Island, Chile

Bright Thursday. Reinaldo lined up Jose and Orlando, the brothers that are amongst the best fishermen on the island, and its only boat builders. They carry on the tradition of making whaleboats. The girls had gotten rather seriously bored on the island when we left them behind yesterday (thank goodness we left them behind, for the sake of my modesty). So, we all made the traverse around the east end in much calmer seas, with the sun shining here and there through the clouds. I was even able to watch and admire the vaulting volcanic scarps rising unbroken a couple of thousand feet from the water—here and there V'd by hanging valleys from which trickled rivulets that fell into the sea.

Halfway up the lee coast we came upon the only whaler with a cabin on the island, under sail. It had 2 jibs out and a mainsail and was cutting along right smart.

We dropped the 2 women off on the long sandy beach at Caravahel while Mac and I went foreward, hoping we could find the wounded animal and deliver the coup de grace. Sure enough, as we approached the cove where I had lain so miserable the day before, there on the rock in front of the fissure cave was the big wounded male. I readied myself in the bow and asked Orlando to creep up as close as we could get. I watched until the animal started to fidgit and began to move toward the water, and then let fly. The harpoon struck, the animal plunged into the pool below and streaked into the fissure, trailing line and a wake of blood. Before he could negotiate the 30 yards, just at the mouth of the cave, he turned in a paroxysm and died, drifting out with the surge. I had mercifully hit him in the heart. He was a huge beast, and it took all our strength to roll him onto the shingle. Mac and I measured him and then began the tedious task of flensing him out. He had a ponderous coat of blubber—perhaps 3-4 inches thick and tightly adhesive to his skin.

Some hours later we finished. I sent Orlando out into the whale boat to start some food going, we loaded our carcass and skin and made for the beach where the girls were waiting. They came aboard waving a skull in obvious triumph. It proved a prize—a waterworn skull of a beaked whale—probably *Mesoplodon* . . . very likely the first record for Chile, though I am not sure of that.

While I watched, chewing on my crust of bread, the others ate delicious broiled lusters, cooked on the same can grill where the mero had been cooked. Reports from the eating public were that it was delicious . . . and I believed them but thought it best to remain moderate. Back at Cumberland we placed a call to Phylly telling her of our delay and new schedule. One hopes these things get through but we could only trust the ejercito, and the intelligibility of what they would say

In the evening we visited a strange poetess—Maria Blanca Luz—in her arty house far up the mounain—surrounded by her 2 young men, sad, blunt to the point of rudeness, loving only the history of the island and not its present. She was worn by years of some kind of dissipation, all this etched on her face. I found her repugnant, her art a travesty, and her hollow and lost like Sergio—even though she only spends 6 months here every year. It is as if she retreats into this bland world as a way of coming to some kind of terms with her own lack of success. We stumbled home through the darkness, down the slippery walk, to the bright happy home of the Greens. I was glad to get there, even if Blanca Luz did have a fireplace in every room. Warmer below than above.

November 8, 1968

Juan Fernandez Island, Chile

Up before dawn as today we are to leave at about 10:00 AM from the airport. The wind was howling and outside the little bay the sea was a mass of whitecaps. With everything stowed we headed out into it—there was no going into the lee this time as we had to land at Padre Bay where the airport trail ended and it was windward today. The whaleboat cut through the sea amazingly well—big swells coming in, blown off at the top, spilling breakers alongside us and the reflected swells from the nearby cliffs confusing the sea into peaks and hummocks that tossed and broke.

All went well enough, though wetly to be sure, until we reached Punta Rinones. We had hit a buoy line earlier and now the shear pin cut and our motor raced impotently. No spare pin was on board. Reinaldo, a calm man, looked around and reckoned on help from 2 other boats that could be seen some distance away. Any substitute for the pin, we wondered? He found a spark plug wrench and if we could somehow cut a piece from the handle it would do. Nothing to cut with. I remembered the cutting pliers in my harpoon gun box. With these Reinaldo soon had a new pin fashioned and we were off as if nothing had happened

Finally, we slipped out of the rough water into the calm Padre Bay, beached the boat, hauled it up with a shore winch and began toting gear up the steep cliff road. The fishermen ran like goats up the steep trail, bearing great burdens, while we shore folk sweated and puffed up the road, stopping every few yards to catch our breath and to let our legs recover a bit. I toted the gun box all the way to the airport, over the objections of the fishermen who came back for a second load. Once there we checked on the plane and found it had started out but had turned back because of some unspecified engine trouble and was now in Santiago. This gave us at least 3 hours, so Mac and I headed back for the beach, to look for bones. We found none but did find some lovely concretions of a hard, heavy white stone, all mammilated and washed by the surf. I provided myself with a burden of them and back up the hill we went.

Then, we waited and called in, waited and called in. The plane was back, it was refueling, it was in the air, it was not in the air, the motor problem had recurred, it hadn't. By this time the wind had picked up and it was growing late, but finally unequivocal word came through that the plane was up and would land at about 6:00 PM. It came in, pretty much on time, and then the pilot informed us that he couldn't take off with this wind. It was too little to fly into and too much to go with. We would have to stay at the airport overnight.

As the passengers that had come in (a lady in nylons and a crepe dress, amongst others) made for the boat and rough trip ahead, we gave them some marizene. Mac and I headed down to Playa Caravahel to get water for the lobsters (we had bought 25) and the peje sapos. It was a long steep climb spidering down the 500-ft. cliff with our 3-gallon jars, and worse coming back. We were recompensed though—I found the jaws of a pygmy sperm whale (*Kogia simus*) and we enjoyed a good stroll on Juan Fernandez' only sand beach. The water crashing on the beach is like glass and one can look into the waves as they hump up and break. Shoals of jureles can be seen rising in the undulation.

A sparse meal of spaghetti, bread, and bacalao (smoked mero) and to bed on the floor. I, for one, slept hard after my 3 hikes up the cliff.

November 9, 1968

Juan Fernandez Island, Chile

At about 8:00 AM we loaded everything on board and took off easily enough, for an uneventful flight back. Phylly was there waiting. Poor gal, she had gone through 3 days of uncertainty at the shore end, waiting for us. Good trip, glad to be back.

November 14, 1968

Letter sent to Phyl from Puerto Montt.

Dearest Phyll and all,

After that wild departure things have been going calmly enough. Kenny lost his jacket on the dock, plus the scotch and candy (woe, woe), though, and we will try to get him another here in Puerto Montt.

Right this moment we are making ready to go through the Canal Chacao that leads between Chiloe Island and Puerto Montt. We have to negotiate it at slack tide as the currents reach as much as 11 knots, and often 9. Since flank speed for this bucket is 10½ we wouldn't get very far.

We'll be in Puerto Montt late this aft. I have given the crew some time there as it is the last port we will hit and even though I begrudge the time the public relations are worth it.

The crew seems excellent to me—all are pleasant and skillful. The skipper is a spare old seaman of a droll turn—very competent and easy to work with. Our own boys seem to be doing well too, though nearly everyone was seasick coming down. I was not and neither was Bob Barrett or Bill Schevill, but Mac and George are just coming out of their problems now. Mac, I suspect, took that long to detank.

We've seen very little so far, but have gotten things in some semblance of order. Tomorrow we will hold harpoon drills and launch drills as well as general shipboard safety drills.

The ship rides nicely, I think—a long easy roll and pitch. She is inconveniently built, I think. One hikes miles of ladders to get anywhere. Our quarters are fine—not *Helix* style, but good enough, though the 4 in the bunkroom have no drawers (we've lent them some of ours).

It won't be long before you start this traverse yourself, I guess. You'll probably find us somewhere near Wellington Island when you fly down. Maybe you can look down on us.

I hope everything goes well up there and that departure is not too hectic for you. Dick's penguin skin is doing fine.

Love to everyone,
Ken

It's all gray fog and drizzle now—maybe what we will mostly get.

November 12, 1968

At sea off Pta. Curaumilla, Chile

After a hectic inauspicious beginning we are finally on our way, beginning our cruise of Tierra del Fuego and the canal country to the north. As our schedule became cut shorter and shorter I finally decided to load everyone in Valparaiso to save time and was unable to notify everyone because they had already begun their trips south. However, everyone finally assembled, Eddie Shallenberger came in from Santiago, Bill Watkins showed up the same day, and Ken Bloome and Bill McFarland, who had arrived earlier spent a hectic day in Santiago obtaining an oscilloscope we badly needed. The convenio had promised it to us but gave next to no help when it was found to be ruined. Another, and better scope was finally borrowed by the grace of one of our friends in the University of Chile.

At any rate, with much gear on the dock, we finally caught a water taxi and climbed aboard. Ken Bloome had had his foul-weather coat and various other personal belongings stolen but nothing useful could be done.

Everyone sagged into his bunk as we headed out into the strong swell.

November 13, 1968

At sea off San Antonio and south, Chile

Fresh breezes today but the HERO rides into them very nicely indeed, with a gentle roll and pitch. Most of my crew is seasick—only Bob Barrett, Bill Schevill, and I escaped. We spent the day trying to organize the gear. Periodically one of the others would pop up, volunteering for work, only to retreat in nausea a few moments later. Even so, we made some progress though the labs are jammed with ship's gear and equipment for future trips. A stowage space is badly needed, but I guess we used that up with our scientific crew of 10.

Not a marine mammal was seen—only sooty shearwaters, phalaropes, albatrosses of 3 species, Cape pigeons, and silver-gray fulmars.

November 14, 1968

At sea off Concepcion, Isla Mocha, and south

More steaming today, and more work getting gear into shape. The whaleboat is an incredible mess. The rudder was too small so a piece was added forward of the post, thus unbalancing it. If the tiller is released it automatically will swing hard over. We are improvising a plywood addition, having removed the other piece. We have laid plans for our anaesthesia work, and will remove the dissecting table to the deck, placing my porpoise box in the lab instead where it can be reached by our instruments. Ken and Bob spent some time in the hot lower lab trying to get the respirator going but have been having considerable trouble. I built a stretcher for handling live porpoises, stitching it out of stout canvas, using pipes we bought in Valpo.

Isla Mocha was passed today. I wanted Anelio to have a good look at it as it is supposed to have a large population of the southern sea lion, *Otaria byronia*. We only saw a single animal in the water but were not able to approach the shore closely enough to see anything else. Our pilot, a thin ascetic Chilean Navy officer named Eduardo Barison Roberts informed us that we would lose a whole day if we spent time inspecting the opposite shore as we would miss the tides in the Canal Chacao, near Puerto Montt, where currents may reach 11 knots at full flood. So we forego a look-see.

Isla Mocha is divided into little farms, like all of the shore along this coast, and is flanked by a long unbroken beach on the lee shore.

Most everyone is still seasick, though they are emerging for longer periods now, and even George Harvey has been eating a bit.

I should list the crew and our scientific party here:

K. S. Norris	Senior Scientist
William Schevill	Asst. Expedition Leader
William Watkins	Acoustics
George Harvey	Acoustics and electronics, support of operative procedures
Bob Barrett	Neurophysiology of trigeminal and sound paths
Ken Bloome	Ultrastructure and anatomy of porpoise organs
William McFarland	Vision of marine mammals, fishes, acclimation studies

Anelio Aguayo	Cooperator on studies of Chilean Cetacea, pinniped populations
Ed Shallenberger	Studies of insularity, general factotum, harpooner
Mickey Barrett	Botany, birds, general factotum

Our Captain is a fine seaman who has spent his life on the water. He is full of stories, good humor, and has really gone out of his way to help us with every request we have made. The same goes for the crew, too. It's interesting to watch them all emerge as personalities and seamen. The mate, a short, wiry seaman named Judson R. Howard, emerges as a steady, skillful helper for us. I am working to keep all our people in his good graces as it is very easy indeed to mishandle his bosun's locker or tools, or simply to demand too much from him. Others in the crew are: Gerald Ouellette (Jerry) the quiet, competent, pipe-smoking engineer; Johannes Bielecki, Assistant Engineer, a German of pleasant disposition; George Trundy, able-bodied seaman, called by all Penny—a bright, hard-working, rising young man on whom everyone relies; Steve Robbins, another AB, a hulking, rather taciturn person of good skill who works very hard (I'm always afraid he is going to lose his pants, he wears them so low); Cardenas Ortego Secundino, a native of Valparaiso, is a seaman, very pleasant and seems skillful. We swap Spanish phrases from time to time; Tom McGuire, the oiler, is a sour-looking fellow who goes about his work silently, but on occasions I have seen him be quick to offer the helping hand—I think he will emerge as time goes along; Hugh Dakers, the cook, is one of the several Maine men on board—a luxury hotel chef during the summer, he can really cook, loves his work, collects menus, and is always on the job, even though he himself may not have slept the night before; Claude Tukey is his shy, young steward, very pleasant and anxious to serve; finally, the electronics-radioman, Malcolm Beaumont, is an old Navy man who comes equipped with a rather rule-book knowledge of his trade—quiet, pleasant, and so far, willing to listen to those who know more—like Watkins and George.

It will be interesting to see how these quick sketches fill in as the trip moves along.

November 15, 1968
Puerto Montt, Chile

As the day wore along the sea became calmer as we entered behind the lee of the northwest cape of Chiloe Island and entered the Canal Chacao. We saw our first marine mammals today, even though I have instituted a continuous watch on the flying bridge the first day. We will continue this whenever the HERO is cruising in daylight hours. Our sightings today consisted first of a school of about 10 *Otaria byronia* plunging along. Bill Schevill, who isn't familiar with sea lions, there being none on the East Coast, thought at first they were porpoises, but I immediately recognized them for sea lions by their plunging leaps, flexible bodies, and lack of dorsal fin. As we entered the Canal a group of porpoises was encountered—plunging swiftly along. I suspect, though cannot prove, they are *Lagenorhynchus*, and that they are also the mysterious llampa which we encountered in Valdivia. They did not run the bow.

Once inside the Canal, which is a mass of boils and tide rips flanked on either side by low bluffs and rolling farm country dotted with graying farm buildings, the water became flat calm.

At dusk, we dropped anchor in Puerto Montt, being unable to find a berth alongside the dock. Here we will pick up some samples from a Universidad Austral professor (Hugo Campos) and obtain some materials for boat repair.

Puerto Montt climbs a gentle hill. It is a fairly large town, undistinguished and much dirtier than Valdivia to the north. I found it graceless and was glad to get back on board ship.

November 16, 1968

Anchored in inlet south of Mechuque Island, Chile

At 11:00, we cast off after having made our purchases. In the calm water and with the time of acclimation behind us, everyone turned to getting everything shipshape. We rigged all our weapons, mounted a line box on the pulpit, prepared weather covers for both guns, fixed nets, worked on the operative gear, had a good orientation meeting in which I laid down various kinds of law about shore parties, safety, cleanliness, protocols when a harpoon is cast, boat operation, duties of everyone, interfacing with crew, and many other items. I'm pleased with my people thus far. Everyone has responded with a will. If only we could get the boat shipshape (the HEROINE), we would be operating full scale, but the radio won't work thus far, the aerial had to be moved and retuned because it was blocking our only available work space, and so forth. The Captain will begin lowering drills tomorrow morning at dawn.

We wanted to leave the perimeter of Puerto Montt in which the porpoises are likely harried for congrio bait, as they are farther north. Hence I picked out a group of satellite islands to Isla Chiloe some 35 miles down the shore, where we could anchor and work the beaches, the small boat, and where the HERO could cruise as well.

About 1800, we entered behind Mechuque Island after a long traverse through the flat water. The water may be flat and devoid of swells but the winds whip it into a whitecap-covered froth all the same, and spotting can be difficult. Anelio, from his position on the flying bridge, once gave the cry "porpoise" but it turned out to be spume on a reef. Only after we had anchored did we see porpoises—2 fairly large animals cruising along within yards of the shore, sharply hooked, tall dorsals—once again, perhaps the llampa. With the launch still inoperative, we simply watched them cruise by. Tomorrow, however, we will use it. The radio gave us the biggest fits today. First, it simply wouldn't work at all, and then the microphone proved to be missing (it was later found, thank goodness) and finally when Beaumont gave up on making it work he called Watt in with a shrug, and said he couldn't fix it, would Watkins help? Watt stood there looking at it, and miraculously it began to play. Now, there's a radio tech for you.

Tomorrow Mac and Mickey will go ashore on nearby Chauques Island and walk the 7-mile beach along its western edge. I will work the HERO with Eddie and Anelio and Bill. Watt and George will try for recordings in the launch after we have a few drills.

It's beautiful here—calm water, inlets, green field-covered islands with wide tidal beaches, clouds scudding overhead from the westerleys that sweep in from the sea.

I've been fighting some low-grade sort of flu and it has now gone (I hope the rest don't get it) and tomorrow we get most of our gear wet.

Mac's up running a dipnet station, and will pickle his goodies in the HERO collection series.

November 16, 1968

Puerto Queilen, Chile

I'm pooped. Up at dawn. It was an interesting day and we almost caught our animals. First thing in the morning I put Bill MacFarland and Mickey Barrett ashore on Isla Buta Chauques to do a bit of beach walking. We could see about 7 miles of unbroken strand for them on this island populated by some 2,000 people. The Captain took them over in the dory and they were soon trudging along, looking for skeletal materials. When Captain Hartshone returned, we began a long tedious effort to get the launch in the water. It is full of bugs. The radio, which Watkin hexed yesterday, quit again today and was quickly brought aboard for further work. Then, the davits had been badly rigged, requiring a lot of additional work. This was finally completed, and then the engine refused to work. Time passed. Finally a loose connection was found. Then, the way of stopping the engine had somehow been removed. In order to stop it one has to remove the hatch covers (inevitably covered with gear), reach in, and twist something. Also the way of stopping the wheel is missing, so we are apprehensive that we may catch our harpoon lines in the screw. Finally, it was launched, being cleverly rigged by the captain, and it chugged off, using my walkie talkies for communication. Bill Schevill was aboard with Watkins and Harvey. They set out to record and then to attempt to capture an animal.

They will rendezvous with Bill and Mickey and we will return on the HERO to pick them all up at 3 PM. Once they left us at 10:50, we quickly set out across the Golfo de Ancud in search of porpoises. The day was absolutely flat calm, clouds piled overhead, and visibility was unlimited. We could pick up penguins for 2 or 3 miles. Our track took us toward the mainland shore, which is here a rugged mass of mountains cut by U-shaped glacial valleys. Anelio and I and Eddie stood spotter watches but could see nary an animal until we turned for the Isla Buta Chauques shore. Then, when we were probably 5 miles from shore, we encountered a pair of small porpoises that ducked furtively out of sight. We circled and circled in the still water but did not find them again—I suspect they were *Phocoena* or *Cephalorhynchus*, but of course, we cannot be sure.

Then, later we encountered a small school (about 5 animals) of what I suspect is called "llampa" in Valdivia. These animals, with a sharp falcate dorsal fin, plunged along splashing the water violently in front of them. Thought I could see at least a small snout, and perhaps a whitish mark on the flanks. They not only ignored us but positively refused to let us come within 150 yards. Knew that porpoises in this mood seldom change and come to the bow, so we called Eddie up from his bow basket, put down the sound-powered phones and made again for our rendezvous. I spent some time today developing a viable harpoon protocol with the bridge. Communication is difficult, especially with a Chilena pilot aboard, and so I moved my position from the bow phones to the bridge wing. All course changes now go through me, and only I request these changes of either the Captain, if he has the helm, or of the pilot. Our pilot is a mid-channel man and rather difficult to convince we want to stop or turn.

Alongside the island we met the HEROINE, with everybody standing up, and the hull glowing international orange. Bill and Mickey had not encountered any marine

mammal bones (they had only walked 7 miles and I calculate roughly 10 miles per skull, so they had 3 to go, I explained). Mickey had his pack full of plant specimens and Mac had picked up a few things like frogs and lizards. I gather that they had a constant retinue of curious islanders following them and asking for cigarettes (neither one smokes). Bill had had a near encounter with the same big porpoise I think is the llampa. He was able to see a white belly, a white flank mark and a very *Lagenorhynchus*-like dorsal. I cannot help but wonder if it is the big animal we could not identify in the Santiago museum. Bill encountered them in less than 3 meters of water in the Canal Tac and within a few meters of shore (30-80 ft.)

Once everyone was on board we made our way south, trying to keep adding a little traverse time to each day's activities. The track took us southwestward toward Chiloe Island and past the Bajo Minna, in the center of the Golfo Ancud. There we encountered 2 small groups of our llampa, feeding on a deep-bodied fish that dappled the sea surface in shoals, around a reef buoy. Bill and Penny and I took the whaleboat out and nothing we did would convince the porpoises to let us close. We never had a shot and finally returned, exasperated, to the ship. Some time later we dropped anchor in the secluded but complete little anchorage of Queilen. On the chart we saw no signs of a town, but there on the shore were a series of brightly painted 2-storey houses, a pier, and the inevitable curious boatmen rowing out to find out who and what we were. When they came aboard we found the town had about 2,000 people in it, the only indication on the chart being a mark for a church.

The trip today was majestic, even though I had little enough time or inclination to admire the scenery. The Andes rise up in some 6,000-ft. peaks from the sea—Corcovado, Coronado, and others, some topped by glaciers and continual snow fields. The Gulf is a mirror, and the sunset over the snowy mountains, turning everything to rose, was lovely.

My day was full of revamping field protocols, getting my crew to finish gear in preparation for live animals, revising various techniques, etc.

We didn't get our animal, but if we can find a stupid one, we'll get them. About this time in every trip of this sort I get maddeningly impatient—a drug on all my friends, whom I hope will put up with me until the porpoise comes.

November 18, 1968
Puerto Tictoc, Chile

Things are looking up. Most of the major bugs in our gear and operations are ironing out, even though we had our moments today. I jumped in the boat with Bill Schevill and Steve Robbins and we took off along the coast of Chiloe Island, north of Tranqui Island. The HERO left to put the shore party [?] and to go off hunting on its own in open water. This arrangement works well—the launch in shallow water where the HERO cannot go, the shore party to comb the beach for skeletal materials, and the HERO for deep water where the launch is not safe.

After an underwater sound check, we left the HERO and proceeded up the channel north of Tranqui Island. We kept near to shore as most of the animals we have sighted thus far have been seen in shallow water. Our course took us in and out of coves, most with a group of clapboard houses, all gray with the weather, a few people on the beach chasing sheep or simply walking slowly along, a dory pulled up above high tide, a

larger boat careened and under repair. The hills above were a patchwork of fields and pastures. Most plowing was done right down the slope of the hills, which gave those of us who worry about contour plowing a twinge or two.

The tidal currents in these restricted waters are extreme. We breasted the incoming current near the inshore end of Tranqui and almost could not make headway against it (6 knots).

The day started in fog and ended clear, bright and lovely. As Bill's vision is not the best I kept a constant watch in the prow, thankful for my foul-weather jacket. Finally, clear across the channel, I saw a dark flash and then focussed my attention until I made sure of a porpoise. It was a pair of llampas, and they were excessively wary. Even though the water was calm, we finally lost them completely after a ½ hour's chase. Never did we come close.

Offshore we could see the HERO putting the shore party on a little islet, and then working with the dory party that was gathering sand. The sand will be used to fill sandbags to prop our experimental porpoises in the operating box in a rigid fashion during anaesthesia and operative procedures. Ken Bloome was one of these and while ashore learned of a whalebone one of the inhabitants had in her garden. He ran up hill after it, returning late to the dory. Mac, whom I had put in charge of the HERO operation, bawled hell out of him for not sending one of the shore party to do the job—with which I concurred wholeheartedly. As I delivered in impassioned fashion in my introductory lecture, one late person holds up the whole operation and time is expensive here.

We worked down the shore to a little estero (Estero Huiladad) and ducked inside it. It was a tranquilly beautiful spot—green hills, little farms, the transparent blue water with flocks of sea birds standing on sand bars along the shore. Most were the brown-headed gull, a graceful species much like the black-headed gull of Europe. Also present were the Magellanic blue-eyed shag, Magellanic penguins in numbers cruising along low in the water, a tern I could not identify, lapwings screaming at us on the beach, and even glossy faced ibises.

As we turned back down the estero to make our way to the 2PM rendezvous, we encountered 4-5 little porpoises swimming in the tide rip at the entrance. They were, with no question, *Cephalorhynchus eutropia*, the same species I had taken earlier as far north as Concepcion. It was Bill's first look and he was glad to see the field characteristics that have already become familiar to me—the peculiar low dorsal fin, very rounded posteriorly, the head bar, the small groups working very close to shore. Try as we did, we could never get close enough to get a shot, even with the shotgun. We tried speeding toward them, going slowly, drifting, but nothing worked. Finally, the HERO, whom we had contacted by radio, steamed in and we went aboard.

Ken's whalebone is probably from a large baleen whale. It will be difficult to identify to species though I will give it a try.

We steamed southeastward, across the Golfo de Corcovado, toward the great snow- and glacier-capped peaks of the Andes that drop right into the sea along this coast. Not an animal was seen in the whole traverse, though watch conditions were good and the watch diligently kept.

As we neared, we could look up on the crest of Montes Yanteles above Bahia Tictoc, and see a plume of vapor issuing from a rent in the snow near the crest of the

mountain, far up in the snow fields. The snow was colored lemon yellow behind the vent, probably from sulfur. The lower mountain slopes are heavily forested. Here and there we could see ribbons of water falling for probably as much as 1,000 ft. The bay itself is spectacular—a deep, curving fjord ending at the base of a mountain with the snowy peaks behind. We dropped anchor at 7, which gave us nearly 2 hours of light, so I requested a shore party to walk the beach on the south limb of the bay. I had Steve put us ashore at mid-beach, and divided my group into 2 parties—Ken Bloome, Bob Barrett, and Mickey Barrett, walking back into the bay, and McFarland and I walking toward the entrance. It was a good productive session. Both groups came up with good skulls of *Otaria byronia*. I talked to the captain and in honor of our first marine mammal material of the trip, we called a happy hour in which 3 bottles of cognac disappeared quickly enough.

Mac and I stirred up some beautiful buff-chested geese with black and white wings. They flew low over us, talking to each other. It sounded like they had engine trouble. The water here is downright chilly—which we found out as we waded out to the launch. The launch, by the way, is functioning pretty well now—the radio works nicely and we were able to keep good contact though the HERO was out of sight. This was a great help in saving time as we could direct the HERO to pick us up after she got the shore party and thus save long traverses.

After dark we returned to the HERO, tired, but after a reasonably good day. The ancillary collections are coming along well—Mac got a chimera, an entirely new class for his vision work. Mickey's plants are piling up at a satisfactory clip, and I think he is getting better and better at making good pressed specimens. Right now I'm busy trying to impress him with the necessity of taking notes as he gathers his plants—size of plant, locale, etc. We've taken several lizards and frogs, which Eddie is working up, and Mac is storing away a few fish specimens as they come along.

One of the interesting birds we saw here was the steamer duck—a flightless species that literally runs and flaps away from you when disturbed, making a long wake on the water. The local folk call them "pato motor"—a fine apt name. Mac picked up a good skeleton of one, which shows some adaptations to flightlessness.

Things are shaking down.

November 19, 1968

Puerto Ballenas, Isla Mulcahey, Chonos Archipelago

The llampa is solved! It is *Lagenorhynchus australis* (Peale), Peale's porpoise. Back to that later. In line with my desire to take part in each part of the operation, I went ashore with Mickey Barrett to walk the beaches on the north limb of Bahia Tictoc. It seemed as difficult as pulling teeth for me to get the ship underway and over near the little cove of Puerto Tictoc. Mickey and I hopped ashore in a little covelet just to the east of the main beach. We soon realized that at the back of the cove was a dark cave, overhung with vegetation and a dripping curtain of water. Upon exploration into the cave, which is wavecut, we found much evidence of human habitation. On the left side as we entered was a midden piled up perhaps 7-8 ft. thick, of shells and fire-burned sand. In the high shelves we could see smoke on the roof and evidence of use as a bed of sorts. It may well be that this cave has been used back into antiquity. We, however, did not have time to find out, but had beaches and cliffs ahead of us.

On the strand we crossed an estuary channel that led in a curving arc back of the beach and almost intersected it again farther west. We walked back on this flat, picking plants as we went. A jungle of various plants overhangs the sand flat. Amongst them were the long red trumpets of the Chilean national flower. A moderate sized tree with compound pinnate leaves was in bloom—large pendant yellow trumpets. We found wild fuschias in abundance and several kinds of ferns. Back deep in the estuary we found a long woven stick fish-trap, and encountered 2 more of the beautiful ashy headed geese. They have always been in pairs thus far. At the deepest part of the estuary we broke through the vegetation for a short way (up to the armpits in ferns, vines, rotting logs, orb spider webs, etc.) and emerged on the main strand.

We trudged on down the sand without so much as seeing a bird bone. The best I could do was to locate the carapaces of several glatheid swimming crabs. It is interesting to me to note them here—this form which is so incredibly numerous off the Baja California coast at times.

We passed the encampment of a group of fishermen. They had a bed of giant saxifrage leaves (the stems of which they chew), a fire, and a sort of wind shelter. Finally we arrived, bushed, at the beginning of the rocks we knew we must traverse to reach the main beach beginning at Isla Falsa. Mickey especially was glad to have a break. It's interesting to me that old types like me can usually outlast youngsters in their teens when one comes to long-term stamina. I think it's that we push ourselves harder and somehow don't feel the exhaustion so soon or so acutely. It comes nonetheless, and finally, hard.

However, I dropped my pack and clambered around in the deep forest along a little cold creek. The water was usually obscured by the density of the vegetation. I collected many shade-loving plants—ferns and lichens especially—during a few minute's break. I heard a 2-noted tinkling call—like the clear clink of dripping water. It came in chorus upstream in the forest, but closer I could hear occasional calls and finally found the culprit—Darwin's frog—*Rhinoderma darwini*—the interesting monotypic family of frogs discovered by Charles Darwin. The male carries the eggs in its double vocal pouches until they have metamorphosed and have even developed their hind legs. I caught 2 and we hoisted our packs and made for the rock barrier.

Once on the rocks, Mickey sighted a school of llampas swimming near shore, so we stopped to watch. There were perhaps 8 animals, and they cruised within 25-30 ft. of the beach, often coming to the surface in unison. I was able to make out an additional 2 animals, swimming isshore of the others—2 *Cephalorhynchus*. It was interesting to see these 2 genera form an essentially mixed school. I tried to run down the beach to photograph them but just then they sped up and swam faster than I could walk so I turned back.

Mickey and I then traversed rocks, now dipping into the surf, now climbing rocks, and now and then being forced into the dense tangled forest to circumnavigate a cliff. It was tough going but we finally emerged through a thicket of bromeliads to a fair-sized beach. I noted a fisherman's skiff working off the rocks at the far end. There we were faced with more cliffs so I hailed the skiff and they came in, put us aboard, and rowed us to Isla Falsa, a ride which we gratefully accepted. Their boat was ancient—made of hand-hewn cedar, with hand-hewn oars. An ancient shotgun rode in the bow—it was held together with wire and looked like a percussion cap modification. They used a gill net to catch what they called "negros". These fish were dried and their catch picked up

once every 10 days by a boat from Castro. They stayed here only in spring and summer as the weather in winter, they said, was horrible, a fact attested to by the high piles of driftwood far up on the beach.

They had almost nothing—tattered clothes, only a loaf of bread and a bottle of peanut butter bummed from the HERO somehow. I promised them a gift in return for their kindness. We shared our lunch with them and then began to walk northward. I was concerned that the HERO would return before we did so I had Mickey stay on this strand, where we planned to rendezvous, and began to walk myself, planning on a 1-hour jaunt northward and back. But I soon made out the outline of the HERO coming in from the west so didn't get very far before having to come back. I poked into 2 driftwood-crammed sea caves with rivulets of fresh water coming from the dense vegetation above. Back at Isla Falsa (a tambolo jutting out into the bay) we climbed to the top of the rocky promontory and made our way down to the shore where we met skipper Stan coming in the dory. The pilot was standing so far offshore that it was a long row back. Once on board we learned 2 things—Bill Schevill and Bill McFarland and Penny in the launch were coming in with a *Lagenorhynchus* which they had harpooned, and the HERO had run briefly aground on an uncharted sand spit in Bahia Tictoc.

As for the ship she was very briefly aground, her foreward numbers indicating that she had been pushed upward 2 ft. or so. I understood it had all been handled calmly and professionally—reversing engines and swinging the helm back and forth to wiggle her. The big screw literally jettied the ship loose. At any rate, I understood a little better why the pilot had us row so far.

I had to pay my fishermen, so I assembled a bag of food, some of my light shotgun shells (they will use the primer, powder, and shot since their gun is .28 gauge), a piece of rather poor manila that I had bought in Valparaiso, and 1 or 2 other things.

This time the pilot dropped us even farther from the beach and Nino and I rolled in. Nino doesn't row very well so we wobbled a bit. In fact it was a helluva row, filled with black thoughts about why NSF hadn't seen fit to put a diesel outboard on board. I figure this jaunt wasted us more than an hour's cruising time. I tied the bag of goodies on the mast at the camp and we rowed back. By this time the HERO had drifted twice as far away in the incoming tide. I decided to row it myself rather than continue the corkscrew and so did it, Portuguese fashion, getting angrier and angrier as I could not raise anyone to get the ship underway. I'm afraid that once I climbed on board I was short with the pilot over the loss of time involved. I hope he gets the message.

Before long we picked up the launch and the porpoise. McF had harpooned it in the copy book spot—6 in. ahead of the dorsal, and the animal, a female, had died in less than 3 minutes. There was no standing by by the other members of the school. All were sure it was the llampa. It was caught within yards of shore when it cut under the bow and Mac alertly nailed it. The party had also discovered 2 southern sea lion rookeries—one on Isla Lipipe, in Bahia Tictoc, where 100-120 animals, including young, were concentrated, and on Farallone los Lobos, to the south, where 11-13 were seen.

Our porpoise is a beautiful animal. Its pattern matches the literature in most regards. It was measured, photographed and its stomach contents taken (octopus and some fish bones). We were all darned tired so will leave the fleshing till tomorrow. As to pattern, there is a double black eye ring extending forward onto the snout, a black cape with a faint saddle of flecked gray, a large lateral grayish white patch flecked with

darker gray, and a darker ventral margin to this patch delimiting it sharply from the white belly. There is a diagonal whitish gray patch extending up from the vent and pinching out below the dorsal. The snout is very inconspicuous.

We cruised in the rain to anchorage some 40 miles to the south in the Chonos Archipelago. In our little comfortless cove we met an ancient sailing boat—open, about 30 ft. long, with 4 men and a dog aboard. They were cod divers. They worked in this frigid water down to 30 meters using hook and rig without wet suits. They wore only wool and had rubber gloves. They slept in the boat completely unprotected from wind or rain. Their lives are surely barest survival.

I tottered off to bed about this time—first taking a delicious shower to wash off assorted layers of scum accumulated during the day. I wondered as I was being washed by the warm water if those fishermen had ever felt such a joy.

November 20, 1968

Puerto Condell, Isla Rivero, Chile

We knew we must make some southing in order to reach the southern waters where we hope for our best collections, so today was spent in travel. We proceeded down the Canal Moraleda, and completed half the traverse across the archipelago to the open Pacific. This will leave us with a rather short trip down the Canal Pulluche, into the Bahía Anna Pink, and into the Pacific west of the Tatao Peninsula.

The day started with high clouds; before it was finished they had settled and we had rain squalls and occasional sleet. The heavily wooded islands are clothed in gray-green—the Antarctic beeches clawing up from the main mass of foliage with twisted trunks. I know from my hikes in similar vegetation how thick it is, almost to the level of impenetrability. The stories of some of the ships that have wrecked near here tell some of the story of this increasingly forbidding land. The HMS WAGER sank near here (south of Golfo de Pena) with 30 survivors (1741) and only 3 survived to reach civilization. Captain Cheat had a canal named after him and various crew members ended up with islands, sounds, and such named after them. At any rate it's no place to make your way easily.

No porpoise has yet run our bow on this trip. Without the launch, we would have seen very little, and without our beach forays, we would have a single skeleton. We hope that reports we hear of schools running the bow farther south prove true. Hence, it is likely that we will make our way south rather more rapidly than we had planned initially. I suspect much of our cruise past Isla Wellington will be involved in resolute southing.

Today we had only a single sighting of a porpoise, in a tidal rip between 2 islands, Watt spotted a single animal and a southern sea lion. The porpoise disappeared like a ghost and was not seen again.

I spent much of the day flensing the porpoise—Kenny made a thorough parasite inspection, and Bob spent quite a long time tracing the course of the trigeminal nerve through the melon. There are external landmarks that will make location of this nerve in the live animal rather simple. The equipment for the operation work is now complete. A trough and operating stretcher have been built, a grounded Faraday cage has been built to cut out 60 cycle hum, and a platform for the micromanipulator has been completed. The dead porpoise was lifted into this set-up to check measurements and positions. So, once we obtain a live animal, this work can go ahead. I should mention that the respirator is

also now functional. A part inside the apneutic plateau control box had come loose and was finally located after 3 days of trying.

We put into Puerto Condell on Isla Riveros at about 6 PM. This little nook is protected from sea winds and fairly snug. I saw time to make a check of the little beach ashore. Before the dinghy reached the *Ulva*-covered beach, we were in a rain squall. Fortunately, we were all decked in foul-weather gear. No bones were found but I did make a pretty good plant collection in about $\frac{3}{4}$ of a hour. The forest is dripping. Branches are covered with foliose lichens, banks of single-leafed ferns feather the upright trunks of trees and matings of low plants come right down to the sea edge.

I was interested to see stands of cycads amidst the forest trees. We hiked to a tumbling cascade and had to turn back. On board, I worked with Mickey Barrett preparing the plants. His collection is now to be measured in feet of thickness and his techniques are getting better under my constant prodding. I think it will be a useful series as we are hitting a variety of nooks not often visited and in the spring when much is in bloom. To be sure, we don't go far from the beach.

At night, several birds came aboard, including, fortuitously, our second diving petrel. Dr. Araya of the Estacion Biologia Marina at Montemar had asked me for any specimens of this group and so they are valuable additions to our collections. My bird man (Mickey) proves to be Audubonish and unhappy about stuffing his feathered friends, so I am breaking in a replacement for this task (Eddie, who couldn't care less).

Tomorrow, Anna Pink and the sea off Tatao.

November 21, 1968

Puerto Barroso, Tres Montes Peninsula, Chile

Up anchor at dawn. George Harvey took the first watch hoping to work in the calm of the canals before mal de mere overtakes him. Poor George is really a chronic case and modest swells take him right out of commission. He has such determination, however, that even in this condition he can be depended on. All his gear waits our command, all charged and ready.

At any rate, down the channel between steep hills islands we went and finally emerged into the Gulf of Anna Pink (named after the "pink" or small craft of the ship ANNA). There we passed several small islands harboring a considerable population of *Otaria*. Anelio, who is taking counts of the population of this species, rushed up and counted what he could—more than 250 animals.

The sky was overcast and the tops of mountains disappeared into the gloom. As we went farther to sea, swells got higher and the wind picked up. By the time we started rounding the Tatao Peninsula it was whipping along at 35 knots, blowing the tops of swells off into lines of flying water. The HERO beat through it nicely, though. My watch donned full foul-weather gear and stood in the storm on the flying bridge. Good thing too, as we began to see porpoises and whales. First I spotted a rank of animals surfing down a big swell off our port bow. At first I thought they were porpoises, and so gave the alarm. But the closer they came the more it was evident that we were seeing pilot whales. They passed 100 yards to starboard as we circled. I could see the big stepped fins of the old adults, and noted their all-dark pattern above and white throat below. There was no diagonal slash of white as usually marks *Globicephala edwardi leucosagmophora*. They were soon lost in the breaking water. Three groups of porpoises

came by but none ran the bow. One group seemed pretty securely *Lagenorhynchus australis*, according to the descriptions of Steve.

Finally at 2100, with dusk descending, we inched our way into the tight little pocket of Puerto Barroso, behind the protection of Tres Montes Peninsula. By this time the rain came in cold sheets, nearly obscuring the gloomy grayish forest slopes of the shore. Everyone felt the malaise of the rough passage, so we did little more than lay plans for the days ahead and to consult with the Captain and pilot. Soon we traversed the Angostura Inglesa, the narrows behind Wellington Island, [drawing] and we must adjust our schedule to conform to the tidal direction.

I stuffed a diving petrel and hit the sack. Poor old Bill Schevill has a sore toe, from an injury of some days ago and spends much time with his foot propped up. He says it's getting better, and I hope so.

November 22, 1968

Puerto Island, Swett Peninsula, Chile

The plan for today was first for me to take a party into the big estero that cuts into the Tres Montes Peninsula and then to cruise in the lee of Tres Montes and Tatao with the HERO looking for animals. If we encounter some, the whaleboat will be lowered and recordings attempted before an attempt is made at harpooning.

My crew, consisting of Eddie, George and myself, with Steve at the helm, descended with the boat and took off into the landlocked waterway. The entrance was toruous and running swift with the outgoing tide.

In the entrance we encountered 2 steamer ducks. When at rest, they ride very low in the water, with just the neck and part of the back showing. We disturbed them and they took off with their combination of running and wing flapping. It is a mode of locomotion that they keep up seemingly far above and beyond the call of duty, until they are sometimes 1,000 yards away and just a white froth mark on the surface. Inside the estero, we cruised near shore, going down one side and returning the other. Steep hills rose into the low-hanging clouds, rain swept us constantly and we saw nothing in the way of porpoises. All during our cruise we were accompanied by giant fulmars, big brownish birds, awkwardly humpbacked but capable of beautiful soaring flight, not unlike that of the albatross for which they are often mistaken.

Our cruise on the HERO fared no better. The pilot would not take us deep enough in the bight to achieve a decent lee, so we ended in a rather strong sea, which required us to turn for shelter as the whaleboat was hung outboard for rapid lowering. No animals were seen.

It was calculated that our passage across the Golfo de Pena would take somewhat over 4 hours and that we would have an additional 2 hours to our planned anchorage on the Swett Peninsula. Hence, I cancelled a planned dogleg out to sea in the Golfo that we had planned as a way of reaching deep water, where we hoped to encounter pilot whales, and other more oceanic animals. Even with the course straight across the Golfo to the Canal Messier, we hit strong swells and considerable wind. As luck would have it, it was here that we saw the day's animals—small groups of *Lagenorhynchus*. In one case they almost ran the bow but shied away some 30-50 ft. away. The HERO plunged into the water, forcing a big spilling wave in front of her, and I suspect this frightens animals away. Only in a calm sea or at slower speeds is she probably optimum for bow riding.

Hence I cut speed on the last encounter of the day, to 2/3 and felt that our chances of drawing animals in were considerably increased, though in this case the animals ignored us, swimming far out to the side and appearing in the wake.

With strong seas running it would have been a feat of some proportions to have harpooned an animal, and an even greater feat to have retrieved him. We face the dismal nexus that where there are animals that we can approach, there is also bad weather and where there are calm seas, we see no animals. All of us hope the reports of bow-riding animals in the Estrecha de Magallanes are true and that we will there encounter catchable animals in calm water.

By the time we reached the Canal Messier the day was almost done. The islands here are very precipitous and drop into channels that are sometimes several times as deep as the water we had traversed in the Golfo de Penas (100-200 meters vs. 1,000 M plus). Our chosen anchorage on the Swett Peninsula is blocked by 2 small islands; the only channel usable by us lies on the western edge and is quite narrow. The ship was obliged to traverse a sill only about 10-14 meters deep. Our fathometer has a noise band that obscures everything shallower than about 10 meters and hence, we were faced with the unlovely situation of having our depth readings disappear into instrument noise at a time when we most needed them. The pilot made one attempt, retreated, and came in again. This time he slipped by the blocking island and into the snug anchorage.

I was terribly physically tired from standing watch on the flying bridge most of the afternoon. The aches and pains don't retreat the way they used to. I'll stay aboard tomorrow while another crew takes the whaleboat out in search of animals.

November 23, 1968

Puerto Grappler, Exmouth Promontory, Chile

We nearly made it today on 2 counts and our first animal had the temerity to run our great foaming bow. But, then, on the other side of the ledger, we didn't make it and the animal that ran the bow got away.

First thing in the morning, Bill Schevill and his boat crew of Watkins, McFarland, and Steve Robbins went out on a hunt in the launch. I sent the dory ashore with Kenny Bloome, Bob and Mickey Barrett to collect plants. There was no beach in the cove but a variety of places where they could land. The chart informed us about the "bosque impenetrable" on the hills above the cove, and that seemed real enough. The fog dropped lower and lower and the drizzle began in earnest. Before long Bill called in that he felt it useless to hunt further in the launch. I tooted 3 blasts on the ship's horn for the shore party to return and both crews came aboard at the same time. The plant collection was small and the going had been a little rough, but they had some material and had collected a steamer duck egg and had watched a mother steamer cruise off with her 5 babies in tow behind.

We began our cruise down channel, keeping watch from the flying bridge as is standard procedure at all times underway. Before much time had passed I spotted a school of some 20 animals leaping in a deep indentation of the channel where we could also see birds diving. Some were leaping from the water and I could guess that they were *Lagenorhynchus* but anything further was impossible. We assembled the crew and lowered the boat, guiding them by radio. The animals began a traverse toward the boat but turned and went the other way. It was some time before we could put the boat crew

on the animals and by then the fog had lowered to water level. The boat was mostly lost to us, appearing out of the fog from time to time, but blessings be, she made a sharp radar target and was always visible to us this way.

Bill announced he was on 5 animals or so, so we waited, dead in the water, for further news. The news came that they had finished recording and would attempt a capture but before long we noted them closing on us and finally they appeared out of the fog and were soon on board. The recordings had been marginal, perhaps because of a fresh-water layer on the salt, and they had never been able to close on the animals.

One of our maneuvers in this exercise had been to run the HERO ahead, spotting the shore, while the HEROINE came up from behind closer ashore where she would encounter the animals. It worked well and would have worked better if the air had been clearer. The radar contact is a great help in all this and I am asking that a roll of aluminum foil be put on board to assist in radar contact should need arise.

Back on board, we began the cruise down toward Angostura Inglesa (English Narrows). The bulk of Wellington Island looms on the west and the precipitous cliffs of the mainland on the east, and they gradually converge, not as 2 cliffs that come together, but as a converging series of islets that dot the channel and make the course tortuous in the extreme. We wanted to fish further, and to make a run up Seno Iceberg, which we thought might be good *Cephalorhynchus* hunting, but the pilot thought otherwise. We wanted time to traverse the narrows, so we slowed nearly to a snail's pace waiting for the current to slow and then began the weaving course through. We have a 4-knot current behind us, meaning we had less control of the ship, but our pilot took us skillfully through, swinging around sharp turns and rocky islets marked with range markers. I could understand his tension, having been through, and wondered how a 350-ft. freighter could negotiate it. One didn't—a freighter had run aground just north of the narrows when a steering engine went out. There she was, 5 months stopped, down at the bows, resting and waiting some long disintegration, between 2 deep channels and flanked fore and aft by rocky shoals.

In the Angostura Inglesa, of course, a group of porpoises raced by, cutting astern of us. They were *Lagenorhynchus* of some kind, probably our associate the llampa. Further in the narrows another group passed us while we resolutely stayed on course. What else could we do? Then, when in the Indian Reach, a long straight channel, we had 2 *Lagenorhynchus* cut in toward the bow, and begin to run us. The pilot, at first, said we could not [drawing] shoot them but finally, after some prodding, relented, and Eddie grabbed up his gun for a shot. The harpoon slipped out of the barrel, its O-ring gone. I replaced it while the animals cut in and out. Finally Eddie fired, and the harpoon slid over the animal's back. My command to the bridge was slow in being answered but the line slipped harmlessly astern. Finally she answered her helm but only in time for us to retrieve the line and harpoon. Eddie, needless to say, was distraught. He wanted very badly to catch a porpoise for us. Once again, he is proving his worth in a field situation—tough, takes orders well, eager, and hard working and bright. He's the kind I'm always happy to have with me when guts or brains are required. Maybe his luck will change. He's now worrying about the effects of refraction on his shot, and next time will shoot low out to the side of the ship, more and more to center as the animal comes under him.

The hills grew into mountains, streams cascaded out of the clouds in long rivulets over the granite cliffs. The trees grew smaller and more and more patches of rock showed through. From time to time through the clouds, we caught a glimpse of a bare rocky peak covered with a patchwork of snow, surrounded by slowly swirling haze. We passed the radio station of these parts, Eden Harbor, where a cluster of wooden shacks lined the rugged shore and a small freighter stood almost anomalously at anchor. Pretty lonely. Bet they don't often hear about VietNam or who is being elected President in Chile, let alone the USA.

After a while we rounded the great granite mountain marked with white cascades and came into Grappler Inlet. The harbor is a snug one, with snowcapped peaks far back from shore, a shell mound on the beach probably from Indians, and a huge glacier-smoothed pinkish granite wall rising to the east, bits of scraggly forest tucked on it here and there, a fine sweep of dense green near the water, and above just tags and tatters.

Plans for tomorrow and to bed. I'm better and so is Bill. Animals running the bow heartened us as did finding schools in the calm canals where they can be recorded.

November 24, 1968

Bahia Corbeta Papudo, Isla Guarello, Chile

At the break of dawn, I roused out the shore party and the 4 of us rowed the dingy ashore to an Indian encampment we could see. It was marked by large piles of Zapatillas (horse mussels) and a large green tree that I take to be an apple. One wonders if this tree grew from an apple core or if it was planted on purpose. At any rate it stands out sharply against the otherwise gray-green forest. The very first thing I came upon was some slabs of whale bone from a large baleen whale. Unfortunately they were unidentifiable any further. We collected quickly as I wanted the HERO to up anchor at 7:00 AM for the day's hunting. The mountains around Grappler Cove are spectacular, glacial-rounded cliffs that tower perhaps 1,500 ft. above the still bay. Back in the U of the canyon forming the cove, one could see a series of mountain crests, increasingly snowcapped, and each with a wreath of vapor or cloud mostly blocking it from our view. The flora is rapidly diminishing in stature as we continue south. Here the forest is no longer a "bosque impenetrable" but instead in many places rocks are exposed and a carpet of mosses and lichens covers large areas. Walking in this carpet is quite an experience. It's a little like walking in a foot-thick sponge saturated with water. Fortunately we were all in full foul-weather gear and pretty impervious to such regional insults.

Cycad-like ferns were everywhere. A crawling juniper bearing tiny little cones was found, as well as a variety of flowering plants. A flaky barked cedar tree was also common—about 15-20 ft. high, and obviously used for wood as several bore axe marks.

Back home in California, I have wondered on occasion where the water marks that stain granite faces like Half Dome came from. Here, it is obvious. With rain an almost constant thing, rivulets flow by the dozens over every exposed rock. In places where a little more watershed exists, these grow to full fledged waterfalls. Thus, around Grappler Cove, there were a dozen sizeable falls in view at once.

Back on board we hove up the anchor and headed out the channel to the south. In distant view up canal arms, we could see the domed white mass of the great "Ventisquero" or glacier that tops the mountains near here and drops icy arms into

various arms of the canyons that become fjords where the sea enters. Mostly, fog and clouds shrouded such views from us. We could see the smoothed granite faces, rising abruptly from the water, disappearing into the gray mist, or catch a fleeting glimpse of a barren mountain peak patched with snow. The canals were often deep—100 fathoms at times.

As we emerged from one of these arms, we met 2 big *Lagenorhynchus*, both of whom raced in to run the bow. It was only then that I realized that this water is not clear but tea-colored, like that of the Rio Negro in Brazil. The animals disappeared a few feet below the surface. I put Eddie down in the pulpit. Finally an animal crossed under and he fired, the harpoon rifling through the water harmlessly inches above the animal's back.

Both disappeared in an instant as we retrieved the spent line. By some effort, I got the pilot to come around in the 100 fathom water for another pass at the animals but they refused to appear again. Too bad, we could use a little "ile in the cask" about this time. It was, however, nice to realize that twice in 2 days we had had animals run our bow.

Then began a long, long tedious day of watching, with wind and rain howling across the flying bridge at times. Our path took us down Canal Wide and the pilot ran us right over the single line of soundings in the middle. Since our animals seem to prefer the edges, I asked to run closer to the canal edge, which precipitated an agreement that any time we left the main track the captain was responsible. This is as it should be, but also, the HERO being a research vessel, should not be expected to conform to shipping lanes. Bill Schevill tried manfully to convince the pilot house crew of the singular navigational advantages of the SIMRAD fish finder which allows sonar vision foreward and down, thus predicting in advance any rocks one might unexpectedly encounter. The pilot quickly switched it back to vertical mode when Bill left. Like all good pilots he is conservative and careful and he had no confidence or understanding of this newfangled gadget. I like him though and respect his professional competence. It is inevitable that his desires should conflict with mine. I want very much for our expedition to succeed and he wants very much for no chances to be taken with the ship. Consequently I will continue to ask and he will continue to demur, and the Captain will adjudicate. The Captain is careful too, but realizes his mission and is willing to navigate into waters away from plotted soundings. For my part, when the captan indicates a bit of temerity I back off at once. All this works pretty well.

The canals became wider and the mountains lower as we pressed south of Isla Wellington and along the shores of Isla Madre Dios. We began to spot seals and I had the ship go in toward a rookery so that Anelio could make his counts. He has logged perhaps 7-9 new rookeries on this trip, a positive contribution of our voyage. Considering that only 5 such rookeries are in the published literature, this is a valuable start.

In the squally weather, we came upon tens of thousands of sooty shearwaters, and they flew up in swooping, swirling flocks as the ship came upon them. I saw some feeding, but most simply flew like swift gliders racing before the wind. They are the "swifts" of the sea, having much the same flight pattern—swooping up into the wind, only to turn with it and to race downward in a long low angle, rising again after nearly dipping wing-tips in the surface.

Not a porpoise was seen though we watched hard, scanning with glasses across the choppy water. My watch is performing well, though the best watchers are

emerging—Mac, Watt, Anelio, George and I, and Eddie. Bill Schevill and Bob Barrett both have bad eyes which cuts their efficiency and Mickey is still unschooled in what to look for.

Our track was to take us out the Canal Oeste to an anchorage near the sea where we would wait for morning before deciding whether or not to go out into the open water for a look at offshore species.

Daylight is long now—it isn't dark until after 9 PM—so we watched and watched. The sun broke through for a time, casting a perfect rainbow ending, believe it or not, at Isla Inocentes. It was about as clear a portent as one could design—we were gloomy and tired with the lack of animals—about 1/10 of the numbers I could expect in Californian or Hawaiian waters—and we need some portents and more, some success in our main mission. The ancillary work goes very well but the porpoises just aren't running the bow.

On down Canal Oeste we went into the teeth of westerly winds sweeping off the sea. The chop was blown into streamers of spray. Just before we were to turn up a side arm to our evening anchorage, Bob and I spotted porpoises simultaneously. A group of *Lagenorhynchus* came alongside the ship. I put Mac down in the pulpit. The damned animals would not run the bow, but played alongside out of reach. Bill Schevill and I noted that there was quite a lot of pattern variation in the animals we could see—ranging from bright white lunate markings on the tail to much dimmer ones. Mac fired—and missed. The harpoon came up with its becket broken completely free of the line. This last batch of harpoons is giving us fits as this is the 4th time we have had this trouble. I inspect every harpoon now to see if the wire becket is at all loose. We've been having trouble with the harpoon lines tangling too, instead of running free from the can. All in all, an uncertain weapon.

Sometimes a school will come back after being shot at so I asked Mac to stay below for a few minutes longer. He had gone down without full foul-weather gear on and was chattering in the cold wind. Sure enough they came in again, and this time Mac did not miss. I could see the stricken animal roll, spilling blood. It did not struggle at all. When we picked it up a few minutes later it was dead from a shot in the lungs. As we went out in the launch to retrieve it much of the school “stood by”, racing along within a few yards of us. They continued this behavior even after the captive was on the HERO. None, however, pushed against the harpoon line or stood between us and the stricken animal. The harpooned animal was an adult female (young adult). Bill Schevill and I studied its pattern, I drew pictures, and finally we concurred that it was like the llama of the north in most respects but that certain pattern differences were evident.

By this time we had reached our anchorage in a limestone mine is in full operation. Many of the peaks around here are scoured limestone—all gleaming white as if covered with a mantle of snow. It was some time before any of us realized that it was rock, not water, making the white. The limestone had responded to ice erosion by formation of some impressive fins of rock, and several rounded plant-free crests. The mine itself operated right at the shore. We could see a little narrow gauge tram, a square tunnel, a pier and some hoists, and a variety of company buildings. Some of the men came on board through the stiff breeze and rain. We gave them coffee and talked. There are 40 men on the beach and the product is shipped to Concepcion where it is used in steel manufacture.

Bill and I decided to wait until morning for flensing, photography and sampling of parasites, etc. So, tired, and with a little more “ile in the cask” we went to sleep.

November 25, 1968

Puerto Bueno, Sarmiento Channel

Up at first light. The shore party cast off in the dory to work ashore while Bill Schevill and I took advantage of an anchored ship to accomplish our cutting up and measuring operation. Accordingly, we laid our animal out, photographed her from all angles, measured her, and then slid her over to the flensing table. This table is one of the nicest innovations on the ship—a wooden table with adjustable sides that make it into a flat-bottomed trough. Thus an animal can be rolled without sliding off the table and the wood keeps one’s knife from becoming dull.

We went through the animal in rapid fashion, fleshing, salting, tying, and tagging. Eddie and I then put her in the barrel and cleaned up the deck. Then Kenny Bloome returned from the shore party and made a parasite examination. The shore party had found it rough going just getting ashore in the dory. In any kind of wind, which we have in great plenitude, she blows like a cork and the thwarts are so close to one another that 2 men rowing either get in one another’s way or lose all power in their strokes. They are tippy, and all in all, no substitute for a good fiberglass hulled work boat. Any kind of outboard would save us endless labor and especially, time. I think the dories are more dangerous than relying upon outboards. It is all too easy to get to lee of the HERO and not to be able to get back. Even a 5-horse Sea Gull would make our work much easier. When Athelstan Spilhaus said of the HERO “she was built as an antique from the keel up” he could well have been speaking of the dories and their goddam hole pins. These relics of the past break (2 sets have gone so far), and because they must be set far apart to allow oar sweep, they put a little hitch in an oarsman’s delivery of pressure and lose much power. I find the only efficient way for me to row with a loaded skiff is Portuguese style, standing up. Curses on the whole rig. If there was ever a conspiracy to keep us all on board the HERO this is surely it.

We stood out of the harbor, sliding down between great limestone promontories. The exposure of these monoliths is so new that water is just begining to make erosional headway. The smooth faces left by the glaciers are rutted with little channels running up the faces of the mountains, in places a foot or two deep. In time, flutings and deep gullies will appear, much faster than with granite which is not so subject to solution

The tree line drops. Most of the mountains are bare a scant 1,000 ft. above the sea line, though much of this may be due to lack of soil. Certainly, however, a true tree line cannot be more than 3,000 ft. high now.

We cut out into Canal Oeste moving toward the sea where we planned to look at the weather to see if a sea traverse to the south was possible or useful. Further, we had had reports that a large sea lion rookery was present on some of the isles near the mouth of Canal Oeste. Bill and I wanted to see if the recording crew could obtain sounds of the school from which our animal came. This would be optimum—a voucher for the producer of sounds, so to speak.

Near where the porpoise had been harpooned, a small group was seen again. The launch was lowered and the listening crew put out their hydrophone gear. Meanwhile the

animals had raced away and could not be heard. More and more we begin to feel that successful listening for these animals will take more animals and likely great patience.

On out the entrance we went into strong westerly winds and increasing swells. The HERO began bucking into the sea sending spray over the bows and against the wheel house windows. Anelio stood outside on the wing and as we passed Conejo Island he began to note “lobos”. On the shoals and on Juan Largo Island a group of about 300 animals was noted—a new rookery area. Only 5 such areas had been recorded previous to this trip. About this time the pilot, who had been growing more and more restive about the sea, turned without a word to us and headed back down the channel from which we had come. Bill and I had already made up our minds that the sea traverse was not a useful maneuver, but neither of us felt the ship was in any danger. At any rate the die is cast and we will go by the inland route to the Straits of Magellan.

The watch produced some porpoises down Canal Oeste and the order was given to put over a listening party. Unfortunately a shackle jammed in the whaleboat and because it was being fixed the pilot did not feel he could turn the vessel for fear of swinging the launch and so our animals left us, and were lost.

Later in the Angostura Guia, I spotted a group of porpoises racing along the ship’s port side and cutting across the stern. They were *Lagenorhynchus* and as best we can tell, the same kind we have been seeing. My call from the bow caused no slowing of the ship or any other indication that my message had been received. When I arrived at the bridge moments later I found that the word was we could not stop in the Angostura but must go ahead. I gave the order to proceed ahead to the nearest turning point and then to return to the position where the porpoises were last seen. This, it turned out, was only a few hundred yards downstream. When we returned, however, the animals were gone. Then, as we returned through the narrows I spotted another school racing along near the bank, heading for the narrows. The HERO was stopped and the whaleboat lowered over the side with the listening crew. They proceeded toward the point where the animals were last seen but we were unable to help guide them from the HERO because the whaleboat radio is out of commission again, this time with a broken wire. The rig on board the whaleboat was such that [drawing] every time the engine needed to be started a hatch had to be lifted that disconnected a watertight connector on the radio cable. It finally gave way and is now being repaired and located elsewhere. The boat failed to locate the animals and returned after something more than half an hour. They did, however, have the chance of working on their routines a bit and becoming more sure of the acoustics of the whaleboat, which are good.

Rather shortly thereafter, just at dusk (2200), we pulled off to the side of Canal Sarmiento into a nice snug anchorage at Puerto Bueno. The skies had cleared during some of this final leg and we could see the rounded outlines of all the mountains, carved down by the slowly moving ice that must have overlain them to some depth.

A happy hour seemed about due so we had a little Pisco in the lower lab, told stories and hit the sack. Tomorrow morning we will try a shore party and a sound mission on the whaleboat simultaneously.

November 26, 1968
Caleta Annelia, Seno Aguila

Before breakfast, I roused the shore party—Mickey and Bob Barrett, Ken Bloome, Bill McFarland, and myself. Donning foul-weather gear (except for Mac wearing tennis shoes which he later regretted rather strongly) we climbed in the dory and were lowered. The wind was howling from the northwest, but rowing across the wind to the south beach, we easily reached our destination. Mac and I were let off and the rest were to go up into the bay to some beaches that showed on the map. They never made it. The wind was so strong on the light, high little cockleshell that ultimately they had to settle for the nearest point of land on the opposite shore, after about 20 minutes of struggle.

Mac and I made our way along the shore. It was high tide and much to our surprise we found that many terrestrial plants could be seen below the sea water—grasses, wild celery, and others. I scooped up a little of the water and tasted it. It proved fresh enough to drink. Probably such a freshwater layer is nearly uniform in the quiet bays and fjords here—there is so much runoff from all the waterfalls and streams.

We made our way up on a boggy point of land, ankle deep in moss and hummocky hillocks of the same. We tried to walk the beach but ran into some rocky promontories, so we headed up the slope to some rocky outcroppings. This path led us through the *Nothofagus* forest. A variety of trees were common too—an *Aralia*, a scaly-barked cedar (*Libocedrus*), a *Mahonia*, and others. As we moved upward, 2 different cushion plants made an appearance—one a soft-leaved white-flowered form, and the other (*Azorella*) with pointed stiff leaves and a yellow flower. *Pernettya*, a shrub with bright-red berries, was also common. I found one of the insect plants (*Pinguicula antarctica*) with yellowish fleshy leaves in a rosette at the base and a single stalk topped by a veined white flower. The sundew plant (*Drosera*) was also common higher on the rocks. Mac noted that the open areas looked rutted as if by animals and about this time I came up with a fresh pile of guanaco dung. On top of the rocky hill, we found a series of little bog pools teeming with tadpoles. Looking down we could see the launch and decided we had better make our way back. On the way down, we met with the wire tail of this area, a beautiful tame little bird with a buff eye stripe, and a reddish tail tipped with long, bare feather shafts, that give the endemic family its name. Other birds called in the gnarled forest as we made our way clumsily through the moss. Mac's feet were darned near frozen when we reached the beach while I was comfortable—even hot—inside my foul weather gear. It would be very difficult to work here without this protection.

The others met us on the beach. Knowing how hard it is for 2 to row these dories, I removed a thwart and rowed all 5 of us, Portuguese style, and to everyone's surprise made reasonable headway against the wind before the launch picked us up and towed us the remaining distance to the HERO. They had not heard animals.

On board we quickly upped anchor and made our way south in the channels. The shore party went below for breakfast while Bill Schevill set the lookout watch.

The weather is alternately squally and overcast and bright with sun. We can often see the snowy tops of nearby mountains now, a thing we all wished for back in glacier country. Perhaps the continual fog and rain keeps the glaciers where they are.

Porpoises like swift water and shallow passages and hence everytime the HERO gets into dangerous water we seem to see our animals. Considering the drought of animal sightings through which we have been going, each one causes us to galvanize into action.

We, the scientific party, know we must take advantage of every opportunity, and the pilot and skipper know that we pick the damndest times for it. This time I spotted some *Lagenorhynchus* running the bow in the midst of the narrows leading into Mayne Channel. I put Mac in the pulpit and within moments he had fired. Bill Schevill on the bridge shouted out his routine “Right full Rudder”, a command designed to swing the stern of the HERO away from the streaming line. The screw will not stop soon enough so the stern must be swung away. The pilot countered with an impassioned “NO”. He will not let the ship off the sounding line, even with sonar on, and especially in these perilous waters, no maneuver, no matter how transient, can be done. I have been cultivating him in order to try to make better interface possible between our 2 objectives and this time he volunteered that we could turn lower down and return. This we did, locating the buoy in the very choppy sea. Mac and the 2 seamen put out in the whaleboat and shortly located the buoy. Mac saw a large animal with the smaller one he had shot. The harpooned animal was still alive so Mac let fly at it with the shotgun. Until the animal was brought on board he did not know if he had hit the adult or the stricken young. Kenny Bloome found the slug in the lung of the little animal, much to everyone’s relief. It is no pleasure to leave an injured animal behind.

Shortly the HERO put into the Seno Aguila, which I had chosen as the anchorage because I thought a cruise by the launch could be made after anchoring, in quiet water where good recording conditions should exist. Also the map showed sandbars where a shore party could work.

The HERO made her careful way into the Seno Aguila and Anelio called out “marsopa” at the entrance—he thought he possibly had seen a different species than the single one we have been working with, but the animals were not seen again. The wind dropped and the walls of rock rose in stature as we entered. The pilot took us to a nook deep in the sound, where the launch was lowered and my shore party began to assemble. Rain came in sheets blown into stinging force by the wind. Still, we know we mustn’t let this sort of weather dissuade us because it, and worse, will be our ration from now on. If it is sunny, put on your foul-weather gear anyway, because it will change in the next 10 minutes.

I worked on the animal while these 2 parties went about their business. I could see the bright-yellow clad men clambering on the rocky shore while not far away in the sound I could see the launch drifting silently. When the launch party came aboard they told of having porpoise swim within 3 feet of the lowered hydrophone but of hearing not a sound. The shore party came back with a modest plant collection. I was able to prepare the animal, salt it, and stow it before they came back. Kenny completed his parasite examination too (very few—a tapeworm and little more than a few stomach ascarids).

The anchorage is beautiful. Toward dusk the clouds faded away leaving bright low-angle sun on the snow and waterfalls of the cliffs, and turning the drab gray-green forest into brightly lighted greens against the pinkish granite of the cliffs.

November 27, 1968

Puerto Angosto, Desolation Island, Chile

Having accomplished both launch work and shore party work we simply gathered up our anchor off the bottom of the bay and made way south. It was reasonably early in the day that we reached Faro Fairway at the entrance to the Estrecho Magellanes (Straits

of Magellan). This little barren rock with its lighthouse and lighthouse keepers dwelling must be one of the world's isolated places to live. The automatic light has replaced most of these tended lighthouses but we received a cheery, almost hungry, welcome in Spanish as our ship slid past. Our all-business "practico" (pilot) answered in militarily clipped phrases, had our position wired to Valparaiso, and on we went, the lighthouseman wanting to talk to us and we slipping farther and farther out of sight.

It's bleak today. The Straits were whipped with strong westerly winds, the tops of swells being whipped off to the east. Once in a while we could catch a glimpse of the snowy mountains of Desolation Island across the Straits, but mostly it was simply a gray pall hung over the landscape. It was early, and I wanted to hunt. To work the Puerto Tamar area we would have to breast the rough water and there was no certainty of a decent lee, so I chose to run up Bahia Beaufort instead. This sound should provide calm water for the recording crew and perhaps they could repeat their effort of the night before and the animals might even be loquacious. At the same time the shore party could be beach walking and making plant collections, while HERO cruised up the arms of the sound in search of animals. A grand, almost heroic plan but not an animal aside from a single big bull *Otaria* was seen. The weather was shifting with the moment as usual, but the boat party had to work in flying spray much of the time and arrived aboard with faces red with the cold, as did the shore people. They reported an island (Isla Leucoton) so covered with mosses and ferns that actual trees were buried in these epiphytes. At one point Ken Bloome dug into the moss and was able to look among dark tree branches to the soil 15 ft. below. They were actually walking on tree tops.

The ship ventured up Icy Sound and from time to time the bluish mass of a great glacier could be seen on the snowy mountain slope above a U-shaped valley from which it had retreated. Under the present circumstances it's hard to understand why a glacier should bother to retreat, but I suppose things were once worse. The terminations of these glaciers are incredible jumbles of ice blocks resting in disarray on slopes often so steep it's hard to understand why they don't fall into the valleys below—perhaps they do.

Deep in the sound we turned the HERO back through waters made milky with glacial rock flour, met our parties on time (the Radio is a big help and mostly is working).

At the junction between the northward passage and the Estrecha de Magallanes we met the day's porpoises—though we didn't know it at the time. A fairly sizeable group of animals (*Lagenorhynchus australis*) came in to the prow and crisscrossed in front of us. The water was so rough I did not want a man on the bow and the pulpit had long since been raised. I should mention that in one maneuver after a single animal a short time before we had turned into a moderate swell and poor ole Bill McFarland who was harpooner, was dunked to his waist. He held on in the 9 deg. C. water, holding the gun high, and came sputtering up the ladder none the worse for wear. Our harpooners wear a harness that is tied to the deck above so there is no serious danger of them washing away, but it is uncomfortable to get dunked in these parts. Even high on the prow spray was coming over with some regularity and I thought it pretty dangerous, so much as we wanted one of those animals, I didn't order a try but watched them play. I also bore a few thoughts of boat launching and recovery to dissuade me from making an attempt.

Our crossing of the Straits was rough, as the swell came at us abeam, along with the wind. We were headed for Puerto Churuca, a famous old hidey hole used by Captain

Reisenberg around the turn of the century as a refuge for a big steamer on which he shipped. We didn't make it. The pilot took one look at the white-capped swells sweeping in the outer entrance and decided to go east or to a port where he would have more control as the ship went into port. He chose Puerto Angosto a few miles farther on. It is indeed "angosto"—or narrow. The HERO slid in between rocky walls only 150 or 200 yards wide and straight as an arrow made for a little rounded bay at the far back. There we could lay out enough scope to hold the ship and still stay safely offshore. Rock walls rose on all sides. Two major waterfalls dropped into the calm circular bay in whose center we rested. All around the slopes were clothed with forest trees—incense cedars, and southern beeches the most important trees, though the winter's bark and the phosphorite were also present. Far above the mountains rose to snowy crests disappearing in the windswept fog.

No porpoises today, and we want to see them badly enough, but it was good to get in from all the weather in such a snug nook, or so we thought. Willi was from the hills swept across our anchorage and finally we began to drag anchor about midnight. The Captain was up quickly and reset it and this time it held, but there is little room for error in this place.

November 28, 1968

Bahia Morris, Isla Capitan Aracena, Chile

Thanksgiving today. For a right proper celebration of this day one should be contemplative and properly contrite about what luck or opportunity has brought. I tried but pretty much failed until along about the second course of our amazing dinner.

My problem was simply that in spite of trying like hell we simply saw no animal today. The day started out with a plant collection at Puerto Angosto. Mac and I went ashore for photography and succeeded in getting [drawings] enmeshed in the mounds of moss and ferns that are piled around the bases of all the trees. We emerged onto some rain-soaked rocks above the trees and made our way back down in time to retrieve the others who were across the bay collecting plants.

I had the joy of rowing across to get them, thus renewing and keeping bright and shiny my low opinion of these dories as work boats for the HERO.

The shore party had left before breakfast and so went below for a bite while the ship hove anchor and made her way into the Straits of Magellan. The wind was howling down the Straits and never abated its entire length. We thought back with wonder to the time when ships made this traverse against the wind, making endless tacks back and forth and spending days or weeks trying to reach the open Pacific beyond the Evangelistas. For our part our pilot took us right down the center line in spite of various entreaties from me that we could expect more animals if we could travel close to one side or the other. We know well enough that the animals can be expected at places where a sound enters the Straits. Bill and I both have been harping on at least a degree of freedom of movement but the HERO is treated as if she were a 300-foot passenger steamer drawing 25 ft. We're safe all right, but our mission of studying the porpoises must wait the chance when we cross a side channel or go out the mouth of a channel into the sea. Otherwise we are largely passengers on a tour.

Except for the Paso Tortuoso, the Straits run as straight as a die northwest-southeast, and take the prevailing wind right down without a lee. In the afternoon we

passed Cape Froward, the southernmost point in the mainland western Hemisphere—below are all islands. It is a prominent bluff with fog and rain on the sea side and sun on the other, resultant from adiabatic cooling and condensation of the air from the west.

Before too long our track took us into the Magdalena Channel and out of the wind. The sea fell flat calm but no animal showed itself. Dawson Island to the east showed snowy summits whose highest points were hidden, all snow-covered with bluish glaciers penetrating below.

Bahia Morris is impressive enough, being set around by snowy peaks, deep and calm with the green forest fringing it. The Chef, Hugh, had worked all day and had prepared an incredible feast—the Captain and I declared wine for the festivities—red and white—and we ate—hors d'oeuvres, shrimp, cold roast beef, meatballs, turkey and dressing, mashed potatoes, green beans, beets, salad, olives and pickles, two kinds of pie, and more that I can't remember. Everyone was stuffed. To bed.

November 29, 1968

Caleta Fanny, Canal Ballevero, Tierra del fuego, Chile

As the shores of Bahia Morris are partly beach I sent 2 parties ashore to collect and the whaleboat out in the bay to listen for porpoises during the shore operations.

Eddie and I took the beach walking duty. The whaleboat dropped us off on a sharp shingle beach overhung with trees. We walked perhaps ½ a mile before being picked up again. The short distance was owing to rocky headlands interspersed with sand and each such traverse took time. I had allotted an hour for this work before getting underway. Many plants were in bloom including a spiky *Ilex*-like plant, an umbellifer and others. We happened on an encampment, perhaps Indian. It consisted of a pole framework lashed together with vines, a little fireplace, and a pot hook of wood. In this dripping forest it's comforting to know that some folks at least, could start and maintain a fire. We watched the ashy headed gese start from the water and fly by. They are remarkably fearless and come within easy shotgun range. Magnificent birds. The kelp goose was common too, the males all white and the females of black-and-white coloration.

The listening party reported almost complete quiet in the bay but no porpoises. They could hear the thrumming of the HERO's auxiliaries a mile away. Not a snapping shrimp was to be heard. An excellent plant collection was made. We noted all this aboard and shoved off down the Magdalena Channel. While the plants were being pressed below we kept watch above. The water was absolutely still but not a porpoise could be seen. The scenery was breathtaking—Mt. Sarmiento stood in the sunlight, temporarily free of clouds—huge and white, with glaciers a flowing jumble on 3 slopes. As these ice rivers [drawing] extend below the main snow fields of the mountain their hundreds of fissures become evident as little rents of blue, all lined up in the direction of ice movement. Typically the terminus of the glacial mass is a no-man's land of jumbled ice blocks piled crazily on one another. The scene was of Sarmiento alone but also peaks in every direction—some triangular monoliths that were once faced on 3 sides by ice and faceted by it.

These deep channels are pretty lifeless. Only occasional birds are seen—surprisingly albatrosses are not at all uncommon, and penguins the most frequently seen bird. Small rafts of 2 to 7-8 magellanic penguins were common enough.

Bill McFarland had set eel traps out, as he has done at several places. This time one came aboard an absolutely solid 5 gallons of hag fish—I don't know how many he had but when sluiced out into a wash tub they filled it half full. I hesitate to guess how many he has taken thus far, but Dr. Hubbs, for whom they are being collected, should be happy.

It amazes me that the only porpoise that has come to our bow in the entire trip is *Lagenorhynchus australis*. Of the other forms reported for Tierra del Fuego we have seen only one—*Cephalorhynchus eutropia* up in the Golfo de Corcovado. It's not the rich area I had been lead to believe.

Our track soon led into the Cockburn Channel with mountains generally becoming lower in profile and the forest trees becoming more and more confined to low fringes and niches in the rocky hills. Birds became more common, with gulls (kelp gulls) making an appearance along with giant fulmars, skuas, and others. Anelio wanted to inspect the rocks out of the mouth of the Cockburn Channel for sea lions so we headed straight out to sea. In the mouth, the welcome cry of "porpoise at the bow" went up from the watch. I put Mac down in the pulpit to try for a live capture with the head net. He tried a couple of times but without several animals at the bow he had little chance. If only one or two animals come to the bow they have freedom of movement but if several come in they crowd each other and their movements become predictable and thus capture is made much easier.

In view of this, I asked Mac to switch to the gun, and it was only moments before he fired, the stricken animal (*Lagenorhynchus australis*) racing off in a trail of blood. I jumped in the whaleboat with Steve and Penny and we set out to retrieve the buoy. The sea was choppy but far from unworkable. I could see that Mac had hit a lung as the animal trailed bubbles. It, however, was pulling strongly so I loaded the shotgun. The rifled ball cartridges we have on board are a fearsome weapon. A proper shot can stop an animal at once. I fired once just as the animal submerged, and was on target but the shot hit the water. The next shot stopped it and we were able to draw the big animal alongside where it died in a few moments. It was too large to bring aboard the whaleboat so we secured it by the tail and had it hoisted on the HERO before the boat was brought up. It was a big female—all our animals thus far have been females.

As Anelio counted seals, Bill and I photographed and measured, Mac took eyes for histology and visual pigments, Moosemeat took an ear for his electron microscopy work, and George collected and preserved the gonads for chromosome counts. Bill and I then fleshed it out as the vessel headed for calmer waters. Anelio had discovered another new rookery for *Otaria* with about 100 animals being sighted. He has added quite a lot to the knowledge of these animals thus far. It is just scratching the surface though, as it seems likely to me that dotted all along the coast are rookeries, the vast majority of which are totally unknown to the biologists. At least he has been able to discover more than were previously known, on this trip.

I wanted to stop at Isla London, just east of the entrance of Cockburn Channel, for shore collecting if we could. The island has never been visited by biologists so our plant collections, especially, should be valuable. The pilot at first recommended anchorage at the east end of the island and then retracted after reading the coast pilot which described the anchorage in less than rosy terms.

Our water temperature is dropping—to 7.5 deg. C, not too far above the 4 deg. C one encounters in the Antarctic. I rather doubt that we will find much further variation here as we don't go much farther south.

Accordingly, we hove to in the channel alongside Isla London and sent a shore party into a little cove a few hundred yards away. The island is a bleak rocky mass, fringed here and there with low tortured trees and covered with moorland cushion plants and moss up to snowline. Once on shore we fanned out, collecting furiously as I had allotted only an hour for the effort. Moosemeat headed for the rocky areas where he could look for crevice plants and I headed for a little copse of trees for understory plants and the hope of finding the incense cedar, which up till now was thought to reach its southern terminus on Chair Island just to the northeast. Bob and Mickey Barrett worked the swampy areas ad down toward the beach. My bit of forest was about 20 ft. high, wind pruned at the top, but still and lush beneath—all ferns and moss, great mounds being piled on tree limbs and on the invisible soil. On my way back I headed for the plant line up on the rocks perhaps 300 ft. above the shore and there found a line of the phosphorito bush in full flower—pretty red pipe-stem like flowers (or match-like, as the name implies) running along the hills. Bob had found them farther along, also in this inhospitable locus.

Moose picked up a sack full of mussels which they cook had been crying for and we boarded the launch and beat our way through choppy seas to the HERO.

The pilot had wanted to go ahead to Londonderry Island but changed his mind and headed instead for Stewart Island and Fanny Cove. I was happier this way as this large island is also uncollected and we will be able to provide another valuable collection tomorrow morning before leaving.

Bill Schevill and I finished our animal, salted and tagged it and stowed it away. The bone pile grows, I only wish the species list would do likewise.

Stewart Island is a big, mountainous, forbidding piece of real estate, and it is a measure of this place that it had not felt the hand of collectors previously. These places are simply unfrequented and here one can truly wander in places where no white man has been. I've often thought I was doing that in some remote place back in the USA and then found a Lucky Strike package at the end of the hike or on top of the mountain, but here it really is the case, I think.

November 30, 1968

Caleta Wulaia, Navarino Island, Chile

In the frosty early morning, with winds whipping, we put our shore party on the beach to collect Stewart. The island is rugged and doubtless will continue to yield flora and fauna for future workers but we had the opportunity of being first. Ken Bloome, Bob and Mickey Barrett headed for shore and came back an hour or so later with a modest collection. I was a bit disappointed as it seemed to me the collectors hadn't understood that every plant is valuable in a situation like this—in flower or not—and that new records or plants they hadn't seen before were not the order of the day. I guess I'm just getting to be an old beezark like, to a modest degree, my old boss Hubbs who always knew he could do a better job than his students. Well, botany is a side issue with us but I do want it to be well done.

Off down the Paso O'Brien we went, past fog and sleet-shrouded Londonderry Island—very bleak wet, and cold, with snowy crests appearing from time to time.

The trees cling in folds of the mountains, being ever more and more restricted. Elsewhere moorland mosses and low clumping plants cover the rock. Finally we entered the Beagle Channel which is a remarkably straight, deep channel between parallel ridges of rugged mountains, glaciers coming down transverse canyons on either side, but especially on the north. As we cruised the wind-whipped channel, glacier after glacier was passed. They poured down into high valleys from shields of ice covering mountaintops back behind and out of our view. One of the largest, Romanche Glacier, is a jumbled mass of ice, literally spilling over from a much bigger mass above that caps the mountains. While we watched, a big cake of ice slid down the cataract of white water running from the melting front of the glacier.

Farther on eastward, Italia glacier was passed—the only one actually reaching the level of the sea in the Beagle Channel. Bill Schevill thinks it is probably the one in which Darwin's party nearly lost their whaleboat to a wave caused by a falling cake of ice.

The pilot mistook my request to anchor in Wulaia, through Murray Narrows, for a request to anchor in Yendegaia, a port just inside Chilean waters off the Beagle Channel. I had no desire to flirt with the Argentine border any longer than necessary and so clarified the situation by asking again for Wulaia. This meant that we quickly approached the portion of the channel in which Chile owns the south half and Argentina the north, cut over to the Chilean side (not far enough to suit me) and made our way into Murray Narrows (4 miles). The terrain changes rather abruptly here, becoming lower in relief and much warmer. We could just see some of the houses of Ushuaia across the channel, and I could look on beyond and see what I assumed was Table Mountain behind Harberton. Right at that moment my family was in Harberton and I could neither guide the boat there nor call them on the radio. They can be reached only on ham frequencies and our ship is not licensed to send on these frequencies. So, it will have to be "so near and yet so far" for another 2 weeks. I hope everyone is braving the rather blustery weather. I can't imagine what it would be like to try to work without my foul-weather gear and the kids and Phyl are not really equipped with that sort of thing. It makes all the difference in the world. One can stay dry, and even hot, while icy rain pelts you and 35-knot winds whip around.

Murray Narrows was an experience. It is really narrow indeed. At the narrowest point the water is thrown into a whirlpool. I could feel the ship fight against being turned and could see the captain adjust and readjust to keep us on an even course.

Not far beyond we entered into Wulaia Bay, a famous old spot where the early missionaries were pestered nearly to distraction by the Yaghans who begged for everything, poked and pulled at the poor souls and yammered in their ears all manner of vile threats. Later it was also the site of the massacre perpetrated by Jemmie Button, one of the Yaghans who returned from England with Darwin.

It is a lovely place. A fine intricate bay, made of rocky headlands and coves, a nice little sheep station, where a man and his family live in an old Navy station. Around their 2-story house are grassy fields, 8 dogs, dozens of wild geese (ashy headed, kelp, and some others).

Bill Schevill and I paid a protocol visit to them and found him very friendly and almost incomprehensible—his Spanish was so fast and so larded with idioms. Further he never seemed inclined to give a direct answer—a thing our Spanish desperately requires. But we learned he tended 2,000 sheep, that he came from Chiloe (Castro) and that he knew about some whalebones down the beach. I, of course, had to look right away and so was off in the direction he pointed, but found only driftwood for my efforts.

We did see a magnificent kingfisher on this walk—very large and blue, red, and white. We also noted that the beech tree is a new species for us and that not only does it bear large tufts of parasitic plants much like our mistletoe, but also on swellings of limbs a large nearly spherical fungus, orange in color and speckled with darker orange. We whacked down a few of these later on for the plant collection. Our friend offered us a lamb and was taken aboard the HERO for a tour and a few gifts. The engineer (asst.) noted he loved matches and generously gave him a cigarette lighter.

Mac and I were dropped off on the beach for some collecting. We had a fine hike down the pocket beach and over the promontories. Everything is much drier here, and spring is much farther advanced. Many more plants are in bloom and some places the soil is actually powdery dry. I collected 2 *Otaria* skulls and an assortment of other skeletal parts. We sat on a rocky point waiting for the launch to pick us up—looking across at the Pasteur Peninsula—a rugged, snow-capped range that set off the quiet bay and its tree-clad slopes and calm water. A lovely place.

Back on board we arranged our specimens and went to bed. Tomorrow, Nassau Bay.

December 1, 1968

Bahia Orange, Hoste Island, Chile

Our first duty this morning concerned the shepherd on the beach. He had promised us a lamb and so we dutifully went ashore in the whaleboat to retrieve it. The man led us to the killing and shearing shed where we found the lamb all dressed. His 8 dogs were joyfully chewing on the entrails outside, and behind a phalanx of wild geese stood watching. I never saw so many geese. The shepherd made it clear that he would guide us in the whaleboat to the whale on the beach. When we began this evolution we went in exactly the opposite direction from my first trek. About 1½ miles north of Wulaia anchorage, we came into a little cove with a pocket beach and there, sure enough, were many parts from a big balaenopterid whale. There was enough of the skull and other pertinent parts to allow a secure identification when I can get to a museum for comparison.

While we were hauling these goodies across the cobbles and into the whaleboat we received word that Bill McFarland and Penny had a porpoise on the deck of the HERO. It later turned out that they had harpooned it just out of Wulaia anchorage and it had rushed into the kelp where it died. They had a terrible task trying to free it. Bill's arms were so tired that he developed a cramp on the row back to the HERO and was tied up for some time. It proved to be another female *Lagenorhynchus*. So, when we hoisted the bones on the HERO, I stayed aboard to tend to the animal while Schevill, Watkins, and Harvey went off to try some recording in the whaleboat.

Later, on the radio (bless the radio, even if intermittent), we learned that they had been in the midst of a school of *Lagenorhynchus*, and that for the first time they had been

able to hear the animal speak. It produced only short click bursts—behavior not unlike our own *L. obliquidens*, which apparently seldom or never whistles. Wat also sighted a pair of *Cephalorhynchus*, getting a good look at the rounded dorsal fins. This is our first sighting of this species since the Gulf of Corcovado. They said nothing that anyone could hear, also like those of the Gulf of Corcovado.

I flensed and measured as the HERO turned out into Nassau Bay. Almost at once we began encountering groups of *Lagenorhynchus*. Mac wanted to obtain an animal for neurophysiological work and so we planned a tail shot that would allow live capture. The head net is a very difficult proposition here—there are never enough animals to crowd them into orderly bow riding schools that can be netted. One needs a predictable path of travel and, especially, surfacing, to net them. So, the shot seemed the most secure method. Mac took one such shot and hit the animal perfectly. It ran off to port, dragging the line under the keel. Something on the skagg entangled the line and tethered the animal. Penny and Bill and I descended into the dory and attempted to free it but failed. We were unable to pick the line on the opposite side in the choppy sea and watched futilely as the struggling animal broke free, leaving us with the buoy and the tag end of the line. The breaks. Most animals do not cut in under the keel.

Word came over the radio that Bill Schevill had harpooned a big porpoise—another female—our 6th in a row. They would wait for us in the vicinity of Wulaia. We met them and hoisted both whaleboat and animal aboard. More flensing.

Out into Nassau Bay, south of Navarin Island we went and quickly encountered more schools of *Lagenorhynchus*. One group quickly cut into the bow and Mac let fly at one animal, hitting it cleanly on the tail stock, right where he wanted it. But, wait, the line came free, sans harpoon. Only the becket came up, pulled loose from the shaft. This fault of the Kongsberg harpoon is giving us serious trouble as about 1/3 of our shots are lost because of it, or of line fouling.

I had Mac reload to see if the animals would run again. This time they came in in some numbers and Mac let fly again and missed. I could see clearly, as could Claude the messman, that the animal previously hit was the one Mac had shot at. The red wound on the tail was clearly seen by both of us. Apparently the harpoon had gone completely through the dorsal musculature and had caused the animal no serious damage.

Then, I had Mac reload again. The animals came in again and he fired—a pretty shot right where he wanted it. The animal dove down and under the ship and the buoy came up bobbing on the water, only a little tag end of line attached. We all decided to quit at that point as our lines and harpoons were getting in some disarray and Mac was a bit dismayed at the losses, as was I. I hate to leave wounded animals behind.

I gave the order to make for Orange Bay on Hoste Island.

As we travelled along we could see the Wollaston Islands in the distance, and finally Hermite Island, just north of Isla Hornos. We are about as far south as we can go. The islands are rather low by comparison with much of the country we have passed, and the moorland covers most areas. Trees are restricted to draws and their tops are wind-pruned into the exact cotours of the terrain as if trimmed with barber's shears. Packsaddle Island was approached—a perfect “montura” of stone. Finally, we slipepd into Orange Bay, the site of observations of a total eclipse by a French astronomical team back in the late 1800's. Many of the local place names are French as a result of their work here. Terrain is low—a few snowy crests, but mostly exposed rock promontories

with rolling grassy lower terrain, here and there splotted with copses of trees—Antarctic beech, winter's bark, and the holly-like shrub (which actually belongs to the Loganaceae). The area is used for sheep grazing—an austere station indeed for the shepherds. Wind and sleet and rain are the usual lot here, though the sun does come through from time to time—low on the horizon and seemingly unable to warm one very much.

The Lieutenant wanted to pay his respects to the “Naval Base” on shore—a cluster of sheep shearing sheds, a pier made of gnarled tree trunks, and a little house over whose ridgepole waved a tattered Chilean flag and from whose chimney stack scudded a trail of smoke. We tried to land, but failed. The tide was too low and so the 2 Navy enlisted men who came down to meet us stood with their little dog waiting for company but being unable for the moment to carry on a conversation. We returned to the HERO, picked up the dory, and came back. By this time the mast sported a clean new Chilean flag, obviously in response to their spotting a Chilean Naval officer in our midst, and not to the execrable Spanish I yelled at them across the water. The Lieutenant smiled a brief knowing smile at this sign of recognition and went ashore.

I put my botanists on shore at a nearby cove, and was myself put ashore across the bay where I hoped to look for bones. Bill Schevill, whose toe still gives him some trouble, stayed aboard to finish flensing and tagging the second animal. My walk took me around the peninsula near the “Naval Base”, as the sign said over the sheepshearing door. They had some badly camouflaged guns hidden in the trees. These were sheltered in A-frames covered with galvanized iron painted in shades of green, and covered with cut branches of the *Nothofagus* tree. Unfortunately for their camouflage the branches had dried and stood out sharply from the remaining gray-green forest. I think they were old anti-aircraft guns of some small caliber. Likely this is why we are not allowed on the south coast of Hoste Island, and I'm surprised we could come here to view these preparations against the Argentinians.

The old sheherd at Wulaia was in Naval employ too—he had a key with which he could report any Argentinians that wandered that far up the bay. I suspect such lookouts are scattered all over these southern islands. Austere lonely duty it is too, but something to keep the Naval spirits up.

My own walk produced no bony mementos and I even failed to reach a decent beach. The entire shore was cobbly, studded with rocky promontories. The flora is sparse, composed of things we have seen before, but much reduced in species. Many plants again grow beneath tidal line in response to the great freshwater run-off. At times the rain came in stinging sheets which cascaded harmlessly off my foul-weather gear. My watertight integrity was held the day before (“All water is one inch over your boot tops”) and my feet were cold.

It was good to get picked up and brought back on board the nice warm HERO. Maine fishermen don't know how to row in kelp. They have only the shorter “weed” there and thus the technique of dipping oar blades only half under water is unknown. Hence they had a pretty tough time getting the dory in to me.

The long days, when light goes to 10-12 PM and starts at 4-6 AM tend to make us overwork. I tend to want to use every available moment of light, our time being so short. Hence it always seems difficult to get these notes down. I'm writing these on a morning sortie out into Bahia Nassau, expcting any moment for a “porpoise alert” to come down

from the bridge. My station is on the headphones on the bridge. We send Mac down on the pulpit (our best shot), Edie is on headphones in the prow watching him. If he fires, Eddie yells “fire” into the phones, calls out “right full rudder” on the bridge. This is given for a few seconds and at the same time the power stopped. The stern swings away from the line (if all goes well and the animal does not dive under the keel). Then we pursue the beast in the whaleboat, if it is not off somewhere listening, or the dory if that’s all we have. Dory duty in a choppy sea is something else, I assure you. [Drawing]

Tomorrow we head out for the Wollastons and hope to spend the night there. Weather looks good. Nassau Bay looks like good hunting territory too, wide open but with a very considerable protection from the circumglobal westerly swells of the Antarctic seas.

December 2, 1968

Puerto Maxwell, Hermite Island, Chile

Mighty close to the Horn, we are at the end of this day. Some could see that impressive rock through channels in between Herschel Islands and others to the east.

It all started out with a recording session in which the whaleboat took off in Orange Bay as soon as breakfast was completed, while the HERO cruised offshore in search of animals. About 2 hours later we met them outside Orange Bay. They had heard nothing and we had seen nothing. The best they could do was report a group of steamer ducks taking off very close at hand, all at once. When I saw “taking off” I, of course, refer to them “steaming off” across the surface. They beat their 2 wings simultaneously in a sort of rapid rowing movement and apparently beat their legs alternately since one can see them yaw from side to side as they move along.

I wanted to cruise around the Wollastons, using them for a lee, in order to traverse some of the open ocean in workable water. Thus we headed east from Orange Bay, north of Grevy Island. There we inspected the rocks at the northeast corner for southern sea lions, made a cut into the indentation of the island on its northeast end and thence out to sea toward Isla Evout. This island is a steep-cliffed one, not very large, but standing rather high out of the water. The sea became too rough to work when we were perhaps 10 miles east of the Wollastons. Back we came, setting a course for Barnevelt Island, and that too proved too rough, so we came closer in still. Rough and very cold—sleet occasionally swept across the decks. At the eastern terminus of Canal Franklin, off Isla Frecinet, we encountered scattered small schools of *Lagenorhynchus australis*. Bill McFarland, by now our gunner, went down in the pulpit and readied himself for a shot. It was to be a shot in the tail to obtain a live animal for our neurophysiologists. The whipping wind and swell made it very difficult for Mac, plus the typical crisscrossing swimming of the animals, which presents targets for instants only. It wasn’t long, however, before Eddie Shallenberger shouted “fire” into the sound-powered phones and the bridge responded by an instantaneous “right full rudder”. The float was thrown over and the ship’s stern swung away as planned. I looked at the float and for a time thought no animal was on it, but soon it began to move. The whaleboat was swung over the side with the head grabber and Eddie on shotgun in case the animal had to be killed.

There ensued a long and difficult fight. Moose handled the line much of the time and returned exhausted. Finally, the animal was brought in close aboard and one of the crew men grabbed her by the tail and she was soon snaked aboard, right in Mac’s lap.

(Mac came aboard a bloody mess.) The whaleboat then made for the HERO through the icy chop ready to be hoisted aboard. Hooking on was done too soon, before the HERO could swing around, producing a lee for hoisting, so surges on the hoisting tackle were extreme and the after block broke into pieces. The captain, by this time, had made his lee and the crew of the whaleboat, after unhooking the boat, came alongside with the animal in a stretcher. It was quickly hoisted aboard alive—another female. The wound was a grievous one—into one lung and out the belly. We had hope that anaesthesia could be performed and perhaps an electrode implant but in the hour it took to get her into position and all gear functioning, she faltered and died. Bob Barrett then spent the next several hours working on her brain, which he was able to obtain intact. Other samples and measurements were also taken. I surrendered skeletal materials to the brain work.

By this time we were on our way down Maxwell Channel off Isla Herschel. The pilot tooted 3 long blasts and we knew we were saluting a Chilean Naval outpost. This one stood on a bleak windswept hill, a single house with a flag slapping its pole above. A more bleak outpost one could not imagine. Not a tree nor a person nor any chance of one as there was not good port for a ship such as ours. Six months they spend in such duty. [Drawing]

The HERO made her careful way in Paso Norte of Puerto Maxwell. This fine little port is rimmed with low hills on 4 sides, the lack of high mountains keeping williwaws at a minimum. We passed rocks on one side, slid over a sill and anchored in nearly the geometric center of the bay. Isla Jerdan on our east had never been collected so at 9:10 PM George Harvey, Mickey Barrett, and I rowed to the beach in the dory. It took forever, and our time with useful working light was cut proportionately. The island was not very rich, and very windswept with the 2 trees (southern beech, winter's bark) no more than 10 ft. high and all gnarled and tisted.

On our way to the beach I had the flattering attentions of 2 *Lagenorhynchus australis* who tried to run our bow—in the dinghy yet! They even followed us into the kelp bed, which here is very thick and about 50-75 yards wide around most of the perimeters of the islands.

On shore were a pair of the lovely kelp geese—the male snow white and his mate strikingly black and white—always we have seen them in pairs.

Back on board I helped a little with the plants and with the porpoise and went to bed.

December 3, 1968

Bahia Gretton (off Isla Grevy), Chile

We're all Horner's now. Our track today took us through remarkably calm seas around Cape Horn from the west, past Cabo Decait, to Isla Barnevelt, and thence to Bahia Gretton where we anchored off Isla Grevy (Wollaston Group) in absolutely calm water.

One of our hopes is to meet some of the oceanic species in this area and hence, we try to move around the margins of shallow water as much as we can, weather permitting. The channels have proven the home of the llampa and *Cephalorhynchus* (though he has shown himself seldom enough) and nothing else. Our kingdom for a pilot whale or a ziphiid!!

I looked at the collection records we have for plants and found that Isla Hornos has been collected 3 times—once by Darwin in the 1830's and twice in the 1880's, hence

we did not plan a landing there planning instead to travel to Isla Varnevelt, a low isolated island of perhaps 75 acres extent. We thought we might find a sea lion rookery to add to Anelio's list, and apparently no biologist had collected it. The chart showed a small cove and a sand beach. I had hopes, as usual, that since the island was essentially oceanic we might find the remains of some animal we hadn't seen.

The day was wonderfully calm; only a slow low swell came in from the west as we passed Isla Hermite and could look into St. Martin's Cove, where the BEAGLE anchored with Darwin aboard and the DISCOVERY I later on. The sailing directions say it is a fine anchorage except for winds sweeping down the mountain behind. Hermite is autere—she was dusted with snow when we passed—trees are bushes and most is either rock or moorland coloring the hills dun.

Ahead of us lay Isla Hal, a precipitous rock of an island and beyond it Isla Hors. A long sweep of table land rises on the haunches of the Horn and seaward, facing south, the island plunges as an abrupt 1,000 ft. cliff. No one tends the light so the island is uninhabited.

Everyone was on deck, even poor sick George Harvey (seasickness over and over), photographing this famous landmark. Mickey Barrett wanted to go around the Horn in a dory and accordingly planted himself in the HERO's dory aft. It was such a splendid idea that the dory soon had a full crew, me in the bow peering resolutely into the engine stack, Moosemeat at oars, and McFarland in the stern sheets looking like Cleopatra sailing down the Nile.

On we went past Isla Deceit. At her southern tip we saw a grand rock looking for all the world like a man in hip boots standing in water somewhat over the knees. I decided it must be Backus Rock, and that it represented perfectly a man with water one inch over his boot tops.

The sea stayed calm so Barnevelt was reached easily. The HERO dipped into the little cove, but we looked in vain for much sand beach. There were cobbles and little coves but only on the west end was there even a hint of sand. Bob and Mickey Barrett, Bill Schevill and I put ashore in the dory while Harvey and Shallenberger went in the launch to attempt recording. Watkins stayed on the HERO as she went out under the scientific command of Bill McFarland to attempt capture of any oceanic animal they could find.

Quite a greeting committee came down to meet us as we neared the shore. First came the Magellanic penguins. A raft of perhaps 100 birds swam ahead of us, from time to time porpoising free of the water like sleek black and white fish. As we neared the beach we could see the rocks and the hill behind covered with a standing troop of penguins all looking anxiously at us as we came nearer. Above the cobble beach they stood on soil that extended up into tussock grass as high as a man's shoulders. We could see that between the bases of the tussocks were runways used by the penguins. As we came closer some birds retreated up into these runways and others tumbled out to run down the beach. Their braying, much like that of a donkey, was heard often, particularly when we disturbed them. Those nearest the shore hopped from their boulder perches onto the cobbles and then thrashed and splashed their way into the kelp bed that rims the shore. I suppose there were 50 birds ashore.

All the while imperturbably watching us from some large boulders nearby were 3 caracaras (Forster's caracara)—lovely dark, eagle-like birds with necks spangled with

yellowish dart-shaped feathers (considered very rare and found only south of the Beagle Channel). They gave every appearance of worrying very little about our approach. We made our way across the little pocket beach toward the tussocks. I planned to hike the ridge above to the west end where the larger beach area was located. The tussocks soon discouraged any such advanced notions of possible progress. It proved an almost impassable barrier. The tussocks had grown here for a very long time, piling up feet of peat moss like material around their bases, through which the penguin runs ran. These runs were sometimes 6 ft. below the tops of the grass and filled with wet penguin-dungy slop. I made my best progress by walking on the tussock tops trying to ignore the abysses beneath at each step. Sometimes the grass would yield to the step and one would inexorably slurp into the depths. In a full foul-weather suit and boots all this made for hard hiking. Furthermore, it ran up the hill for perhaps 200 yards. Heaven only knows how many penguins were sequestered in the stuff—but one thing sure—they were safe.

I looked back and could see Bob and Mickey thrashing along and occasionally Bill Schevill's bearded, bespectacled visage would hoist itself above the grasstops. We were all out of breath when we reached sedge land beyond the grass. Even this was up to the knees and not the easiest going. The island is low and rolling, edged in bluffs and stacks, and offshore looks deceptively easy to traverse.

[Radargram of Bahia Gretton Anchorage]

Bill came huffing up from the tussocks and we converged upon a Forster's caracara sitting in a low bush. Thinking the bush might hold a nest we pressed on. He flapped off, literally running on the bush tops like a terrestrial steamer duck, but refusing, for some reason, to take off. No nest.

Many flowers were out on the island. Plants that had not yet flowered on the larger islands or mainland were here in full flower. I suppose this is due to the maritime climate around Barnevelt resulting from the low relief and absence of mountains. Islands with snow-covered mountains must feel their effects. At any rate yellow violets were flowering everywhere—a little orchid was dotted among the sedges and many other plants were collected.

Bill and I could not make the hike we planned as time grew short so we began the trek back, this time traversing the grass much more easily by following the penguin runs even though at times we could not see ahead. We ended by sliding down a vegetation-choked canyon to the beach. On the way we encountered the same little wire-tail Mac and I had seen in Puerto Bueno, much to the north. It peeped an insistent little call and hopped in the bushes within a few feet of us.

Before leaving the island I watched Bill standing on the cobbles while a school of penguins came in through the kelp. they popped out of the kelp right at Bill's feet and then retreated in utter consternation to the water again. Soon Bob and Mickey appeared—very tired from the struggle—and we all rowed to the whaleboat. I asked to be towed around to the sandy beach as the HERO was some distance away. We rounded the rocky cape and saw 20 lobos (*Otaria*) on the beach. Bob and Mickey and I rowed in in the dory. The animals "scrouffed", and lumbered into the surf. They came up all around us, looking reproachfully at us. The old males are incredible beasts—their snouts turn up and their heads are huge—like great sad-eyed hairy bears, only larger and infinitely more ugly. After watching them for a time we retreated to the whaleboat and were towed to the HERO. Mickey and Bob and I prepared plants while the ship steamed

toward Grevy Island where I wanted to anchor and work next. Our watch saw nothing in the calm sea. In fact Bahia Nassau is about as dead as an area can be, it seems.

At Grevy I looked at the magnificent stretch of beach that lines this low part of the island and called for a shore party to look for bones. We sent one crew northward (Barrets, Shallenberger), and Mac and Kenny Bloome and I headed southeast. Our skiff had been accompanied ashore by 2 llampas who raced on all sides of us so we hoped other samples might be found on the beach.

A long walk on a lovely strand produced some baleen whale bones, a skull of a *Lageorhynchus australis*?? and a reasonable plant collection.

The whaleboat had been out on a recording session during all this and was scheduled to pick us up at 9:30 PM (light ends about 2200 here). Mac and I sat on a rock inside a huge kelp bed watching the speck of a boat (the international orange really shows up) pick up the opposite party. Much later it came our way and then Steve began the most incredible assault on the kelp—he got in the bow of the dory—a big muscled giant of a man—and began hand over hand, to pull himself through. Before very long he was ashore and we in the dory. Mac and I paddled back out—a much easier way of negotiation in kelp. In Maine where Steve comes from they don't have kelp.

Anyway—through the increasing dark we cruised to the anchored HERO, her lights shimmering over the calm bay and the moon slipping behind clouds to the Navarin Island side. Shore birds like phalaropes and shearwaters cut as dark shapes past us. Enough is enough and we all hit the sack most gratefully, and very tired.

December 4, 1968

Bahia Windhond, Navarin Island, Chile

If the morning had proved as flat calm as the night we would have headed out to sea to look for oceanic animals, but instead a SW wind came lightly over the low isthmus of Grevy Island and even in that protected water began to ruffle the surface into little whitecaps. I thought it better, therefore, to head northward for Bahia Windhond and Seno Gradi, where we hoped for launch work to listen for the little *Cephalorhynchus* which we know occurs on the coast there, or at least a little to the north on Wulaia. Bill Schevill and I had our usual conference and decided on the plan. Bill and I have a nightly discussion of the next day's sailing, and once we reach unanimity we accost the Captain and often the pilot to lay out courses, and to locate ultimate anchorage. This gives the pilot time to dig into his literature for information on channels, rocks, winds, etc. Bill's and my problem is largely one of opportunity. What wind conditions will allow what work, what topography will allow what work, and what programs are in need of help? We have worked smoothly and easily, having no major differences of opinion. Together we wish for more animals, however.

I stood the watch across Bahia Nassau from the Wollastons. Viewing conditions were excellent; I could see for miles over reasonably calm water—but no cetacean hove into view. We were only accompanied by our usual skuas, wheeling and dipping around the ship.

Early in my musings over the charts of this area (a favorite pastime of both Bill and myself) I had noted a long strand at the head of Bahia Windhond and had noted that the configuration of the bay, wide open to the south, seemed excellent as a stranding place for animals. I had announced I wanted to walk that beach sometime before we left.

Now, with the HERO standing that way, I asked to be taken closer to see if I could look the beach over. It was beautiful—windblown sand frosted the bluffs in the deepest part of the bay, indicating the convergence of 2 sets of long-shore currents, one from each limb of the bay, meeting and cancelling at the deepest part, and probably dumping their load of floating animals as well. The coast looked as good as any for *Cephalorhynchus* and we had passed a colony of about 100 *Otaria byronia* at midbay (they might be recorded for underwater sound)—all these things added up to a combination launch and beach party, with the HERO standing out into Nassau for an attempt at animals while we worked. I put Bill McFarland in charge of the ship, Bill Schevill, George and Watt went in the launch, and the Barretts, Ed Shallenberger and I went ashore. Our shore party divided and went in 2 directions. Ed and I going west and the Barretts east. We hadn't set foot on the beach for more than 2 minutes before Bob called out "whalebones". Sure enough, among the great piles of driftwood were big vertebrae of baleen whales. Before long we had gathered a cairn of memorabilia and began to despair at the amount. I then found the skull embedded in the beach, buried 3 ft. down in places. It, of course, was huge. It would require perhaps 6 men to lift it. Then we found the jaws, each 8-10 ft. long. Then we located parts of a smaller whale, perhaps a pilot whale, and assorted bones of *Otaria*. I added these to the cache as we simply couldn't carry all this.

We looked up and coming toward us in a slow glide was a huge vulture, its primaries poking out, curved up like so many fingers. The bird, whose wings spread 10 ft. or so, came right over us at 20 ft., and I could see the white neck ruff, and as it passed, the white upper wing coverts—a magnificent Andean condor!

Geese were everywhere. Kelp geese in pairs, ashy headed geese sitting on nests amongst the driftwood—most with half a dozen big brownish eggs set in down. Mother would not fly until we were very close. I had asked Eddie to collect some for Bill McFarland, who wants to look at the visual pigments of these amphibious birds. So, he was off, stalking them over the bluffs. When the day was over he had 5—4 kelp geese and 1 ashy headed.

The beach groups split. I wandered off picking amongst the beach wrack and before very long came upon a fine pilot whale skull half buried in the sand. And then another, and another. I felt I had come upon a stranding and sure enough, when the collection was all gathered I had found 14 skulls, 11 in good condition, plus innumerable appendicular skeletal parts. I stacked my prizes in groups of 4 on the beach for later pick-up. This find is an important one as very little is known about this southern pilot whale—many features suggest close lineage with the northeastern Atlantic species, *Globicephala melaena*, and others with the Californian *G. scammoni*. Such a series could go far toward delineating this relationship. A prize indeed.

Along the way I passed baleen whale skeleton after baleen whale skeleton—6 adult animals in all—all apparently the finback whale. The Barretts recorded 3 more. I suspect they are cast-offs from Antarctic whalers working in this area.

Finally the whaleboat came in for a rendezvous. They had recorded *Otaria* under water for the first time, and Bill thought he might have found a southern right whale skull on the beach. This is a very rare animal and would be a find indeed.

Bill Schevill and I rode in with Steve in the dory to pick up the pilot whales. It took 2 trips but all materials were safely stowed in the whaleboat and thence on the HERO.

Then we headed for the suspected *Eubalaena* but closer inspection proved it to be a *Balaenoptera* so it was left on the beach. As vouchers of the big baleen whales I asked to return to the original cache. We rowed in and took a few parts that we thought would allow positive identification, including a big lower jaw. This fit in the door by dint of lifting out the thwarts, placing the bone in and replacing the thwarts. Steve and I rowed back straddling the bone.

Mickey Barrett came in asking if I was interested in some birds he had seen. Of course. He then proceeded to tell me he had seen 7 males and 1 female of the Magellanic woodpecker, a very rare relative of our pileolated and ivory-billed woodpeckers, and a bird we had been asked to watch for, and if possible, collect. It had been seen, some birds at close range, amongst a *Nothofagus* thicket ¼ mile N of Caleta Bevan in Bahia Windshond, perhaps 300 yards from the beach and no more than 150 ft. in elevation.

Only Bill McFarland's group had seen nothing, but with all those pilot whales on board and the material from the baleen whales, I didn't care as much as usual about such blanks. All the each party was fagged out. I was creaking in every joint, wet, cold, and tired. I wolfed down food that had been held for us (we made it to the ship about 8 PM) and then wrote notes and went to bed. A very successful day.

December 5, 1968

Bahia Allen Gardiner, Peninsula Hardy

First thing in the morning we set off a launch party, first to attempt to obtain 2 individuals of the Magellanic woodpecker that Mickey had seen near Puerto Bevan, and second to obtain some photographs of the 100 animal *Otaria* colony just to the south of Puerto Bevan. I went with the *Otaria* hunters.

The little rock occupied by the southern sea lions is about 1 acre in extent, low and the home of numerous cormorants and gulls in addition to the sea lions. Of sea lions there is one old male, a couple of sub-adult males and many females and juveniles. As we approached one male began irritably to bark and snap at his females, often a sign of agitation in these animals. Out of water his massive head and neck were even more grotesque than in water. The contrast between these massive body parts and the modest abdomen and flippers was ludicrous. We approached within 50 ft. or so before any animals went into the water. Even then only a few made the trek and the rest remained on the rock looking reproachfully at us.

The day was calm and clear so many photographs were taken quickly before we returned to pick up the shore party which had not obtained any woodpeckers.

On the HERO we set out to obtain a live animal for the neurophysiologists. I decided we would keep the launch onboard and spend the whole day for them because it is impossible for us to work for live animals without the assistance of the launch. Trying to deal with a powerful animal like a porpoise is extremely difficult from the dory and I won't ask Mac or others to try, so if we were to get a live animal we had to pack up launch and HERO and concentrate solely on that. Out of Bahia Windshond and into Nassau Bay we went, finally heading toward Bahia Tekenika (Yaghan Idian for "Whatsisname?"). I thought we had our best chance with the harpoon gun trying to shoot an animal in a non-vital region. The schools of animals are simply too small to stabilize the animals that ride the bow. Anyway, we headed into Bahia Tekinika, a lovely deep fjord rimmed with snowy peaks of the Pasteur Range. In the mouth we encountered a

pretty good school of porpoises, once again *Lagenorhynchus australis*. With Mac in the bow we tried everything in the book—head grabber, harpoon gun, etc., and nothing availed us. The animals began to get wary and refused to run the bow, but instead gathered at the waist and around the stern. Mac and Eddie transferred their activities there, setting up station on the tethered dory. Before very long Mac fired and announced he had missed, but Eddie threw the buoy in anyway. Then we noticed it begin to pull against the current. An animal was on. We lowered the whaleboat and took off. The buoy became tangled in the HERO's rudder again and I tried desperately to pick up the harpoon line with the boat hook. No luck. Finally, the buoy swung free and we went after it, shortly coming up with the porpoise on the end of the line. Then followed one of the usual wild melees in which the animal was fought to the side and horsed aboard, struggling and bleeding all over Mac who, as usual, landed underneath.

It was badly hit—through a lung and out the ventral surface. But anyway, Kenny and Bob tried to get everything going for an attempt at anaesthesia and were all set when the animal shivered and died in my hands. It was a big male and the engineer (Jerry) told us that Mac had indeed missed the animal he shot at but hit the one swimming beyond. That we reasoned, was why our lady killer Mac, who had shot 6 females in a row, happened to hit a male. Bill Schevill and I began our by now weary process of measuring and flensing. It is a process that takes probably 2½ hrs. when working flat out, and is bloody and not always pleasant. With the same species always coming across the dissecting table we are getting a little blase.

We had chosen Bahia Allen Gardiner as our next port, one that was not sounded on the chart and hence one that we would have to enter with caution. It lies on the south shore of Bahia Tekenika, the bay mentioned before. The first capture has come in Ponsonby Sound. A big school of llampas appeared.

This time I put Eddie down in the pulpit. He had to vindicate himself after his previous misses, though he said nothing to me. We tried the gun and he missed when the animals crisscrossed the bow. The school numbered at least 15 animals and they were beginning to crowd one another at the bow, which gives us our best chance. Eddie switched to the hand harpoon. He struck and the animal rushed off throwing the harpoon, and losing the pole. Tough luck. We switched to Bill Schevill's hand harpoon, which is purposely short for the whaleboat. Eddie struck again and the harpoon pulled free. Still they came. I announced I wanted a turn after Eddie's next shot. This time he didn't miss and off we went in the whaleboat after an animal struck on the side.

We horsed[?] the animal in in rough water. It was small so we easily hauled it aboard. I disengaged the harpoon and could see that the wound had tipped one lung, even though the harpoon had bounded free. We brought it on board and put it in the surgery where an attempted was planned for a brain implant.
